**Adenocarcinoma of the Rectum.**—Charles B. Ball<sup>3</sup> discusses the pathology of these malignant tumors. He states that 95% of rectal cancers are of the adenomatous type. The degree of malignancy is indicated by the tendency to recur after operation. If the case comes under notice before the disease has completely penetrated the intestinal tunic, the prospect of complete removal and cure is good. Otherwise, and unfortunately this embraces the vast majority of cases, it is bad. It occurs most frequently after middle life, but cases have been observed as early as 16 to 18 years. Clinically, we observe two types: (1) begins as a flat tubercle in the mucous membrane and submucous tissue. It increases somewhat rapidly by exuberant growth at the margin wall, the center breaks down and forms a crater-like ulcer. The perforation of the muscular coat occurs early. It is most frequent in young subjects; (2) is a more superficial ulceration, and has not the exuberant edges seen in the other variety. The adenomatous tissue is less in quantity and more atrophic, dense connective tissue surrounds the ulcerated surfaces, which tends to contract and narrow the lumen of the bowel, producing intestinal obstruction. The early symptoms of cancer of the rectum unfortunately are trivial, otherwise relief would be sought and found at a time of much greater use and hope to the patient.

Usually the first symptom is a slight chronic diarrhea, more marked in the morning, also blood-stained mucus stools, a large increase in mucus being due to great increase in gland-tissue which the adenomatous growth has caused, this functioning as does the normal. Pain as an early symptom is not prominent. Digital examination should be made in all suspected cases. The growth is usually sufficiently low down to be reached by a well-lubricated finger, especially if bimanual examination is resorted to. [A.B.C.]

## GYNECOLOGY AND OBSTETRICS

FRANK C. HAMMOND

### REVIEW OF LITERATURE

**Iodipin in Cases of Uterine Fibroid.**—J. A. Shaw-Mackenzie<sup>1</sup> has tested the value of iodipin as a remedy for uterine fibroids in two cases, and reports the results, hoping to lead others to similar experiments. Both were instances of large movable fibroids reaching to the umbilicus. The treatment in the second case was by hypodermic injection of two cubic centimeters of iodipin (25% in strength) into the cellular tissue of the buttock and continued injection daily for 10 days on alternate sides, doubling the dose on the fifth day. On the sixth day the tumor was two fingers' breadth below the umbilicus, and the right lobe was easily defined. On the tenth the patient went out of town feeling very well; but returned on the nineteenth, the tumor being much swollen again. The treatment was renewed, the dose increased in amount, and continued for several weeks with marked improvement, and in about two months' time she appeared restored to excellent health. The tumor and lobe could still be felt, but deep palpation was required to make them out. Although the reduction in size of the tumor in the first case was not as remarkable as in the second, still there was a very decided improvement. This treatment does not confine the patient to the bed or house, nor is there apparently any disagreeable effect. [w.k.]

**A New Method of Managing the After-coming Head.**—Stiffek<sup>2</sup> considers the following method of managing the after-coming head an improvement over all others. As soon as the child is delivered as far as the scapulas, he places the patient transversely across the bed and frees the child's arms by raising its legs; the patient is placed in the Walcher position (buttocks elevated, legs hanging down over side of the bed) and the physician, standing between the limbs of the patient, presses with both hands slowly and at short intervals downward and backward directly upon the head of the child. He does this without troubling the least about the position of the head or the breathing of the child. As soon as the head has fully entered the pelvis, the delivery is terminated by him by means of the Veit-Smellie method. He sees in this method a great saving of time, and claims to be able to prevent grave asphyxia by it. The injuries to the child are very rare indeed. He has practised this method in 36 cases with excellent results. [E.L.]

**The Surgical Treatment of Puerperal Pyemia.**—Ernst Michels<sup>3</sup> cites a case of pyemia which Trendelenburg cured by ligature of the right internal iliac vein and the right ovarian vein. He then reports a case of puerperal pyemia in his own experience, in which through the usual methods of treatment the local conditions had been greatly improved, the uterus had contracted, the fetid uterine discharge had ceased, but the general condition continued very alarming with very high temperature and repeated rigors. A distinct fulness was noted in the left inguinal region which suggested a thrombosis of the ovarian vein. Accordingly an operation, which is fully described, was performed and the ovarian vein, which was thickened and dilated, was ligated in two places about half an inch below the renal vein, and then divided between the ligatures. The vein was then exposed to its point of exit from the broad ligament, slit open and a fetid mass of softened thrombus with small accumulations of pus removed. The effect of the operation was surprising; no more rigors occurred, her general condition improved rapidly and, although the wound

<sup>3</sup> *The Lancet*, April 11, 1903.

healed slowly, it healed completely and she left the hospital strong and well. [w.k.]

**A Case of Procidencia.**—O'Callaghan,<sup>1</sup> surgeon to the French Hospital, London, reported a case of procidencia in a single girl; aged 18. Two years previously, while working in the fields, she lifted a heavy pannier, and while doing so she felt something suddenly protrude between her thighs; the poor girl was so frightened and ashamed that she kept her condition secret for two years, until at last the pain and scalding caused by the urine and discharge voided over her excoriated thighs and ulcerated mucous membrane drove her to confide in her mistress who brought her to the hospital. The uterus was anchored by two deep silk ligatures passed through the upper and posterior uterine wall, which caused an anteflexion of this organ thus tilting the cervix backward and upward, giving a maximum tension to the vaginal walls. The operation was a perfect success. No record was found of such a condition occurring at such an early age. No cause for the abnormality could be found. [w.k.]

**A Rare Specimen of Uterine Monoma.**—At the meeting of the British Gynecological Society, November 13, Snow<sup>2</sup> called the attention of the society to a rare specimen of what he designates as uterine monoma complicated with three myomas of the ordinary type. He calls monoma what Lawson Tait denominated soft edematous myoma. He pointed out that the monoma was always solitary; was steadily progressive toward death, which it caused within a short term of years, was accompanied by severe and continuous h morrhage; was more painful and attended by relatively acute symptoms. On the other hand, the much more prevalent uterine myoma is always multiple, need not involve any symptoms whatever, slowly grows throughout a very prolonged period, is never fatal except indirectly, as by bulk or degenerative phenomena. There is thus a wide gulf, clinically and pathologically, between the two varieties. In the specimen shown both forms of tumor were found to exist. [w.k.]

**Uterine Myomas.**—Cullen<sup>3</sup> reports four cases of uterine myoma of very rare character. The first case was a large myomatous uterus with a subperitoneal nodule molded to and filling the pelvis. Strangulated umbilical hernia. Removal of hernial sac. Hysteromyomectomy with recovery. Case 2: A myomatous uterus with very large pedunculated submucous myoma filling the vagina, also with a large subperitoneal nodule adherent to the right ureter and bloodvessels at the pelvic brim. Complete hysteromyomectomy with great difficulty in delivering the submucous myoma per abdomen. There was accidental temporary ligation of the right ureter. Recovery followed. Case 3: A partially parasitic myoma receiving its blood-supply chiefly from the enlarged omental vessels and a densely adherent bladder. Also associated with over 50 liters of ascitic fluid and clinically presenting the typical picture of a patient suffering from a tremendous ovarian cyst. Removal of parasitic myoma was followed by recovery. Case 4 involved removal of a large interstitial and partly submucous myoma. There was subsequent sloughing of inner layers of uterine walls. Removal of the necrotic tissue was followed by recovery. [w.k.]

**Vaginal Tear During the Period of Expulsion.**—Baumbach<sup>4</sup> reports the case of a woman with kyphoscoliosis and ankylosis of the right hip-joint who, after passing through six normal confinements (once with twins) came to labor the seventh time again pregnant with twins. The first child was delivered normally; examination a short time after revealed the uterus empty, the posterior wall of the vagina torn, and the second fetus lying in the abdominal cavity within the unruptured amniotic sac. Delivery was accomplished and the tear packed daily thereafter with sterile gauze. The patient made an uninterrupted recovery. The woman was delivered twice afterward, and in each instance was the fetus driven through the posterior vaginal wall into the peritoneal cavity. The treatment each time was the same as at first, and recovery resulted without undue prolongation of the puerperium. [E.L.]

## TREATMENT

SOLOMON SOLIS COHEN  
H. C. WOOD, JR. L. F. APPLEMAN

### EDITORIAL COMMENT

**On Systemic Antisepsis.**—Ever since the introduction of the antiseptic method into surgery, physicians have had the thought to apply the principle to internal diseases of microbic origin. The earlier germicides have all of them proved more toxic to the patient than to the bacteria, so that for several years the idea of sterilizing the blood attracted but comparatively little attention. Recently, however, the work of Cred  and the dramatic effects in one or two cases of formaldehyd injections have again brought the problem prominently before the profession. Of the various drugs which have been tried from time to time but three today are worthy of serious consideration; these are quinin, Cred 's soluble silver, and formaldehyd. In this review we shall consider only the possibilities of germicidal or antiseptic action; the subjects of antitoxic, fixator, and amboceptor action need much more investigation, and may prove to be fruitful.

**Quinin.**—Quinin has for years been employed in septicemia with the idea that it is of benefit either by virtue of its effect on the leukocytes or else on the infecting microorganism. It is to be remembered, however, that the lower forms of vegetable life, as represented by bacteria, are much less susceptible to the action of quinin than are those of the animal kingdom, such as the plasmodium. According to Sternberg, the lowest strength in which quinin exercises a distinct inhibitory influence on the growth of bacteria is in the proportion of 1 to 800, while Miquel places the antiseptic strength of quinin at 1 to 182. Taking even the lower figures of Sternberg it would require a dose of 72 grains in a man of 130 pounds to exercise any action upon the infecting germ. It is evident, therefore, that if quinin does any good in septicemia it is not by virtue of its direct bactericidal influence.

**Collargolum.**—Although there has been recorded a large number of cases of septic conditions in which Cred 's soluble silver has been of apparent benefit it does not seem probable that the remedy acts directly on the cocci. It will be recalled that soluble silver (collargolum) is an allotropic modification of the metal. Cred 's supposition that it retains the bactericidal action of metallic silver is a pure assumption and contrary to our experiences with other allotrops. For example, the so-called "red" phosphorus bears to the animal body relations very different from those pertaining to the ordinary form of this element.

Experimental evidence bears out this conclusion, for it has been abundantly demonstrated that colloidal silver is comparatively feeble either as germicide or antiseptic. Cohn found that it required six hours to kill the Loeffler bacillus even with a solution of 1 to 30. If we accept Cred 's own figures and grant that staphylococci will not grow in media containing 1 part of collargolum in 5,000, it would require much larger doses than he recommends to act even as a feeble antiseptic. It is impossible to have any idea of the amount of drug introduced into the blood by an inunction, and we can therefore judge of the concentration in the blood only by the intravenous dose. Cred  recommends 0.08 to 0.12 gram of collargolum intravenously. In a man weighing 125 pounds this would make a concentration in the blood of about 1 in 100,000. It would, therefore, require at least four times the advised dose to have even the slightest direct effect on the cause of the disease.

**Formaldehyd.**—A remarkable case reported by Dr. Barrows<sup>1</sup> in which the intravenous injection of a formaldehyd solution appeared to save life in what seemed a hopeless case of puerperal septicemia has directed the

<sup>1</sup> December meeting British Gyn. Soc.

<sup>2</sup> British Gynecological Journal, February, 1903.

<sup>3</sup> Johns Hopkins Medical Bulletin, March-April, 1903.

<sup>4</sup> Deutsche medicinische Wochenschrift, January 8, 1903.

<sup>1</sup> New York Medical Journal, January 31, 1903, p. 177.

attention not only of the profession but also of the laity to the possibilities of this substance as a systemic antiseptic. It seems to have been the fate of formaldehyd since its discovery to have made theatrical promises of probable utility which have not always been fulfilled. We may recall that at its introduction as a germicide it was alleged to be in corresponding solutions more powerful than even mercuric chlorid; but how far short of this has it fallen! Barrows bases his assertion of the value of formaldehyd in septicemia on the statement that 1 part in 250,000 is germicidal. This is contrary to all recent authorities to which we have access. According to Burgess,<sup>1</sup> a solution of 1 to 250 requires an hour to kill *Bacillus coli communis*, and is equivalent to a 1 to 40,000 corrosive sublimate solution. Marion<sup>2</sup> says that a 1 to 20,000 formaldehyd solution will kill most bacteria if the exposure be long enough. This seems certainly to be the lowest concentration at which formaldehyd is germicidal, although it is antiseptic in more dilute solutions. There is no room for doubt but that formaldehyd is distinctly more feeble than corrosive sublimate. In Barrows' case he injected first 500 cc. and later 750 cc. of a 1 to 5,000 solution of formaldehyd. Supposing the patient to weigh 120 pounds, this would make the concentration in the blood about 1 to 100,000 for the first dose, and 1 to 60,000 for the second. It is possible that such concentrations might prevent temporarily the development of microorganisms, but it is hardly likely that the germs would be destroyed. That larger doses are not safe is shown by the experiments of Maguire.<sup>3</sup> This observer having injected 260 cc. of a 1 to 2,000 solution into his own arm, passed bloody and albuminous urine. So much for theoretic considerations. In the absence of sufficient number of cases to draw conclusions, the most available clinical evidence at our disposal is the experiments of Snodgrass and Elbrecht<sup>4</sup> upon septicemic rabbits. Although their reports are so imperfect as not to permit of accurate interpretation their conclusions are apparently justified by their work. According to these authors the injection into the veins of rabbits inoculated with streptococci of solutions of formalin corresponding in strength and proportionate in dose to those of Barrows, lessened the mortality, but *no more so than a like amount of normal salt solution*. Dr. Park<sup>5</sup> has very recently made a series of experiments in which the animals which received formalin died more promptly than those that had no treatment. He has also had a case of septicemia die after the use of the formalin treatment. It would seem plausible, therefore, to argue that Dr. Barrows' patient was saved not by the formaldehyd, but by the salt solution in which it was dissolved! We are not prepared, however, to give so positive an opinion. The whole matter must be considered at present *sub judice*.

REVIEW OF LITERATURE.

**Ethereal Oxygen.**—Sir Benjamin Ward Richardson<sup>6</sup> believed what he termed "etheral oxygen" to be one of the most useful of his many contributions to therapeutic resources. In a two-necked Woulff bottle, one neck of which was furnished with a delivery-tube and a valved mouthpiece, he placed 2 fluidounces or more of "ozonic ether" (which is a "30 volume" solution of hydrogen dioxide in ether), poured through a funnel in the other opening, 1 fluidounce of a solution of potassium permanganate (8 grains to the ounce) and then corked that opening while the patient inhaled ether and oxygen through the mouthpiece. He also demonstrated the usefulness of oxygen as a carrier of many other vapors—as ethylene, chloroform, methylene, methylal, amyl nitrite, ammonia, iodine, bromine, benzoine, turpentine, and volatile oils. The oxygen may be freshly evolved from hydrogen dioxide in a flask containing the volatile substance on or in the

dioxid solution, or a gentle current of oxygen from any convenient reservoir may be passed through the medicated solution into the inhaler. When water is not admissible, the volatile substance—say iodine or turpentine—is placed in a good-sized flask with a double neck, and the oxygen simply flows over it on its way to the inhaler. Another method is to charge an elastic receiver with oxygen that has passed over the volatile medicament, and to have the patient inhale directly from this a fixed quantity. Clover's (chloroform) inhaling bag and the cellulite mouthpiece of Richardson are the best appliances for use in this manner.

FORMULAS, ORIGINAL AND SELECTED.

- Influenza (Grip).**—For the cough:  
 Ammonium chlorid . . . . . 5 drams ( 20.0 grams)  
 Dionin . . . . . 8 grains ( 0.5 gram)  
 Tincture of hyoscyamus . . . . . 5 drams ( 20 cc.)  
 Syrup of wild cherry . . . . . 2 ounces ( 60 cc.)  
 Distilled water to make . . . . . 4 ounces (120 cc.)

- Teaspoonful every two or three hours.  
**For catarrhal symptoms:**  
 Powdered extract of bella-donna . . . . . 4 grains ( 0.26 gram)  
 Codein . . . . . 5 grains ( 0.32 gram)  
 Powdered capsicum . . . . . 4 grains ( 0.26 gram)  
 Euquinin . . . . . 1 dram ( 4.0 grams)  
 Acetanilid . . . . . 1 dram ( 4.0 grams)

- Dispense as 20 powders.  
 One every three hours.  
**For malaise and pain:**  
 Powdered camphor . . . . . 6 grains (0.40 gram)  
 Powdered extract of belladonna 2 grains (0.13 gram)  
 Powdered capsicum . . . . . 2 grains (0.13 gram)  
 Saloquinin . . . . . 40 grains (2.60 grams)

Put into 12 capsules.  
 One every two or three hours till relieved.  
 —Merck's Archives.

FOR INVESTIGATION.

Brief reports of results of the use of drugs mentioned in this section are invited, for the Editor's information and for publication. (See editorial article in issue of January 4, p. 42.)

**Vinegar as an Antidote for Carbolic Acid.**—In a recent number of the *Boston Evening Transcript* appears a letter from C. H. Ames recommending the use of vinegar as an antidote, both locally and generally, in carbolic acid poisoning. According to this letter several cases have appeared in homeopathic literature in which it has been found efficacious. [H.C.W.]

THE PUBLIC SERVICE.

**Health Reports.**—The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended April 25, 1903:

Changes in the Medical Corps of the U. S. Army for the week ended April 25, 1903:

WEBBER, Captain HENRY A., assistant surgeon, now at Pasay Barracks, Manila, will proceed to Neuva Caeceres, South Camarines, for duty.

PATTON, First Lieutenant IRVINE W., assistant surgeon, now at Calamba, Laguna, will proceed to Santo Tomas, Batangas, for duty, relieving Contract Surgeon Edw. N. Bowen, who will proceed to Fort William McKinley, Manila, for duty.

FULLER, Captain LEIGH A., assistant surgeon, now at Pasay Barracks, Manila, will report at Post of Manila, for duty as surgeon at Cuartel de Espana, Manila, relieving Contract Surgeon Edgar W. Miller, ordered to the United States.

NOBLE, First Lieutenant ROBT. E., assistant surgeon, now at Fort Santiago, Manila, will report at Post of Manila, for duty as assistant surgeon at Pasay Barracks, Manila.

CRABTREE, First Lieutenant GEO. H., assistant surgeon, now at Cuartel Melsic, Manila, will report at Post of Manila, for temporary duty as surgeon at Fort Santiago, Manila, in addition to his duties as surgeon at Cuartel Melsic, Manila.

SHAFFER, JOS. J., contract surgeon, is granted leave for one month, to take effect upon being relieved from duty on the Army transport Thomas, and with permission to apply to the adjutant-general of the Army for an extension of one month.

DEVEREUX, First Lieutenant THOMAS, assistant surgeon, is assigned to duty as transport surgeon, Army transport Sumner.

CLEARY, Colonel PETER J. A., assistant surgeon-general, will proceed to Fort McIntosh, Fort Ringgold, and Fort Brown on business pertaining to the inspection of the medical and hospital departments at those posts.

FULLER, Captain LEIGH A., assistant surgeon, is relieved from duty in the division of the Philippines, and will report to the commanding general of that division for assignment to duty with troops en route to the United States via the Suez Canal.

FIELD, First Lieutenant PETER C., assistant surgeon, is granted leave for one month, from about May 15, with permission to apply for an extension of twelve days.

MINOR, JAMES C., contract surgeon, is granted leave for one month, from about May 4.

McCLURE, S. B., contract surgeon, leave granted March 14 is extended one month.

The following-named officers are detailed to represent the medical department of the Army at the twelfth annual meeting of the Association of Military Surgeons of the United States, to be held in Boston, Mass., May 19 to 21: Major Wm. C. Borden, surgeon; Captain Geo. D. DeShon, assistant surgeon. Major Borden will proceed to Boston in time to reach that place on or before May 19 and upon the adjournment of the association will return to his proper station.

ANDERSON, ROBT. A., contract surgeon, is relieved from duty at Fort Du Chesne to take effect upon the arrival at that post of First Lieutenant Geo. H. R. Gosman, assistant surgeon, and will then proceed to his home, Clarkedale, Miss.

MCCALL, JAS. H., contract surgeon, is relieved from duty at the United States General Hospital, Presidio, and will proceed to Columbia Arsenal, Tenn., for duty, to relieve Contract Surgeon Frederick D. Branch, who will proceed to Fort Ethan Allen for duty.

SHOCKLEY, First Lieutenant-Major A. W., assistant surgeon, leave granted March 8 is extended fifteen days.

BIERBOWER, HENRY C., contract surgeon, is granted leave for one month from April 13.

FISHER, Captain HENRY C., assistant surgeon, will proceed from Baltimore, Md., to Fort Preble and report to the commanding officer Artillery District of Portland for temporary duty at Fort McKinley during the Army and Navy maneuvers of 1903. After closing up his official business in the district at the termination of the maneuvers Captain Fisher will return to his proper station.

LYNCH, Captain CHARLES, assistant surgeon, will proceed about May 1 from Fort Porter to Fort Preble and report to the commanding officer Artillery District of Portland for temporary duty at Fort Levett during the Army and Navy maneuvers of 1903. After closing up his official business in the district at the termination of the maneuvers Captain Lynch will return to his proper station.

Changes in the Medical Corps of the U. S. Navy for the week ended April 25, 1903:

STREETS, T. H., medical director, detached from the Naval Laboratory, New York, and to duty at the Naval Hospital, Philadelphia, Pa.—April 17.

HARMON, C. E. H., medical inspector, ordered to the Naval Laboratory, New York—April 17.

STEPP, J., assistant surgeon, ordered to the Naval Hospital, Portsmouth, N. H.—April 17.

PARKER, J. B., medical director, detached from the Naval Hospital Philadelphia, and ordered home to wait orders—April 18.

HAAS, H. H., passed assistant surgeon, detached from the Naval Hospital, Portsmouth, N. H., and granted sick leave for four months—April 18.

GATEWOOD, J. D., surgeon, detached from the Lancaster and ordered to the Yankee—April 22.

Changes in the Public Health and Marine-Hospital Service for the week ended April 23, 1903:

SMITH, A. C., passed assistant surgeon, leave of absence for fifteen days from April 8, 1903, granted by Bureau letter of March 25, 1903, amended so that it shall be for ten days only—April 21, 1903.

NYDEGGER, J. A., passed assistant surgeon, relieved from duty at Baltimore, Md., and directed to proceed to Gulf quarantine and assume command of the service at that port—April 21, 1903.

LUMSDEN, L. L., passed assistant surgeon, to proceed to New Orleans, La., and report to medical officer in command for duty and assignment to quarters—April 20, 1903.

ANDERSON, J. F., passed assistant surgeon, to proceed to Great Falls, Mont., for special temporary duty—April 23, 1903.

KERR, J. W., assistant surgeon, to proceed to Gallipolis, Ohio, and Point Pleasant, W. Va., for special temporary duty—April 23, 1903.

RICHARDSON, T. F., assistant surgeon, to proceed to Bay St. Louis, Pascagoula, Pass Christian, Long Beach, Handsboro, Gulfport, Biloxi, Ocean Springs, and Scranton, Miss., for special temporary duty—April 20, 1903.

GOLDBERGER, JOS., assistant surgeon, relieved from duty at Ponce, P. R., and directed to proceed to Vera Cruz, Mex., for duty in office of the United States Consul—April 21, 1903.

FRANCIS, EDWARD, assistant surgeon, to report to director of Hygienic Laboratory for special instructions—April 11, 1903.

FOSTER, A. D., assistant surgeon, relieved from duty at Charleston, S. C., and temporary duty at Cape Fear quarantine, and directed to proceed to Baltimore, Md., and report to medical officer in command for duty and assignment to quarters—April 22, 1903. That portion of Bureau order of April 22, 1903, directing Assistant Surgeon Foster to proceed to Baltimore, Md., revoked, and directed to rejoin station at Charleston, S. C.—April 22, 1903.

EHEMENDIA, D. M., acting assistant surgeon, granted leave of absence for seven days from April 15, 1903, under provisions of paragraph 210 of the regulations.

FRICK, JOHN, acting assisting surgeon, relieved from duty at Havana, Cuba, and directed to proceed to Tampico, Mex., for duty in office of United States Consul—April 21, 1903.

GOLDSBOROUGH, B. W., acting assistant surgeon, granted leave of absence for three days from April 23—April 23, 1903.

MASON, W. C., acting assistant surgeon, granted leave of absence for three days from May 5—April 21, 1903.

SAFFORD, M. V., acting assistant surgeon, granted leave of absence for two days from April 10, under provisions of paragraph 210 of the regulations.

MAY 9, 1903.

\$5.00 YEARLY.

**Immunity from malaria** has often been alleged of natives of malarial countries, but the most recent observations show that such immunity is only partial, not being sufficient to kill the invading organisms though able to resist their poisons. Malays as well as negroes though harboring the germs seem to be uninjured thereby until the host loses resistance from some other cause, such as another infection, exposure, fatigue or starvation. The practical bearing of this discovery is very important to our troops in the tropics, for it shows that every native though apparently healthy must be considered a source of infection and that native servants must not be permitted to sleep in houses with white men unless they all use mosquito-bars. These matters are now becoming the subject of military orders, as shown by reports from the Philippines. They also illustrate the extreme necessity for the employment of expert sanitary advice in tropical warfare. Gradually the sanitarians are making it possible to campaign in places where formerly warfare was dreadfully fatal from unavoidable diseases. Every new discovery must be put to practical use at once by our army surgeons, and the line officers must carry out the recommendations if our soldiers are to benefit by the new discoveries constantly being made. Perhaps it may thus be possible to make service in the tropics as safe as at home so far as infectious diseases are concerned. The need of constant scientific observations on tropical subjects is evident, for at present it seems certain that some tropical places will always have garri-sons of American soldiers.

**The Tuberculous Prisoner.**—The deathrate of prisoners from tuberculosis is far in excess of the ordinary rate and it is held that this is chiefly due to the fact that the walls, floors, etc., are so thoroughly infected with the germs that new prisoners contract the disease and those already affected are made worse by constant reinfection. A movement is therefore on foot to construct separate prisons for the tuberculous, and it has even been urged that these should be placed in the distant and more healthful regions of the State. We have little sympathy with the plan, for instance, to locate the New York penitentiaries for tuberculous criminals in the Adirondacks, and not much more for building separate institutions nearer by when the prison facilities of a State are already ample. In build-

ing new prisons such separate buildings should be planned and isolation carried out. But in the meantime the pressing duty is to institute a long needed reform in systematic and frequent disinfection of the old walls and floors according to rigid and approved scientific methods. Cornet has demonstrated the need and the effectiveness of such measures. Moreover, the prisoners should be taken in hand and taught the most effective methods of personal and institutional hygiene. The absolute control over them should make this an easy and inexpensive task. In these ways the terrible mortality of these institutions may be immediately lessened at least 50%.

**The Government Laboratories of the Philippine Islands.**—The recent report of Paul C. Freer, Superintendent of Government Laboratories, Manila, P. I., contains much of interest to physicians and sanitarians. No stronger evidence is needed of the wise foresight which is being exercised by the Department of the Interior of our new possessions than that afforded by the account of these government laboratories and the work already accomplished and inaugurated. The serum institute in its temporary quarters at San Lazaro is pushing the preparation of prophylactic serums and is accomplishing splendid work in combating that scourge of herds, the rinderpest, and will soon be able to supply antipestic, antidipteritic, and other serums. The chemical laboratory has done efficient service in the preparation of quantities of benzoylacetlyperoxid, which has proved to be a valuable intestinal antiseptic in cholera and dysentery. The report of the biologic laboratory is of particular interest, and we shall soon print the detailed report of Director Richard P. Strong of a series of investigations of far reaching importance, and deserving of the highest commendation.

**The Etiology of Smallpox.**—In last week's issue brief reference was made to the reputed discovery by Professor Councilman, of Boston, of the elusive parasite of smallpox. Dr. Councilman, whose wellknown scientific caution and conservatism add great weight to the announcement, claims that the parasite is a protozoan with a definite cycle of development, consisting of two stages. In the first stage the organism is extranuclear and presents itself as a small, homogeneous body in the protoplasm of the epithelial cell. The body grows

larger and becomes granular and irregular in outline, acquiring a distinct resemblance to an ameba. When it has attained a certain size or age it breaks up into numerous small dots or rings, with which phase the first stage in the life cycle of the protozoan comes to a close. The newly-formed bodies, or spores, may now do one of two things. They may repeat the first stage by infecting other cells, or they may enter the nucleus and pass through the second stage, which is looked upon as being sexual. The first stage unaccompanied by the second is supposed to be characteristic of vaccinia and cowpox, while in true smallpox both stages are found together. The intranuclear body appears first as a small ring, which enlarges and eventually becomes transformed into a mass of rings, which fills the nucleus and destroys it. Coincidentally with the destruction of the nucleus the ring body breaks up into a vast number of spores, which, it is presumed, represent sexual elements. The spores are contained in countless numbers in the ripe smallpox pustule, and when the latter dries and falls off are scattered far and wide. It is through them that the contagion spreads. Dr. Councilman and his assistants, Drs. Magrath and Brinkerhoff, have followed the organism through all its stages without a break. They were particularly fortunate in discovering ocular proof of the mode in which infection of the skin takes place—in one of their slides they found a dermal blood-vessel containing many of the small ring-bodies, the youngest form of the parasite. As in the case of other protozoan organisms of man artificial cultivation has not succeeded. It is *a priori* highly probable that Dr. Councilman's parasite is the cause of smallpox, inasmuch as the great majority of variologists have for more than a decade clung to a belief in the protozoan origin of the disease. Van d. Loeff, R. Pfeiffer, Guarneri, Funck, Jackson Clarke, Monti, v. Sicherer and others have described almost identical sporogenic organisms. Guarneri, as the first, performed inoculations of the cornea with vaccine virus, and confirmed Pfeiffer's observations on the cycles of the parasite. Among the most recent studies are those of Wasielewski, who succeeded in propagating active vaccine bodies in the rabbit's cornea to the forty-eighth generation, proving the efficacy of the material on a calf and on several children. Even if the organisms seen by Dr. Councilman prove to be identical with the so-called Guarneri's bodies, the achievement of the former is none the less remarkable and worthy of the greatest praise. There are many interesting questions the answers of which will be brought nearer by Dr. Councilman's work: How does the organism gain entrance into the body? Is there an intermediate host? Does the parasite produce a toxin, as was suggested by Pfeiffer and Huguenin? What share do bacteria, chiefly the streptococcus, have in producing the clinical features of smallpox? These are a few of the questions pressing for solution. Furthermore, impetus and direction will be given to search for the parasites of chickenpox, scarlet fever, and measles.

**The Department for Mental Diseases in the Albany Hospital.**—The report<sup>1</sup> of the first year's work

of this department furnishes exceedingly valuable data for those who advocate the reception by general hospitals of cases of acute mental disease. Though this department was instituted practically as an experiment, one year has sufficed to demonstrate conclusively that it is a necessary adjunct to the facilities of the hospital. The modest statement of results by the attending specialist in mental diseases, Dr. J. M. Mosher, is well worth a careful perusal. Following the notation of the hospital wards the new department was designated Pavilion F, thus avoiding a title that was in any way suggestive. During the year 174 patients were admitted. Of these 4 came from the outpatient nervous department and 12 from other departments of the hospital, 8 being surgical cases, 2 medical, and 1 each ophthalmologic and obstetric. There were 6 deaths. Of the patients discharged 41 were transferred to State hospitals for the insane. Quoting freely from the report it has been demonstrated that mental patients from all classes may be received upon voluntary request, and that a small minority resent the confinement and cannot be held. The number of malcontents is not greater than in other departments of the hospital. The length of time patients should remain is still undetermined. Some, while distinctly improving, had to be removed because of lack of means. A fund to furnish aid to such patients has been founded. That class of patients best treated by the diversion of amusement or occupation needs greater resources than can be furnished by the pavilion in question. It is also stated that certain probably curable cases have not been benefited. This indicates the limitations of the pavilion, and suggests that patients whose condition does not demand the active medical treatment provided by a general hospital should not be too long detained. The following conclusion is reached: "It appears, consequently, that we have done more than establish an emergency hospital for temporary care. Prospect of cure has been extended to many patients whose minds have been seriously involved. The principle may be stated that any patient, whose case may be regarded as curable with the means at hand, should be offered the ministrations of this pavilion." The city and State authorities have watched closely the workings of the pavilion, with the result that an appropriation has been granted for doubling its capacity. Many valuable ideas originate in the Albany hospital, but those in charge are to be especially congratulated upon the inception and splendid showing of Pavilion F.

**The Source of Crime, the Drink-habit, and Government Revenue.**—No one will deny that Sir Robert Anderson is exceptionally qualified to speak as an expert on crime and its origin. All temperance reformers, and none more thoroughgoing than we, will have pleasure in voting Amen! to his statement that "to the drinking habits of the people may be attributed most of the crime, and a very large share of the ill-health and the poverty of the laboring and lower classes." Sir Andrew Clark said that 70% of the cases treated in the London hospitals were due directly or indirectly to drink. Lord Cairns said that the practice

<sup>1</sup> Albany Medical Annals, April, 1903.

of temperance "would empty our gaols," and Lord Chief Justice Coleridge is reported as saying that judges were weary of calling attention to drink as the principal cause of crime. But now comes the great expert who wishes, instead of talking about the matter, actually to get rid of crime. Sir Robert, the expert, he who would prevent both crime and the criminal, he who knows whereof he speaks and is thoroughly in earnest, this man says that the temperance people in England, or rather the teetotalers and prohibitionists, form the one sole compact opposition to temperance reform and to the prevention of crime. Sir Robert's words are these:

But it would seem that no legislation upon this question may be looked for at present; and for the simple reason that the political teetotalers are strong enough to wreck any measure in the nature of a compromise, and no other kind of measure is practicable. Moreover, any radical reform of the drink code would, if successful, involve the abandonment of our present fiscal policy; and that policy commands the almost fanatical support of the great majority of the temperance party. It is not my purpose to enter on a discussion of the merits or demerits of what is called "free trade." But I wish to point out that it operates to keep His Majesty's Treasury "in the same boat" with the public-house interest. For the Treasury largely depends for its revenue on the drinking propensities of the population. The contribution to the general taxes, paid by an ordinary working man with a family to support, amounts to not more than a half-penny a day; but his contribution to the excise in paying for his daily drinks averages at a low computation not less than five pence a day. That is to say the man who drinks pays some ten times more to the public chest than the teetotaler.

This is a sad pass, or *impasse*, to which immoral politics may bring a great nation. We Americans, of course, are not in such a sorry plight. Our government draws none of its revenue from such polluting sources, and our temperance reformers are not involved in such political and illogical absurdities!

**Progress in Spelling Reform.**—We have no sympathy for the *fonetik folks*, nor for the devisers of Volapuk or other expressions of philologic nausea, but we have every desire to rid the language of barbaric illogicalities and follies that have grown with the unconscious development of the past. It is therefore an exceptional pleasure to note the evidence of effected reform shown in the adoption of sensible spelling by the United States Census Office. This fact puts the reform beyond the stage of doubt and discussion, and renders absurd the efforts of the reactionaries to retain outgrown spellings. Publishing houses which control medical periodicals and publish dictionaries devoted to antique orthographies will henceforth find that their "conservatism" and profound interest in "etymology" and "pure English" will no longer avail. In the "Classification of Causes of Death," and in other circulars issued by the Census Office, we notice the modern instead of the medieval forms of words. We are gratified that even *oedema* and *oesophagus* are forever done away with, and are replaced by *edema* and *esophagus*. *Hæmorrhage*, *leukæmia*, and the more ridiculous *leucæmia*, *anæmia*, *gangrene*, *diarrhœa*, *septicæmia*, *æstivo-*, *anæsthetic*, *sapremia*, *pyæmia*, *hæmoptysis*, *gonorrhœa*, *ozæna*, *goitre*, *perinæum*, and a hundred other solecisms are deleted and replaced by the simpler and better forms. *Aneurism* is wrongly pre-

ferred to *aneurysm*, and *diphtheric* should have been given instead of *diphtheritic*. We are grateful that *lach-* has not been retained in this tearful part of a word, but are sorry that *lacrymal* is preferred to *laerimal*. And at last we are rid of *chorioid* and *chorioiditis*, and also of the pepper-and-hyphen-box in *cooperation*. With such great progressive steps it seems strange that the incongruities of some old-time forms of compound words should have been retained. We find *retro-uterine*, and in the next line *periuterine* without the absurd hyphen; *gastroenteritis*, and close by *entero-colitis*; *cardiovascular*, and then *cerebro-spinal*; *gastroenteric* and soon *broncho-pneumonia*. There are no such words as *sarco-*, *broncho-*, *pseudo-*, *cerebro-*, *retro-*, *entero-*, etc., and in thousands of such compounds we do not hyphenate. We do not even see the need of any hyphen in *beriberi*. *Noncancerous* and *nonpuerperal* are correctly spelled.

**The International Medical Congress at Madrid**, if we may judge from the reports that have reached us, was a sorry affair, and leads to the hope that it may be the last of the series. Science, and especially medical science, does not come out with much credit in these huge gatherings. This feeling on our part does not originate in any sort of political or national sentiment or pique, and is wholly uninfluenced by the unaccountable mismanagement, whereby the United States delegation was not represented in the official responses of the delegates and "was denied admission to the stage." There were said to be 5,000 in attendance at Madrid, but it was a heterogeneous assemblage, including many persons and professions that could be called medical only by a dangerous stretching of the term. Oratory, banquets, and social festivities were apparently thought of more importance than science. "The greatest confusion prevailed," says the cabled report of our amiable contemporary, the *Medical Record*, and "there was an utter lack of systematic arrangements for the meetings. They were held in out-of-the-way places, were not properly announced, and consequently were very poorly attended. No one seemed empowered to give any information regarding what was to be done or how it was to be done. The committees were even more confused than the delegates. The result was that the greatest confusion prevailed during the entire session, resulting in the omission from the program of some of the most important addresses." According to the *British Medical Journal* (to which we owe our thanks for advance reports) the medical and surgical interest of the people of Spain was centered upon a wounded bullfighter rather than upon the Congress. The addresses appear to have contained little that was new or of interest.

**Some suggestive figures as to the birthrate** are supplied by the pastors of churches at a recent meeting in Jersey City. One pastor of a church, described as the oldest in the country, and attended by people of prominence, reported that the 402 families of his congregation had brought but 19 infants to be baptized during the year. Another pastor, with 360 families in his congregation, had baptized 17 infants, and one with 123 families had baptized but 2, the whole

number of infant baptisms reported from seven congregations, comprising 1,521 families, being only 95, or 1 infant to 16 families. In contrast to this was the report of the pastor of another church in which there were 253 families, and he had baptized 158 infants. Another reported 91 baptisms in 104 families. Now these figures at first sight seem to be without interest or teaching, but they at once become startlingly suggestive when it is learned that the seven congregations with the low birthrate are English speaking, "the oldest in the country," etc., while the average of the German speaking congregations was 3 baptisms to 5 families. The Germans are probably more mindful to bring their children to baptism than are their American coreligionists; but, even making allowance for a decline of faith, the decline of productiveness suggested by these figures is unmistakable. The figures are still more astonishing when it is learned that the gathering of ministers was of the Reformed Church, including the German Evangelical. Thus the older the German stock the lower the birthrate, and those so recently coming here as to still require German in its pulpits have the high birthrate. Race suicide has a new showing in these figures.

**Shakespeare's Knowledge of Medicine.**—In the April number of the *Westminster Review* a most interesting writer on medico-literary subjects, Dr. John Knott, has a capital article on "The Medical Knowledge of Shakespeare," in which he concludes that the greatest of the poets had an understanding of the principles of surgery and medicine nowhere behind the professional knowledge of the day, and that when he differed from the current authorities it was in the direction of greater accuracy. Most noteworthy is Dr. Knott's demonstration that Shakespeare was in advance of Harvey's discovery, published after the poet's death, as evidenced by the following quotations:

The second property of your excellent sherris is the warming of the blood, which, before cold and settled, left the liver white and pale, which is the badge of pusillanimity and cowardice; but the sherris warms it and makes it course from the inwards to the parts extreme. It illumineth the face, which as a beacon, gives warning to all the rest of this little kingdom, man, to arm, and then the vital commoners, and inland petty spirits, muster me all to their captain, the heart; who great and puffed up with his retinue, doth any deed of courage; and this value comes of sherris. . . .

In the play of *Coriolanus*, the stomach, replying to the attacks of its enemies, proceeds to say:

True is it, my incorporate friends, quote he,  
That I receive the general food at first,  
Which you do live upon; and fit it is,  
Because I am the store-house and the shop  
Of the whole body; but, if you do remember,  
I send it through the veins of your blood,  
Even to the court, the heart, to the seat o' the brain;  
And through the cranks and offices of man,  
The strongest nerves and small inferior veins  
From me receive that natural competency  
Whereby they live.

**The Early History of Quarantine.**—In *Yellow Fever Institute Bulletin*, No. 12, J. M. Eager has published a valuable review of the history of quarantine

in general, and of the origin of sanitary measures directed against yellow fever in particular. During the epoch of the Crusades, however, lazarettoes and leper houses were common throughout Syria and Europe, and leprosy takes precedence as a quarantinable disease. It appears that the Venetians practised quarantine measures against malignant contagious diseases as early as 1403, and that the Portuguese established the first quarantine against yellow fever in 1421. The origin of the theories of contagion is traced in a concise but interesting manner, as is the development of maritime quarantine and of early maritime sanitary laws. Sanitary bulletins (*bulletones sanitatis*), so-called because they were stamped with the "bollo" or seal of the authority issuing them, are first mentioned in Italian writings of the year 1300; they served as bills of health for merchants and other travelers. This little pamphlet of 27 pages supplies an important chapter in the history of preventive medicine.

**Hospitals and Nurse-training Schools for Colored People.**—The latest annual report of the Frederick Douglass Memorial Hospital and Training School of Philadelphia makes a plea for better support which should enlist the attention of the benevolent. Such institutions, as the report suggests, exist chiefly for the benefit of the rapidly growing colored people, "whose fears and prejudices against hospitals have been almost proverbial." The report also says that a special reason for supporting these northern hospitals is that in the south in the few hospitals that exist the negroes get only the poorest care, being placed in inferior wards set apart for them, and that they "suffer the brunt of all that is experimental in treatment." Is this true? We hope not; and yet, if so, it only adds to the argument already sufficiently strong in favor of these special hospitals for the negro. Is there any such complaint in reference to the treatment of colored patients in northern hospitals? And another question is pertinent: Do colored patients prefer treatment by white physicians and nurses rather than by those of their own race? Good ground for support is urged by the management of the Douglass hospital in that outside physicians may attend their own patients while in the wards.

"Had never been vaccinated at all," "or presented old doubtful scars of vaccination performed in infancy,"—such are the reports, published with most commendable pertinacity, by the Health Department of Chicago, of all the smallpox cases occurring in the city during the week. We hope these reports will not be discontinued, and would suggest at least an annual recapitulation of them, "*pour encourager les autres*," especially the antis.

**Football Statistics.**—Professor Dexter writes to say that his statistics concerning football show that "the number of men playing football is increasing more rapidly than the number of accidents is increasing, although it is true that the *percentage* of students playing football is somewhat less than it was 10 years ago."

## AMERICAN NEWS AND NOTES.

## GENERAL.

**Smallpox**, as officially reported in the United States from December 27 to May 1, amounts to 16,700 cases, with 466 deaths, as against 30,804 cases, with 924 deaths, for the same period in the previous year.

**Opium Habit in Hawaii.**—A House committee report on an act to regulate the sale and use of opium contains the statement that the opium smoking habit is spreading alarmingly among the natives.

**Plague in the Philippines.**—Latest news from Manila records the fact that there have been 101 cases of bubonic plague, mostly among the natives and Chinese, in Manila since January, and the disease is apparently gaining ground.

**Army Hospital in the Philippine Islands.**—Arrangements have been made to erect a large modern hospital and convalescent home at an elevation of nearly 3,000 feet in the mountains near Mariveles for the use of officers and men suffering from the effects of the tropical service.

**Cholera in the Philippines.**—News from Manila states that cholera again is threatening the Island of Luzon. The bad outbreak in the Camarines is apparently spreading northward. The Cagayan Valley is infected, and it is feared the epidemic will extend over all the islands. Past epidemics have generally lasted more than three years.

**Recrudescence of Plague at Mazatlan.**—A late report states that plague has reappeared at Mazatlan. Two persons who were serving a quarantine at the observation station have succumbed to the disease. Another case is reported to have occurred in the city. According to official reports, from December 1 to April 15 there were 487 cases of the disease, with 328 deaths.

**Hospital Benefactions.**—LOGANSPOUT, IND.: Judge D. D. Dykeman has given \$50,000 to Logansport for the establishment of a hospital as a memorial to his wife who died recently. Upon the death of Judge Dykeman his entire estate will be available as an endowment to the institution. BOSTON, MASS.: The late Mrs. Lucy R. Read, of this city, bequeathed \$5,000 to the Sharon Sanitarium.

**Rats and Bubonic Plague.**—U. S. Surgeon Glennon's report with reference to the rats examined in San Francisco during the month of March is interesting as evidence that the plague has been entirely eradicated. The number of rats delivered alive at the laboratory number 142; those found dead and delivered at the laboratory number 31; those showing lesions of phosphorus poisoning, 21; total number of rats examined, 173. Rats show plague infection first.

**Railway Accidents for Three Months.**—The Interstate Commerce Commission has issued a bulletin on railroad accidents for the three months ended December 31, 1902. It shows that during that period in train accidents 266 persons were killed and 2,788 injured. Accidents of other kinds, including those sustained by employes while at work, and by passengers in getting on and off cars, etc., bring the total number of casualties up to 938 killed and 11,873 injured. The damages to cars and engines and roadbed by these accidents amounted to \$2,462,056.

**Association of American Medical Colleges.**—An interesting feature of the meeting of the Association held in New Orleans, La., May 4, was the report submitted by the special committee appointed at last year's convention in Saratoga upon requirements for admission to the freshman year of a medical college. The majority report holds that students applying for admission to the colleges of the Association shall have pursued a four years' course of instruction in a high or normal school, or present a certificate of admission to the freshman class of a State university. The minority report requires a four years' high or normal school course preceded by not less than a six years' course in primary and intermediate schools. The amended report, which was finally adopted, requires four full years of work in a high school or its equivalent for eligibility to admission in a medical college.

**Miscellaneous.**—BALTIMORE, MD.: Dr. Florence R. Sabin, assistant in anatomy at the Johns Hopkins University Medical School, has been awarded the prize of \$1,000 offered two years ago by the Naples Table Association for the best piece of scientific research work done by a woman. Dr. Sabin presented the results of an investigation on the origin of the lymphatic system. ST. PAUL, MINN.: Dr. Charles Lyman Green, of this city, has been appointed professor of theory and practice of medicine in the medical department of the State University of Minnesota. PHILADELPHIA, PA.: Dr. Edward Martin, professor of clinical surgery in the University of Pennsylvania, has been appointed Director of the Department of Health and Charities. NEW YORK CITY: Dr. Robert F. Weir, professor of surgery; Dr. George M. Tuttle, professor of gynecology, and Dr. G. M. Peabody, professor of materia medica and therapeutics, have resigned from the Faculty of the College of Physicians and Surgeons.

## EASTERN STATES.

**Oldest Medical Society in the United States.**—At Winsted, Conn., on April 28, the Litchfield County Medical Association, the oldest medical society in the United States, not excepting National or State societies, held its one hundred and thirty-ninth annual meeting. The proper officers were elected.

**Country Home for Poor Children.**—It is stated that Bloodgood H. Cutter, of Long Island, who is known as the "farmer poet," has given to the Episcopal Diocese the old Queenstown Court House at Jamaica, which he has owned since 1894, for the establishment of a country home where children and invalids under the care of the church in the borough of Brooklyn can be taken to secure the benefits of country air and healthy surroundings.

**New Issue of Bank Notes to Prevent Smallpox.**—At Holyoke, Mass., owing to the prevalence of smallpox the Home National Bank will make an entirely new issue of \$1.00 and \$2.00 notes to lessen the danger of contagion. The bank officers say that the money is probably as dangerous to the community, from a sanitary point of view, as any other means of contagion. The small notes in circulation for a year or two have become very worn and soiled, and give evidence of hard usage. The money is passed from smallpox quarantined blocks for purchase of supplies, notwithstanding the danger of spreading the disease.

**Campaign Against Mosquitos.**—It is stated that the Brooklyn Board of Health is to begin its annual onslaught upon the mosquito. The comparatively cold weather has, it is said, prevented the board from beginning the work sooner. The plan is to petrolize all ponds and pools where mosquitos are likely to congregate and breed. The board is able to prosecute the work on a larger scale this year than formerly, owing to the fact that it has more funds at its disposal. In addition to the light fuel oil heretofore used, the heavier crude oil, which evaporates less quickly, is also to be used. The lessened number of malarial cases in Brooklyn is evidence that the work of last year has borne fruit. There is good reason to believe that a like decrease will be witnessed during the present year.

**To Combat Tuberculosis.**—It is said that in three years nearly 3,500 cases of pulmonary tuberculosis in Boston have been reported to the Board of Health, and during that period the physicians have been required to report only such cases as are classified among the infectious diseases, and it is believed that many cases of tuberculosis are not reported. In view of the fact that the nature of the disease, the means by which it is acquired, its course and treatment, are but poorly understood by its victims an association has been formed known as the Boston Association for the Relief and Control of Tuberculosis, whose object it is to prevent the spread of tuberculosis by educating people, showing them how the patients may be treated at home, so as to get well without danger to the other members of the family. It is hoped that this commission may cooperate with the Tenement House Association recently appointed by the Mayor. Work of a similar nature is being done in New York, Montreal and large cities of Europe, to say nothing of the work which has lately been organized in Philadelphia, whose nucleus is the Phipps Institute. Circulars are being distributed by the Association giving the aim, rules and titles, with reference to the prevention, care, and treatment of tuberculosis.

## NEW YORK.

**Smallpox Aboard.**—The French Line steamer "Gascogne" arrived April 29 from Havre with 243 cabin and 999 steerage passengers, and was detained at Quarantine on account of a smallpox case in the steerage. Giovanni Cittadin, aged 19, was sent to a hospital and 122 of his fellow passengers were taken to Hoffman Island for observation. The steamer was disinfected.

**Registration for Trained Nurses.**—Governor Odell has signed the bill providing for the registry of trained nurses by the New York State University. Only those who are so registered may hereafter legally sign "R.N." after their names, or wear these initials upon their uniforms. The purpose of this law is to enable employers to know the qualifications of persons whom they hire to do nursing. It does not attempt to dictate who shall be employed as a nurse, or who shall undertake to do a nurse's work. It simply provides that persons of insufficient training shall not be permitted to palm themselves off as being qualified equally with those who have spent years in patient study.—[Evening Post.]

**Open-air Sanatorium.**—It appears that the institution founded in the Adirondacks by Dr. Trudeau for the treatment of tuberculosis was the first in this country to institute the open air and hygienic method of treatment. In 1873, being afflicted with tuberculosis, the doctor went to the Adirondack Mountains in the hope of effecting a cure, when the prevailing sentiment among physicians in this country was to send all tuberculous patients to the warm lowlands, such as Florida. In time the physician became entirely well and conceived the idea of the Adirondack Cottage Sanatorium. Since its founding many tuberculous patients have been treated in the institution, although it is comparatively little known. According to

the figures given about 30% of those treated have been discharged practically cured; 41% with the disease arrested; 19% as improved; 7% in which there was entire failure to arrest the disease process. The expense of running this sanatorium is almost \$50,000 a year, almost one-third more than the receipts the patients would provide. The deficit has been made up in the past largely by private subscriptions from wealthy individuals.

**Sale of Mineral Waters.**—A timely editorial appears in the New York *Sun* giving the figures of sales of mineral waters in the United States. We quote: "In 1890 47,000,000 gallons of mineral waters from springs in the United States were sold; in 1901, 55,775,000; and in 1902, 65,000,000. The value at the point of shipment now reaches \$10,000,000 a year, and taking into account the expense of transit, bottling, and the profits of retailers, \$18,000,000 or \$20,000,000 must be expended each year for American mineral waters. Following any epidemic of any zymotic disease there is generally reported a marked increase in the sale of mineral water in hotels, in dining-cars on railroads, and in theaters; and very likely this increased care in the use of water is of immense effect toward counteracting the dangers arising constantly from the neglect to care for the public water-supply in accordance with the growth of population. The productiveness of the mineral-water springs of the United States is practically unlimited, and at the rate which the product is increasing it can not be long before the amount sold each year will reach 80,000,000 gallons, nearly equivalent to a gallon per inhabitant. Americans are the greatest water-drinkers in the world."

#### PHILADELPHIA, PENNSYLVANIA, ETC.

**Chester Free from Smallpox.**—It is stated that Chester is at the present time free from smallpox after a battle of over two years with the disease. No new cases have been reported since March 28.

**The Medical Club, of Philadelphia,** will give a banquet on May 15, 1903, in honor of Dr. George H. Simmons, of Chicago, secretary of the American Medical Association; Professor von Mikulicz-Radecki, of Breslau; Professor C. A. Ewald, of Berlin; Professor Hans Kehr, of Halberstadt, and Professor Hermann Tillmanns, of Leipsic, Germany.

**Rabies.**—At Montclair, N. J., a veterinary surgeon having in detention a dog said to be afflicted with rabies invited the school children of the town to view the incarcerated animal. This was done to eradicate the idea in the minds of many persons that a rabid dog is violent in demeanor, has frothing at the mouth, and other alarming objective symptoms. The surgeon showed on the contrary that the animal is ordinarily quiet but has dry parched mouth and tongue as would ordinarily be seen in a person suffering from a high fever.

**Campaign Against Smallpox.**—The State Board of Health has inaugurated a systematic campaign against smallpox throughout the State, and the appropriation of \$50,000 by the Legislature for this purpose will very materially assist the board in its purpose to eradicate this evil. It is stated that smallpox exists in many villages throughout the State, and in such places nothing short of a house-to-house inspection, proper quarantine, and vaccination can accomplish the desired end. In Philadelphia and vicinity the disease appears to be dying out, and it is only by such an emergency appropriation as that recently made by the Legislature that the disease can be stamped out in other parts of the State. Vaccination must be continued vigorously until every vestige of the disease disappears.

**In Reference to Medical Testimony.**—The bill designed to relieve physicians and surgeons from testifying in civil cases with reference to communications made to them by patients has been vetoed by Governor Pennypacker. The Governor is of opinion that the act is so vague and indefinite in character as to deserve the stigma of dangerous legislation. He concedes that there are many circumstances in which it would be highly proper to preserve inviolate communications made by patients to physicians, yet there are circumstances under which it would be highly necessary for the State to be in possession of the facts known to the physician, the keeping of which would defeat the ends of justice. Hence his veto act. The bill does not sufficiently define and make clear the circumstances under which communications to physicians shall be considered private communications.

**The Prince of Peace Maternity Hospital.**—This institution has been in existence now over four years, during which time it has shown its right to be by the way in which it has been continually overcrowded. It is the only home in the city of Philadelphia, or in fact in the State of Pennsylvania, where a girl who has made her first misstep can be cared for without coming in contact with inmates who have had deeper and sadder experiences. It is also the only maternity hospital where a girl about to become a mother can enter several months before her confinement, and thus be enabled to hide her shame, and where she will be kept afterward until she can return to her friends, or until a suitable position may be obtained for herself

and child. Thus an opportunity is given her of becoming a self-supporting, self-respecting Christian woman. It has also a well-equipped hospital department for the treatment of diseases peculiar to women, and a dispensary, both in active operation.

#### SOUTHERN STATES.

**Deaths in District of Columbia.**—In the District of Columbia during the week ended Saturday, April 25, there were 127 deaths. During the week before they numbered 90, and in the corresponding period of last year 118. Of the late decedents 76 were white, representing a deathrate of 19.0, and 51 colored, the deathrate being 29.1. For all the deaths the rate was 22.1 as compared with 15.7 last week and 20.0 last year.

#### WESTERN STATES.

**Typhoid at Stanford University.**—The latest reports indicate that the typhoid epidemic prevailing at Stanford University is becoming more extensive. New cases are being reported. The total number of cases up to the present writing is 35 on the campus and 83 in Palo Alto.

**To Combat Tuberculosis.**—An appropriation of \$200,000 by the next General Assembly for the erection of a sanatorium for the care of tuberculous patients was recommended in a report submitted to Governor Nash by the Ohio Commission on Tuberculosis appointed by the General Assembly a year ago. The report states that 6,000 die annually of tuberculosis in Ohio, and that the disease is not hereditary, but is communicable, and can be prevented and cured. There are said to be 15,000 now in Ohio afflicted with tuberculosis.

**Football Prohibited.**—After much debate, the bill to prohibit the playing of football in South Dakota has passed the Legislature of that State. By this South Dakota has shown herself to be the only State in the Union which was willing to consider the proposition as anything beyond a joke. Bills to prohibit football have been introduced in the Legislature of at least 10 States during the past six months, but in most cases they have been the subject of ridicule. At Madison one legislator got up before the assembly and moved to amend the bill to include ping-pong, croquet, and golf.

**War on Drug Habit in Illinois.**—The State of Illinois has declared war on the drug habit and every State's attorney in the various counties has been directed to make a thorough investigation of the conditions and to present his findings before the grand jury. The State Board of Pharmacy is making a determined fight against druggists who sell cocaine, opium, and other opiates, in violation of the law. It has been found that the improper use of drugs has grown to a very large extent, and that it is not confined to any particular class of people. Residents of fashionable hotels and on fashionable boulevards in Chicago are said to be as thoroughly addicted to the cocaine habit as those in the slums and lower walks of life.

**Negligent Hospitals.**—In his report to the Children's Hospital Society the chairman of the Hospital Inspection Committee, of Chicago, charged that the majority of the children's wards connected with the large general hospitals are overcrowded, contain insufficient air space and deficient ventilation, that the children's departments are in most cases not organized, and that this lack of system in their management defeats their purposes. The committee denounced the antiquated method of feeding infants which is used in institutions devoted to their care; condemned the milk supply as tending to breed disease rather than nourish; deplored the total lack of provision for the care of mentally defective children, and the inadequate facilities for the care of crippled children and infants, those suffering from infectious diseases.

**Work Accomplished in Chinatown.**—The report of Surgeon Glennon, of San Francisco, gives the work accomplished in Chinatown for the week ended April 18. His summary is as follows:

Number of rooms reinspected.....	2,507
Number of buildings reinspected .....	354
Persons inspected.....	2,491
Sick inspected.....	52
Dead inspected.....	10
Number of necropsies.....	1
Rats examined bacteriologically .....	125
Rats found with pest infection.....	0
Places disinfected.....	576
Number of times streets sprinkled with bichlorid solution .....	3
Number of sewers flushed .....	6
Notices served to correct plumbing .....	82
Number of plumbing nuisances undergoing correction.....	27
Number of rat-poison boards rebated.....	80

#### CANADA.

**Sir James Grant Honored.**—The physicians of Ottawa, Canada, recently gave a banquet to Sir James Grant, to celebrate the golden jubilee of his entry into medicine. He was presented with a handsome loving cup. He has been located in Ottawa 49 of the 50 years that he has been engaged in the practice of medicine.

## FOREIGN NEWS AND NOTES

## GENERAL.

**Plague in Bombay.**—The Marine-Hospital reports state that the outbreak of plague in the city of Bombay occurred in September, 1896, and continues to the present time. During the last year there were more deaths from plague than in any other year since the outbreak. Over 100,000, or nearly one-seventh of the entire population of the city, have died of plague within the last seven years, being an average of over 13,000 a year.

**Secret Medicines in Japan.**—Very stringent laws have been enacted in Japan in regard to secret proprietary medicines. The importation of those containing a poison from which accidents might result is absolutely prohibited, as is also the sale of those that have deteriorated. The retailer must be informed in regard to the ingredients, proportions and doses, and must specify them in applying to the authorities for permission to sell the medicines.—[*Canadian Journal of Medicine and Surgery.*]

**History of Compulsory Notification of Tuberculosis.**—The first edict requiring compulsory notification of pulmonary tuberculosis was issued by a king of Spain in 1751. The decree describes the motives for it, and enjoins destruction of the furniture and wearing apparel used by consumptives and replastering the room after a death. Physicians who fail to notify the alcaide of a consumptive patient, or the death of a consumptive, are fined 200 ducats at the first offense and suspended for one year, and for a second offense 400 ducats and exiled for four years. Nurses, servants, and others waiting on the consumptive are required to see that the authorities are notified of the case under penalty of 30 days in prison for the first offense and four years at the galleys for the second. The edict also contains a paragraph directing that dealers in second-hand clothing must keep a record of the persons from whom the clothes are bought and to whom sold.—[*Journal of the American Medical Association.*]

## CONTINENTAL EUROPE.

**Students at the University of Paris.**—During the year 1901-02 there were registered at the University of Paris 12,414 students. Of these 3,827 were students of medicine as compared with 3,957 in 1900-01. Among these were 405 foreigners. In the school of pharmacy there were 1,683 students as against 1,742 the previous year.

**Pasteur Cure for Epilepsy.**—It is related that a high Servian official afflicted with epilepsy recently went to the Pasteur Institute at Budapest for treatment for hydrophobia. Under the Pasteur treatment the wound caused by the bite of the dog soon healed, and with this cure his epilepsy also disappeared. The case is attracting much interest in medical circles.

**The Spanish public** is at present deeply interested in medical or rather surgical subjects from a far different reason. The *torero* Conejito who was wounded in a bullfight a few days ago lies dangerously ill at Barcelona, and all the papers contain full bulletins sometimes issued almost hourly, with full clinical reports of pulse, temperature and sleep. The last accounts are discouraging, and indicate general septic infection. Amputation of the injured limb is talked of as a last resource, and with but little hope of saving life. If a fatal termination should ensue, it will undoubtedly cast a gloom over Spain that the most brilliant successes of the Congress will do little to remove. Meanwhile the small band of *toreros* who stand in or promenade the Calle de San Geronimo are watched with the deepest interest and a respectful reverence that we can never hope to appreciate.—[*British Medical Journal.*]

**Attendance at the International Medical Congress at Madrid.**—According to the Spanish newspapers the number of foreigners who had inscribed their names as members of the Congress up to April 18 was more than 3,000. This number added to that of Spanish members makes up a total of nearly 6,000. It must be remembered, however, that the Congress can scarcely be called a purely medical assemblage inasmuch as pharmacists, veterinarians, dentists and generally all persons interested in medicine and sanitation are admitted to membership. It would, therefore, be interesting to know exactly what proportion of this motley gathering consists of members of the medical profession. It is anticipated that some 400 Germans and Austrians will attend; among those expected are Professors von Bergmann, Eulenburg, Leyden, Ewald, von Schrotter. France and Belgium are expected to send between them 600 representatives; among them are Professors Brouardel, Cornil, MM. Robin, Hayem, Doyen, Tuffier, Chantemesse, Lapersonne.—[*British Medical Journal.*]

## OBITUARIES.

**J. V. Laborde**, Professor of the School of Anthropology, Founder of the Société de Médecine Publique et d'Hygiène Professionnelle, and one of the most active members of the Société de Biologie, of which he

was vice-president, died recently in Paris. He was graduated from the Académie de Médecine in 1887, and is especially well known to the profession for his discovery of the method of rhythmic traction of the tongue in the treatment of cases of apparent death.

**William Holbrook**, in Palmer, Mass., April 27, aged 79. He was graduated from the New York University in 1848. He enlisted as assistant surgeon in the Tenth Massachusetts Regiment and was soon after appointed surgeon-in-chief of the First Brigade of the First Division, Fifth Corps of the Army of the Potomac. He represented his district in the Legislature in 1882. He was medical examiner for eastern Hampden from 1877 till his death.

**Joseph S. Eastman**, Berkeley, Cal., April 19, aged 48. He was graduated from the Missouri Medical College, St. Louis, in 1878 and was one of the founders and the first president of the Oakland College of Medicine and Surgery. He was a member of the California State Medical Society and of several county medical societies.

**James Conlan**, of Brattleboro, Vt., May 3, aged 52. He was graduated from the medical department of the University of Vermont in 1878 and has practised his profession in Brattleboro for the past twenty years. He was a member of the State Tuberculosis Commission and had served two terms in the State Legislature.

**James A. Roache**, of Brooklyn, N. Y., May 3, aged 44. He was graduated from the Long Island College Hospital in 1891 and at the time of his death was one of the staff of St. Mary's Hospital. He was a member of the Long Island Medical Society and the Kings County Medical Society.

**J. W. Taylor**, of Leesburg, Va., April 28. He was graduated from the Jefferson Medical College, Philadelphia, in 1854, and had been for many years a leading practitioner in Loudoun county, Va.

**Frederick A. Sweet**, in Bisbee, Ariz., April 17. He was graduated from the New York University in 1889, and was chief surgeon of the El Paso and Northeastern Railway.

**Henry C. Bunce**, in Glastonbury, Conn., April 15, aged 78. He was graduated from Yale College, New Haven, in 1850 and served as assistant surgeon during the Civil war.

**John F. Gaylord**, in Plymouth, Mass., April 14, aged 45. He was graduated from Yale College, New Haven, in 1878 and was a member of the Samoset Medical Association.

**Andrew G. Selman**, a retired physician of Indianapolis, Ind., died April 17, aged 81. He was graduated from the Transylvania University, Lexington, Ky., in 1843.

**Deuman R. Kensell**, in Columbus, Ohio, April 17, aged 75. He was graduated from the Homeopathic College Hospital, Cleveland, Ohio, in 1859.

**William S. Robertson**, near Mount Hermon, Va., April 21, aged 72. He was graduated from the Medical College of Virginia, Richmond, in 1854.

**Leonard Kittlinger**, in Wilmington, Del., April 17, aged 68. He was graduated from the Hahnemann Medical College, Philadelphia, in 1863.

**Allen R. Smith**, of Baltimore, Md., May 4, aged 57. He was graduated from the Baltimore College of Physicians and Surgeons in 1881.

**Arthur Jones**, in Bellevue, Ohio, April 15, aged 37. He was graduated from the Jefferson Medical College, Philadelphia, in 1898.

**John W. DeVaughan**, in Milltown, Ala., April 19, aged 72. He was graduated from the Vanderbilt University, Nashville, in 1883.

**Uriah M. Gibbs**, in Hanceville, Ala., April 18, aged 83. He was graduated from the University of Nashville, Tenn., in 1897.

**Morton M. Dowler**, in Topeka, Kan., April 13, aged 69. He was graduated from the Rush Medical College, Chicago, in 1865.

**Joseph A. Stegmenn**, of Philadelphia, April 24, aged 40. He was graduated from the Hahnemann Medical College in 1886.

**Thomas J. Elam**, near Rucker, Tenn., April 20, aged 71. He was graduated from the University of Nashville in 1858.

**Doctor von Kahliden**, Professor of Pathologic Anatomy in the University of Freiburg, in Eresgau, died recently.

**George M. MacMillan**, at Sewickley, Pa., April 16. He was a graduate of the Ohio Medical College, Cincinnati.

**Charles L. Youmans**, in Baxley, Ga., April 8. He was graduated from the Atlanta (Ga.) Medical College in 1895.

**L. H. Kitchel**, in Aiden, N. Y., April 20, aged 57. He was graduated from the University of Buffalo in 1870.

**Harris E. Paige**, of Dover, Del., aged 45. He was a graduate of the Jefferson Medical College, Philadelphia.

**Julius Victor Carns**, Professor of Comparative Anatomy in the University of Leipzig, died recently, aged 80.

**John T. Hendershot**, of Otley, Ia., April 5, aged 61. He was a graduate of the Rush Medical College, Chicago.

**John C. Wilby**, in New Orleans, April 18. He was graduated from the University of Zurich in 1874.

**Henry A. Mix**, in Oregon, Ill., April 22. He was graduated from the Rush Medical College in 1864.

**M. B. Borgono**, Professor of Clinical Surgery in Santiago, Chile, died recently.

**William M. Lemen**, of Martinsburg, W. Va., May 2, aged 72.

**John E. Gardner**, of Duluth, Minn., May 2, aged 64.

## CLINICAL NOTES AND CORRESPONDENCE

[Communications are invited for this Department. The Editor is not responsible for the views advanced by any contributor.]

## AN OBSTETRIC SUGGESTION.

BY

ARTHUR DEVOE, M.D.,  
of Seattle, Wash.

What may be called the first function of the newborn child is respiration. This failing, the condition of the eyes and the possible need of Credé's antiseptic therein, nowadays so constantly in mind, is a vanished consideration. So many babes are born into the world on the border line between easy viability and advanced asphyxiation that the question of a ready method of promoting respiration is of daily interest to the accoucheur. Here is a point not new except as it is suggested for universal use and not to be reserved for the half suffocated or very tardy breathers.

I do not remember to have seen anywhere the recommendation to make a routine practice of stretching the sphincter ani in all newborn babies before tying the umbilical cord and as an aid to securing prompt and forcible respiration.

I desire to urge this general practice for the promotion of infantile life and have a number of considerations to offer in support of it:

1. Stretching the sphincter ani gives immediate aid to respiration at a moment of partial or advanced asphyxiation which is present in so many of the newborn.

2. For this purpose the little finger may be quickly cleansed and oiled and the operation done for the child while it is in a more or less anesthetic condition; later on the operation becomes more objectionable as causing more suffering.

3. This routine supplies early the important knowledge as to whether a competent sphincter and anal opening exist.

4. As this stretching of the sphincter is an important aid in establishing respiration, so also it may be considered a help to peristalsis and the due establishment of intestinal function, thus probably forestalling an incident like the following:

A baby, 11 days old, having defecated, and voided his bladder, with fair regularity since his birth, was reported by telephone to have frequent crying spells and to strain and grow red in the face as though trying to defecate. The nurse reported that there was no appearance of a tumor either inguinal or umbilical, no intimation of a hernia; and not being a trained nurse she refused to act upon my suggestion to insert a finger and stretch the sphincter ani.

So I must visit this patient, whom I found crying and straining as reported. The anus looked slightly reddened and irritated, and the defecated matter emitted slightly before my eyes looked granular and not of the normal soft consistency. The insertion of my finger caused some crying which soon ceased after the removal of my finger, and the tenesmus and straining did not reappear. One more treatment two days later was given, though it did not really seem necessary. Improved intestinal action as shown by the character of the stools soon became manifest.

The moments immediately following the birth of a child and before severing the umbilical cord are precious and should be seriously employed. I would not wish to suggest a needless care or thought to the attention of the officiating doctor. But this little procedure will not prove burdensome. It is in fact much easier to do than the making of rhythmic traction of the tongue and is of kindred reflex interest. It is safe, easy and timely, conveying vital stimulus to varied functions. Why should it ever be omitted?

## CHOREA AND EYESTRAIN: A CRITICISM.

BY

CHARLES J. ALDRICH, M.D.,  
of Cleveland, Ohio.

To the Editor of *American Medicine*:—In your issue of March 14, 1903, appears a short article by Dr. Albert R. Baker in reference to eyestrain as a cause of chorea, which seems to me to contain statements that ought not to go unchallenged.

I was present at the reading of this paper, which was the opening discussion of Dr. Dickey's paper on chorea, before the Ohio

State Pediatric Society, at Toledo, January 9, 1902, and listened with some amazement to Dr. Baker's statements, and sincerely hoped that they would not be published. I did not discuss the paper at that time because it seemed to me that a very noted neurologist from Philadelphia, who was present, summed up all there was to be said in the discussion by the simple statement that he did not believe the winking and grimacing of children described by Dr. Baker and which was relieved by glasses was chorea, and that chorea proper could not be caused by eyestrain, since it was undoubtedly an acute specific nervous affection of more or less definite onset, course and limitation. He further expressed himself as believing that lenses when needed would, in genuine chorea, operate favorably by removing a source of irritation and consequently aid in the calming of the nervous system which is so necessary in the treatment of the affection.

Since Dr. Baker's article has appeared in print it seems to me a duty to refute the most evident error which he seems to entertain and which he attempts to perpetuate when he states that the lesson which he wishes to teach is, "*Send the patient to the oculist first and not waste valuable time in giving drugs. Give the spectacles first and follow up with your hygienic and medical measures if necessary.*" (The italics are my own.) This very sweeping, almost squinting observation does not fit in very well with the expressed opinion of Dr. M. Allen Starr, who after examining 2,000 cases collected from various authorities says, "While it is possible that local twitchings of the muscles of the eyes or face or neck may be produced by eyestrain or by irritation in the nasopharynx, true chorea is never, in my opinion, produced by these causes, and treatment directed to the relief of so-called muscular insufficiencies in the eye muscles is useless." Again in an article in the *Festschrift* in honor of Dr. Abraham Jacobi, he takes a survey of 1,400 cases of chorea treated in the nervous department of the Vanderbilt clinic, and yet does not even mention eyestrain as a cause.

Krafft-Ebing in an analysis of 200 personally observed cases mentions shock, fright, rheumatism and infectious disease as causes of chorea, but has not observed, or has forgotten to mention eyestrain as a causative factor.

Osler in his book on chorea gives special consideration to the relation of eyestrain as a cause of the disease, and disposes of all the claims of Stevens by the assertion that of the five cases presented to the New York Neurologic Society by Stevens not a single one was chorea minor.

Ranney's later report on chorea and eyestrain is commented on by Osler, who states: "I do not think that any one of the 12 cases could be really called true Sydenham's chorea, but that nearly all were one or other of the varieties of habit-spasm, or tic, some possibly of hysterical chorea." Since this is quoting the words of neurologists and one celebrated internist, let us quote from one who is recognized as perhaps one of the highest authorities in the United States on diseases of the eye, de Schweinitz, who states that "ordinary chorea and many of the forms of facial spasm, habit-spasm, etc., are materially benefited by correcting refractive errors and anomalies of the ocular muscles, just as they are helped by a variety of other treatments, but I do not believe that there is any proof to show that eyestrain of itself is responsible for their origin, with perhaps the single exception of the so-called habit-spasms affecting the orbicularis and immediate facial area. Certainly many of these will disappear promptly after the refractive error is corrected without any treatment whatsoever, and they will not disappear if you do not relieve the eyestrain. In a constitution predisposed to chorea I presume eyestrain is a very important factor in fostering and perhaps provoking attacks, but that is all." Writing again upon the subject, the same author says: "The evidence, however, seems quite lacking that hypermetropic refraction is the basal cause of chorea, as it is that the chorea is the cause of the hypermetropia."

Now in view of these few facts quoted from the large array of eminent, scholarly men who do not believe that eyestrain can be anything but an occasional exciting cause of chorea, the rather cruel criticism of the profession in which Dr. Baker indulges in the following quotation is certainly regrettable: "It does seem sometimes that the profession as a whole are very

obtuse in adopting new ideas and new methods." It is not a question of new ideas but one of diagnosis, and it has been established that the two New York ophthalmologists were not treating chorea, nor do I believe from Dr. Baker's description that his cases were chorea, and am glad that he conscientiously expresses his doubt as follows: "It is possible that these are not true choreas and should be called habit-choreas, in any event they are met frequently and often are not treated intelligently."

Although not germane to the question of chorea and eye-strain the following quotation from his article should not be offered without comment: "Migraine, that typical eye headache which can almost always be cured with spectacles, is still doped, purged, and dieted, world without end, forever, until the patient takes the matter in his own hands and consults an oculist."

In true migraine, while many remedies and measures may relieve the severe attacks and render them less frequent, yet it remains practically an incurable neurosis. I, who am a victim of this markedly hereditary affection, and unfortunately have transmitted it to my two children, one of whom has been carefully glassed and reglassed without benefit by Dr. Baker and other oculists for the cure of this malady, may be pardoned for having pronounced views upon this question. Indeed, I have sent many other patients to be spectacleed by Dr. Baker and other oculists, but fail to recall a single case of genuine migraine that has been cured. Had Dr. Baker treated his subject as eyestrain and habit-spasm I would not have a word of fault or a criticism to indulge in, but chorea certainly is of itself either an acute specific infection or else the reaction of an especially susceptible nervous system to the toxins of various other acute infections. I myself have so constantly observed increase in the size of the various lymphatic glands of the body occurring in acute chorea and in the absence of history of rheumatism or other acute infections that I have come to look upon it as an acute specific infection expending its force upon the motor cells of an especially vulnerable nervous system.

Guthrie believes chorea to be a selective action of the rheumatic diplococcus upon a nervous system with special predisposition to chorea. Campbell and Thompson have found chromatolysis and swelling of the cells. Dana and others have found embolism of the minute arteries of the brain.

It is an attested fact that rheumatism frequently complicates or precedes chorea; that its occurrence in children of rheumatic parents is not uncommon; that not infrequently when no rheumatism is present it is complicated by endocarditis; that embolism of the arteries of the brain has been known and even of the arteries of the retina.

Now, in view of this array of pathologic findings, how, in the name of common sense could we hope to cure chorea with spectacles, unless to use almost Dr. Baker's own words that after the victim has been refracted "without end, forever, until the patient takes the matter in his own hands and consults," not the oculist, but a physician.

## AN UNUSUAL CASE OF ANGINA.

BY

MILTON GOLDSMITH, M.D.,

of Pittsburg, Pa.

Physician to the Medical Dispensary, Mercy Hospital, and to the Pittsburg Free Dispensary.

H. M. N., a white male, aged 36, came to me August 18, 1902, stating that for two years he had been suffering with attacks of pain in his left arm. The attacks were usually brought on by excitement or exertion and even by rapid walking. He had been treated by several physicians and only a few weeks ago had undergone two operations upon the nerves of the arm without obtaining relief.

*Family History.*—His mother died of gastric catarrh at 67 years of age. His father died at 54, from the rupture of a blood-vessel, blood gushed from his mouth and nose and a diagnosis of apoplexy was made. He had been a hard working man and during the few years preceding his death had been compelled to do heavy hauling for both the Union and Confederate armies. Two sisters died in infancy, two later of typhoid fever and one was drowned. The only living sister is said to have mammary carcinoma. One brother is living and well. There is no history of tuberculosis.

*Social History.*—The patient has been an ironworker most of his life. He was a bartender one year and a policeman four-while for nearly eight years he carried on professional prize-fighting. He has used alcohol and tobacco moderately and insists that he never drank heavily. He is married and has two healthy children; his wife has had no miscarriages.

*Previous History.*—He is uncertain as to the usual infections of childhood. Seventeen years ago he was jaundiced for three or four months, during which time he was constipated and occasionally nauseated, but had no pain. Several years later one knee became slightly swollen, but under local applications the condition subsided in a few days. He had specific urethritis four times but had no lues. With these exceptions he has never been sick. Several years ago he was drugged during a prize-fight, and since that time he has been slightly constipated, but by taking some proprietary cathartic, has been able to have a daily evacuation. His appetite has always been good; he sleeps well; is not subject to headache, and except for the attacks of pain mentioned considers himself a very healthy subject.

*Present History.*—About two years ago, while performing some ordinary motion with his left arm (no suddenness, violence, or twisting) he was seized with severe pain in that member, starting just in front of the middle of the deltoid, immediately below the acromion, then shooting down the outer side of the arm and forearm to the back of the thumb. Since that time he has had attacks varying in frequency from 1 or 2 to 10 or 12 in 24 hours, never being free from them for a period longer than two or three days. Attacks have usually appeared after running, rapid walking or exertion of some kind, occasionally after excessive eating, but they have appeared while sitting perfectly still, or even during sleep. They are more frequent during damp weather. At first the pain could be relieved by pressure over the point of starting, but this means of relief was soon lost. The attacks last 15 to 20 minutes, as it seems to him; they have never been actually timed. He could continue walking, but knows from experience that absolute rest will shorten the attack, so he always stops immediately.

During the paroxysm he notices the radial arteries throbbing, gets very pale and sweats profusely, but has no dyspnea or sense of impending dissolution. Eructations of gas generally end the attack. Several times he has had the sensation of something clutching at his heart, but the pain never begins there, and it is the knowledge that to continue walking will produce this feeling of something clutching or constricting his heart which causes him to stop the moment the pain appears. The arm has lost neither strength nor usefulness; there has never been any tenderness; between the attacks he has absolutely no pain and feels perfectly well so long as he keeps his bowels open. He has been seen by several physicians and told that his trouble was perineuritis.

Treatment has been varied. Blisters over the course of the pain have been tried; he has used a battery and taken strontium iodid with no effect except to upset his stomach. At his request venesection was performed. He has taken morphin and anti-kamnia; the former gave some relief for a time, but soon lost its effect; the latter had little, if any, effect.

About July 25, under chloroform anesthesia, the median nerve was stretched. August 3, under local anesthesia, an incision was made over the seat of pain, the muscles around the joint loosened up and the circumflex nerve stretched. (The descriptions of these operations were given me by the surgeon who performed them.) The first operation had no effect; following the second there was some lessening in the frequency of attacks, but when they did appear they were as severe as ever.

For a few weeks preceding these operations the patient had been at a health resort, drinking largely of the waters there, and was probably taking very good care of himself, and the slight relief obtained was probably the result of this improved hygiene, rather than of the second operation.

Shortly before applying to me he was told to try nitroglycerin. This advice was given by some physician to whom he had told his story, who probably suspected the nature of the trouble, but made no examination whatever.

*Examination, August 18, 1902.*—The patient is a strapping looking fellow, of large bony and muscular development. His complexion is slightly like that in argyria. There are no enlarged superficial lymphatic glands. The left arm shows a scar at the middle of the inner border of the biceps and one below the acromion, the results of his recent operations. Both are healthy in appearance, the second being somewhat tender, the last operation having taken place only 15 days previously. There is no atrophy or flabbiness of the muscles of the shoulder or arm; no trophic lesions; no tenderness over nerve trunks or in any part of the arm, except at the scar of the last operation. All motions can be performed equally well with both arms, though at present he voluntarily restricts movements of left arm because of tenderness in scar already mentioned. With these exceptions, and some discoloration due to counterirritants, the arm appears perfectly normal. Several healthy scars, results of former injuries, are found on the face and right leg. Pulmonary resonance on the right extends to the sixth rib in midclavicular line; to the level of the eleventh dorsal spine posteriorly; on the left it extends to top of the fourth rib at the left sternal border and to the level of the twelfth dorsal spine posteriorly. All borders descend with inspiration. Fremitus, resonance and breath sounds are normal.

*Heart.*—Apex beat in fifth interspace  $\frac{3}{4}$  inch outside the

midclavicular line; impulse at apex is quite distinct, while there is a less marked impulse to the entire precordia; no thrill.

Superficial dullness begins at the top of the fourth rib at left edge of sternum; extends to left as far as position of apex beat and to the right as far as the left sternal border. Because of the large muscular development, deep dullness could not be satisfactorily determined, but apparently does not extend beyond the right edge of the sternum. At the apex the first sound is roughened, while the second is obscured by a murmur, to be described presently. Pulmonary second sound is somewhat accentuated and also partly obscured by this same murmur. At the aortic area the first sound is roughened and a short systolic murmur is heard in the carotids. A long, moderately loud diastolic murmur is heard, most distinct in the second interspace at right edge of sternum, but also plainly heard in the pulmonary area and less distinctly in the mitral region. This murmur is transmitted toward the apex. The superficial arteries throb visibly; they are not distinctly atheromatous, possibly hard for a man of 36. No arcus senilis. The pulse can be easily felt at the ends of the fingers; it is decidedly of the water-hammer character. With these signs a diagnosis of aortic regurgitation is proper. No capillary pulse, pulsating uvula or murmur in the femorals. No symptoms of failing compensation.

*Abdomen.*—Practically negative.

*Urine.*—Amber, clear, acid; sp. g., 1.020; no albumin; no sugar; microscope showed a few leukocytes and epithelial cells. Several subsequent examinations have given practically this same result.

*Hemoglobin* (by Tallquist scale, 75%). This moderate anemia may be the result of venesections and operations, although enough time has elapsed to make up for this loss.

In deciding upon the diagnosis, it is unnecessary to differentiate from all the conditions this case might correspond to. While the correctness of my views cannot be absolutely proved, I feel satisfied that the case belongs to that group of affections of which true angina pectoris is the type, and shall merely mention those features in which it differs from the classic description of that disease:

1. Early age; disease began at 34.
2. Great frequency of attacks, often 10 to 12 in 24 hours.
3. Pain begins in arm, appearing at the heart always secondarily, and then only after patient fails to become perfectly still upon the appearance of pain.
4. Pain travels along the outer side of arm (the possibility of an anomalous nerve or artery is suggested).
5. Apparent relief in frequency, not severity, following second operation (as previously mentioned, this is probably accounted for by improved hygiene).
6. Normal urine.
7. Absence of positive signs of arteriosclerosis.
8. Moderate degree of cardiac hypertrophy.

Despite the evidence of organic lesions, the possibility of a neurotic basis cannot be ignored. Without taking time for detailed argument, I will simply state that after studying the case for a considerable time, I have not been able to ascribe the condition to a functional basis. The effect of nitroglycerin is in itself strong evidence as to the genuineness of the condition. About two weeks before coming under my observation he began to use this drug, and by taking 1 mg. ( $\frac{1}{30}$  gr.) by mouth was able to shorten the attacks markedly.

I began treatment by putting him on .6 mg. ( $\frac{1}{100}$  gr.) with tr. aconite .06 cc. (1 minim) every three hours, also ordering syrup of hydriodic acid 4 cc. (1 dram) t.i.d., and giving the usual directions against excitement, overexertion, etc. He did not know he was taking nitroglycerin. During the week previous he had had a number of severe attacks, showing the improvement following his second operation to have been merely transitory.

The subsequent history of the case is as follows:

Immediately following the regular doses of nitroglycerin the number of attacks dropped to less than half the former number, becoming at the same time much less severe. He found himself able to run short distances and indulge in other forms of moderate exertion which had hitherto always brought on an attack. Within a few weeks, against my advice, he decided to return to work, after an idleness of two years. He secured a position in a rolling-mill, where he was simply an overseer, but occasionally had to assist in emergencies. As a rule he was able to take part on these occasions without exciting an attack. Improvement continued steadily for about two months, after which he remained stationary. During this time there was a slight increase in the size of the heart, while all the murmurs became more marked.

In a paper by Dr. J. H. Musser<sup>1</sup> attention is called to the fact that dilation of the heart in a patient the subject of angina pectoris is frequently attended by a subsidence of the symp-

toms and at the same time by a change in the physical type of the individual. The patient under consideration may be an illustration of this rule. The only physical change noted was a decided diminution in his sexual sense.

The pulse for a time lost its Corrigan character. After reaching this stationary stage, with the dose of nitroglycerin already mentioned, beside taking 1 mg. ( $\frac{1}{30}$  grain) whenever attacks appeared, I hesitated to increase the quantity.

Erythrol tetranitrate, .06 gram (1 grain) 4 times a day was tried for two weeks, but had to be discontinued because of the expense; it had no effect during the brief time it was taken. Another point of interest was the fact that after the first great improvement attacks appeared only in damp weather. Thinking of the possibility of a rheumatic tinge, a course of salicylates was prescribed but with no effect whatever. One attack came on just as he was entering my office. It lasted about five minutes, and did not differ from his own description. Pulse was 128 at the beginning and 100 at the end of the attack.

I immediately gave him two hypodermic tablets of nitroglycerin, 6 mg. of each ( $\frac{1}{30}$  grain); they happened to be some I had had on hand about two years, probably of no more value than so much saccharum lactis; the effect was what might have been expected from the latter article, in fact he insisted that there was nothing in them.

Shortly after this the man disappeared, and I did not see him until ten weeks later. He had decided to stop "doctoring," and had bought 1,000 nitroglycerin tablets, 1 mg. ( $\frac{1}{30}$  grain) and was taking them only when he felt attacks coming on, these varying from 1 or 2 to 10 or 12 a day, rarely the larger number; on bright days there were rarely any. This has been the only drug which ever gave quick and certain relief. When the weather is fair he can undergo moderate exertion with impunity, but during damp weather very little exertion will excite an attack.

Examination at this time, January 22, 1903, showed apex in fifth interspace, one inch outside midclavicular line. Superficial dullness begins at top of fourth rib at left edge of sternum.

Auscultation at the apex shows a systolic murmur transmitted to the anterior axillary line. A systolic murmur is heard at the aortic cartilage and in the carotids. The second pulmonary sound is obscured by the aortic diastolic murmur, which is transmitted down the sternum and toward the apex. Pulse is typically Corrigan and drops a beat occasionally. There is a slight capillary pulse apparent, though it should be mentioned that this examination was made at night. His general health is good and he is still at work and taking a fairly active interest in a local political campaign. I have not seen the patient for nearly three months, but while the further study of the case must be left to the future, it has seemed of sufficient interest to justify its presentation in its present unfinished state.

## EMANSIO MENSIMUM.

BY

WM. HIMMELSBACH, M.D.,  
of San Francisco, Cal.

*To the Editor of American Medicine:*—I desire to place on record the following cases of emansio mensium:

I have had under observation for the past four years a young, white, unmarried woman of 23, in whom there is complete suspension of the menstrual function, and she has furthermore assured me that she has never had a flow at any previous time. Examination showed an infantile uterus; it was impossible to palpate the appendages. At long intervals there has been a slight hemoptysis; otherwise she has been perfectly well in every respect.

A second case is that of a married woman, aged 28, who has a child 3 years old. She menstruates once or twice a year, but has gone 14 months (no pregnancy) without losing a drop of blood vicariously or otherwise. She is well nourished, and as a rule of a cheerful, sunny disposition, excepting at times a marked irritability manifests itself of sometimes a day's duration.

An Italian translation of Dr. J. Madison Taylor's and Dr. William H. Wells' wellknown "Manual of Diseases of Children" (second edition, 1901) is being published by the Unione Tipografica Editrice, of Turin, Italy, the first of the twenty fascioli of which the Italian translation will be composed having just been issued from the press. The translation has been undertaken by Dr. Mario Flamini, of the Pediatric Clinic of Rome; Professor Luigi Concetti, director of the Pediatric Clinic of Rome, has written a preface, and Dr. Francesco Valagussa, adjunct professor and docent of the Pediatric Clinic of Rome, has made various notes and additions. The translation also has been somewhat revised by the authors, who have been in constant communication with Dr. Flamini, forwarding him notes, etc. The occasion is one of felicitation not only to the authors, but to American medicine generally, inasmuch as the manual was chosen as being especially adapted to clinical teaching in Italy.

MEDICAL EDUCATION IN THE UNITED STATES.<sup>1</sup>

BY

FRANK BILLINGS, M.S., M.D.,  
of Chicago.

One of the chief objects of the organization of the American Medical Association was the elevation of the standard of medical education in the United States. In the president's address, the Father of the Association, Dr. N. S. Davis, stated that "the purpose of the organization was the improvement of our system of medical education and the direct advancement of medical science and practice."<sup>2</sup> That medical education in that day was defective, as recognized by the founders of the Association, is shown by the report of the Committee on Medical Education in the year 1850. The committee said, in part, as follows: "Medical education is defective because there are too many medical schools; the teachers are too few. There are too many students. The quantity of medicine taught is too limited; the quality too superficial, and the mode of bestowal of the honors of medicine too profuse and too unrestricted."

For many years the Association showed its interest in and attempted to influence the elevation of the standard of medical education through a committee on medical education. The Transactions of the Association of the earlier years show many reports of this committee, which display much thought and effort on the part of the Association to improve the status of medical education at that period of time. James R. Wood, as chairman of the committee, in the year 1858 recommended that the various medical colleges of America be requested to send delegates to a convention of medical colleges, to consider the matter of medical education. This movement finally resulted in the formation of the Association of American Medical Colleges, which thereafter represented, to a degree at least, the American Medical Association in its efforts to improve medical education. Later, the Southern Medical College Association was formed. Together these associations represent about 80% of the regular medical schools of the country, and these colleges have, in a general way at least, fulfilled the minimum requirements prescribed by the rules of the associations in regard to the preliminary education of students, the length of the college course, and the character of the curriculum.

About 25 years ago the Illinois State Board of Health, through the splendid efforts of Dr. J. H. Rauch, its secretary, made a report on the number and character of the medical schools of the country. This board adopted a minimum of requirements of medical schools as a necessary step toward the recognition of their diplomas by the State Board of Health of Illinois. This minimum requirement of the State Board of Health was gradually increased from time to time, with the result that many of the medical schools were obliged to raise the standard of medical education to enable their graduates to obtain licenses to practise in Illinois. Other States followed Illinois in requirements for better methods of medical education, with the result that the standard of education in the country was very much improved.

## MEDICAL SCHOOLS OF THE COUNTRY.

In the earlier days of our country, the need of physicians was met by the organization of medical schools which were, as a rule, proprietary in character. These schools attempted the education of physicians on the then existing conditions of medicine by teaching in a didactic way the principles and theories of medicine and surgery. The branches usually taught at that time consisted of anatomy, physiology, chemistry, materia medica, obstetrics, the practice of medicine and of surgery. But little opportunity was offered in the great majority of the schools for extensive, practical teaching in anatomy or chemistry, and but a moderate amount of clinical work in the so-called practical chairs. The course of medicine in the college

consisted of two annual sessions of four or five months. The course was not graded. The student attended all the lectures and clinics taught during his first year, and the second year was a repetition of the first. This class of schools was rapidly increased in the course of time. The chief reasons therefor were the fact that it was recognized that a connection with a medical school was profitable, directly and indirectly. The prestige which the teacher enjoyed among the graduates and the laity brought him a remunerative consultation and private practice. In most of the States it was easy to incorporate and obtain a charter for a medical college. It cost comparatively little to conduct and maintain the institution. Lecture-rooms were obtained at trifling cost. The dissecting-room was not worthy of the name of a laboratory, and the chief expense in maintaining it was the cost of dissecting material, which was usually deficient in quantity and poor in quality. Medical schools were organized all over the country, without reference to the needs of the people. Medical education was prostituted. To obtain a sufficient number of students many institutions showed a most degraded disregard of the moral and mental qualifications of the matriculates. The income of the school was wholly derived from the tuition of students, and no applicant was turned away who had the cash with which to pay his way. To add to the facility of obtaining a medical college course, there were organized in some cities evening schools, the hours of college attendance occurring from 7 to 9 or 10 o'clock at night. These sundown institutions enabled the clerk, the street-car conductor, the janitor, and others employed during the day to obtain a medical degree.

In spite of the general tendency to increase the facility by which a medical degree could be obtained, there was a force at work to improve the methods of medical education. A few older medical colleges and an occasional new one set the standard high in relation to the existing status of medicine. There were earnest, forceful medical men in some of the schools who fought for a higher standard for matriculation and graduation.

The medical college associations exerted a splendid moral influence for good, and the State boards in all the more advanced States have, by mandatory legislation, compelled the colleges to raise the requirements in reference to the preliminary education, the length of the annual session, the time of medical college study, the character of the curriculum, etc. As a result, the status of medical college education has been very much improved in the last 20, and chiefly in the last 10 years. But, improved as it is, there are evils which menace us, the chief of which still are, too many medical schools, too many students, and inadequate facilities for the proper teaching of medicine.

The improvement in medical college requirements has increased the cost of the maintenance of the medical college to a degree that it is no longer a profitable financial venture. There can be no dividends. Indeed, the proprietors of the private institution must often make up a deficiency in the annual budget. In spite of this fact, medical colleges have continued to increase steadily.

In 1877 there were 65 medical schools in the United States. In 1882 this number had increased to 89, and 1901-02 to 156. The enrolment of students and the number of graduates have also increased, in spite of the fact that the requirements for matriculation and graduation have been increased. In 1882 there were<sup>1</sup> 14,934 matriculates, and this number was increased in 1901 to 26,417, and in 1902 to 27,501, an increase of about 100% in 20 years.

The number of graduates in 1882 was 4,115; in 1901, 5,444; in 1902, 5,002, an increase of about 25% in 20 years. If, in 1850, there were too many medical schools and too many students, what can we say of the condition today?

It has been estimated that there is an average of one physician to 600 of the population of the United States at the present time. The natural increase in the population of the country, and the deaths in the ranks of the profession, make room each year for about 3,000 physicians, based on the proportion of

<sup>1</sup> President's Address, delivered at the fifty-fourth annual session of the American Medical Association, at New Orleans, May 5-8, 1903, and published synchronously with the *Journal American Medical Association* by courtesy of the Editor.

<sup>2</sup> Transactions A. M. A., Vol. xvi, 1865.

<sup>1</sup> The Journal of the American Medical Association, Vol. xxxix, No. 10, p. 574.

one physician to 600 of the population. With 5,000 or more graduates each year, a surplus of 2,000 physicians is thrown on the profession, overcrowding it, and steadily reducing the opportunities of those already in the profession to acquire a livelihood. The evil of an overcrowded profession is a sufficient cause of complaint, but the cause thereof is the important point for us to consider and, if possible, remove. To correct the evil, the ease and facility with which a medical degree may be secured in this country must be diminished. As before stated, there are now 156 medical schools in this country. Of these, 30 are sectarian, and 136 are so-called regular schools. Fifty-eight are medical departments of universities, of which 24 are State institutions. The relation of the medical school to the university in most instances is a nominal one only. In but few of them is the control of the faculty or the finances of the medical department vested in the university proper. In a very few of them the sciences fundamental to medicine are taught in the university. In the majority of these schools these departments are duplicated in the medical department, and are taught by members of the medical faculty. In most instances, too, the teachers of the fundamental branches are physicians who devote but a part of their time to teaching. They teach without salary or for a nominal one only. Their remuneration is obtained by private practice, to which they must devote their best energies, to the detriment of their value as teachers. The clinical department of these schools is, in most instances, wholly inadequate. The majority of such schools depend on the general hospitals situated near them for the privilege of the use of clinical material. Necessarily, these clinical advantages have great limitations, inasmuch as they can not be fully controlled for the purpose of proper bedside teaching, or for scientific investigation. Some of the medical schools which are connected with State universities are situated in small cities where it is impossible to command an adequate amount or variety of clinical material. The connection with a university which many of the schools enjoy is, therefore, almost valueless in a pedagogic sense. The majority do not differ materially from the private or proprietary schools in their value as teaching institutions. Ninety-eight of the medical schools in the country are private corporations, organized, maintained and, as a rule, owned by the faculty. If, in earlier years, these institutions were sources of direct financial profit to the owners, they have ceased to be so now—at least most of them. The evolution of medicine has made it necessary to extend the laboratory method of teaching. As these schools attempt to teach the whole curriculum, the erection, equipment and maintenance of the necessary laboratories have so increased the cost of conducting the schools that they are usually no longer self-supporting. The temptation is in such schools to conduct them on a plane which shall just comply with the minimum requirements of the various State bodies which regulate medical practice in the several States. They are maintained ostensibly to teach medicine, but in reality for the prestige which a professorship affords the teacher in his private and consultation practice. Proprietary schools depend on general hospitals and dispensaries for clinical material. What was said of the status of clinical teaching of the medical departments of the universities is true also of the proprietary college. These schools can not hope to improve their present standards. The majority attempt to maintain laboratories and other expensive means of teaching which a modern medical education demands. But in how many are the laboratories worthy of the name? What kind and variety of instruments and apparatus do they afford? Are their teachers of the sciences of the fundamentals of medicine capable? They can not hope for better conditions, because the time when a student's tuition will pay the school for his instruction, if he is properly taught, will never return. Medical education of the future must be based on the status of medical science. That basis is recognized now, but is attempted in the great majority of our medical institutions in a very superficial way.

#### SCIENTIFIC MEDICINE.

The great and important discoveries of Pasteur and the practical methods devised by Koch in bacteriology marked a new era in medicine. Before the facts made clear by these dis-

coveries, the hypotheses and theories of other days have disappeared. Our knowledge of man and the lower animals and of the diseases and evils which afflict them has been revolutionized within the last 20 years. The advance in medical knowledge has been greater in that period than in all preceding time. Medicine now embraces many more subjects, chiefly fundamental ones, than were known 20 years ago. Formerly a very superficial knowledge of a few isolated facts in general chemistry and human physiology and a memorized knowledge of human anatomy and of *materia medica* enabled the student to learn the practice of the art of medicine and surgery. Now, the problems which confront the clinician and investigator in medicine and surgery compel him to have a good and working knowledge of general, physical, and physiologic chemistry, of general biology, bacteriology, pathology, physiology, embryology, pharmacology, histology, and anatomy. The physician who has not a practical knowledge of these fundamental subjects can not clearly understand the methods of others engaged in scientific investigation, nor can he rationally utilize the discoveries of others in his work. Medicine today is applied science. If we utilize the knowledge of today in an attempt to cure and prevent disease, it must also be an experimental science. No one can practically apply or rationally experiment with what he does not know. The fundamental studies of medicine must, therefore, be acquired by all who desire successfully to apply them as sciences. The successful experimental application of these sciences has given us within 10 years a knowledge of the method by which the invading bacteria affect the host, and has likewise developed a principle of wide application as a preventive and cure of certain diseases by the use of antitoxic sera. It has confirmed the principle of preventive inoculation, accidentally discovered by Jenner, and has enabled us to apply the principle in other diseases than smallpox. It has enabled us to know the methods of transmission of certain infectious diseases and to know how to stamp out scourges like yellow fever, the plague, and malaria.

Through the evolution of Listerism, it has enabled the surgeon to invade every region of the animal body, and to save scores of lives formerly doomed to death. The freedom with which the surgeon may now operate has not only saved lives, but indirectly, the knowledge of disease processes so studied during life has taught us many new facts in symptomatology, and has cleared away many fallacies concerning pathologic processes. It has given us many new methods of clinical study, and furnished data from the blood, the spinal fluid, the exudates, the sputa, the sweat, the feces, and urine, which enable us to recognize disease much more readily than before.

Much as has been accomplished by experimental medicine in a comparatively brief period of time, there are vast fields to which the method has not been applied. With most of us, our present methods of clinical observation enable us to do little more than name the disease. In the vast majority of the infectious diseases we are helpless to apply a specific cure. Drugs, with the exception of quinin in malaria, and mercury in syphilis, are valueless as cures. The prevention and cure of most of the infectious diseases is a problem which scientific medicine must solve. What is true of the infectious diseases is also true of the affliction of mankind due to chemical influences within the body. We know but little of diabetes, of the primary blood diseases, or of the various degenerative processes of age and disease. We hopefully look to chemistry to reveal to us the cause of these and other conditions. Experimental medicine must be the means of removing the ignorance which still embraces so many of the maladies which afflict mankind. Not every student, nor every physician, can become an experimenter in applied medicine. Nevertheless, every physician must be so educated that he may intelligently apply the knowledge furnished him by experimental medicine in the cure of such diseases as can be cured. He will no longer juggle with the life of his patient by an attempt to cure with drugs or otherwise, where no help is possible.

#### METHODS OF MEDICAL EDUCATION.

The phenomenal evolution of medicine has multiplied the subjects of medical study. The character of these sciences requires that they shall be taught by the laboratory method.

The laboratory method, too, has been adopted as the chief method of instruction in anatomy, pharmacology and chemistry, formerly almost wholly taught in medical schools by didactic lectures. The laboratory method, while necessary to the proper and practical instruction of the student, involves an expense which is appalling when compared with the methods of teaching formerly practised in all schools, and still adhered to in many medical schools. The method is expensive, inasmuch as it involves more extensive buildings, much expensive apparatus and an increase of the teaching force. The instruction must be individual or to small groups of laboratory workers, and this involves also an extension of the time of instruction. A physician engaged in private practice cannot possess and retain the general and technical knowledge necessary to enable him to teach one of the fundamental sciences properly nor can he devote an adequate amount of time to it. The teachers of these fundamentals must be investigators in the province of their respective sciences. They must give their whole time to the instruction of students and to original investigation. The thoroughness and accuracy of the training of the special senses, and in experimenting, which a student will receive from such teachers in properly equipped laboratories, will make him keen in intellect and sound in judgment. His desire for knowledge will be stimulated by the atmosphere of his surroundings, and will awaken in him a consciousness that through him and his work the knowledge of the world will be increased and humanity benefited thereby. But teachers of this character must be paid salaries quite as large as the remuneration of professors in the departments of arts, literature and science. The salaries of such professors and of the corps of assistants which the laboratory method implies make the cost of the university or college far beyond the income which could be derived from the tuition of students. I believe it has been estimated that the laboratory method of instruction, now followed by all first-class institutions of learning, costs annually from \$400 to \$500 per student. But great as the cost seems, it must be conceded that the present status of medicine demands the thorough instruction of students in these fundamental studies. It matters not whether his future may be that of a teacher or a practitioner of medicine. In either event he must apply his knowledge of the fundamental sciences to his work, and the result will depend on the thoroughness of his education.

#### APPLIED MEDICINE AND SURGERY.

To enable the student to utilize the knowledge of a thorough training in anatomy, physiology, chemistry, pharmacology, physiologic and physical chemistry, embryology, neurology and pathology, he should be afforded facilities of equal rank in clinical medicine and surgery. To supply the student with proper clinical facilities involves several important features. Special hospitals, which would be absolutely under the control of the medical school, would be necessary. The hospital should be constructed with a definite idea of teaching students and of making researches into the nature, causes and treatment of disease, as well as to care for a definite number of patients. Hospitals for general medicine, surgery and obstetrics would be essential. Such hospitals, with laboratories and equipped with instruments, apparatus and library, would cost for their building and maintenance a very large sum of money. With such hospitals it would be necessary to choose the professors of medicine, of surgery, and of obstetrics, with competent assistants, of the same type as the teacher of the fundamental sciences. They should give their whole time to the work of teaching and to original research in the hospital. They should be men who have proved their scientific fitness for the important positions, by the contributions they have made to medical knowledge. They should rank with and receive the pay given to professors of important departments in arts, philosophy, and science. When so paid, they would be free to expend all their energy to teaching and to experimental medicine—a career which would enable one to be of the greatest possible service to mankind. No life's work could be fuller or of greater self-satisfaction, and surely none would be more honorable. From these teachers and investigators the student would obtain instruction of the same systematic methods of accurate observation and investigation which were employed

in the fundamental branches.) He would receive thorough conscientious drill in the fundamental methods of examination of patients, and his knowledge of the fundamental sciences would be constantly applied in this work. The trained clinical teachers would direct the student in thorough careful observation in the wards and at the operating table, would collect data to be submitted to experimental tests, and would conscientiously carry out the experiments in the laboratories of the hospital.

The brilliant discoveries which have made our knowledge of the cause and means of transmission of many of the infectious diseases have been chiefly due to the introduction of the experimental method of investigation. Teachers and investigators of the type mentioned will have the opportunity to make equally important discoveries in the broad field of the unknown in medicine. They will train students in the methods of research work and constantly increase the number of investigators in the domain of medicine. And there is need for such men. We may give the great practitioners who have taught clinical medicine their due meed of credit for their excellent, painstaking, unselfish efforts as teachers. They have added to the sum total of our clinical data, have utilized the knowledge of the pathologist and the physiologist in diagnosis, and have tested and judged the worth of therapeutic aids in the treatment of disease. But as teachers they have not made students investigators or experimenters. Not one of the recent great discoveries in medicine has been made by such a man. He has used as clinical material hundreds of cases of pneumonia, rheumatic fever, tuberculosis and chronic diseases by the score; his experience has taught him to recognize these diseases, even when the clinical manifestations are obscure, but he is no more successful than when he began to practise in saving the life of the patient with pneumonia, in preventing endocarditis in rheumatism, in curing tuberculosis, or in checking the advance of a chronic hepatitis. It is time, therefore, that the clinical teacher should have the knowledge necessary to carry on experimental investigation, with hospital facilities for the work, that the profession may become purged of the shame of helplessness in curing so many of the common diseases of mankind.

The patients who will be received in these hospitals will be fortunate. They will receive the most painstaking examination and study, and the experiments made on animals in the laboratory will benefit the patients directly, inasmuch as more rational therapeutic measures will be applied in cases so investigated. In addition to the clinical teachers, who will devote all their time to teaching and research work in the special hospitals, there will be quite as much need for the clinical teacher, who is in private practice, in the general hospitals. Under his direction the student may himself investigate a hospital or ambulatory case, and undertake the care of the patient. His rich and varied experience in hospital and private practice will enable him to round out the student's college education. He will impart to the student a better idea of medicine as a whole. He will coordinate and arrange the isolated facts of clinical and laboratory investigation, and give them their true and relative value. He will teach the student the art of medicine; he will teach him that human sympathy and encouragement of the sick and dying are a part of his duty as a physician.

It would be most practical to make the clinical work of the third year a clinical drill and experimental course, given in the special hospitals, and assign the students of the fourth year to the general hospitals and to the clinical teachers who are in private practice. All the general hospitals and dispensaries controlled by the medical schools could be utilized in the fourth year for this purpose, and afford the student an abundance of clinical material and the benefit of the experience of many clinical teachers. Many of the assistants in the special hospitals of the third year course would doubtless engage ultimately in private practice, and would, because of their scientific attainments, make excellent clinical teachers in the fourth year. A medical school conducted on the high plane advocated must necessarily be under the control of a university. Such a medical school would cost an enormous amount of money, and this can be commanded only by the trustees of a university of the highest order. That the money for the purpose of establish-

ing and maintaining university medical schools with research hospitals and university clinical courses will be forthcoming can not be doubted. The world is awake to the great discoveries recently made in medicine. The wealthy men of this country have had their interest aroused as never before in reference to the possibilities and benefits which medical investigation will give to mankind. They now recognize that they and all posterity will be benefited by every new fact discovered in medicine, and that physicians thoroughly and scientifically trained are necessary to conserve the health of the people.

Three years ago Professor W. W. Keen, in his address as president, deplored the fact that medical schools received relatively little aid in the form of endowments as compared with universities and colleges of philosophy, art and theology. Since that time several millions of dollars have been given for medical education and scientific research. The signs of the times point to a brighter future of medicine in America.

#### EDUCATION PRELIMINARY TO MEDICAL STUDY.

The subject of the educational requirements for matriculation in medical schools has been discussed at many meetings of this Association in its earlier years, and later by the college associations, by the American Academy of Medicine, and by the various State boards of health.

The requirements were at first lamentably low, and the efforts of the Committee on Education of the American Medical Association and of the college associations had but little effect, because they possessed no legal power to control the schools.

The influence of the various boards of health of several States, notably Illinois, was more marked, inasmuch as these State boards possessed a mandatory power. The colleges were forced to adopt the minimum educational requirements of the State boards of health if their diplomas were to be recognized by the respective State boards.

These moral and legal influences to improve the preliminary requirements were almost nullified by the practice of a majority of the medical schools in admitting students whose educational status was examined into and judged by a committee of the college faculty.

This practice is still followed by a majority of the medical schools and results in the admission of many students who are unable to fulfil the prescribed requirements. As a subterfuge, students are often matriculated conditioned in one or even several subjects. Then the student and the faculty committee forget all about the subject and the student completes his course, goes into practice, and dies with the conditions still undischarged.

The present requirements of the college associations and of the various State medical examining boards and State boards of health amount on the average to a high school education. The curricula and length of course of the high schools of the different States, and even in the same State, differ very substantially. However, if the medical schools now in existence would honestly require as a minimum education the diploma of a high school, without regard to the rank, it would be a marked advance over the present requirements as practised by most schools.

We must admit, too, that there are medical schools of such a low educational grade that they have no right to demand of their matriculates as much even as a common school education. This fact that low-grade medical colleges exist is one of the most satisfactory explanations of the difficulty encountered in elevating the standard of preliminary requirements.

To get at the root of the matter the medical college must be brought up to the proper educational standard, and then, and then only, can be made a proper preliminary educational requirement.

#### UNIVERSITY MEDICAL COLLEGE.

The present status of medical science requires and demands a university medical college course. By university medical college is meant a medical school which is directly connected with and a part of a university; the university fixing the requirements and controlling the admission of students to the medical department. The method of teaching both the funda-

mental and the clinical branches is on the principles outlined above. To prepare properly for such a course the student should have as a minimum preparation at least two years of study in a good college or university. The requirements to enter a good college or university would insure a sufficient knowledge of the ordinary school branches and also Latin or Greek. During the two years' course in college his time would be well spent in the study of English, French, German, mathematics, history, philosophy, physics, chemistry, general and organic, and qualitative analysis, comparative anatomy and general biology. The amount of time to be devoted to each of these subjects would be the same as that of students of general science, as arranged in all college curricula, with the exception of a much more thorough course in chemistry, biology, physics, and comparative anatomy.

So prepared the medical matriculate would be able to grasp all the intricacies of the subjects of the fundamental branches of medicine. With the addition of the full medical college course as outlined above his education would be equal in culture to that of the graduate in arts and philosophy, at the same time it would be practical and especially fit him for his work as a scientific investigator or practitioner, or for both.

With the medical profession so educated a physician would be, in truth, a member of a learned profession. From an educational point of view he would rank as an equal with the scholar in philosophy, law, and theology. As a man he would be recognized as the greatest benefactor of mankind.

With the establishment of university medical schools the first two years of work in the medical school will consist of courses in pure science. Then, doubtless, all universities will adopt the plan which two or three universities have already put in practice. That is, that the student who completes the first two years of the science course of a university, or at a college of good standing, may enter the sophomore year of the university and take the first two years' work in medicine as the sophomore and senior years of the bachelor's course, when he would receive the degree of S.B. The student who completes the three years of the arts or philosophy course at a university, during which he should take a large amount of work in physics, chemistry and biology, could then enter the medical college, and after two years receive the degree of A.B. or Ph.B. After two years spent in the clinical school he would receive the degree of M.D.

This telescoping of the literary and medical courses affords the advantage of an economy of time, while it does not in any way lessen the value of the result to the student. In the one case the student secures the degrees of S.B. and M.D. after about six years of study, and in the other the degrees of A.B., or Ph.B., and the degree of M.D. at the end of seven years' study.

#### THE OUTLOOK OF MEDICAL EDUCATION IN THE UNITED STATES.

Medical education must advance to its proper level if it complies with the present status of the medical sciences and the demands which continued evolution in medicine promises.

What does this imply? It means that the private—the proprietary medical school which is conducted for commercial reasons must go. Acknowledge, as we must, the great value which the best of these schools have been to the profession and to the country, all such schools have lived past the time when they can be of value. The continuation of these institutions henceforth will be harmful. They can not command the money to build, equip and maintain the laboratories and hospitals which a proper and adequate medical education demands. In the past their graduates have furnished the many great and influential medical and surgical clinicians of this country. In former days a graduate poorly prepared has been able, by indefatigable labor and postgraduate work, to place himself in the front rank as a clinical physician and surgeon.

Today medical science demands primary instruction to fit a man as an investigator and scientific physician. If not properly educated he can not grasp the great problems which medicine presents today as he did the more simple clinical facts which comprised the art of medicine and surgery a few years ago. In the future medicine must be taught in the large universities of the country and in the State universities which are

situated in or near large cities, where an abundance of clinical material may be commanded.

The State university and the college which desires to teach medicine, and is so situated that it can not command clinical material, should confine itself to teaching the sciences fundamental to medicine. These should be taught as pure sciences, and should be included in the course for the degree of S.B. A college or State university ambitious to teach the medical sciences can do so without great cost. To attempt to teach applied medicine without proper and adequate hospitals, and with an insufficient number of patients would be irrational, nor can they command the necessary funds with which to do it. From such colleges and State universities the students could go to the larger institutions which are able to furnish the proper facilities for teaching applied medicine and surgery.

The general hospitals of many of the cities, now used by proprietary schools, could be utilized as clinical schools for both undergraduate and postgraduate teaching, conducted by the clinical teachers in the existing proprietary schools. Indeed, these hospitals could be utilized as university extension clinical courses. Necessarily they would have to be under the control and direction of a university medical school.

How many schools may be necessary to educate the number of doctors of medicine required annually in the United States? The question one can not answer, but it is safe to say that 2,500 graduates annually will fully supply the demand. This would imply about 10,000 to 12,000 matriculates. A minimum number of 25 and a maximum number of 35 medical schools should offer sufficient facilities to educate 10,000 students. The various State universities and the colleges which offer adequate science courses would educate a great number of students in the fundamental branches, or in the first two years of the medical course.

#### MEDICAL RECIPROCITY BETWEEN THE STATES OF THE UNION.

The low requirements of some medical colleges, and the want of uniformity in the requirements for a license to practise in the different States, has resulted in a condition which entails much hardship on a physician who desires to remove from one and to engage in practice in another State. The rules of most State boards of medical examination and of health are so stringent that a physician or surgeon of years of experience and of acknowledged skill and education, and the specialist who may be renowned in his field of work, are obliged, like the recent graduate, to take an examination in all of the branches of medicine and surgery in order to secure a license to practise in the State of his adoption.

To correct this evil it has been suggested by a member of the American Medical Association, and concurred in by others, that a national board of medical examiners be organized; that the board hold examinations at different seasons of the year in the various large cities, and that the diploma so obtained shall be recognized as a license to practise in any one or all of the States and Territories. The measure suggested seems to be practical and feasible.

In addition to this plan, it remains to be said that the degree granted by the future university medical school will be undoubtedly recognized as an evidence of fitness to practise in any State in the Union. When we shall have a less number of schools and annual graduates the various States may safely and rationally become more liberal and discriminating in the conduct of their office.

#### THE INFLUENCE OF THE AMERICAN MEDICAL ASSOCIATION.

The American Medical Association should maintain its interest in the elevation of the standard of medical education, one of the chief reasons of its organization. Its influence in former years was principally moral. This was of considerable value, for the reason chiefly of the high ideals of the founders and first members of the Association, who advocated and fought for a higher standard of medical education. In the future its influence should be many fold that of the past, for with the reorganization of the profession, the better methods of conducting its affairs, the increased and probably very large membership, and its great medical journal, should wield a great influence for good.

As the direct agent by which the American Medical Association may exert its influence in the elevation and control of medical education, the Committee on Medical Colleges and

Medical Education should be made permanent and should be given adequate power and sufficient annual appropriation to make its work effective.

This Association should, therefore, stand for, and should use its whole power to improve medical education in this country. It is said that we never exceed our ideals in practice, and that if we lower our ideals our conduct sinks to a lower level.

The American Medical Association should take as its ideal and standard of medical education the university medical college, with all the name implies in regard to the fundamental medical sciences and to the clinical branches. It should use its influence to drive out of existence those proprietary medical schools which are conducted solely as money making institutions. These measures can not be accomplished at once; but medical science demands it, the profession demand it, the people demand it, and look to the American Medical Association as the chief influence which shall accomplish this end.

### SOCIAL CONDITIONS IN AMERICA IN THEIR RELATION TO MEDICAL PROGRESS AND DISEASE.<sup>1</sup>

BY

J. M. ANDERS, M.D., LL.D.,  
of Philadelphia.

Another spacious year with its varied channels of energy and activity in medicine has closed. Whilst a faithful chronicle of the facts, data and achievements showing the progress of internal medicine for that brief period would have proved an appropriate topic, I have availed myself of the choice privilege granted by this Association of selecting my theme, and purpose to consider the subject of the relation of American social conditions to the progress of medicine and disease and the import of modern economic and professional tendencies in forecasting the immediate future.

The state of American society, founded on democratic ideals, is one in which the true function of the physician has ever been both intellectually and morally beneficent. It has ever been the fate of the medical profession, however, to have its past outgrown and stifled by the enthraling energy and life of its present and to forget to fix its gaze on what is grand and significant in inherited associations and opportunities. Conversely, the fundamental principle of human development, to wit, that the present is quickly passing under the control of the future, which transcends an enlightened self-interest in the present, is yet to be fully realized and appreciated. In the life of our civilization the physician has constantly found himself in the presence of golden opportunities to render a service to the community, to add his private thought to the public opinion. His high calling and the stage of social development from which he has proceeded have ever invited to the development of an expanding and humane spirit. He has been, however, in many cases too closely chained to his special work. Per contra, the individual member of commanding worth and formidable individuality, like the Spartan and the Greek, has fortunately lent his own spirit to the genius of the great organism—the medical profession—and its higher destiny. That genius is no sluggard, and the motive of action is not the pursuit of gain or of personal aggrandizement, but an incessant advancement of our art and science and an application of the faculties to the higher interests of civilization. What is needed in medicine from the standpoint of sociology at the present day in America is the true "scientific spirit clothed with human interest," to give force and direction to the means available, not only with a view to the application of science to the healing art, but also to enable our profession to find its true place in the body politic and its intrinsic importance as a factor in modern civilization.

While there are certain things and events common to all in our psychic and social development, enlightened society will grant that the larger events in American history, assuming that "the first duty of society is the preservation of life and the comfort of its units," have not been so much dominated by

<sup>1</sup>Address in Medicine, delivered at the fifty-fourth annual meeting of the American Medical Association at New Orleans, May 5, 6, 7, and 8, 1903, and published synchronously with the *Journal American Medical Association* by courtesy of the Editor.

legislative authority and social customs as by the march of science, more particularly medical and hygienic. In a country so vast as ours, however, there could be no uniform law covering the details of results in matters medical. These have been in the past and will in the future vary somewhat with the climate, physical conditions, degree of culture and opportunities presented by the widely separated regions. As a consequence, in displaying proportions and the practical results of scattered sections, the final adjustment of their claims only becomes perceptible and appreciable in their broader and higher generalization. The whole range of American historic data and events indicates an imperishable foundation of scientific achievement and furthermore establishes firmly a relationship between medicine and the scientific principles underlying social conditions and phenomena that is both positive and vital. As touching the American medical history of the long past, we can see the major advances and their influence on social laws and the progress of civilization only by grouping data and established facts and applying the process of generalization to these composite phenomena. In this connection it is to be regretted that our possession of unclassified facts is increasing with uncomfortable rapidity. A comparative and historic study of the medical literature of America, taking any of the older countries as a standard of comparison in respect to this method of generalization, can scarcely prove even measurably satisfactory. Much of the history of native medicine is crude and it were impossible to give it either crystallized or concrete form. Epoch-making discoveries and important, far-reaching scientific effort is justly the boast of the American profession. Systematic effort at a rigid classification of facts by the modern statistical method, however, has not been made, and only a partial scientific use of the ever-advancing events for the different historical periods has been attempted.

The concrete, comparative and historic method of study which alone furnishes a proper basis for generalization and serves to point out the relations of medicine to other human activities, would ensure a wholly fresh treatment of the earlier medical annals of America. The physician in his economic or professional dealing has not followed his self-interest in comparison with his measure of enlightenment to an equal extent with men in other lines of human activity, but the fruits of his unselfish labors are, when taken collectively, presented in the form of a heterogeneous mass of details. It should be recollected that it is only the larger events, the accurately grouped facts after the method of generalization to which I have referred, that go to make up the bulk of medical history and medical law. The practical results of the method of simple generalization would show clearly the final utility of medical and sanitary knowledge in the social universe and manifest its relation to everyday life. Obviously in a young republic like ours something must be allowed to propinquity—to nearness to a confusing and disordered mass of facts and phenomena.

It has been well said: "A landscape is beautiful because distance has reduced its chaos of details into order."

Those endeavoring to make a personal study of the medical and sanitary requirements of our insular possessions, more especially under new and changed conditions, can not hope to gain more than a fragmentary knowledge. Much important and accurate information touching the social, climatic and medical conditions and necessities, however, is available through the Division of Insular Affairs in the War Department at Washington. It is clearly incumbent on the organized profession of the United States to undertake studies on a larger scale than that of individual effort. Moreover, the interrelations between tropical medicine and the sciences before alluded to, *i. e.*, social and sanitary, is a question for the immediate future; thus step by step may we hope to erect a stairway that will lead to a new temple of knowledge.

The foundation for social order, education and a fair measure of self-government under military rule having been laid both in Porto Rico and the Philippines, there is presented to the profession of the United States an opportunity amounting to an obligation to carry into those new possessions the light of modern sanitary and medical science. The peoples of those islands are as clearly entitled to the benefits offered to our science and art as they are to those pertaining to their funda-

mental civil and personal rights, as guaranteed by the Constitution of the United States.

From the America that Cortez invaded until the present the most treasured resource of our nation to the physician has, in a peculiar sense, been human life, and in respect to this economic principle we are at present writing merely following in spirit our thoughtful forebears. The medical profession never has valued life in terms employed in denomination nor by its productive power, but rather measured it from a divine and humanitarian standpoint. Certain it is that with advancing civilization there has come a higher and higher appreciation of the value of agencies intended to promote longevity and minimize disease and suffering. And this tendency to preserve human existence, apart from sentimental considerations, is born of a principle long adhered to by the medical profession and continuously unfolding itself in the individual and in organized medical bodies. It is clear, without seeming extravagance of statement, that greater justice is done by the medical profession of America to the condition of society just pointed out than in foreign lands, since it is more thoughtful for the youth and hope of our profession. It is to the flower of that youth, with its new and hidden virtues, that we must look for disclosures in the province assigned to the higher and more complex professional bodies of the future. Modern democratic institutions, including medical schools, are in the ascending scale of civilization, infusing into our profession men who are armed with potent resources from the pedagogic world.

The present-day educational facilities and developments show an ever-increasing beneficent tendency, and the standard of qualification has passed, or is passing, beyond the stage in which there is a mere desire to acquire an elemental knowledge of disease and its treatment in this country; a new character and a new vital and moral force is happily presuming to show itself in public action for the benefit of mankind. This genius stands ready to kindle its fires and materially aid in offering the means of human welfare and the revelation of new truths.

An appreciation of this fact by professional bodies is necessary in respect of the future; for medical societies organized to obtain the highest potency must compete successfully with other societies or they will vanish from view in the stress of social and scientific evolution.

But though the obscure rival of the Goddess of Minerva, who had broken the loom of Arachne in her jealousy, executed wonderful tasks by her unaided strength, in the process of progress toward higher efficiency the individual ceases to be a factor of first importance. The process of development, whether considered in its economic, political or purely professional relations, demands the subordination of the interests of the individual to the larger interest of the organic whole. The dominant and controlling feature underlying an infinite variety and complexity of details of that upward movement of professional and social evolution is compatible with a remarkable simplicity of governing principle. Our plain duty is accordingly to endeavor to understand the nature of that governing principle which is distinctive and characteristic in that it does not regard the interest of existing members as supreme, but is seeking to establish conditions which are favorable to the interests of a larger future.

As regards the question of the relation of medical work and progress to our social system, the time is probably ripe for a revision of certain elemental and fundamental principles and customs, although it is obvious that neither social agencies nor the general public manifest a proper comprehension of its necessity. Whilst science is telling us about the pathologic intricacies of disease processes, their bacteriologic causation and cure with unparalleled rapidity, important social and economic questions that affect especially the comfort and health of our teeming town-bred populations are subordinated. Again in a land of popular civil government the medical profession should be organized in a manner that would render it equal to enlarged duties which naturally should devolve on it. I refer to such matters as the control and regulation of asylums for the insane, municipal health boards and the municipal hospitals for the sick poor, for contagious diseases and the like.

Certain tendencies of modern American life, considered with reference to the welfare both of the medical profession and

general public, offer a most promising field for investigation and progress. The temptations of the practical, over-strenuous life of the present and past generations have left their impress on our profession. Something, however, must be ascribed to our nervous climate, reinforced by certain elements of the American spirit-aggressiveness and an unconcealed idealism. Neither should the power of the initiative of the American, his shrewdness and his energy be overlooked. It may be doubted, however, whether there have been accomplished achievements and results commensurate with the impetuosity that characterizes all paths of professional activity. The universal spirit of haste has taken possession of our professional life; it permeates the air of the age, and the principal cause of this state of affairs is to be found in our ardent everyday ways of living, and its cure must result from a readjustment of the home life and habits of the professional and other classes. It means a return from our present day restlessness and rush to a quieter period, to a "Mansfield Park," with its charm of quiet village life; a return to a normal life, with natural intellectual tastes, and to calm, patient, original observation that fosters vital force and successful endeavor.

If authors and investigators were to bring forward only definitive and well-weighed pronouncements on all points at issue, it would carry us from the surface to the heart of things, and our labors would be more strongly marked by originality and power.

The spirit of undue haste which characterizes our national life is nowhere better exemplified than in American medical literature, despite its many virtues, its broad liberal spirit and freshness. Never in American history, whether deliberately or unconsciously, has so much current literature been placed at the disposal of physicians. Too generally medical thought and opinion, which is not of necessity medical truth, finds literary expression. The obvious weakness of it all is an enforced tendency to waste one's time in reading matter which is unapproved by common opinion. Extending this thought, it may be questioned whether to carry views and ideas beyond the domain of existing knowledge does not hinder rather than facilitate progress.

There is a list of honor among American writers, and it embraces authors whose literary product shows not only a sharp scrutiny of facts, but also the highest and most characteristic utterances in medicine. Indeed, the worth and power of American medical literature, either in its content or method, scarcely receives an unprejudiced estimate abroad.

In the field of letters we point with inordinate pride to the late Dr. Oliver Wendell Holmes, and our contemporary, Dr. S. Weir Mitchell. Fiction by medical authors lives and will live in America.

It may be questioned whether American nationalism, as evidenced by the creation of a native literature, should be the principal aim, although the consistent use of American material is to be advised and encouraged. We need to retain the conservative European spirit and keep wide ajar the door that leads to the treasures of continental literary traditions. Foreign peoples are and have been immigrating by the hundreds of thousands yearly; they have penetrated into the remotest points of this country, carrying effective training with them in many instances. Hence, admitting that the prescience of genius is the possession of many, there are fewer distinctly American medical authors than at first blush would appear.

"The Celt is in his heart and hand,  
The Gaul is in his brain and nerve;  
Where, cosmopolitanly planned,  
He guards the Redskin's dry reserve."

Acknowledgment is due the great value and significance of the unparalleled heritage handed down by the older nations, particularly England, Germany, and France. The path of fame for a nation no less than for an individual lies in the direction of constructive effort and sensitive receptiveness of the impressions and tendencies of the age irrespective of territorial limitations, and of a keen sympathy and close touch with the movements of the times in all lands.

Our literature is not an indigenous growth, yet stern of purpose; it is not, and, let us hope, never will be, sluggish in turning to foreign sources. It has, however, developed certain

characteristic features, a distinct national flavor and a perfume "as plainly native as the arbutus."

American industry, with its attendant wealth and power, and the enlarged opportunities it offers to all classes of society for successful business enterprise, has quite generally proved attractive to and often filled with fervent hope the American physician, and with increasing means he has found his social position to improve.

In America the achievement of considerable financial success, however, is possible without taking high ground in a professional or ideal sense. The medical profession is integral in the effects of our economic evolution; it obtains stray glimpses of the avenue of glittering gold; but its central effort, if it desires to remain true to human perspective, contemplates a systematic development of its pecuniary, mental, moral, and social powers.

The tendency to gregariousness in American cities is in no specific direction more evident than in the medical profession; hence, success is and will continue to be an increasing difficult problem, a circumstance to be reckoned with, no matter what our meaning and ideals as a national profession. This portends in its last analysis the necessity of better training and equipment for everyday duties of the practitioner.

America stands in need of further reform in medical education and the immediate establishment of one authority—one licensing body; and self-created schools must place themselves in a position in which they can worthily assist in the execution of a scheme of higher national medical education. Professional ascendancy in future will demand the creation of a homogeneous and adequate standard of qualification for entrance into medical schools.

The relation of social conditions to disease is a topic that is becoming more and more insistent with the reflections that are the natural accompaniment of advancing knowledge.

A backward look reveals an embryo nation steeped in an arduous task, the subjugation of a continent, at the expense of unceasing physical toil. This necessitated an open-air existence, which resulted in a vigorous, hardy race. Then followed the integration of frontier villages, of larger and smaller towns, and life meanwhile became brighter and more piquant. For long generations the abandonment of rural life, the changed habits of living, the enforced pursuit of new and less healthful callings, too often from motives of personal comfort and even social expediency, and the universal tendency to overcrowding in town populations, resulted in a modification of the character and incidence of all leading diseases. It goes without saying that respecting the effects of our social conditions and climate on disease, the particular standpoint of our fathers was radically different from that of their children. Floyd M. Crandall has recently directed forcible attention to the fact "that never have such radical changes been witnessed in the habits of life and in human diseases as those in this country during the last half century."

Fortunately, agencies are at work looking to the socialization of the American agriculturist and the amelioration of the ills due to overcrowding in large municipalities. This is a movement which in the entirety of its scope embraces numerous potent forces whose federation promises to effect in time rural social regeneration. An organized effort has in several States been already initiated, and in the conferences held and in contemplation looking to the betterment of rural life, the cooperation of the medical profession is invited. Modern agencies, as improved highways, the introduction of the telephone, trolley lines, rural mail delivery, are socializers no less than economic facilities. In addition to these physical influences, marked improvement also comes from increased educational opportunities, farm organization and the various functions of the Church.

These socializing influences and forces tend to counteract the current of bygone days from the farm to the city; they likewise bid fair to become a factor of first importance in minimizing, if not actually counteracting in due season, the ill effects of over-dense urban populations. It may, however, be remarked that the impoverished classes, especially the great immigrant contingent, will be far less likely to return to a rural environment than the well-to-do, and yet it will shortly affect the social

and economic conditions as well as the vital statistics of the wage-earning classes. We may confidently expect a greater physical efficiency, a higher bodily standard, though municipal sanitation will be always required, and remain the principal factor in strengthening the powers of resistance to hostile environment. One point of common agreement is that as a result of the rapid advances in sanitation and improved methods of treatment, there has been a notable decrease in prevalence and fatality of most infective diseases, particularly those more or less fostered by overcrowding (*e. g.*, tuberculosis, diphtheria, diarrheal diseases, etc.). Three well-defined classes, however, have according to the census for the decade ending May 30, 1900, distinctly increased; they are cancer, affections of the kidneys, and the degenerations, fatty and fibroid. Thus during an increase in the population of 50% in the United States myocardial degenerations have increased 150%, and certain types of chronic nephritis have also risen in frequency to nearly 200%. The determination of the causes of this rapidly increasing frequency of these morbid states is clearly the task of the medical profession.

Respecting the degenerations—myocarditis, arteriosclerotic changes and kidney diseases—Crandall says: "The power of alcohol in the form of malt liquors to produce degenerate changes is so well known to pathologists that the conclusion is irresistible that the radical increase in these diseases comes largely from changed drinking habits."

The notable increase in these morbid conditions, however, is not due to a single cause, and substantial progress can not result from too much emphasis on any one agency whose undoubted potency remains undemonstrated.

It is probable that a more universal application of refined methods of diagnosis accounts in a measure at least for the apparent disparity in the number of cases of nephritis and myocardial degeneration in recent times as compared with the showing of older statistics.

The census between 1890 and 1900 indicates an increasing prevalence of two additional diseases, in respect to both of which progress in our knowledge has been slow and never encouraging. I refer to diabetes mellitus and lobar pneumonia. The census previously referred to indicates that chronic diabetes mellitus has nearly doubled in point of frequency in a single decade.

Whilst we shall continue to look to the bacteriologic laboratory for the discovery of the definitive cause of this metabolic ailment, and to the pathologist for a mind's-eye picture of the morbid state of the tissues, the data obtainable from an investigation of the manner and habits of life, which exert more or less etiologic influence, are of intrinsic medical importance and would serve as accessory factors in diagnosis as well as straws for the application of measures for treatment.

Although impossible to recognize a boundary line between the "variables of health" and disease in chronic diabetes mellitus, it can not be doubted that abnormalities of the glycolytic functions of the liver and pancreas, associated with inappreciable structural changes (more especially in the cells forming the islands of Langerhans) which interfere with proteid metabolism and the metabolic disturbances, are dependent in large measure on the overuse of the mind, intemperance and irregular habits of body; in a word, on improper modes of living.

Physiology has contributed much to the intricate processes involved in the nutritional diseases. Morbid physiology (general pathology) is most intimately bound up with the modes and predilections of American life, particularly of the so-called privileged classes.

Diseases and conditions that are successfully treated by a correction of the mode of life are apt to be regarded as functional in nature, when in reality definite although undiscoverable structural lesions already exist, the foundation of an insidious and progressive disease already laid.

Now it is conceivable that a broader application of data as yielded by vital statistics would render more clearly recognizable the terrible significance of an enlightened public, living in idle acquiescence to positively injurious prevailing customs. A federation of forces, however, in connection with the investigation of special diseases even, is necessary to make this branch of inquiry productive of really important information; for

example, the cooperation of committees on vital statistics with the creation of centers under the auspices of a national organization, such as the American Medical Association, would prove effective. I would instance lobar pneumonia, which, as before stated, is increasing in prevalence, as a disease in which the light of future investigation after this method of research would prove preliminary to important discoveries and decisions. Indeed, the local diversity in social conditions and climate in different sections which are far separated by geographic distances in this country renders such a procedure an absolute necessity. The statistical data gathered by individuals, notably those of E. F. Wells, are of real value, and one point approximately settled is that the deathrate by decades during 80 years is practically unaltered—"certainly not decreasing." The census for the decade between 1890 and 1900 shows an increased prevalence of this disease from 186 to 191 per 100,000.

A marked numerical increase in the number of cases of pneumonia has taken place since the advent of epidemic influenza,<sup>1</sup> but this does not account for the slowly rising incidence of the disease during previous non-epidemic seasons. Other reasons have been given for the augmenting prevalence of pneumonia: increased facilities for travel and the tendency for people to congregate (Wells), the highly infectious character of the disease and the neglect of prophylactic measures in crowded centers (Walsh). Among accessory causes of the increased prevalence of pneumonia may be mentioned a change in the prevailing meteorologic conditions. As shown elsewhere the wanton destruction of the native forests has been attended with an exaggeration in the range of variability of such meteorologic conditions as temperature and humidity. It has been long known and universally recognized that this disease bears a vital relation to the seasons, and that the greatest morbidity coincides with the most pronounced climatic changes. It is probable that the increased incidence of the disease will be shown to be dependent in part on augmenting prevalence of visceral degenerations, particularly of the cardiovascular system and the kidneys. Be it remembered that in a large measure these are the direct or indirect result of an era characterized by undue devotion to business, social excesses and club life, with its attendant unseemly hours and unconcealed conviviality. It must be confessed that the extent to which lobar pneumonia is dependent on these degenerations acting as predisposing factors is imperfectly known, but it cannot be doubted that a conservative attitude toward the question accords to them a prominent position among the agencies unfavorably affecting the prognosis.

I have made a study of all necropsied cases of lobar pneumonia at the Philadelphia Hospital for a period of six years, from January 1, 1896, to March 1, 1903.<sup>2</sup> Out of a total of 275 cases 250, or about 90.9%, showed cardiovascular lesions, principally chronic endocarditis and general atheroma of the vessels. A small number of the cases, 14, or 5%, showed acute plastic pericarditis, and 11, or 4%, chronic pericarditis. Renal lesions were recognized in 90.5% of the totality of cases. Chronic interstitial nephritis was noted in 145, or 52.7%; chronic parenchymatous nephritis in 50, or 18%, and acute nephritis in 38, or 13.8%. Among the remaining 25 cases was one of renal calculus, another of renal tuberculosis, and in many of the remainder subacute nephritis was noted.

These figures afford strong presumptive evidence that renal and cardiovascular degeneration rank as potent predisposing conditions, and clear and convincing proof that they bear a close and vital relation to the high mortality rate of lobar pneumonia. It should be stated that the patients admitted into the Philadelphia Hospital belong to the pauper element of society, and the subjects are principally adults.

The reports of the health departments of leading cities, in particular that of New York, furnish valuable data from which important tentative influences may be drawn, but sure ground can result only from research work of a broader character than has yet been undertaken in this country. From the record of vital statistics of Philadelphia and New York I have compiled two tables (*vide infra* Tables Nos. 1 and 2), which show that pneumonia is more or less limited to centers, and these correspond in the main to the most densely populated areas, with their allied conditions of squalor and poverty.

Pneumonia, like other acute infections that prevail epidemically, shows a wave-like character, on comparing different years for the same locality. Exclusive of epidemic outbreaks there is an evident tendency to a preponderating incidence in

TABLE 1.

Wards.	Area in acres.	Population U. S. census of 1900.	Population per acre.	Percentage of deaths from pneumonia.			
				1899	1900	1901	1902
First.....	154	9,516	62	11.2	11.8	10.9	12.1

\*Population and deaths occurring in almshouse (Twenty-seventh Ward) do not appear in this table. Deaths in almshouse, 1,637. Forty-one (41) percent of deaths from pneumonia occurred after the age of 40 years.

The Fourth, Sixth, Seventh, Tenth, Eleventh, Thirteenth, Fourteenth, and Seventeenth wards of New York City were embraced in this estimation. In contrast with the figures just given, eight wards, representing the most sparsely settled por-

tions of the city of New York (e. g., First, Fifth, Eighth, Ninth, Fifteenth, Sixteenth, Eighteenth, and Nineteenth) gave for the same period of four years an average mortality of 14.3%.<sup>3</sup> It was observed in the compilation of these mortality statistics that an elimination of the epidemic periods would make the differences in percentage dependent on the population somewhat greater.

In arranging the statistics for Philadelphia I have included only those wards in which the inhabitants were equally distributed throughout the entire ward. Per contra, wards having large area and a low population per acre, but this population, located in certain sections of the ward only, have not been included. Thus the following wards became available for the purpose of contrasting those giving the highest with others showing the lowest mortality: First, Second, Third, Fourth, Fifth, Sixth, Seventh, Ninth, Tenth, Eleventh, Twelfth, Thirteenth, Fourteenth, Fifteenth, Sixteenth, Seventeenth, Eighteenth, Nineteenth, Twentieth, Twenty-eighth, Twenty-ninth, Thirtieth, Thirty-first, Thirty-second, and Thirty-seventh.<sup>4</sup> The Eighth ward was not included on account of being inhabited principally by a better-to-do class and on account of containing the Pennsylvania Hospital, the former condition lessening the liability of pneumonia, while the latter institution named would tend to increase the mortality from this disease since many of its patients come from the Third, Fourth, Fifth, and Sixth wards.

The portion of the city west of the Schuylkill river was excluded from this computation for reasons similar to those just mentioned.

Out of 25 wards included in our figures I have estimated a percentage of deaths from those showing the most dense population per acre, allowing for the location of hospitals, homes, etc. (e. g., Second, Third, Fourth, Seventh, Thirteenth, Seventeenth, and Nineteenth wards), and I find the percentage of deaths from pneumonia to be 12.8%. Those wards showing less dense population, the First, Ninth, Tenth, Sixteenth, Twenty-eighth, and Thirty-second, gave an average of 9.5%.

The Second, Third, and Fourth wards were occupied largely by foreigners (Italians, Russians) and showed the highest percentage of deaths from pneumonia, while the Seventh ward, which contains a large colored population, also shows a very high deathrate.<sup>5</sup>

As shown by MacDougall's statistics, unfavorable occupational conditions probably have less effect in causing pneumonia than pulmonary tuberculosis. In my own investigations it was observed that divisions of Philadelphia having an industrial population modestly though comfortably housed furnished a deathrate but little in excess of that of the sections inhabited by the well-to-do. The whole subject of occupational diseases, eminently important to the medical world, is closely united with the social and economic conditions of the wage-earning classes, but its consideration here would lead me too far a-field.

REFERENCES.

- <sup>1</sup> Phila. Hospital Reports, Vol. xiv, p. 57, 1896, by the writer.
- <sup>2</sup> For permission to examine and employ the records of this hospital the writer is indebted to Dr. J. V. Shoemaker, president of the Board of Charities and Corrections.
- <sup>3</sup> The writer desires to acknowledge, with thanks, the kind aid of Dr. William H. Guilfoxy, registrar Department of Health, New York, in furnishing data for the above table.
- <sup>4</sup> The following wards have not been included in the estimation of the lowest percentages for the following reasons: The Twelfth ward, while it shows a low population per acre (86), has a number of hospitals and homes which contribute largely toward its high deathrate from pneumonia. The Second and Third wards show a population of 18 and 19 per acre; there are but few children under 5 years and few aged persons living in these wards and this lessens the mortality from pneumonia. The Twenty-first and Twenty-second wards because they are occupied mostly by the well-to-do classes. The Fifteenth, while it has been included in my calculation, contains a large colored, Italian, and French population.
- <sup>5</sup> My acknowledgments are here due to Dr. L. Napoleon Boston for assistance rendered in connection with the statistics gathered in Philadelphia.

Jefferson College Library.—Four years ago Jefferson Medical College undertook the establishment of a reference library for its students, and through the efforts of its Women's Auxiliary Board some 3,500 books have been collected. The library is managed and supported by the Women's Board, and is constantly increasing in value and effectiveness by the purchase of new books and gifts from friends interested in the college. The last monthly report shows how much it is appreciated by the students, as there were 1,276 calls for books, the largest number in one day being 86. The average daily loan is 53 and is steadily increasing.

CANCER AND IMMUNITY.<sup>1</sup>

BY

A. F. JONAS, M.D.,  
of Omaha.

On such occasions as this we take great pleasure in recalling the past, and dwell with great delight on the achievements along the lines that have most engaged our attention. We, as surgeons, especially those whose professional activity began in the preantiseptic period, review the successive changes from that period of expectancy to the present period of aseptic accuracy with the greatest satisfaction. No one can fully appreciate the present status of surgery who is not personally familiar with the period when wound complications were the rule, and when faith was pinned on the belief in "laudable pus."

However great the change has been in surgical mortality, in the great improvement in wound repair and in the comparative freedom from wound complications at present, when we consider the number of diseases treated surgically we must confess that many problems remain unsolved. We are not prepared to say, even now, as Boyer did in his great work, "Traité des Maladies Chirurgicales" (1814-1822), that he believed that surgery had reached perfection. The great advances of the past have taught us the imperfections of the present, and have pointed out to us the lines of research for the future.

At the outset, we are not unconscious of the fact that the profession itself is not yet agreed on many well-founded propositions. Many still cling with too much tenacity to old and deeply-rooted doctrines. Progress has been so rapid. The surgeon has, perhaps, been in advance of the physician along scientific and practical lines. The physician has observed that the surgeon has gradually invaded his field, thus creating some antagonism, but it has become less apparent and more cooperation has been the rule since bedside observation and a clearer pathology have demonstrated the actual conditions.

In this connection, we are convinced that there is still too much difference of opinion between the physician and the surgeon regarding the so-called borderland cases. In that class of affections which primarily are so-called medical, and later may become surgical, in which the early stages are obscure, where no positive diagnosis can be made, where there is no improvement from the usual internal treatment, these constitute a class where an exploratory incision would not only make a diagnosis clear, but would frequently lead to a cure.

Still, too much time is wasted in the medicinal treatment of such affections as goiter, tuberculous lymph nodes, pulmonary abscesses and gangrene, empyema, abscesses, and tumors of the liver, obstruction of the biliary passages, diseases of the pancreas and tuberculous peritonitis. Chronic Bright's disease and ascites due to hepatic affections, always believed to be purely medical, have recently received the attention of surgeons and the success has been sufficient to give much encouragement. The foregoing constitute a class of borderland cases in which it is often impossible to state where medical management ends and where surgical treatment begins.

Surgical advancement in the future will not consist so much in the radical changes in operative technic as in improvement in diagnosis and diagnostic aids. Many of our diagnostic formulas are even now undergoing complete changes, and the future will lead us to a precision in the recognition of disease that we little dream of now. The early recognition of malignant disease is a problem of future development, especially malignancy affecting the internal organs. With our present aids it is impossible to recognize internal cancers sufficiently early to do a radical operation. Our only course at the present is an exploratory incision as soon as reasonable grounds for malignancy exist.

The field that seems full of promise and gives us hopes for great expectations in the future is that of immunity and immunization. It now seems that many tissue changes will be solved along these lines.

<sup>1</sup>Oration in Surgery, delivered at the fifty-fourth annual meeting of the American Medical Association, held at New Orleans, May 5 to 8, 1904, and published synchronously with *Journal American Medical Association* by courtesy of the Editor.

From our present viewpoint the question of immunity seems to tower above and overshadow all others. It involves the greatest problems for the future investigator to solve. Out of these researches will be evolved methods for the exact treatment of that great list of surgical affections which, at present, we can fortunately, to a great measure, avoid by exact asepsis and can control, to a great extent, by antiseptic measures when once developed. But we still stand helpless in the presence of severe forms of septicemia, pyemia, tetanus, and other toxic invasions. Infections sometimes occur after the most carefully executed operative procedures. Accidental infections will always comprise a large proportion of our surgical material, a group of cases that furnishes a fatality all too great.

Our present helplessness in the presence of extreme toxemia, we must confess, lies in our imperfect knowledge of the exact conditions under which the toxins operate. We may say, in a general way, that toxic bodies attack and destroy cellular elements. When, however, we study this question of infection in a more serious manner, we find that a flood of light has been thrown on this problem by Ehrlich and his followers.

The two greatest problems of the future, cancer and immunity, shall engage our attention today. Malignant disease seems to be on the increase. We stand so helpless in its presence when fully developed that we exert our feeble energies and grasp eagerly for any fact that seems to offer new light for its better understanding. It will be our effort at this time to, as briefly as possible, review the more important facts known regarding the etiology of cancer, and then, after making clear to ourselves the revelations thus far made in the recent studies of immunity, determine, if possible, what relations, if any, exist between the two.

These considerations were prompted by personal observations made in a number of cases of undoubted malignancy that indicated the probable infectiousness of cancer. It is well known to us all that the infectiousness of most infectious diseases was first determined clinically and that the clinical observations were later determined and confirmed microscopically and experimentally. The cases to be here related came under the author's personal care, and it is hoped that they may serve as contributory evidence to the observations already recorded by others that *malignant disease, under certain conditions, is infectious*.

CASE I.—Mrs. H., age 40, of spare build, very small amount of adipose tissue, presented in the outer and upper quadrant of the left breast a hard, nodular, painful, movable, walnut-sized growth, of one year's duration. In the axilla could be felt a hazelnut-sized nodule. She had frequent lancinating, radiating pains in the breast. There were no evidences of acute or sub-acute inflammatory signs, no local redness or elevation of temperature. The clinical diagnosis of cancer of the breast was made and a radical operation was advised. Various family matters prevented her from submitting to an immediate operation, so that several months passed, after which it was observed that the neoplasm had diminished in size and it finally disappeared.

It may be urged that this may not have been a cancer or that no one should make a diagnosis unless there be a confirmation by the microscope. Is the microscope always certain? We have all observed cases that ran a clinical course of malignancy after the microscopic findings indicated benignancy, and *vice versa*. The pathologist always inquires after the clinical features. He is disinclined to give an opinion unless he can know something of the history and symptomatology. The above case, in every detail, resembled many others that were demonstrated microscopically to be malignant, consequently it would appear that we were justified in the clinical diagnosis of cancer.

CASE II.—Mrs. J., age 35, presented herself with an inoperable, extensively ulcerating carcinoma, involving the outer half of the right breast. The breast was unusually large. The outer portion of the ulcerating surface had been in constant contact with the upper and inner side of the arm. Portions from both breast and arm were removed for microscopic examination and proved to be alveolar carcinoma. No operation. She died in three months.

CASE III.—Mrs. D., age 35. She came under observation with a typical epithelioma of the cervix uteri. The vagina was large and relaxed, so that the neoplasm rested in contact with the lower portion of the posterior vaginal wall. Hysterectomy was recommended but was refused. She presented herself

again in two months, in which time there had developed an epithelioma at the point of contact between the cervical growth and the posterior vaginal wall. An operation was done, but the patient died from recurrence eight months later.

CASE IV.—Mrs. G., age 45. Came under observation with a typical cauliflower growth involving the cervix uteri. Small particles were removed, which proved, microscopically, to be carcinoma. The uterus was fixed, the growth appearing to be too extensive for operative interference. No operation was advised. After several months the neoplasm became smaller and gradually disappeared, the uterus becoming movable. At the present time, eight years later, she appears well.

Here we have four cases of undoubted cancer, each one of which presented some of the features of an infection, as in lupus or syphilis. Cancer is extremely slow in its development, its premalignant stage often lasting many years. This fact possibly may account for the negative outcome of inoculative experiments hitherto conducted. This long developmental stage is not unlike lupus, leprosy and other forms of undoubted infection. In two of our cases we observed secondary growths which appeared at points where the primary neoplasm was brought, more or less continuously, in contact with previously healthy surfaces, a very common occurrence in nearly all forms of infection. In two of our cases the neoplasm disappeared spontaneously, the disappearance depending, no doubt, on some form of katabolism not yet understood. The elucidation of this form of cytomorphosis will give the key to the control, inhibition and elimination of the atypical cell proliferation which constitutes malignancy.

The term cancer, so commonly employed, refers to growths made up chiefly of epithelial cells. There is really no good reason why the term cancer should be limited to epithelial growths. Cancer signifies "crab." It was originally used to signify malignancy and meant connective tissue growths as well as those of epithelial origin. For our purpose at this time we will limit the term cancer to epithelial neoplasms and we will confine these considerations to its etiologic factors.

The mystery of its origin seems as deep almost as in the days when cellular pathology was unknown. No problem in pathology has received more thought and speculation, no subject has had bestowed on it more earnest effort and unremitting toil. Regarding its etiologic evidence we must confess that we have only a mass of negative proof. When observers believed that they had found the specific organisms, scores of workers in the same field soon demonstrated their error. So, today, we can only say that the evidence which shows what we do not know of the cause of cancer is voluminous, and we must admit that we know little of its etiology.

We know something of its cell characteristics. We know that malignant disease is essentially a cell proliferation that has biologically many features that are opposed to the physiological tissues in which they take their origin. We find an atypical life history in the cancer cells. The nucleus divides in an asymmetrical way. We note that unusual karyokinetic figures in the nucleus are usual in newgrowths, pointing to changes in the cellular life history. Regarding carcinoma, certain bodies have been demonstrated, believed by some to be parasites, having some causal relation to the cell changes.

It is a well-established fact that the nucleus perpetuates the nature and function of the cell, and any change in the nucleus changes the cell in its function and process of division. According to W. V. Shaw, "the growth of cancer cells is then to be looked on as an effort of reproduction in damaged tissue, the incidence of the damage falling on the nuclear structures."<sup>1</sup>

This statement is based on observations made by him in connection with experiments on free swimming larvae which developed from the stimulation of ova of certain lowly organized animals, causing a proliferation of cells. The ova had not been fertilized by spermatozoa. Adult organisms were not developed, but larvae capable of independent life. These results were obtained by stimulating the ova with strychnia and by mechanical movements of the ova. This cell-growth was compared to growth of tissue in partially damaged structures. Shaw believes that such damage alters the nature of these cell structures so that the vegetative functions of the cell run riot and the cells become parasitic toward the organism in which the growth is taking place. This view seems to find

support in those connective tissue growths that develop in tissues that have sustained a trauma and in which the sarcoma develops; or in epithelial growths that form on surfaces that have been subject to prolonged irritation, as exemplified by the chimney-sweep's and paraffin-worker's cancer forming on an old chronic dermatitis; or in cancer forming on the site of a prolonged irritation by the smoker's pipestem on the lower lip. We have seen many times that cancer develops in epithelial tissue that has been subjected to irritation for a long time, usually extending over a period of years. We have long recognized irritation to be at least one of the causative factors. Just what metabolic disturbances take place and what the underlying causes are is not yet clear. That cancer is infectious has been proved by many clinical observations. This has been shown by Eberth, who collected 22 cases where cancer was transmitted from lip to lip, tongue and palate. Behla reported eight instances of death from malignant growths in physicians and surgeons who were inoculated from tumors and four instances of apparent human infection from cancerous animals, dog and hen. He also alludes to a cancer epidemic among the white mice in the Pathological Institute at Freiburg as evidence of the contagiousness of cancer (Hektoen). Roswell Park believes that, for New York State at least, cancer is increasing at an alarming rate.

Attempts have been made to show that cancer is endemic, peculiar to certain localities. Behla cites cases of Behrens, who found in a village 10 deaths out of 38 to be due to cancer. Pfeiffer, Powers, and Friesinger maintain that in certain houses (cancer houses) and marshy districts in the vicinity of ditches and streams containing sluggish water, especially if the stagnant and polluted water were used for watering garden vegetables and for drinking purposes, cancer is relatively frequent (Hektoen). This would point rather to a microphyte than to a microzoan as the etiologic factor.

Since infection of living tissue is believed in every instance to be due to bacterial invasion, naturally bacteriologists directed their attention toward the discovery of a specific germ. Very soon we had a long list to enumerate. Plimmer, of London, examined in six years 1,298 carcinomas and in 1,130 he believed that he found parasitic bodies. Sjöbring laid much stress on cell inclusions. Russell described his fuchsin bodies, which were spherical or oval. L. Pfeiffer, of Weimar, published several monographs on the protozoa as a cause of cancer. Eisen brought out his *Canceri amœbae*. Korotneff believed that he had found an organism which he termed *Rhopaloccephalus carcinomatosus*. Bosr found and described an organism that he called *Myxosporidia coccidia*. Gaylord, of Buffalo, described at great length bodies that he believed bore an etiologic relation to cancer. Sanfelice, of the University of Cagliari, emphasized the etiologic importance of bodies that he named *Saccharomyces neoformans*. A very large number of other publications on this subject made their appearance, none of which differed in any essential point from those bodies just mentioned.

While the presence of the aforesaid bodies described by the different observers can be demonstrated and are present in a large proportion of the cases of cancer, all the requirements necessary to prove them to be the organisms solely responsible for cancer have not been fulfilled. The requirements necessary are: (1) the organism must be isolated; (2) a cancer must be produced when the organism is introduced into another body; (3) the organism must be recovered from the cancer produced. It has been shown that while the first requirement has only apparently been fulfilled the second has been, in a number of cases, seemingly produced. More careful investigations have proved that the experimental growths were not cancer. The third requirement has not been fulfilled.

All of the work mentioned above was carefully reviewed in all its details by the cancer committee, who in their second annual report to the surgical department of the Harvard Medical School showed conclusively that the bodies described by the various investigators under different names were not cancer nor the cause of cancer. I can do no better than to quote in full the results of their labors. They bear the marks of painstaking and conscientious work. The conclusions of the Harvard cancer committee were written by Edward H. Nichols and were as follow:

<sup>1</sup>The Lancet, September 20, 1902.

It has been claimed by the adherents of the theory of the parasitic origin of cancer that

1. A proliferation of epithelial cells analogous to the lesions seen in cancerous tumors can be produced by certain wellknown protozoa (nodules caused by the coccidium oviforme).

2. Certain skin lesions characterized by epithelial cell proliferation are due to the action of a so-called protozoon (molluscum contagiosum).

3. Blastomycetes are constantly present in human cancers and are the cause of the lesion.

4. By experimental inoculation of animals with blastomycetes true epithelial or cancerous nodules can be produced.

5. Finally, the wellknown endocellular bodies seen in the protoplasm of cancer cells have a definite morphology, are parasites and the cause of cancer.

It has been the object of the investigators, the results of whose work appear in the preceding pages, to study each of these questions. As a result of the lines of work pursued by them under the direction of the Cancer Commission during the past year it is concluded that:

1. The lesion produced by the coccidium oviforme is essentially a process of chronic inflammation and is not analogous to the lesion seen in cancer.

2. The lesion of molluscum contagiosum is characterized by certain changes in the epidermis, is not due to the action of a protozoon and is not analogous to cancer.

3. The so-called "blastomycetes" (saccharomycetes) of Sanfelice and Plimmer are torulas.

4. The lesions produced by these "blastomycetes" (torulas) are, essentially, nodules of peculiar granulation tissue, are not cancerous, nor in any sense true tumors.

5. Blastomycetes are not constantly present in human cancers.

6. The peculiar bodies seen in the protoplasm of a cancer cell are not parasites nor the cause of the lesion, but probably are, in part at least, atypical stages of the process of secretion by glandular epithelium.

It is clear that in the present status of the etiology of cancer, bacteriologically considered, the case has not been proved. But it does not follow that it will not be shown that cancer is due to a specific and well-defined organism. It may be an organism so minute as not to have been brought within the range of the microscope. It is possible that no stains have yet been found that possess the requisite affinity for its complex molecular constitution. The necessary artificial medium for its cultivation remains for some future investigator to solve. Be it what it may, since the clinical features give strong evidence of the infectiousness of cancer, the search must and will be continued along the same lines.

In this search for a specific contagium, cellular metabolism must not be forgotten. Its consideration and study is perhaps more important than the isolation of a specific germ. It can not be denied that the more exact our knowledge of cytomorphosis becomes the clearer will be our understanding of cell proliferation. It has long been understood that there must be certain stimuli that cause cell growth and certain inhibitors that limit cell development and exercise control in accordance with the requirements of the tissues. Certain other influences bring about a disturbance of the normal equilibrium between the stimuli and the inhibitors. It is evident that the exact nature of the stimuli, the inhibitors, and the disturbers must be ascertained. This involves a study of the cell constituents and the fluids that surround it. As we see, it is a question of chemistry.

In this connection it is important to take note of a very novel hypothesis bearing on the formation of newgrowths propounded by Homer Wakefield.

He believes that a neoplastic formation is not an exaggeration of anabolism, increased or excessive proliferation, but that it is a product of katabolic stasis; that is, normal cell division is unimpaired, the anabolic process continuing to the point of maturity of the cell. It attains the meridian in its life and reaches the postmeridian state when it should undergo normal katabolism, a complete dissolution and disappearance of the cell. Instead, something has supervened to check katabolic changes, the cell becomes superannuated and its existence is

prolonged until finally it undergoes various degenerative changes. Normal cell production continues, but normal cell dissolution is retarded or abolished, hence the cells accumulate, producing the appearance of what is regarded as cell proliferation.

This condition Wakefield has termed katabolic stasis or subkatabolism. He states that the intercellular substance is richly alkaline, and that the tissue cells are more or less soluble in it. The cells, during the period of their growth, generate sarcolactic acid, and during this period they are richest in protoplasm. After the meridian the cells offer decreased resistance to the solvent powers of the alkaline medium and lose their protoplasm, the nucleus alone remaining.

He infers that before the meridian is reached the acidity produced by normal cellular activity protects the cells by its neutralizing effects on the intercellular alkalies and that this preserves the investment of protoplasm. Now, if from any cause the normal alkaliescence of the intercellular substance is reduced, or if in a given area the acidity increases, katabolic stasis affects all the cells in that area. Suboxidation consequently takes place. It is therefore believed that cancer formation is an acid process.

Briefly, tumor formation, according to this hypothesis, rests on a stasis of katabolism, subkatabolism and suboxidation, in the presence of normal anabolism. The cell inclusions, observed by many investigators and regarded by them as protozoa, cancer parasites and as blastomycetes, Wakefield regards as products of disturbed nuclear division. This new hypothesis at present rests only on theoretic grounds, but the arguments are so thoughtful and so suggestive that they deserve careful attention. Their chief importance at this time consists in the bearing out and support of the methods of research along chemical lines.

We are all familiar with Virchow and the birth of cellular pathology, with Ehrenburg and the growth of bacteriology, and now we have arrived at and are in the humoral or chemical era. The trend of all research at the present time is beyond cells and beyond bacteria. It is to determine the chemical operations in and around the cells. This line of research began in the leukocytes because they were the most available. In their study it was possible to establish basic principles. From the leukocytes to the erythrocytes was only a step and then the epithelial and connective tissue cells received attention. This field of research is a new one. It is occupied by a vast army of patient and earnest toilers. The fruits of their labors will be beyond our greatest expectations. It is our present purpose to see if the cancer problem can be solved along these lines.

What has malignant disease to do with immunity? The entire subject of immunity has to do with infection. It has to do with its nature, mode of action and control. Has cancer any characteristics that pertain to infection? Bacteriologically we have found none. Clinically, we have a mass of evidence that would seem to place cancer among the infectious diseases.

In order to have a clear understanding of the modern conception of immunity it is necessary to review as briefly as possible and in barest outlines without comment the most important features of our present knowledge of the subject. Much material that may seem essential to a complete elucidation of this great and important subject had to be eliminated on account of the limited scope of this dissertation.

More than a century ago we find that John Hunter was familiar with some antiseptic properties of the blood. He found that a small amount of putrefying material could be added to a given quantity of fresh blood without producing putrefaction. Consequently, he advanced his doctrine of "the living principle of the blood." This, as an observation, was almost forgotten, and its import was not fully realized until Nuttall, in 1888, began his systematic work in Flüggé's laboratory, studying the antibacterial properties of the body fluids especially the blood-serum.

The greatest impetus to the study of immunity was given by Metschnikoff in calling attention to the participation of the leukocytes and other cells in the process of infection, establishing his wellknown theory of phagocytosis. His views are so well understood that we need only to call attention to them at this time.

Following Nuttall, Pfeiffer discovered, in 1894, "the extracellular disintegration and solution of cholera spirilla in the peritoneal cavity of immunized guineapigs."

The greatest attention and interest was aroused by Behring's great discovery of antitoxic immunity. Bacteriologists at once endeavored to elucidate by elaborate researches the exact way in which immunity was established. Chief among these was Ehrlich. It was soon shown, however, that immunity in most bacterial infections did not depend, in the main, on the antitoxic principle.

Pfeiffer's phenomenon afforded a starting point from which Metschnikoff, Bordet, Ehrlich, and Morgenroth began their labors and brought forth a series of discoveries that have been epoch making.

A series of antibodies were differentiated and classified as antitoxins, antienzymes, cytotoxins, agglutinins, precipitins, and coagulins. Antibodies were in turn produced by these, with the exception of the antitoxins.

It was determined that to every cellular group of an animal species there appears to correspond a specific cytotoxin. These various toxins have been termed leukotoxin, neurotoxin, spermotoxin, nephrotoxin, thyrotoxin, etc.

These antibodies have been divided into two groups, first, the antitoxins which are single bodies; second, the cytotoxins, whose antagonistic effects require the cooperation of two bodies.

Of these two bodies, the one which actually destroys the foreign cells is normally present in the cells or fluid of the organism, but it seems incapable of action without the intermediation of a body which is distinguished from it by a greater resistance to heat. The two elements composing cytotoxins exist quite independently of each other so that one may be present without the other or be artificially removed without affecting the other.

To demonstrate the mode of action and constitution of the specific antibodies, Ehrlich has propounded the theory of receptors or side-chains. The atomic grouping of the toxin molecule, which affects the union with antitoxin as well as with a particular cell, he has designated as haptophore groups.

In view of the fact that certain molecule groups of the living protoplasm favor the taking up of certain poisons, he has termed them receptors. According to his theory of antitoxic formation, after the introduction of toxins, the receptors are produced in excess and finally are thrown off into the blood as useless ballast. The free circulating receptors are the antitoxins, termed amboceptors, intermediary bodies. The action of antitoxins is explained thus. They take charge of the haptophore groups of the toxin molecules and prevent them from approaching the receptors of the tissues.<sup>1</sup> There are as many receptors as there are toxins, while almost every day new ones are discovered.

Behring gives the most exact and brief definition of Ehrlich's antitoxin theory: "The same substance, which, when incorporated in the cells of the living body, is the prerequisite and condition for an intoxication, becomes the means of cure when it exists in the circulating blood." Every antiserum protects only against substances through which it becomes immunized. Every antiamboceptor protects only against its particular amboceptor.

Ehrlich and Morgenroth found, in experiments with goat's blood, 13 different new lysins which represent so many receptors. "The receptors are in the cells, not for the purpose of linking poisons to the cells, but to seize certain foodstuffs, particularly proteids, and the toxins, bacterial and other foreign cellular substances, if capable of inducing the immunizing reaction, chance to have the requisite combining affinities for the receptors."

The living body possesses bactericidal and cytolytic substances which may protect it by destruction of invaders or may injure it by destruction of its own cells, according to the mates with which they are paired.

In considering the physiological mechanism of the cells we find that they are designed primarily for the assimilation of food, and secondarily to meet pathologic conditions, the pro-

duction of antitoxins, cytotoxins and other similar bodies. The receptors are in the cells for the purpose of taking up foodstuffs, chiefly proteids. The toxins and bacterial cellular substances have combining affinities for the food receptors, if they are capable of inducing an immunizing reaction.

In producing immunization against bacteria, it is the intermediary body (amboceptor) which is generated. It has been found that these antibodies have a specific relation to the substances which caused their formation, as has been shown by the injection of a specific serum into an animal at certain intervals, of toxins, against which an antitoxin is desired.

The specific nature of these antibodies is further shown in their application to serum diagnosis, as shown by the Widal agglutination test for typhoid fever and the serum test in the diagnosis of *Bacillus dysenteriae* Shiga, an organism shown to be the cause of acute dysenteries by Flexner, Vedder, and Duval.

When Roux and Yersin discovered diphtheria antitoxin, and Ehrlich the origin and mode of action of antitoxin, a lasting foundation for the study of immunity was laid. It was positively shown that "soluble toxins enter, as assimilable substances, into combination with constituents of the body cells for which they have an affinity," and are enabled to produce immunity or to exert toxic effects.

The expectations that we should soon be enabled to solve all questions regarding the action of toxins after the discovery of soluble bacterial toxins, have only partly been realized, especially regarding the action of the pyogenic micrococci, which concerns us most as surgeons.

However fruitless hitherto the practical results regarding toxins of many pathogenic and especially pyogenic organisms, the principle has been established, and it is only a question of method and time when all body toxins and their antitoxins shall be definitely known.

Pfeiffer directed his attention to the bacteria and found substances, toxins, in cholera spirilla, which became free only after the bacteria were dead and which were termed intracellular poisons. This was a most important step in advance, but we must acknowledge that we know as yet very little about the action and nature of intracellular bacterial poisons.

It is interesting to note from the result of Flexner's experiments with venom that their action on red blood-corpuses, leukocytes and nerve cells is like that of duplex cytotoxins, which depend on the combination of intermediary bodies contained in the venom on one hand, with corresponding complements in the cells or fluids acted on. This is shown by the addition of venoms to fresh blood, which brings about the quick destruction of the red blood-corpuses. If the fresh blood has been washed with an isotonic salt solution, so as to remove all the complement, we find that the corpuses are not dissolved, but agglutinated. It seems that the venom serves chiefly to bring "into necessary relations with constituents of the body cells poisons we already harbor or may generate, but which are harmless without the intervention of intermediary bodies."

Flexner and Noguchi have shown that the leukotoxic, the neurotoxic and other cytotoxic properties of venom depend on combinations of venom, intermediary bodies with complements contained in the cells poisoned by venom, or in the fluids bathing these cells, indicating that the snake venom contains only a part of the complete poison.

Flexner and Noguchi also demonstrated that hemorrhages in various tissues of the body resulting from poisoning from certain venoms is due to the presence in venom of a cytotoxin which has the power to dissolve endothelial cells, which they termed endotheliolysin (hemorrhagin). It causes extravasation of blood through its direct solvent action on capillary endothelium.

The hemolysins have been most extensively studied because of their great pathologic significance, and it has been found that many bacteria have hemolytic power. The secondary anemias, so constant in streptococcus infections, in pneumonia, typhoid fever, and other diseases, afford a most striking example.

Normal blood-serum contains antihemolysins which protect red blood cells from bacterial hemolytic agents. Asso-

<sup>1</sup> Ehrlich: Schlussfolgerungen, p. 176.

ciated with hemolysins are bacterial hemagglutinins, possessing the power to clump red corpuscles.<sup>1</sup>

Heuter and Klebs believed that thrombi were due to the coalescing of red blood-corpuscles. Welch calls attention to hyaline thrombi formed by agglutinated red corpuscles. White corpuscles are agglutinated by certain bacteria and also by pus cells.

What is urgently needed is a separation of these poisons and a determination of their source, constitution, mode of action and degree of specificity.

It will not be out of place here to allude to the studies made of the ductless glands, because of their supposed bearing on immunity. Sajous urges that the adrenal extractives have a decided affinity for oxygen, offering a key to tissue respiration and to the functions of all other organs now classed as the ductless glands. It has been found that the red corpuscles are not the only carriers of oxygen, but that the blood plasma contains and distributes this gas. Schmiedeberg, Jacquet, Claud Bernard, and others, demonstrated the existence of an oxidation ferment in the plasma, and these bodies are now entertained as an oxygen-laden secretion. This secretion is believed to permeate nearly all the body elements. The blood also contains a fibrinogen body which combines in certain quantities with fixed portions of the plasma's oxygen. The changes in the temperature of the blood were traced to variations in the amount of the fibrinogen in the plasma. The adrenals have been shown to be connected with the anterior pituitary body by various sympathetic ganglia. The anterior pituitary body is regarded as the governing center of the adrenal system. Over-activity of this body increases the adrenal secretion, consequently oxidation, therefore vital resistance. Depression of the activity of the pituitary body causes decreased supply of oxygen, consequently depressed vital processes.

The thyroid secretion, thyreoidin, has been shown to sustain the efficiency of the pituitary body. Excessive thyreoidin production stimulates the pituitary body and produces exophthalmic goiter. Deficient thyreoidin production leads to myxedema. The adrenals, the pituitary body and the thyroid gland constitute the adrenal system. According to this line of research it is believed that toxins act directly on the adrenal system, and, by decreasing or increasing its secretion, decrease or increase the oxidation process. Certain toxalbumins and many drugs stimulate the adrenal secretory powers to a certain limit, and when exhibited in excessive doses, depress or arrest the functions of this system.

The posterior pituitary body has been shown by Berkley, Andriezen, and others, to be the chief functional center of the nervous system. It is the center for such emotions as shock, excitement, etc. It governs all organic functions through the nervous system. The secretions of the pancreas and spleen, according to Schiff, and later by Herzen, unite and change trypsinogen into trypsin, a solvent for the albuminous bodies in the pancreatic juice. This ferment performs an important part in immunizing processes, in that it destroys toxalbumins.

Viewing these labors in the light of Ehrlich's researches, the oxidizing substance represents the amboceptor; the spleno-pancreatic internal secretion, trypsin, represents his complement. To produce a proteolytic action of trypsin, fibrinogen and the oxidizing substances are required. These views are somewhat at variance with those commonly accepted, but are of sufficient importance to deserve consideration in this connection.

From the foregoing it would seem that the doctrine of phagocytosis plays an unimportant role. But we find that the French or phagocytic school, at head of which is Metschnikoff, recognizes the full significance of acquired immunity and the cytolytic principles represented by the cooperative action of intermediary bodies and complements. The German, or humoral school, led by Ehrlich, recognizes the leukocytes to the fullest extent.

The chief difference between the French and the German schools consists in the belief by the advocates of phagocytosis, that the complements reside in the leukocytes, whereas the

adherents of the humoral school believe that they exist in the blood-plasma.

While in what has here preceded we have been concerned in the consideration of chemical problems, we must not overlook the fact that behind all is a governing force which resides in the central nervous system.

The practical outcome of these studies has been found in the production of antitoxic sera, some of which have been proved to have a definite and exact effect under certain conditions. We find these sera divided into two principal groups: (1) Those that have an antibacterial action; and (2) those that have a purely antitoxic action. Of all the sera, the diphtheric is best known. According to Welch the mortality of diphtheria has been reduced from 40% to 15% by its use.

Antitetanus serum has been disappointing. Reports coming to us from different sources are conflicting, the mortality ranging from 0% to 70% from practically the same methods, which consist in administering the serum by the subcutaneous, intracerebral and the spinal methods. Antityphoid serum has failed to fulfil expectations even more than antitetanus serum. The antistreptococcus serum of Marmorek, while it seems to have exerted a specific effect in purely streptococcal infections, appears to exert no influence in the presence of mixed infections. The antipneumococcal serum has not yet emerged from the experimental stage. Nothing can be said of its effects. The antiplague sera of Haffkine and Yersin demonstrated that, as a preventive, it reduced the number of cases to one-twentieth and the mortality in a given number of cases was reduced from 33% to 13% (Calmette). The antitubercle serum has been shown to have a specific effect on tuberculous tissue, but remains powerless in the presence of mixed infections. The antivenom serum has been demonstrated to have a positive usefulness in certain snake bites. Calmette's antivenin has been proved to be of undoubted use in leprosy.<sup>1</sup>

Many other sera have been described, but their usefulness thus far has been shown to be of an uncertain nature. Consequently, we will leave them out of consideration at this time.

When we pass in review all that is positively known in relation to the question of immunity, we can not deny that some of the principles underlying this great question have, in a measure at least, been revealed. The evidence is conclusive that "the same substance which, when incorporated in the cells of the living body, is the prerequisite and condition for an intoxication, becomes the means of cure when it exists in the circulating fluid."<sup>2</sup>

Ehrlich, in his investigations of diphtheria toxins, demonstrated "that soluble toxins enter as assimilable substances into direct combination with constituents of the body cells for which they have an affinity, and only thereby are enabled to bring about immunity or to exert toxic effects." Further, in connection with Metschnikoff, Bordet, Morgenroth, and Ehrlich, it is shown that "the organism possesses a power to produce substances specifically antagonistic to all sorts of foreign cells, cellular products and derivatives. The substances capable of inducing this immunizing reaction appear to be mainly of an assimilable, albuminous nature, or at least intimately associated with such material."

The principle of toxins and antitoxins has become as firmly established as any other in medicine or surgery. We have noted that antitoxins from pure cultures have a certain affinity for and possess immunizing power in specific infections, but fail in the presence of mixed infections. We see at once that failure to immunize does not violate the principle, but that the method of application has been at fault. We know that diphtheria toxin has a specific effect for the products of the Klebs-Loeffler bacillus, and that it controls and cures in the presence of these, but fails when there is an admixture of other forms of infection. This is shown by the 15% mortality which still exists. We have noted that antistreptococcus, tuberculous and plague sera have a specific and a decided effect in pure infection, but that they fail in the presence of other specific germs. We observe with satisfaction the certainty of the action of a

<sup>2</sup> Behring's Definition of Ehrlich's Theory Concerning Antitoxin. Welch.

<sup>1</sup> Heuter-Klebs, p. 731.

given antitoxin in its union with the toxin from which it was produced. It at once becomes apparent that, in the presence of several toxins or a mixed infection, it will require several antitoxic substances, a combination of antitoxic sera, or a serum containing different kinds of amboceptors, so combined as to meet and unite with the several toxins in a given case. Coley endeavored to meet such indications by combining *Streptococcus* and *Bacillus prodigiosus* sera in treating inoperable sarcoma.

These observations presage a revolution in therapeutics, which perforce means a refinement in diagnosis beside which what we do now will scarcely bear comparison.

The inferences to be drawn from the foregoing indicate that the future work will be biochemic. It appears that the solution of cell metamorphosis, as it is observed in pathologic conditions, will be in the field of chemistry. Ehrlich's theory of the side-chains has given us a working hypothesis almost as practical as the atomic theory when applied to chemistry. It is not an idle dream to believe that the revelations of the future will not only consist in a complete exposition of cells and body fluids, or a perfect understanding of the governing brain centers, but may extend to the life principle itself, although life itself may and will ever belong to the unknowable.

Our chief interest, however, will always center in the cell and its governing influence. Just what influences are responsible for normal cell division may never be known. But it is within the bounds of human possibility to know what influences may be responsible for atypical and excessive cell growth. Excessive cell growth, both in the leukocytes and connective tissue cells in acute infections, we can assume to be due to toxins that are in excess of the amboceptors. The existence of cytolytins and anticytolytins is now undisputed. The one destroys, the other protects the cells. We have noted that the chief function of a receptor molecule is to combine with nutrient molecules a metabolic, a chemical process. The birth and growth of the cell is restricted within certain limitations and is regulated by chemical law. Now the problem depends on our ability to ascertain the exact influence that carries cell division beyond its normal bounds and causes excessive cell growth as we observe it in malignant newgrowths. That the process is one of localized excessive nutrition is apparent. The localities of predilection are frequently at points where the cellular elements are exposed to frequent insults, where the tissues are damaged, establishing a *locus minoris resistentiae*, as, for example, in the mouth, gastrointestinal tract and the female reproductive organs. A point of least resistance, damaged tissue, if you please, always offers a soil for bacterial invasion. Cancer very often develops in tissues that have long been irritated, no doubt liberating a complement that unites with a specific infection when introduced under proper conditions. Such is not always the case, however. In fact, we know that in the majority of tissues that sustain irritations and almost constant traumatism for many years never become malignant. The simple traumatism does not develop cancer. A specific toxin must be introduced, probably also an intermediary body to complete the side-chain, which increases karyokinetic energy. We have noted in our studies of immunity that the life or death of the cell depends on its intracellular and extracellular composition, so we may say that the whole process, whether it relates to normal or excessive cell-growth, is chemical.

An objection may be urged at this point, which consists of the fact that the propositions of immunization thus far considered affect groups of cells extending over a wide range, *i. e.*, the vascular, the muscular, and the glandular or cerebrospinal systems. It has been shown that cancer is always at the onset, and often throughout its entire course, absolutely a local disease. It would not seem rational to attempt immunization of the entire system against a strictly local disturbance. We will naturally turn our hope toward a method that will enable us to affect local immunization.

That local immunization is possible has been demonstrated by P. Römer in the following convincing abrin-immunization experiment: As is well known, abrin, which is the toxalbumin of the jequirity bean, will produce a severe conjunctivitis in animals and men. Ehrlich had demonstrated that rabbit's con-

junctivas became immune after the instillation of abrin. Römer instilled into the right eye of the rabbit weak abrin solutions, the dosage being rapidly increased until immunization was produced. In three weeks the rabbit was killed. It was then shown that if the right conjunctiva, which had undergone severe inflammation, were rubbed and macerated with a certain amount of abrin and injected into a healthy animal it had no effect. But if the conjunctiva of the left eye, which had received no instillation, were rubbed and macerated with abrin and injected into an animal death always followed. Römer concluded from this observation that in conjunctival immunizations a part of the autotoxin existed in the conjunctiva itself. A local antitoxin was produced.

It would seem that these results establish definitely the principle of local immunization in indifferent tissues. These observations have an important bearing on the adaptation of the cells in local affections. That local affections of various forms or general affections with local manifestations can be best managed by the local introduction of exceedingly small doses of the specific remedy was shown by Professor Bouchard before a recent meeting of the Egyptian Congress. He found that articular rheumatism disappeared after the injection *in situ* of small doses of salicylic acid, in some cases only half a grain. We must conclude that local cell metabolism can be influenced by local rather than by general diffusion. The inhibition of excessive cell growth must be accomplished in the same way.

It would seem, then, that the cancer question must be solved along the lines of chemistry. Since we know that contagious or infectious energy does not depend on the bacterium itself but on its products, which are purely chemical, it would seem that it matters little whether the specific parasite is found or not. Since the cancer germ has thus far successfully eluded the most vigilant search it becomes more and more evident that in the field of chemistry will be found the solution for our problem.

It will be difficult to rid ourselves of time-honored views. Purely theoretical speculation, like the hypothesis of cell proliferation from inclusions of embryonal matrices, according to Cohnheim, must give way to the demands of modern science that insist on actual observations and practical demonstrations.

Now, then, will it be unreasonable to hope that when protoplasmic changes are thoroughly understood, and when the body sera have given up their secrets and the influences that govern cell growth, that we may also find the antibodies which will inhibit cell multiplication beyond natural bounds?

The studies in the field of immunity have as yet only assumed the proportions of the initiatory stage. A vast unexplored wilderness lies before us. The pioneers have begun their work well. They have outfitted themselves in a manner that will in the near future enable them to throw unexpected light in the pathway of their conquest of discovery. They are only on the verge of this vast domain. What lies beyond the borders we can no more foretell than could Boyer know that in 24 years after his death we should have anesthesia and that in 50 years the world would have antiseptic surgery. And yet, in the light of our present knowledge, the hope, amounting to a conviction, arises in us that even in our lifetime, if we are spared a few years more, we will have an exact biodynamic and biochemic science that will make diagnosis accurate and precise, and one that will enable us to treat and control all infections with an exactness not now possible. While the surgeon is now constantly encroaching on the field of the internist, the time is not far distant when the physician may not only reclaim his own, but with it that large group of neoplasms known as malignant growths that from time immemorial has been the exclusive property of the surgeon.

13. Morphine and Cocaine Intoxication. GEORGE P. DALE.
14. A Note on the Value of Auscultatory Resonance and Auscultatory Percussion as Aids in Diagnosis. CARL C. WARDEN.

**1.—Red-light Treatment of Smallpox.**—J. F. Schamberg does not believe that exposure to diffuse winter daylight could cause any irritation of the skin. The predilection of the eruption for the face and extremities is due to the greater vascularity. Congestion of a part prior to eruption augments the lesions, but irritation after its appearance does not influence it unfavorably. If Finsen's theory were correct the negro should suffer less severely than the white. Scarring is less determined by any special treatment than by the vaccinal condition of the patient and the severity of the disease. The vast majority of once vaccinated patients suffer mild attacks and are not scarred. Even in the unvaccinated a mild attack may leave no scars. In determining the value of a remedy conclusions should be drawn only from nonvaccinated patients. The favorable reports of the treatment in Denmark, Sweden and Norway are due to those countries, after Germany, being the best vaccinated in Europe. [H.M.]

**2.—Cicatricial Ectropium.**—F. C. Hotz describes an operation which prevents unsightliness and subsequent eversion. The skin flaps used should be thin and adaptable. If the eyebrows are absent and there is sufficient cicatricial skin above the everted lid a curved incision is made upward, beginning and ending 5 mm. above the canthi. The flap outlined is dissected up to the lid border, the lid turned into normal position, and the edge of the flap fastened to the upper border of the tarsus. Its contraction cannot then turn the lid over, as to do this the point of purchase must be without the lid. The lid is then drawn down by two ligatures passed through the free border and fixed on the cheek by plaster strips. The wound above is covered by a Thiersch graft. If the presence of eye-

brows prevent the above operation an incision is made along the lid border, the lid drawn down and a graft sutured to this border and the upper edge of the tarsus. A similar operation may be done on the lower lid, beginning 1 mm. below the canthi, the edge of the flap being anchored to the tarsoorbital fascia. Before anchoring, the overstretched lid margin is shortened by removing a four-cornered piece (except the conjunctiva) near the outer canthus and bringing the horizontal edges together by sutures. The lid is held up by ligatures plastered to the forehead. At the end of the first week the ligatures and sutures may be removed. [H.M.]

**3.—Prescribing Unknown Compositions.**—A. A. Eshner points out that if the identity of a medicine is not known through its composition the prescriber has no assurance that he will always receive the same article, the cost to the patient is higher, the physician surrenders originality, and independence in his therapeutics and the practice is unnecessary, as the same results can be achieved by medicines of known composition. If physicians will cease demanding illegitimate preparations manufacturers will stop producing them. [H.M.]

**4.—A New Method of Shortening the Round Ligament Intraperitoneally.**—H. T. Byford folds the ligaments anteriorly, according to Dudley, but stitches the loop to the abdominal parietes about opposite, or behind and a trifle above the internal inguinal ring. The ligament is drawn as far out of the inguinal ring as possible without doing violence to the tissues. A catgut suture is passed through it a quarter of an inch from the uterine end and a half inch from the ring. This includes only half the caliber of ligament in its grasp. The inner edges of the loop are touched with a chemic irritant and sewed together. The end of the loop is also touched with the irritant before being sutured to the abdominal wall. When there is a tendency to prolapse he sutures the whole side of the fold to the peritoneum beside the bladder, or even sutures the portions of the round ligament external to the folds to the parietal peritoneum in front. When there is decided prolapse he stitches the infundibulopelvic ligament forward, the fundus uteri itself, and even takes folds in the sacrouterine ligaments. In cystocele he separates the urachus with a strip of peritoneum, and after twisting and drawing it up sews it into the abdominal wound. [H.M.]

**5.—Significance of Leukocytosis.**—R. N. Willson reaches the following conclusions from his investigations: The term must include every increase in the absolute number of leukocytes, as well as every increase in the percentage count of the various leukocytic forms. Leukocytosis is a clinical sign of importance but never of such weight as to influence against equally convincing physical signs. A high percentage of the polymorphonuclear forms in the absence of an absolute leukocytosis indicates the presence either of pus or of some grave inflammatory process, with low vitality. Special factors may interfere with the usual reaction of the polymorphonuclear cells. One instance has been noted in which the total leukocytes were increased with marked reduction in these forms. Single counts are often misleading. A series seldom fail to aid in diagnosis. A gradual but steady rise in total count usually indicates an augmenting inflammatory influence. When it reaches large proportions it indicates an active leukocytic process (serous, purulent effusion, localized pus, pneumonic exudate, etc.), provided the clinical picture also bears out the suggestion. [H.M.]

**6.—Is the Tuberculous Chest Flat?**—W. Hutchinson presents further data substantiating his previous observations that the typical tuberculous chest is round instead of flat, and has an average index of about 80 (taking the transverse diameter as 100), nearly 10° above the normal. This type of chest precedes the disease and is the abnormal persistence of the fetal and child type. The chests of growing boys and girls should be systematically measured at stated intervals, and active steps taken to remedy this defect when found, including all those sports and exercises which involve wide-swinging play of the arm, chest, and shoulder muscles. [H.M.]

**7.—Blood-pressure.**—H. W. Cook describes an instrument which applies the Riva Rocci principle in a compact form serviceable to the general practitioner. The three essential parts, manometer, arm piece, and bulb with valve attachments are

connected by rubber tubing. These form a closed air system throughout which pressure is everywhere transmitted equally. The manometer is entirely of glass. A vertical tube projects into a glass reservoir containing mercury. An outlet tube allows free communication with the rest of the system. The scale is etched on the glass, and the tube is divided by a glass joint to permit packing. An extensible rubber bag completely encircles the arm and transmits pressure equally to every point of the artery. The rubber bulb by which pressure is raised and the reservoir bulb are similar to that used in the Paquelin cautery. A reading should not take longer than a half minute. This instrument is intended for maximum pressure readings. Minimum readings may be determined approximately by noting the point of maximum oscillation of the mercury column after the tube leading to the bulb is clamped off. Blood-pressure reports should all be given in the same terms. A maximum reading requires the least time and the simplest technic, is the more accurate, and of the greater clinical value. Pulse-rate often affords a good index of pulse force, but a blood-pressure reading is the force. [H.M.]

**8.—Increased Blood Counts Due to High Altitude.**—J. Weinzirl and C. E. Magnusson record observations made on men and rabbits, supporting the view that high altitudes have no permanent effect on the number of red cells, a fall in temperature producing the same effect as high altitude. They believe that the temporary increase is largely due to change in the temperature factor, and not to diminished barometric pressure. [H.M.]

**10.—Shock from General Anesthesia.**—F. B. Turck concludes from his researches that the circulatory disturbances from ether and chloroform result from the effect on the vasomotor centers. Their prolonged action on the splanchnic circulation results in congestion, with fall in temperature. Toxic products may be formed. Elaboration of these causes symptoms of auto-intoxication. Disturbances of elimination cause indirect toxic effects. The blood-serum is less resistant to normal and bacterial toxins and there is diminished resistance to saprophytic and pathogenic microorganisms. This may be due to diminished antiferment. Reflex irritations of the elementary tract may result from excretion of the anesthetic into stomach and intestines, or atony may increase the formation of toxins in the stomach, and the accumulation of gases interfere with the circulation. There is increased toxicity of the stomach contents in the presence of chloroform and ether. [H.M.]

**11.—Antitoxin and the Pharmacopeia.**—W. R. Hubbert bases his system of standardization on the Ehrlich unit of measurement except that he substitutes for the imported Ehrlich standard serum a standard toxin prepared by himself, and originally standardized to conform in L + to one Ehrlich unit. Toxins preserved with trikresol in a dark cool place in glass-stoppered bottles will keep as long as serums. A standard toxin like this could be kept in the laboratory of the committee for testing biologic products recently appointed by Congress and could be furnished each laboratory in the country, or could be procured by any pharmacist, and from it with a few guineapigs and sample apparatus for measuring doses an estimate could be made of the antitoxic value of a given bulb of serum which would come within 5% of being correct. There is so great variation in the value of different serums on the market that some uniform test should be adopted. This test is urged on account of its simplicity. [H.M.]

**14.—Auscultatory Resonance and Auscultatory Percussion.**—C. C. Warden assumes that diagnosticians are familiar with the latter. The former has been evolved from it. By substituting a vibrating tuning-fork for the percussing finger a musical tone is transmitted through the stethoscope, varying in intensity, quality and character with the size and density of the subjacent organ. Pressure of stethoscope and fork should be uniform. The stethoscope should be placed over the viscus and the fork brought toward it. Each lobe of the lung, the separation between heart and liver, and sometimes the septum of the heart can be made out by this method. No matter how obese the patient the method is applicable. It should be used to check over results obtained by ordinary procedure. The writer lists a number of obscure conditions in which it has proved valuable. [H.M.]

### Boston Medical and Surgical Journal.

April 30, 1903. [Vol. CXLVIII, No. 18.]

1. Albumosuria. CHAUNCEY REA BURR.
2. A Case of Juvenile Aortic Stenosis, with Subsequent Insufficiency: Sudden Death; Autopsy. ALBERT N. BLODGETT.
3. Mountain Sanatoriums for Tuberculosis. WALTER LINDLEY.

**1.—Albumosuria.**—C. R. Burr notes that peptones and albumoses are both found in the chyme, neither in the blood, a reversible zymolysis having occurred. The conditions are favorable for this in the intestinal mucosa. When there is a break in the mucosa absorption into the blood and reappearance in the urine occurs. The condition is often marked by albuminuria. Albumosuria may also often be due to excessive production and destruction of leukocytes. It is found where there is leukocytosis, and peptonuria where there is pus. It is highly probable that a large part of the albumoses in febrile blood are derived from leukocytes. For their detection the writer prefers Ogden's methods, which he describes. He lists the diseases in which this manifestation occurs. He tends to the belief that fever is due to albumose poisoning. Albumoses contain neurotoxic and hemolytic principles as in serpent venoms. The higher centers of the brain and cord appear specifically affected. Albumose poisoning is in general coextensive with that of the septic states, and the treatment is that of the latter. The neurotoxic element is best combated by oxygen and strychnin. He recommends magnesium dioxid ("brogen") and rectal injections of normal salt solution. [H.M.]

**3.—Mountain Sanatoriums for Tuberculosis.**—W. Lindley sums up the desirable points as an altitude of about 5,000 feet, the greatest amount of sunshine and of days permitting outdoor exercise, purity of atmosphere and water supply, pine forests for their balsamic effect, and beauty of scenery. He notes the fulfilment of these desiderata in Idyllwild, and asks the cooperation of the profession in making the sanatorium a success. [H.M.]

### Medical Record.

May 2, 1903. [Vol. 63, No. 18.]

1. Cranial Form in Man, Together with Some Remarks on the Attitude of the Profession Toward Anthropology. ARTHUR THOMSON.
2. Reciprocity in Pathology. S. B. LAACHE.
3. The Antituberculous Campaign in Latin America. EMILÉ R. CONI.
4. The Expansion of a Specialty. HOWARD A. KELLY.

**1.—Cranial Formation in Man.**—Arthur Thomson gives a somewhat lengthy, interesting, and exhaustive study of the human cranial forms, together with some remarks on the attitude of the profession toward anthropology. His aim is to prove that the shape of man's head in his higher developments is not the result of those physical and intellectual environments which have led on the one hand to the reduction in size of his jaws and on the other to the increased volume of his brain. These attributes are perpetuated by the influence of heredity and modified by sexual selection, but they are inconstant. He traces the gradual ascent in the form of man's cranium from one type to another, thus disposing of considering the dolichocephalic and the brachycephalic types as due to independent origin. In regard to the cephalic index, he agrees with Professor Boas, who considers that while that index "is a convenient practical expression of the form of the head, it does not express any important anatomic relation." The writer's observations confirm those of Boas in that the relation between capacity and head diameters is of fundamental importance that among these the relation between the transverse diameter and the capacity is most significant. [A.B.C.]

**3.—Antituberculous Campaign in Latin America.**—E. R. Coni notes that today antituberculous leagues exist in Brazil, the Argentine Republic, Chile, Uruguay, Paraguay, Bolivia, Ecuador, and Cuba, and others are planned or in process of formation in Peru, Colombia, Venezuela, Mexico, San Salvador, and Costa Rica. The Argentine Republic occupies the first rank in South America, and Cuba in Central America in relation to work accomplished through the creation of dispensaries, sanatoriums, vacation colonies, seaside hospitals, and promotion of popular education. The work is done through public cooperation, not private initiative as elsewhere. He discusses some of the details, especially the measures inaugurated in the Argentine Republic. [H.M.]

## New York Medical Journal.

1. The American Italy. CHARLES E. NAMMACK.
2. The Kidney of Pregnancy. JOHN O. POLAK.
3. Report of a Case of Infection by *Bacillus Coli Communis*. A. JACOBY.
4. The Surgical Treatment of Empyema. FRANK MCMORROW.
5. Fatal Meningitis with Myosis and Salivary Suppression as the Only Symptoms; Autopsy: A Study in Diagnosis by Exclusion. H. ALTSHUL.
6. Sarcoma of the Femur Following Traumatism: Amputation at the Hip-Joint by Wyeth's Method. GEORGE S. BROWN.
7. The Surgical Treatment of Ascites of Hepatic Cirrhosis, with Report of a Case. L. W. PEARSON.
8. Operation in a Case of Extradural Hemorrhage the Result of Whoopingcough. GEORGE S. BROWN.

1.—**The American Italy.**—Southern California is designated by Charles E. Nammack as "The American Italy." He says that this section has fully as varied a climate as Italy; it also has extremes of condition, which, however, unlike the Italian extremes, are favorable to health and longevity. It has six distinct classes of climate, all having a therapeutic value and application, as follow: 1. A purely insular climate at Catalina, Coronado, and the other channel islands. 2. The peninsular climate. 3. The coast climate. 4. The foothill and valley climate, 200 to 2,500 feet elevation. 5. The mountain climate, 2,000 to 9,000 feet elevation. 6. The desert climate, from 360 feet below sea-level to 2,500 feet elevation. The feeble and invalid may hope for benefit in southern California. Neurasthenics will find the recuperation which comes from restful climatic surroundings. Sufferers from malarial poisoning and its sequels will find almost certain relief on the seacoast. The free action of the skin which comes of a milder climate, the freedom from sudden changes of weather, and the risk of chill, and the choice of a wide range of diet make a very favorable combination for prolonging life in kidney troubles. The tuberculous who go there before the disease is far advanced, who have the means to secure reasonable comforts and the sense to follow the advice of a competent local physician, have a fair hope of checking the disease and even of apparent recovery. Asthmatics can generally secure immunity from the attacks. [C.A.O.]

2.—**The Kidney of Pregnancy.**—The changes in the kidney during pregnancy, the recognition of these changes, and their clinical importance as viewed from the standpoint of the obstetrician is the subject discussed by J. O. Polak. He believes that these changes are due to the fact that the kidneys are called upon to rid themselves of an excess of waste material the result of fetal as well as maternal metabolism. He says that while albumin indicates a renal insufficiency, its appearance, unless in quantity, is of little clinical significance, except it is associated with diminished excretion, deficient urea elimination, or fatty, granular, or waxy casts. The presence of these abnormal constituents determines the necessity of interrupting pregnancy. The kidneys are involved in about two-thirds of the cases of eclampsia, and albumin in considerable quantity has been demonstrated in the urine of 84% of women during the convulsion. A diminution in the excretion of urea is, however, the most important preeclamptic signal, and positively indicates kidney inadequacy; a fall to 1.5% is always dangerous. [C.A.O.]

3.—**A case of *Bacillus coli* infection** is reported by A. Jacoby. The case is of particular interest on account of the fact that it resembled typhoid fever so closely. So much so was this noticeable that it was only the negative reports of Widal's reaction and the presence of *Bacillus coli communis* in large numbers in the urine that enabled a positive diagnosis to be made. [C.A.O.]

4.—**Surgical Treatment of Empyema.**—Frank McMorro reports a case of empyema in a girl of 7, in which a piece of the seventh rib about two inches long in the axillary line on the left side was resected and a Wilson empyema tube inserted. An uninterrupted recovery followed. [C.A.O.]

5.—**A case of fatal meningitis with myosis and salivary suppression as the only symptom** is reported in full by H. Altshul, his patient being a man of 53. Full autopsy findings are added. From a consideration of all the features in

the case the author concludes: 1. That extensive meningitis can exist without giving rise to its characteristic and usual symptoms. 2. That sepsis does not always cause changes in pulse and temperature, and that their being normal does not warrant our excluding this condition. 3. That a spasmodic and complete occlusion of the ureter, which is not due to impaction of renal calculi, may last for some time and thus prevent the detection of extensive pyonephrosis. 4. That myosis and salivary suppression may be the first symptoms of meningitis or myelitis. [C.A.O.]

6.—**Sarcoma of the Femur.**—A case of sarcoma of the femur following traumatism in a woman of 18 is reported by G. S. Brown. Wyeth's method of hemostasis was employed and was entirely successful. Uninterrupted recovery followed. [C.A.O.]

7.—**Surgical Treatment of Ascites.**—L. W. Pearson reports a case of hypertrophic hepatic cirrhosis in a man of 30 in which Thalma's operation was performed. The patient died at the end of the second day. The author has reviewed the literature of the subject thoroughly and gives a number of important references. [C.A.O.]

8.—**An operation in a case of extradural hemorrhage, the result of whoopingcough,** is reported by G. S. Brown in a boy of 7. In course of time severe headache, somnolence, semidelirium, slow pulse, and fever came on after severe paroxysms of coughing. Later, convulsions ensued. A diagnosis of clot in the right cortical motor area was made, but on opening the skull no clot was found. The dura was then opened. Two days later convulsions returned and the wound was opened up. A button of bone higher up was removed and the dura again opened, but with the same negative result; but on cutting away a small corner of bone from the last trephine wound a small clot was found the size of a white bean. This was removed, and in two weeks the boy was well. [C.A.O.]

## Medical News.

May 2, 1903. [Vol. 82, No. 18.]

1. Indications for Extirpation of the Gallbladder. MAURICE H. RICHARDSON.
2. Some Practical Points in Anatomy of the Gallbladder Region. GEORGE EMERSON BREWER.
3. The Diagnosis of Gallstones. J. B. MURPHY.
4. The Mortality in Appendicitis: Its Cause and Limitation. A. J. OCHSNER.
5. Prompt Operation in the Beginning of the Attack Will Save Nearly All Cases of Appendicitis. A. C. BERNAYS.

1.—See *American Medicine*, Vol. IV, No. 21, p. 804.

2.—**Practical Points in the Anatomy of Gallbladder Surgery.**—G. E. Brewer, of New York, gives a number of points more interesting than practical with reference to the anatomy of the gallbladder and the region in which it is situated. He states that the important points in the anatomy of the region for the surgeon are: 1. A knowledge of the position of the nerve-trunks of the abdominal wall. 2. A knowledge of the normal position, size, shape, and relations of the gallbladder and ducts, their blood supply, and the normal position of certain constant lymph-nodes. 3. The most frequent variation from the normal in these structures, both congenital and acquired. 4. Variations in the arrangements in the blood supply of the liver and gallbladder. 5. The relations of the duodenal orifice of the common bile duct. 6. Anatomy of the entire hepatic peritoneal basin. The writer then proceeds to give in some detail various findings which he has discovered either anomalous in character or normal, which differ from the teachings in the ordinary works on anatomy. For instance, he states that from 100 measurements of the gallbladder 9 may be classed as simply measuring 6 cm. or less; while 12 were large, measuring 12 cm. The lengths of the remaining 79 were between these two measurements, the average length being 10 cm. Considerable attention is given to the arterial supply of the gallbladder and the neighboring structures. So many points with reference to the subject matter are considered that the article does not lend itself well to abstracting. [A.B.C.]

**3.—Diagnosis of Gallstones.**—J. B. Murphy states that with experience in 334 cases of gallbladder and liver disease he classes pain as: 1. The acute, inflammatory or infective type, which occurs in virulent infections and is accompanied by muscular contraction of the organ or tissue in which it is situated. 2. The aching, cumulative or tension type, which is not guarded by abdominal tension. The most characteristic reaction in this type of pain is that elicited by pressure between the right costal arch. 3. The referred ache or pain which accompanies either of the preceding types. Colic is used in connection with gallstones as entirely different in significance from the term pain. Colic is due to a foreign body in transit through the ducts. It is absent in two conditions: (1) When the foreign body is too large to be grasped by the canal, as in the case of stones over  $1\frac{1}{2}$  inches in diameter, and (2) when they are too small to produce spasm of the duct in their passage. The nausea and emesis of biliary obstruction are reflex symptoms. Of the patients operated upon by the author jaundice was absent in 86%. Jaundice due to gallstones is always preceded by colic. Jaundice due to malignant disease or catarrh of the ducts accompanied by infection is never preceded by colic. According to von Recklinghausen, gallstones exist in 12.2% of individuals. This was ascertained after many necropsies and in the dissecting-room. A number of cases are reported by the author. [A.B.C.]

**4.—The Mortality in Appendicitis.**—A. J. Ochsner states that the mortality resulting from the extension of infection from the appendix to the peritoneum may be prevented by early removal of the appendix. Extension of the infection is produced by a peristaltic action of the small intestine. This can be prevented by limiting peristalsis. In case neither food nor cathartics are given from the beginning of an attack of acute appendicitis, and gastric lavage is employed, the mortality is reduced to an extremely low percentage. Patients who have received food and cathartics during the early part of the attack and are consequently suffering from beginning diffused peritonitis, will still exhibit a mortality rate of less than 4%. Measures to limit peristalsis are instituted. In this way dangerous acute appendicitis may be changed into relatively harmless chronic appendicitis. In his personal experience no case of acute appendicitis has terminated fatally in which absolutely no food of any account and no cathartics were given by the mouth from the beginning of the attack. Were peristalsis inhibited in every case of acute appendicitis by the methods described, appendectomy during any portion of the attack could be done with much greater safety. He makes the following suggestions for the treatment of appendicitis with a view of reducing mortality: In chronic cases operation should be done in the interval; in acute cases operation should be done so soon as diagnosis is made, provided the acute infectious material is still confined to the appendix. In case of acute appendicitis, regardless of the treatment contemplated, food and cathartics by the mouth should be interdicted. Employ gastric lavage for the nausea, vomiting, or gaseous distention. If no operation is performed, neither nourishment nor cathartics should be given by the mouth for at least four days after the pain has ceased. Water by the mouth should be interdicted early. The slightest amount of food given by the mouth may set up peristalsis and increase the danger. The most convenient form of rectal feeding consists in 1 oz. of concentrated, liquid, predigested food, dissolved in 3 oz. of warm normal salt solution. [A.B.C.]

**5.—Early Operation in Appendicitis.**—A. C. Bernays states that the mortality of operation during an acute attack of appendicitis will be from 4% to 20%. His own mortality in the last 100 cases was 3; in 566 patients operated upon during the last 15 years is 9.5%. Operations done during the first 48 hours are easier, more complete than later operation, and the results are more satisfactory. He concludes that the question of appendicitis can be scientifically solved when we have advanced far enough to compare the similar stages and the similar pathologic conditions with each other and cease trying to solve the many-sided problem as an undivided whole. He advises early operation. [A.B.C.]

### Philadelphia Medical Journal.

May 2, 1903. [Vol. XI, No. 18.]

1. A Case of Perforated Ulcer in Typhoid Fever. JAMES C. WILSON and GEORGE G. ROSS.
2. Report of a Case of Painless Amputation of the Leg After the Intra-neural Injection of Cocain. JOHN H. GIBBON.
3. Practical Points on Pessaries, Many Old, Some New. ERNEST GALLANT.
4. The Radical Cure of Inguinal Hernia in Infants and Young Children. CHARLES GREENE CUMSTON.
5. The Paradoxical Reaction of the Pupil in Accommodation, with a Report of Three Cases. WILLIAM G. SPILLER.
6. A Study of Brain-weights of Men Notable in the Professions, Arts and Sciences. EDWARD ANTHONY SPTZKA.
7. A Case of Endothelioma Occurring Within the Nasal Fossa. WM. HITSCHLER and GEO. B. WOOD.

**1.—Perforated Ulcer in Typhoid Fever.**—James C. Wilson and George G. Ross detail the case of a machinist of 29, in whom a perforation about  $\frac{1}{8}$  inch in diameter occurred on the twentieth day of the disease. From 18 to 20 hours prior to the probable time of perforation the patient became extremely nervous and restless and perspired very freely. The initial pain of the perforation was referred to the penis and persisted there for 12 hours without being referred to the abdomen. Collapse was not present. The temperature remained high,  $104^{\circ}$  F., and there was no syncope, vomiting, nor sweating or pain in the abdomen. The delay in making the diagnosis was unavoidable. There was difficulty in obtaining the family's consent to operate resulting in a loss of five hours of valuable time. Death occurred three hours subsequent to operation from general purulent peritonitis. [F.C.H.]

**2.—Painless Amputation of the Leg.**—John H. Gibbon reports a case of painless amputation of the leg after the intra-neural injection of cocain. The patient was a man of 50, suffering from far advanced tuberculous disease of the ankle-joint and bones of the tarsus. Because of the man's age, his general condition, and the extent of the disease, it was deemed wise to consider only amputation. Fifteen minutes before beginning the operation the patient was given morphin  $\frac{1}{4}$  gr. and atropin  $\frac{1}{16}$  gr. hypodermically. The sciatic and anterior crural nerves were then exposed by infiltration anesthesia (Schleich's fluid), and injected with a 1% cocain solution. There was a total absence of pain during the operation. The technic followed is that described by Matas. The cocain solution must be pure and fresh and the technic perfect in order that it may give good results. [F.C.H.]

**3.—Pessaries.**—A. E. Gallant details the usual indications and counterindications for the employment of the pessary. For virgins, after manual dilation under anesthesia, in nulliparous and married women, he prefers the Hodge or Albert-Smith pessary for all purposes. A certain percentage of post-partum displacements may be obviated by the use of the sterile gauze tampons for one or two weeks after the uterus has involuted down to the pelvic brim, thus compelling that organ to resume its natural position, and often, after this treatment and the wearing of a pessary for two or three months, the patient is practically cured of her old displacement. [F.C.H.]

**4.—The Radical Cure of Inguinal Hernia in Infants and Young Children.**—C. G. Cumston concludes as follows: Experience has demonstrated the innocuity of radical operation for hernia in infants; the operation is indicated in all cases of strangulation, in cases in which the contents of the sac cannot be retained by a truss, and in every case in which irritation of the skin is produced by the mechanical appliance, and in children of the poor who cannot receive the necessary attention at their homes. [F.C.H.]

**5.—The Paradoxical Reaction of the Pupil in Accommodation.**—W. G. Spiller details three cases of the paradoxical reaction of the pupil in accommodation. This phenomenon is not the same as the better known paradoxical reaction to light, in which the pupil becomes larger when the eye is exposed to light. [F.C.H.]

**7.—Endothelioma Occurring Within the Nasal Fossa.**—Wm. Hitschler and George B. Wood detail the case of a man of 44, in which a microscopic examination of a piece of tissue spontaneously ejected from the nose showed that the growth was a typical endothelioma. The patient refused operation. [F.C.H.]

## CLINICAL MEDICINE

DAVID RIESMAN

A. O. J. KELLY

## EDITORIAL COMMENT

**The Virulence of Tubercle Bacilli Cultivated from Different Tuberculous Foci in Man.**—What are the causes of the differences between the behavior of tuberculosis of the lymph-glands, of the skin, and of the bones, and that of tuberculosis of the lungs? Clinically, the first three are slow in course; and there is little tendency for them to become generalized. Three theories suggest themselves in explanation: (1) A difference in the virulence of the bacilli; (2) a difference in their number; and (3) a difference in the resistance of the tissues. In the early bacteriologic era succeeding the discovery of the tubercle bacillus, in what Hüppe calls the orthodox period of bacteriology, the influence of the soil was disregarded, and the course of tuberculosis was made entirely dependent upon the virulence and the number of the bacteria. At the present day, however, there is no longer any doubt as to the important part played by tissue-resistance; and the question arises whether, in addition to this, the factor of varying virulence has a role in causing the clinical differences between tuberculosis of the lungs and the other forms of tuberculosis mentioned. E. Krompecher and K. Zimmermann<sup>1</sup> have made this question the object of study. Hitherto all investigators, with the exception of Vagedes, in studying the relative virulence of stocks of tubercle bacilli, have inoculated animals with the material containing the bacilli, and have tested the virulence with cultures obtained from the experimental animals. It is well known, however, and is again shown by Krompecher and Zimmermann, that by this passage the virulence of the bacilli is modified; and when rabbits are used it is distinctly enhanced. The only way in which to obtain an accurate idea of the native virulence is to cultivate the bacilli from the human body directly upon artificial media; and then, using identical quantities, to test the virulence on experimental animals. Krompecher and Zimmermann have cultivated the bacilli on glycerinated potatoes. The potatoes were first prepared in the ordinary way, and then softened in 5% glycerin, and placed in the customary test-tubes containing 5% glycerin water below the constriction. From two to three oesefuls of material were spread upon the potato, two such cultures being made in every case. Within from five to seven weeks the cultures were of sufficient development to permit of their being used for inoculation. A total of 30 cases of surgical tuberculosis were studied in this way; and the bacillus was obtained by culture 26 times; 15 times from tuberculous lymph-glands; 9 times from tuberculous arthritis or osteitis, and twice from tuberculous tendovaginitis. In three cases there was mixed infection and the bacillus was rapidly overgrown by the other organism. In one case no culture was obtained, though animal experiments proved the case to be tuberculous. The failure was probably due to the fact that too little material had been used to inoculate the potato. The authors are convinced that the culture method is as good as that of animal inoculation for demonstrating tubercle bacilli, if not better. When the bacilli are few they will still be shown on the potato, while they may be destroyed in the animal body by the antagonistic juices. Colonies are visible to the naked eye as early as the twenty-third day. Occasionally the cultures are colored; this is probably dependent on different degrees of alkalinity or acidity in the medium. To come now to the point at issue, viz., the relative virulence of bacilli cultivated from different forms of tuberculosis—Krompecher and Zimmermann, utilizing the results of Vagedes, who worked with

bacilli cultivated from pulmonary tuberculosis—have come to the conclusion that there is no difference in the virulence of these bacilli. The bacilli from cases of surgical tuberculosis proved to be as virulent for rabbits as did the bacilli cultivated from the lungs by Vagedes. The authors point out the fact that experimental animals (in their cases rabbits) do not all react alike to injections of identical doses, a fact that must be taken into account in making experiments. Inasmuch as there is no noteworthy difference in the virulence of tubercle bacilli from the lesions of surgical and of pulmonary tuberculosis the conclusion is that the differences in behavior must depend upon differences in tissue-resistance or susceptibility.

## REVIEW OF LITERATURE

**"False Cardiacs."**—Under this title E. Barié<sup>1</sup> includes those patients who complain of cardiac symptoms without having any demonstrable pathologic condition of the heart. The author describes several cases, illustrating various types. The symptom complained of most frequently is palpitation, although in a great many cases various kinds of precordial pain and distress are experienced. The patients are usually adults or adolescents, and are either dyspeptics, smokers, neuropaths, or victims of incipient tuberculosis. In dyspeptics the symptoms come on after eating, and may reach the severity of an intense orthopnea, with cold extremities, cyanosis, physical signs of dilated right heart, and even a temporary tricuspid insufficiency. These cardiac phenomena are brought about through a spasmodic contraction of the capillaries in the lungs, causing a sudden rise in the blood-pressure in the pulmonary arteries. The capillary spasm is produced reflexly through the sympathetic system by irritation of the gastric mucous membrane. Palpitation of the heart may be one of the first symptoms of pulmonary tuberculosis. The cardiac symptoms may be due to a dyspeptic condition frequent in incipient pulmonary tuberculosis, or to cardiac complications, or to reflex action. In adolescents palpitation may occur as a result of chlorosis, exophthalmic goiter, or the so-called pseudohypertrophy of growth. In the latter condition there exists a disproportion between a normally developed heart and an incompletely developed thorax. Barié also includes under the head of false cardiacs pseudoangina pectoris, and the palpitations occurring at puberty, the menopause, in affections of the uterus and adnexa, in gout, diabetes, and other diathesis. [B.K.]

**Sitzbaths, Their Physiologic Action and Indications.**—The short, cold sitzbath (50–60° F. for 3–5 minutes) is indicated in the weakness of the male sexual organs, in scanty menstruation and amenorrhea, in leukorrhea the result of anemia, in atony of the uterus, chronic constipation and intestinal distention, gastric dilation and motor insufficiency, paresis of the muscles of the bladder and rectum, and in congestion of the various organs of the body. They are contraindicated in acute inflammations of the abdominal, pelvic, and sexual organs. Cold sitzbaths of longer duration (50–66° F. for 5–30 minutes) may be used in instances of hemorrhage and inflammation of abdominal and pelvic organs, in chronic diarrhea and dysentery. They are contraindicated when there is colicky pain of the abdomen, vesical catarrh, and tenesmus. The temperate sitzbath (beginning with 88° F. and gradually lowering to 65° F. for from 5–20 minutes) is indicated in inflammation of the pelvic organs, urethra, rectum, hemorrhoids, vesical catarrh, nervous dyspepsia, sexual and other neurasthenia, sleeplessness. The warm sitzbath (90–102° F. for 30 minutes and more) are useful for colicky attacks and cramps of the pelvic and sexual organs, frequent pollutions, inflammatory exudates. A combination of hot sitzbath followed by cold may be ordered in amenorrhea and weakness of sexual organs. B. Tschlenoff<sup>2</sup> discusses their physiologic action at some length, but states that our knowledge of this is purely hypothetical. He gives some excellent advice regarding the details of procedure in each variety of bath. [E.L.]

**The Knock-out Blow on the Point of the Jaw.**—J. C.

<sup>1</sup> *Centralb. f. Bacteriol., Parasitenk. u. Infektionskrank., Originale, Bd. xxxiii, No. 8.*

<sup>1</sup> *La Semaine Médicale, February 11, 1903.*

<sup>2</sup> *Korrespondenz Blatt für Schweitzer Ärzte, November 1, 1902.*

Duncanson<sup>1</sup> states that this point of jaw is situated on either side of the symphysis menti, and corresponds nearly with the mental fossa. If a line is drawn on the skull from this point to the center of the odontoid process as the axis, which is the chief center for rotation of the head, it will be seen what a powerful lever there is to turn the head in any direction. The attachments and feebleness of the muscles for rotation prevent much resistance being offered. The blow must be dealt hard and sharp, but weight is not necessary. It is delivered more or less at right angles to the anterior posterior plane of the body and slightly upward; hence the head is jerked around suddenly to the full degree of rotation, and is likewise thrown backward. Such a blow, while it may not be so very powerful, is sufficient to knock down a very strong man, and is the one especially sought to be inflicted by the pugilist upon his antagonist. It is almost never fatal. An after-examination of the victim shows the heart's action to be excited only in a minor degree, respiration good, pulse normal, and there is practically no shock or concussion. [A.B.C.]

**Desquamative Obliterating Pneumonia.**—In this form of pneumonia desquamation of the alveolar epithelium is the principal feature, fibrin and leukocytes taking small part in the exudate. F. Galdi<sup>2</sup> reports such a case, with autopsy findings, in which the alveoli of both lungs were found to be filled with swollen and fatty degenerated epithelial cells. The alveolar walls were thickened and contained distended capillaries. The thickening was due to connective tissue, which sent trabeculae into the lumen of the alveoli. There was considerable round cell infiltration. The inflammatory process evidently started in the small bronchi and bronchioles, and extended to the lung parenchyma, progressing from the upper lobes to the lower in the form of a lobular infiltrate. Desquamative pneumonia in general cannot be considered as a separate disease, since more or less extensive desquamation occurs in various pneumonic processes. The obliterating, lobular, desquamative pneumonia, of which this case is an example, is distinguished from other pneumonias by its diffuse and progressive character, the widespread epithelial desquamation, the connective tissue increase in the alveoli, and the absence of fibrin. [B.K.]

**Cardiac Hypertrophy in Diseases of the Kidney.**—The relationship existing between cardiac hypertrophy and diseases of the kidney has never been satisfactorily explained, and it is only within the last few years that undeniable evidence has been produced, proving that it is usually the left ventricle which is hypertrophied, even though both ventricles are enlarged. H. Senator<sup>3</sup> reviews the various theories by means of which this hypertrophy has been explained at different times, and after showing the weak points of Traube's mechanical theory and the theory of increased blood viscosity of Ewald he forms a new one, which is based on work done by Strauss in his clinic during the last few years. In chronic parenchymatous and in acute nephritis the molecular concentration of the blood, the nonalbuminous nitrogen, and the toxicity of the urine remain normal; in chronic interstitial nephritis they are increased. The albuminous nitrogen is decreased in the former, normal in the latter. The increase in the molecular elements of the blood leads to an irritation of the heart and the bloodvessels and injures the bloodvessel walls. In parenchymatous nephritis, on account of the slighter degree of this injury, the permeability of the vessel walls is at first increased and edema results. Cardiac hypertrophy rarely occurs during this period, and is slight until the vessel walls are sufficiently thickened, and the lumen of the vessels contracted to prevent exudation. Blood stasis results, and the heart hypertrophies quicker. In the atrophic kidney, the abnormal elements being present in larger quantities, contractions and narrowing of the bloodvessels occur earlier, and the enlargement of the heart is greater and takes place quicker. [E.L.]

**Congenital Goiter.**—J. T. Hewetson<sup>4</sup> refers to a case of congenital goiter reported by Ballantyne and two cases reported

by Sir James Y. Simpson in 1855 and Professor A. R. Simpson in 1886. In each instance the mother had been taking potassium chlorate during pregnancy. The author states that congenital goiter generally assumes one of three types: (1) Adenomatous, being perfectly encapsuled tumors, occurring in the substance of the thyroid gland, containing one or more cysts and frequently masses of cartilage; (2) parenchymatous goiter, which is similar in all respects to the same variety seen in adults; (3) vascular goiter, which is probably the most common variety, in which the acini of the tumor remain fetal in character, showing an entire absence of colloid material. Large bloodvessels and widely dilated blood sinuses are present in considerable numbers. Cysts do not appear. Heredity appears to play some part in the causation of congenital goiter. Demme, of Switzerland, reported 642 cases of goiter, 53 of which were congenital, and of these 53, 14 had parents, both of whom suffered from goiter; 23 in which the mother alone had goiter and 16 in which neither immediate parent suffered from this affection. The male child is more prone to congenital goiter than the female. Many are born prematurely, and of those that survive birth the great majority die from mechanical pressure of the developing goiter. The severe forms call for operation and are dealt with as is goiter in the adult. The case reported by the author was the seventh child, born at the seventh month of gestation, and when the mother was 32. All the previous fetuses had been born dead, or at least no child had survived more than a few hours. The mother had never taken anti-syphilitic treatment until during this gestation, when she was given potassium chlorate and potassium iodid daily for a considerable time. When the child was delivered it was noticed that it had a large goiter. Both lobes were involved and were about symmetric. When removed from the dead fetus and examined microscopically it was found to conform to the vascular type described above. [A.B.C.]

**Acute Purulent Strumitis.**—Inflammations of the normal thyroid gland occur very rarely; on the other hand, the strumous gland is likely to develop inflammatory complications. These remain as yet obscure in etiology, and the clinical picture itself is far from being definitely established. Hence the necessity of new clinical reports. A. A. Abrajano<sup>1</sup> has observed acute suppurative strumitis in a woman of 54. A week before she had drunk cold water after a hot vapor bath, and the next day was seized with difficult breathing. A painful swelling appeared over the throat and increased rapidly in size. Fever and sweats, dysphagia, increasing dyspnea, cyanosis, finally stenotic noisy breathing followed. Suffocative seizures threatened her life. While preparing for an operation she suddenly gasped for air, became unconscious, and stopped breathing. Some 30 seconds passed before an incision could be made. A plunge of the scalpel brought abundant pus, and artificial respiration soon restored the patient. Breathing became free and easy. Intestinal gurgling was the last symptom of CO<sub>2</sub> poisoning. The abscess was found to have been located in the thyroid gland, about 1 cm. below its surface. A complete recovery took place in 20 days. [L.J.]

**Heart Disease in Children.**—J. Cassel<sup>2</sup> gives an analysis of 107 cases of heart disease in children; 26 of these were congenital. Cyanosis is the most characteristic symptom of this class; it occurred in 65% of the 26 cases. Clubbed fingers are also characteristic, and were found in 9 patients. Murmurs in congenital heart disease are always systolic; they were found in only 80%; 11 patients showed enlargement of the heart. Under-development with anemia was seen in 5 cases. In the patients with acquired heart disease articular rheumatism was the cause in 62%. Out of 75 cases of rheumatism observed by the author, 51 were complicated with endocarditis. Out of 38 patients with chorea 15 had rheumatism, and of these 9 also had endocarditis. The author has never been able to demonstrate gonorrhoea as a cause of heart disease in childhood, although he has observed 82 cases of precocious venereal disease. Scarlatina caused valvular lesions in 4 cases, and diphtheria in 1 case. In 18 patients no cause could be determined. Mitral insufficiency was diagnosed in 58 cases, mitral stenosis in 12, and

<sup>2</sup> Zeitschrift f. klin. Med., Bd. xlviii, p. 389.

both in 3 cases. Aortic insufficiency occurred 3 times, and stenosis once. Serous pleurisy complicated the heart disease in 7 cases, and cerebral hemiplegia in 3. Three cures are claimed, all symptoms and physical signs having disappeared. [B.K.]

**Diagnostic Importance of Leukocytes in Typhoid Fever and Surgical Suppurations.**—Diminution in the number of leukocytes is one of the earliest and constant signs in uncomplicated typhoid fever, occurring in 92% of Kühn's<sup>1</sup> cases. Ten cases studied from the very onset of the disease presented leukopenia about the fourth day. The other symptoms and signs—Widal, diazo, roseola, splenic tumor, etc.—usually came later. The number of leukocytes usually varied between 2,000 and 5,000. Leukocytosis is occasionally noted when there are complicating conditions. The only diseases which at times present the same blood-picture are malignant septicemia and miliary tuberculosis, but in both of them is leukopenia as rare as it is common in typhoid fever. He publishes his leukocyte observations in 33 cases of various diagnoses, and finds that the number of leukocytes is important not only in diagnosing appendiceal suppurations, but also for other surgical diseases, inflammations, and suppurations. Absence of hyperleukocytosis usually indicates nonsupuration, but even a diminution in the white corpuscles may occur in grave septic conditions or general infections. In chronic suppurations leukocytosis is less marked, and in fully developed, and particularly in encapsulated abscesses, it may again be absent. He cites a number of interesting cases to illustrate his conclusions. [E.L.]

**Six Cases of Goiter.**—E. M. Payne<sup>2</sup> believes that goiter is much more common in England than is generally supposed. He reports six cases. The first was in a woman of 38, who at 3 years of age had an abscess in the region of the thyroid, which healed leaving a small tumor the size of a pea. At 8 years this had grown to the size of an egg and at 12 the other side of the neck became involved. Some treatment for the condition was instituted when she was 14. This failing to give relief all treatment was abandoned. The tumor-mass has become exceedingly large, pendulous, and extends down to a level with the nipples. The patient is bright and cheerful and shows no mental weakness. Thyroid extract was tried without avail. The other cases are without particular interest except that all showed marked improvement on the administration of thyroid extract; three of the cases showed a strumous family history, and a like number gave a family history of goiter, two of the latter were of the three showing a strumous family history, two showed marked cardiac complications and one was considered an instance of acute myxedema, which the author considers rare. In no instance were there any marked mental symptoms. [A.B.C.]

**Blood Changes in Syphilitics Undergoing Treatment.**—W. Ossendowski<sup>3</sup> gives the following conclusions: (1) Hemoglobin is diminished during the secondary and still more diminished during the tertiary stage; (2) under the influence of treatment the percentage of hemoglobin increases. The most marked increase follows intramuscular injections of insoluble mercurial salts, the least marked is brought about by internal administration of mercury. Potassium iodid causes a higher rise than mercurial inunctions; (3) red corpuscles show a decrease in number during the secondary period and rise to normal toward the tertiary. Treatment with mercury always causes a numerical increase of red cells up to normal. Hypodermic injections have the most marked effect, next come inunctions and intramuscular injections, while internal administration again ranks last; (5) the number of white corpuscles is about normal until the gummatous period is reached, when it is increased. Under mercurial treatment this number falls to normal or even below that, the lowest level being due to hypodermic injections; (6) the ratio of white to red cells remains near normal throughout, irrespective of treatment; (7) bodily weight rises under all usual forms of treatment. [L.J.]

#### Suppuration of the Lacrimal Duct in the Newborn.

<sup>1</sup> Münchener medicinische Wochenschrift, December 9 and 16, 1902.  
<sup>2</sup> British Medical Journal, March 21, 1903.  
<sup>3</sup> Dissertation, Dorpat.

—According to E. Heimann<sup>1</sup> this condition is easily diagnosed by making pressure over the duct, when pus will exude from the opening. It is probably due to a stasis of the tears, the result of an atresia of the duct at some point; the stasis produces the dacryocystitis. The treatment consists of massage of the duct, followed if necessary by dilations with a probe. [E.L.]

**Lead-poisoning and Epilepsy.**—W. C. Gill's<sup>2</sup> case is that of a man 34 years of age admitted into the Ohio Hospital for Epileptics on account of dementia following a number of epileptic seizures. The patient had worked as a painter and had had painters' colic and lead palsy, the latter being still present when he was admitted into the hospital. As there was a vague history of former epileptic attacks and a family history of epilepsy the case could not be considered genuine saturnine epilepsy. Lead palsy is a very rare cause of epilepsy. Out of 2,175 cases of epilepsy admitted into the Ohio Hospital lead-poisoning was given as the cause of the disease in only two, and in one of these it was but a remote cause. Gill agrees with Gowers in the belief that lead-poisoning plays only a small part in the production of epilepsy, but that plumbism in an adult renders epileptic attacks more severe. [D.R.]

**Severe Pneumococcal Infection.**—A case of pneumococcal infection which caused an acute glossitis, arthritis, double pneumonia, and double empyema is reported by N. Raw.<sup>3</sup> The patient was a woman of 41, who was seized with an acute glossitis. Three days later pneumonia of the left base developed, followed in eight days by pneumonia of the right base and suppurative arthritis of the left temporomandibular articulation. Bilateral empyema later developed. The woman was then in such condition that extreme measures were demanded, and both sides of the chest were opened and drainage tubes inserted. Improvement rapidly took place. The pneumococcus was found in the pus in each instance. During the course of the pneumonia 2 drams of paraldehyd were given each night with excellent effect. Raw thinks there is no better hypnotic for pneumonia patients, the great advantage of the drug being perfect safety. [A.G.E.]

**"Wheat Coffee."**—Weissmann<sup>4</sup> reports eight cases of poisoning in one family, which was traced to "wheat coffee." It was found that the artificial coffee contained in addition to wheat-flour, flour made of *Agrostemma Githago*, which contains the poisonous alkaloid *Agrostemmin*. One of the patients died. [E.L.]

**Chronic Acromegaly.**—C. H. Cattle<sup>5</sup> reports the case of an unmarried woman of 30, who was first seen in 1902. Her health had become impaired four years previously. The patient's family history was negative. She had gradually become worse, and her most prominent symptoms were violent paroxysmal attacks of headache, sometimes accompanied by vomiting, pains in the joints, and gradually increasing debility. Menstruation had become scant and finally ceased. She formerly wore a No. 4 shoe, but at the time of observation required a No. 6. When she came under observation her head was massive in appearance, elongated, the nose was broadened, the lips thick, the hands enlarged, the fingers broad and flattened. The feet were likewise enlarged to the size of those of a man of more than average height and strength. The skin was muddy and pigmented and the thyroid gland was uniformly enlarged. The pulse was 120. The eyeballs were prominent, but von Graefe's sign was absent. The author states that although enlargement of the thyroid is somewhat common in acromegaly its association in this case with a quick pulse, prominent eyeballs, and pigmentation, seems to suggest a relationship between this and Graves' disease. He has had the patient under observation for seven months, during which time there has been comparatively little change, but such as occurred has been merely to augment the classic signs of acromegaly. [A.B.C.]

**Artificial Feeding of Infants.**—F. Szontagh<sup>6</sup> reports the studies of metabolism, each extending over four days, in a nursing given equal parts of whey and milk. All the organic ele-

<sup>6</sup> Jahrbuch für Kinderheilkunde, 1902, Vol. lvi, p. 341.

ments were well assimilated (from 95% to 96%); fat, albumin and sugar were equally well taken up; lime, on the other hand, was not well absorbed, only from 11% to 15%. The child thrived for four months, then, on account of beginning cranio tabes and convulsions, the child was put on cow's milk. The nutritional improvement continued, the convulsions ceased, and the rachitis did not develop any further. Szontagh sees an accidental coincidence in the simultaneous occurrence of the cranio tabes and eclampsia. [E.L.]

**The Relations of the Acid-proof Saprophytes to the Tubercle Bacilli.**—F. Klemperer<sup>1</sup> has investigated the question whether animals may be immunized against the tubercle bacillus by inoculations with the acid-proof saprophytes. His experiments were made with guineapigs, by injecting cultures of grass, milk, and butter bacilli, in gradually increasing doses, and after varying periods of time inoculating them with tubercle bacilli. The results of his experiments show that inoculations of these acid-proof organisms have a weakening and limiting effect on the tuberculous infection. The conclusion may be drawn that the acid-proof saprophytes are closely related to the tubercle bacilli. Their differences in virulence and methods of growth are not fundamental, but are merely due to adaptation to various environments. At any rate, they are not greater than the differences between the tubercle bacilli of mammals and those of birds and cold-blooded animals. It is probable that all these organisms are phylogenetically related, and form a continuous line of evolution from the acid-proof saprophytes, through the tubercle bacilli of cold-blooded animals and birds, up to the human and bovine bacilli. The course of evolution has been marked by an increasing selectivity of culture media and temperature of growth, by a decreasing rapidity of growth, and by an increasing virulence. The tubercle bacillus may thus be regarded as an acid-proof saprophyte that has become parasitic. [B.K.]

**Cheyne-Stokes Breathing in Acute Disease.**—The occurrence of Cheyne-Stokes breathing during an attack of erysipelas is reported by H. C. Mabley.<sup>2</sup> As the patient was 68 years of age, and had pus, albumin, and a trace of sugar in the urine, the possibility of autotoxemia having been a factor should be considered. The author collects from the literature cases of Cheyne-Stokes breathing in scarlet fever and in typhoid. [D.R.]

**Chronic Joint Disease in Children as Described by Still.**—F. P. Weber<sup>3</sup> reports the case. The patient, a boy, had a definite attack of articular rheumatism in April, 1902, preceded by an attack of endocarditis, accompanied by a lesion of the mitral valve in November, 1901. In the attack of articular rheumatism the knee-joints and elbow-joints, the articulations of the hands and thigh were all swollen and stiff, as was likewise the case with the spinal vertebra articulations of the cervical region. The spleen and liver were enlarged and extended below the ribs, the lymphatic glands in the neck, axillas, and groins were moderately enlarged; the cardiac apex beat was 1 inch outside the nipple line and there was a systolic murmur heard at the base. The patient was kept under observation until March, 1903, at which time the report was made, when it appears that all of his joints had become normal with the exception of a crackling in the knees. His head could be moved freely and the rigidity of the upper spinal column had entirely disappeared; the lymphatic glands could nowhere be palpated; the spleen was still slightly enlarged; in the heart there had been no material change. This case appears to show that rheumatoid articular affection in children as characterized by Still is sometimes practically recovered from so far as the joints and glands of the body are concerned. The damage to the heart is of course irreparable. The author considers that probably the most important part of the treatment consisted in keeping the child away from the insanitary and unhygienic conditions of his home since the original attack of endocarditis. [A.B.C.]

**Bacteriology of the Blood in Typhoid Fever.**—E. H. Ruediger<sup>4</sup> gives the results of bacteriologic examination of

the blood in 30 cases of clinical typhoid fever. In 20 cases bacilli were found, and of these two were of the paratyphoid variety and one was doubtful, the remaining 17 being true typhoid bacilli. In each case the organisms were found while the temperature curve of the patient was still rising. Two flasks of bouillon, containing 100 cc. each, were inoculated with 10 to 15 drops of blood, the blood being obtained by puncture. Ruediger concludes that blood cultures are the best means of making a positive diagnosis of typhoid, provided that method is applied early while the temperature is still rising. [A.G.E.]

**A Case of Leukemia in a Child.**—This case, occurring in a boy of 6½ years, is reported by T. N. Nikolsky.<sup>1</sup> A month before his admission to the hospital the boy suffered from follicular tonsillitis and malaria. In spite of quinin and arsenic he grew steadily worse. Great pallor of skin and mucous membranes, and enlarged cervical, axillary and inguinal glands were noted. Thyroid gland normal. Liver and spleen considerably enlarged. General hyperesthesia noticeable. Blood of chocolate color, containing 1,500,000 red and 80,000 white cells to the cubic millimeter. Hemoglobin was 42%. Severe bleeding from the nose, bloody vomiting, a hemorrhagic petechial rash, and fever experienced, ending in death. [L.J.]

**Suprarenal Diabetes.**—F. Blum<sup>2</sup> has found that the adrenal gland contains a substance which, when entering the circulatory stream, is capable of producing glycosuria. When adrenal glands are fed to dogs by mouth, even in large quantities, nothing but gastric disturbances are noted, but if injected subcutaneously or intravenously in doses not too small the invariable result, even if the diet is free of carbohydrates, is sugar in the urine. His experiments include 22 dogs and 3 rabbits, and inasmuch as the diabetic state was noted in all of these Blum feels justified in stating that the adrenal substance will produce the disease in all mammalia; he also feels justified in speaking of an adrenal gland diabetes. [E.L.]

**The Influence of Antiseptics on the Quantity of Bacteria in the Intestines.**—J. Strasburger<sup>3</sup> has found by clinical observation and animal experimentation that it is useless to attempt intestinal antiseptics by the administration of drugs. A slight decrease in bacterial growth may at first occur, especially in the small intestine. But this is soon followed by an increase, owing to interference with the natural protective powers of the bowel. The bacteria of the bowel are for several reasons necessary for the wellbeing of the organism; and a rational antiseptics should have in view the holding of the number and kind of bacteria within normal bounds. Purgatives are the most effective antiseptics, as they remove the culture-media upon which the bacteria flourish. But even here there is the danger of interfering with normal functions, as is shown by an increase in the bacteria some time after their administration. The best way to accomplish a practical intestinal antiseptics is by producing a normal condition of the intestines themselves, and by administering food that is easily and rapidly digested. [B.K.]

**The Practical Application of the Determination of the Freezing Point of Blood and Urine in Diseases of the Kidneys.**—O. Rumpel<sup>4</sup> discusses the theory and method of cryoscopy. It depends upon the constancy of the osmotic concentration of the blood in normal renal activity and an increase of this concentration in diseases of the kidney. As the concentration of the blood increases, the urinary concentration decreases, due to the fact that when the kidneys functionate normally all of the nitrogenous molecules are excreted with the urine; when their function is disturbed some of these substances are retained. The great constancy of the osmotic concentration of the blood makes the determination of the freezing point a very accurate and important physical method of examination. Two frequent errors must be guarded against in the examination: The thermometer must be completely submerged in the fluid being examined but must not touch the bottom of the vessel, and the fluid must be stirred with the platinum rod until the mercury begins to fall after its primary rise, as the highest point which the thermometer reaches is the freezing

<sup>4</sup> Münchener medicinische Wochenschrift, January 6, 13, 20, 1903.

point. Three hundred patients in all were examined. In 125 patients the kidneys were found normal, as shown by the freezing point of the blood being  $-0.55$  to  $-0.57$ , the normal freezing point of the blood; the freezing point of the urine being  $-0.9$  to  $-2.3$  on the Centigrade scale. He found that typhoid fever and other diseases do not produce any change in the freezing point so long as the kidneys are normal. 2. He examined 77 cases of bilateral kidney disease, 41 cases of chronic nephritis, 15 cases of cystitis and pyelonephritis, 13 cases of bilateral nephrolithiasis, 3 each of tuberculosis and cyst of the kidney, 2 of tumors. The freezing point in all cases was lowered far below the normal; 66 cases varied between  $-0.59$  to  $-0.66$ , 11 cases between  $-0.66$  and  $-0.81$ . 3. Eighty-three cases of kidney disease proved to be unilateral by physical examination, and confirmed either by operation, catheterization or autopsy, showed normal concentration of blood, thus proving that the normal kidney is able to compensate fully for the diseased kidney. From these tables it may be seen that not only is the method of importance from the standpoint of diagnosis, but also of prognosis and surgical treatment. In cases in which the freezing point is below normal, it certainly would not be safe to extirpate the more diseased kidney, as the other could not carry on the work by itself. He cites several cases in which operations were performed in precryoscopic times; upon the patient's death the autopsy revealed bilateral instead of unilateral disease. Since Rumpel has examined the blood and urine of his patients by means of cryoscopy before determining on operation, he has not lost a single case. The method in conjunction with other tests is also of importance in cystitis, prostatitis and pyelitis. [E.L.]

**Hypernephroma of the Kidney.**—A. P. Ohlmacher<sup>1</sup> reviews the clinical and pathologic aspects of adrenal tumors of the kidney, of which four examples have come under his notice. [D.R.]

**Cardiac Bradycardia.**—H. Silbergleit<sup>2</sup> reports a case of bradycardia, the first occurring in a patient with arteriosclerosis, probably including the coronary arteries, and the second being a case of aortic stenosis. Bradycardia may be physiologic, as observed after labor, during fasting, or normally in some persons. Pathologic bradycardia is a frequent symptom in diseases of organs other than the heart, but is very rare as a manifestation of cardiac disease. A diagnosis of cardiac bradycardia may be positively made only when the inhibitory action of the vagi can be excluded. This may be done by injecting atropin; if the heart's action is not materially increased, the slow pulse is due to disease of the heart muscle. Sixty beats to the minute is assumed as the upper limit of bradycardia. The condition produces lowered blood-pressure in the aorta and pulmonary arteries, and higher pressure in the veins. The ventricles are dilated, through accumulation of blood in them, during the long diastole. If compensation is established, the heart's impulse becomes abnormally strong, and arterial pressure is raised. If compensation is disturbed the pulse becomes very small and weak. Exertion may cause arrhythmia, and even attacks of syncope, and occasionally Cheyne-Stokes breathing. Autopsy in cases of bradycardia may reveal disease of the heart muscle, the coronary arteries or great vessels, or valvular stenosis. [B.K.]

**Primary Actinomycosis of the Bones of the Tarsus.**—O. Bollinger<sup>3</sup> discusses the position of the actinomycetes among the fungi, the manner of cultivating them, and the routes by which they enter the organism to infect it, also the pathology of the disease. He then relates the case of a man of 64, who at the age of 11 injured the dorsum of the left foot with an iron instrument. After several weeks of suppuration the wound healed, and he had no further trouble with it until he was 61, when pain and swelling appeared. Later he was unable to walk. A diagnosis of suppurative osteitis, possibly tuberculous, was made, and the foot amputated. An examination showed the bones riddled with actinomycotic sinuses and filled with fungi. It is possible that it was a recent cryptogenic infection, but it is much more likely that the infection occurred 53 years before, being latent all these years. [E.L.]

## GENERAL SURGERY

A. B. CRAIG      MARTIN B. TINKER      C. A. ORR

## REVIEW OF LITERATURE

**Albugineotomy in Chronic Orchitis, with Report of Case.**—E. J. Senn<sup>1</sup> advocates in chronic orchitis when all therapeutic resources have proved futile and when there is no reason for believing that the entire integrity of the organ has not been destroyed, a procedure which he terms albugineotomy, or incision of the tunica albuginea from pole to pole on the convex surface of the testicle. The case is detailed of an unmarried man 27 years of age, in whom the tunica albuginea was incised on the convex surface of the testicle from pole to pole, and the margins of the wound mobilized from the subjacent structures for a distance of a quarter of an inch. The wound surface was an inch wide in the central part of the incision. A small portion of the cortical substance was removed for examination. The testicle was dropped back into the scrotum, and the external wound closed. The pain which had been nearly constant for four months was immediately relieved by the operation. Examination of the testicle five days subsequent to the operation showed it reduced to its normal size, and painless. There were firm adhesions between the denuded surface of the testicle and the parietal layer of the tunica vaginalis. The patient was allowed to leave his bed on the seventh day. The benefits derived from this operation are, relief of tension, direct drainage of the intercellular spaces and resolution of primary pathologic products. In performing future operations he would modify the technic by scarifying the parietal tunic vaginalis, and attaching this surface to the testicle by several sutures of catgut through the cut margins of the tunica vaginalis albuginea, thus facilitating a firmer, and more rapid organic union between the two structures. [F.C.H.]

**Symposium on Diseases of the Pancreas.**—The *California State Journal of Medicine* for March, 1903, contains the histories of several instructive cases of pancreatic disease. W. F. Cheney reports a case of cyst of the pancreas in which recovery followed evacuation of a quart of fluid. Glycosuria developed after operation, but the patient wrote a year later that he was in good health. An elaborate discussion of the differential diagnosis is given by Cheney. A case of chronic interlobular pancreatitis with pancreatic calculi and multiple cysts is detailed by L. W. Allen. This case was complicated by pyonephrosis, supposed to be bilateral from the pain in both lumbar regions. Operation on the pancreas was followed by death. Autopsy showed the absence of a left kidney, emphasizing the significance of left lumbar pain in pancreatic disease. P. K. Brown contributes an article on the chemical pathology of pancreatic disease. E. E. Kelly detailed a case of pancreatic cyst and cholelithiasis, recovery following the evacuation of four quarts of fluid from the cyst and evacuation of gallstones and drainage of the gallbladder. [A.G.E.]

**A New Radical Cure for Inguinal Hernia.**—The method described and practised by E. Estór<sup>2</sup> succeeds in partially closing the inguinal canal by a musculoaponeurotic valve, leaving only sufficient space for the passage of the spermatic cord. After making an incision along the axis of the inguinal canal, passing through skin and subcutaneous tissue, the hernial sac is opened, dissected, and excised as high as possible, without cutting the aponeurosis of the external oblique. The latter is then dissected for 2 cm. ( $\frac{3}{8}$  inch) all around the external ring. The spermatic cord is held by an assistant close down upon the pubic bone. A silver wire suture is then inserted into the outer pillar of the inguinal ring 1 cm. ( $\frac{3}{8}$  inch) from its edge and a little shorter distance above the pubis, is guided upwards, inwards, and backwards along the index finger of the left hand, inserted for the purpose, and is then passed from behind forward through the entire abdominal wall, except peritoneum and skin, in such manner that it emerges 1.5 cm. ( $\frac{3}{8}$  inch) above and inside the external inguinal ring. In like manner a second suture enters the inner pillar of the ring, includes the pyramidalis and rectus muscles, then traverses the abdominal wall

<sup>1</sup> Cleveland Medical Journal, March, 1903.<sup>2</sup> Zeitschrift für klin. Med., Bd. xlviii, p. 145.<sup>3</sup> Münchener medizinische Wochenschrift, January 6, 1903.<sup>1</sup> Annals of Gynecology and Pediatrics, March, 1903.<sup>2</sup> La Semaine Médicale, March 4, 1903.

above the ring, and emerges 1.5 cm. ( $\frac{3}{8}$  inch) to the upper and outer side of it. Care must be taken to include the transversalis fascia in the sutures. By closing and twisting the sutures, the transversalis muscle and fascia, the internal oblique and aponeurosis of the external oblique are drawn down to cover the inguinal canal. The aponeurosis of the external oblique should now be plaited on itself by a parallel series of catgut sutures, entering and emerging at intervals of 1 cm. ( $\frac{3}{8}$  inch). The skin is then sutured. The great advantages of this method are that it is easy of execution, and that the inguinal canal is closed by all the layers of tissue in the abdominal wall, with the production of a thick cicatrix. [B.K.]

**Symptomatology and Diagnosis of Brain Tumors, and Chronic Hydrocephalus.**—Finkelnburg<sup>1</sup> reports in detail a large number of cases of brain tumor from the standpoint of their symptomatology diagnosis and pathology; also a number of cases in which a wrong diagnosis of brain tumor had been made. Twenty-two of the cases were cerebellar; 27 cerebral and 4 multiple tumors. He finishes his valuable paper with a clinical report of three cases of hydrocephalus, all of which showed the following characteristics: 1. Slow onset and chronic development without distinct initial meningitis. 2. Very slow course extending over years, with considerable fluctuations. 3. Considerable pressure-symptoms at the onset of the disease, which in some cases entirely disappeared, or were followed by optic atrophy. 4. Absence of focal symptoms during the entire course of the disease. 5. Early appearance of visual disturbances and choked disc. 6. Diminution of the knee-jerks. [E.L.]

**Surgical Treatment of Cancer of the Rectum.**—Sir Charles B. Ball<sup>2</sup> states that only when the growth is freely movable, or at any rate but slightly invades the perirectal tissue, is it a case suitable for surgical treatment. The route of attack depends entirely upon the situation of the disease; that is, the growth may involve the anal canal only, it may be situated low down in the rectal ampulla, or it may originate high up above the peritoneal reflection, or the entire area which involves all of these points may be involved. There are four routes of attack: The perirenal, the sacral, the vaginal, and the abdominal. Some surgeons prefer to do a previous colotomy in all cases in which the bowel can be sufficiently affected. The writer prefers not to perform this previous operation in many cases. The perirenal route should be adopted only in those cases which involve the anal canal. The sacral route is suitable for those cases in which the cancerous growth is a considerable distance up in the rectum and which cannot, therefore, be successfully attacked by the perirenal route. Kraske's original method has been much modified by various operators, but the principle remains the same—the removal of the coccyx and so much of the sacrum as is necessary to expose and permit free attack of the rectum within. The removal of the coccyx and the transverse division of the sacrum as recommended by Bardenheuer is the one preferred by the author. The diseased portion of the bowel is resected and whether the operator shall form a sacral anus or do an end-to-end anastomosis depends considerably on the operator as well as upon the conditions present. Formerly the sacral anus completed the operation in most cases. The author's earlier cases were so treated. Very frequently now he resects the diseased portion, draws the proximal severed end down, and unites it to the remaining sphincter. End-to-end anastomosis after resection of the diseased portion is very unfavorable for good union on account of mechanical conditions. It is well, therefore, if this method is attempted to commence free saline purgation after the second day. In three cases in which the author attempted to do an end-to-end junction a posterior fistula formed, though a good result was finally obtained. Subsequent operations had to be done to close the fistula. He prefers now to suture only the front and sides of the bowel in the first instance, leaving the posterior portion open, and close this by subsequent plastic operation. One case so treated resulted very satisfactorily. The vaginal route is adopted in those cases in which the posterior vaginal wall is involved in malignant growth. In three cases primary results

were good but recurrence was repeated, as is frequent in these cases. The excision of cancer when confined to the rectal tunic by incision through the healthy posterior vaginal wall has been practised with success by some surgeons. The abdominal route is suited to those cases in which the malignant growth is high up. The author believes that this route has not yet assumed the position in surgery which it will eventually hold. Its advantages are ability of the operator to determine exactly the extent of the disease and the involvement of the lymphatics, easy control of the hemorrhoidal vessels, and prevention of hemorrhage, complete removal of the lymph glands, which are usually involved. Wound-soiling from the escape of intestinal contents can be reduced to a minimum. [A.B.C.]

**Four Cases of Snap or Trigger-finger.**—These cases are reported by H. L. Barnard.<sup>1</sup> One patient refused operation and one is but 11 months old, too young for operation. This patient is believed to be the youngest of recorded cases. The other two cases were operated upon, and in both there was found a nodule in the tendon that, becoming fixed between the sesamoid bones, caused the peculiar symptoms of the condition under consideration. Resection of the nodule was not thought justifiable, the method adopted being that of dividing the ligament between the two sesamoid bones and leaving the tendon sheath open for about three-fourths inch, the skin being sutured. Passive motion was begun within a week or ten days and perfect recovery followed. Barnard refutes the theory that snap-finger may be produced by contraction of the fibrous arch opposite the metacarpophalangeal joint without any change in the size of the tendon. When operating and synovial fringes are found they should be removed, but when a fibrous nodule is buried in the tendon it is better to make room for its passage up and down by removing a part of the fibrous ring. [A.G.E.]

**Extraction of Bullets from the Cranial Cavity.**—O. V. Angerer<sup>2</sup> treats recent bullet wounds of the skull in a purely expectant manner. He disinfects the skin, dusts the wound and surrounding parts with iodoform, and puts over all a sterile dressing. He never attempts to disinfect or probe the wound, as this can only do harm. If the bullet has not entered the skull cavity, or if there is considerable bleeding from the skin wound, this may be enlarged and examined. The only other reason for operating he sees in hemorrhage from the meningeal artery, in pressure symptoms, or some localized lesions of the motor area, characterized by convulsions or headache. He relates two such cases, the first one a case of Jacksonian epilepsy, beginning 10 months after the injury; the second patient complained of headache and pain in right eye 10 days after the accident. This showed choked disc. In both cases the bullets were located with the Röntgen rays and removed. He uses Wagner's osteoplastic method in opening the skull. [E.L.]

**Adenoma of the Rectum.**—C. B. Ball<sup>3</sup> states that he cannot subscribe to the opinion held by a number of pathologists that adenocarcinoma begins essentially as such and never has a simple adenoma. Results of early surgical interference being so very much better than late interference frequently suggests at least that cases of adenocarcinoma frequently begin as pure adenoma and by a transition process instead the epithelial cells penetrate the basement membranes and the tumor thus becomes malignant, forming the adenocarcinoma. Adenoma in children is not infrequent and the close analogy between adenoma of intestinal mucosa and cutaneous warts is marked. There is a tendency in both for the surface to increase by tuberculation and fusion. Origin of an adenoma can often be traced to local irritation. The symptoms of simple adenomas of the rectum when of small size are trivial. If, however, the pedicle becomes sufficiently long to form a "polypus," the tumor becomes congested, surfaces abraded and hemorrhages is a common symptom. Rectal hemorrhage in young children should always arouse the suspicion of adenoma. Another important symptom is the copious discharge of glairy mucus. This is caused by a great increase of the secreting structure showing that the adenomatous tissue of the newgrowth remains functional. Adenomas may be of sufficient size to produce mechanical symptoms by pressure. Treatment consists in the removal of

<sup>2</sup> Münchener medizinische Wochenschrift, January 6, 1903.

<sup>3</sup> British Medical Journal, February 21, 1903.

the pedunculated forms after ligation of the pedicle. The sessile varieties are to be excised. The use of curet may be necessary in some cases. [A.B.C.]

**Spinal Analgesia.**—E. D. Martin<sup>1</sup> obtains the best results by using concentrated solutions of cocain. He believes that untoward after symptoms are due to disturbed tension of the spinal fluid, and, perhaps, to some extent by the position of the patient, gravity allowing the solution to reach the upper part of the cord when the head is low. When patients are strong enough to sit up he places them in the so-called scorchers' position. When the needle reaches the cavity of the cord not more than one or two drops of spinal fluid are allowed to escape. Five minims of a 2% solution of cocain is injected for operation about the rectum, or the same quantity of a 4% solution for operations upon the extremities. The patient is then put in a recumbent position with the head and shoulders elevated, this position being maintained for several hours after operation, or until all the effects of the cocain have worn off. Martin appends brief notes of 18 cases, practically all of which were free from after effects. Another operator has used the concentrated solution in 33 cases with very satisfactory results. [A.G.E.]

**Narcoses with Schleich's Mixture No. 1.**—To test the value of Schleich's narcosis mixture No. 1, consisting of ether, chloroform and ethyl chlorid, and for which Schleich claimed such excellent results, F. V. Winckel<sup>2</sup> made observations comparing such narcoses with others, in which the anesthetic used was either ether alone or ether and morphin. Using Schleich's mixture the narcosis is brought about quicker (1.2 to 3.2 minutes) than when using ether; the amount of the anesthetic needed until the beginning of the operation, as well as the total amount for the operation, is less when using Schleich's mixture; the temperature of the patient remains higher, and bronchitis does not follow as often; albuminuria does not occur any oftener. In 10% of the cases, however, the anesthetic had to be changed from Schleich's mixture to either chloroform or ether, because of dangerous symptoms arising, and in two of these cases death resulted. Winckel does not attribute these deaths to ethyl chlorid mixture, but prefers to emphasize that it did not prevent them. His terminal conclusions are that Schleich's mixture, although it narcotizes quicker, and less of it is required, has no advantage over ether, inasmuch as unpleasant and life-threatening symptoms occur even oftener in it than in ether. [E.L.]

**Internal Strangulation Through a Hole in the Mesentery.**—A. Anderson<sup>3</sup> reports the case. The patient was a boy of 14, who was seized with sudden pain in the abdomen, attended by vomiting. Pain became worse. Shock was threatened. There was no distention of the abdomen, no dulness on percussion, but there was pain on deep palpation in the right iliac fossa. After 24 hours there was marked tympanites. Increased muscular rigor and threatened shock. The provisional diagnosis was perforative appendicitis. Operation showed that a loop of the bowel had passed through a narrow opening in the mesentery and this was tightly constricted. The constriction was released, opening enlarged, the bowel reduced, and the mesentery opening, which was apparently a natural one, was closed. The patient passed into shock, which resisted all treatment. He died some hours after the operation. Necropsy showed the strangulated bowel, which was some three feet in length, was part of the ileum. [A.B.C.]

**An Operation for Incontinence of Feces Due to Relaxed or Paralyzed Sphincter Ani.**—Mayo Robson<sup>4</sup> describes an operation for the cure of the above condition. It is a modification of the operation for complete laceration of the perineum, the latter having suggested the technic in cases having no laceration, males as well as females. With the patient in the lithotomy position, a semilunar incision is made at the junction of the skin and mucous membrane around the anterior half of the anus. The upper and lower margins are then separated by being drawn apart with forceps attached at the mid-point of the incision, thus converting the semilunar slit into a lozenge-shaped cavity. This cavity is then closed by bringing

together the sides by buried catgut sutures, and the skin by silkwormingut sutures. This procedure not only diminishes the size of the anus, but restores the power of the sphincter muscle, acting in one or both of two ways: (1) By shortening the sphincter and thus enabling it to grip the anal orifice; (2) by bringing together the torn ends of the muscle. [A.G.E.]

**Chemistry of Chloroform Oxygen Narcosis.**—Falk<sup>1</sup> has studied the different contrivances used in combining chloroform and oxygen for the purpose of anesthetizing. Of the Roth-Dräger apparatus, in which oxygen passes through chloroform, he says that it is unsuitable for the purpose, as it does not consider the chemic and pharmaceutical properties of chloroform. In a narcosis lasting but 20 minutes the chloroform shows marked decomposition, and the higher the temperature of the room and the brighter the light the greater is this decomposition. This is also greater when the same chloroform is used the second time. [E.L.]

**Ruptured Urinary Bladder.**—Hugh Lawrie<sup>2</sup> reports the case. The patient was a woman of 29. While walking along a dark road she was knocked down by two men. Cries for help brought assistance and she was taken to a hospital. The principal symptom complained of was pain in the lower part of the abdomen and the discharge of bloody urine. This not abating she was operated on by median incision above the pubes. Bloody urine was found in the pelvis and the bladder was ruptured on the anterior wall. The hole, which admitted three fingers, was entirely extraperitoneal. The patient's condition being very grave, drainage was instituted and further operation postponed. Progress was fair for two weeks and a second operation was undertaken for the purpose of closing the wound in the bladder. This was accomplished. Progress was slow, but after seven weeks a third operation was done for the purpose of closing the abdominal wound. After the third operation there was a severe cystitis and threatened pyelitis, which yielded to very large doses of urotropin. This drug had been previously used but had been discontinued in the hope that it was not necessary, when the symptoms of cystitis soon appeared. The author states that this may have been a sequence, rather than a consequence, but the fact that the temperature fell rapidly and the symptoms of cystitis disappeared after copious administration of urotropin leads him to think it was probably a factor in abating the symptoms. His belief now is if the rent in the bladder had been closed at the first operation the result would have been a speedier convalescence. [A.B.C.]

**The Subcutaneous Injection of Paraffin as a Treatment for Sunken Nose.**—Stephen Paget<sup>3</sup> briefly states what he has learned from 29 of these cases, the youngest patient being 19, the oldest 52. The subject is considered under the following heads: 1. The melting point of the paraffin. Eckstein's paraffin, melting at 136°, was used in the first 12 cases, but has been discarded, Paget saying that it ought not to be used. He has some distrust of Gersuny's, which melts at 104°, and believes that paraffin for sunken noses should melt at a point between 105° and 115°. Two paraffins, one melting at 110°, the other at 115°, have given excellent results. 2. The best syringe. Eckstein's has given the most satisfaction. 3. The method of injection. This is given in detail and must be read in full. 4. General results. These were very good in the 29 cases, no disaster of any kind following the injection. Danger from absorption, sloughing, suppuration, or embolism is slight, if it exists at all. Cases reported are very hard to trace and can generally be attributed to faulty technic. [A.G.E.]

**Lung Surgery.**—Rochelt<sup>4</sup> reviews lung surgery from its infancy to the present day. He cites examples of wounds, tumors, echinococcus cysts, apical tuberculous infiltrations and tuberculous cavities, abscesses, gangrene, bronchiectases, foreign bodies, and actinomycosis. The Röntgen rays have not made the diagnosis of the various conditions, especially not of the cavities, much easier. He insists on the presence of adhesions to prevent pneumothorax before operation is done. Adhesions may be brought on artificially. He discusses the

details of the method employed. Where large tuberculous cavities come in question he thinks well of Quincke's procedure, who removed large parts of the bony chest wall to produce mobilization of the chest wall and collapse of the cavity. When cavities require opening he prefers the cautery to the knife. [E.L.]

**Cases Simulating Acute Appendicitis.**—A. E. Barker<sup>1</sup> asserts that the opinion is prevalent that appendicitis is comparatively easy of diagnosis. While this may be true in the vast majority of cases, the opinion has gained ground with those of wide experience that the diagnosis is often attended with difficulty. In the brief lecture he mentions and discusses a number of pathologic conditions which in his experience and observation have been mistaken for acute appendicitis. These are: Ruptured pyosalpinx, ovarian cyst strangulated by twisted pedicle, twist and strangulation of omentum, perforated gastric ulcer, retrocecal hernia, broken-down caseating glands, ileocecal cancer with abscess, hematoma of broad ligament, reduction of hernia *en masse*, intussusception. He describes a case of perforated gastric ulcer simulating appendicitis. The patient was a servant woman, apparently in previous perfect health, and she was suddenly seized with pain in the right iliac fossa, which later spread over the entire abdomen. The abdominal walls were rigid and tender. Temperature was 100°. The pulse remained fair and there was no shock. Operation at the usual site showed the appendix normal but from the opening a glairy fluid welled up from the pelvis and from the direction of the stomach came additional fluid and gas. Exploration found stomach all perforated. Median incision was made over the stomach, the perforation closed, the abdomen was thoroughly flushed with a saline solution, the wounds saturated, and the patient made a complete recovery. [A.B.C.]

**Acute Pancreatitis.**—The clinical, operative, and autopsy notes of a case of acute pancreatitis are furnished by W. Hogarth and B. G. A. Moynihan.<sup>2</sup> The patient was an obese man of 75, who was under observation for three weeks before he would consent to operation. Pancreatic disease was not suspected, the early diagnosis being perforated gastric ulcer and later that of abscess of the lesser peritoneal cavity following perforation. Operation revealed pus in the lesser peritoneum and a necrotic, sloughing pancreas. The patient died in twelve hours from shock. Autopsy showed that all the body and tail of the pancreas was necrotic, that portion of the head immediately surrounded by the duodenum alone being healthy. There was extensive fat-necrosis in the omentum and the surrounding fat. [A.G.E.]

**Ureteral Surgery.**—In a patient whose urine escaped through a fistula in the anterior abdominal wall, and who when examined with the cystoscope was found to have but one functioning kidney, J. Israel<sup>3</sup> made a diagnosis of single hydronephritic kidney. By closing the fistula a small amount of the urine could be forced through the ureter into the bladder, but the hydronephritic pelvis soon became so full and painful as to force removal of the plug. To make the patient comfortable Israel performed a suprapubic cystostomy, producing a vesical fistula. He next inserted rubber tubes into both fistulas, connecting them with each other by means of a silver tube. After a number of slight changes in the apparatus, the most important of which was the insertion of a ballvalve to prevent backflow of urine during micturition, the patient was discharged. He was made perfectly comfortable by the operation, his urine escaping by the normal passage. The apparatus did not prevent him from attending to any of his duties. In the second part of his paper he describes his method of uniting the ureter with the bladder by the extraperitoneal route, showing two patients who were thus cured of ureteral fistulas. Having tried other methods as well, he is convinced that his method permits the more rapid performance of the operation, and produces more satisfactory results than any other. [E.L.]

**Surgical Treatment of Sciatica.**—J. C. Renton<sup>4</sup> reports that in the *British Medical Journal* of November 5, 1895, he reported 8 cases of sciatica treated by exposure of the nerve

below the gluteus maximus, the separation of the inflammatory adhesions around the nerve and up to the sciatic notch. In the present article he reports 10 additional cases similarly treated, all with good results, except 1 case, which was not benefited by operation. The other 9 are well after periods varying from one to two years. These patients had almost all visited the various spas without benefit, and they all illustrated the symptoms produced by adhesions around the nerve; hence the operation. No stretching of the nerve was employed, as mere separation of the adhesions was sufficient to relieve the pain. The symptoms of perineuritis as distinguished from neuritis are distinctive and should be borne in mind. In perineuritis there is no pain when at rest, but on motion, especially on walking for a few minutes the pain becomes marked. Mild cases of adhesions improve with massage movements, electricity, etc. When, however, the pain is persistent, the sooner an operation is done the better. In some of the cases six or eight weeks elapsed before improvement took place, because the nerve had been dragged upon by the adhesions. The patient should be warned of this probable result. [A.B.C.]

**Primary Sarcoma of the Appendix.**—P. Peterson<sup>1</sup> reports this case, which he believes to be the second one recorded, the first being that reported by Glazebrook in 1895. The patient was a man of 39, who had a feeling of uneasiness in the right iliac region for three months. During this time there had been four painful exacerbations lasting several days each. Operation revealed an appendix bent almost to a right angle  $6\frac{1}{2}$  inches in length along the greater curvature and 4 inches in circumference at the thickest part. The cecum for a distance of  $\frac{1}{4}$  inch around the attachment of the appendix was also thickened. Microscopic examination showed the increased bulk of the appendix to be due to a round-cell sarcoma, involving all the coats but the peritoneal. The wall of the cecum showed but little infiltration, the neoplasm having evidently begun in the distal portion of the appendix. The patient died from the shock of operation and a careful postmortem revealed no trace of tumor formation elsewhere. [A.G.E.]

**Inflammation of the Pancreas with Hemorrhage and Necrosis.**—H. Hochhaus<sup>2</sup> adds three cases of pancreatic disease to those already reported. The symptom-complex as noted in these cases does not tend to make the diagnosis of such affections any easier. The onset in all three cases was sudden, and they were characterized by violent abdominal pain, vomiting, abdominal distention, constipation, and intense prostration; the pain throughout the entire course was localized to the region of the pancreas. There were no changes in the character of the stool; but the second patient presented a characteristic condition of the urine. Sugar, acetone, and diacetic acid, as well as other urinary signs, left no doubt regarding the diagnosis in this case; none presented leukocytosis. In two of the patients a mass could be felt in the region of the pancreas. Hochhaus therefore considers the pain as the most characteristic of the various symptoms, but it needs to be differentiated from the pain of biliary colic, intestinal obstruction, and circumscribed peritonitis. The great intensity of the pain, as well as the long duration, even into the period of convalescence, will serve to do that. The causes of pancreatic disease are chiefly inflammations of the biliary passages, the duodenum, and the stomach; many other factors, however, are found contributory agents to the disease. He does not advise operation in the early stages of the disease, as the patient is too much prostrated. If the patient lives beyond the first stage, and his condition becomes chronic, an operation will very often produce a complete cure. [E.L.]

**Intestinal Anastomosis: Special Forceps.**—T. Carwardine<sup>3</sup> describes the method of effective intestinal anastomosis by means of two forceps, each  $6\frac{1}{2}$  inches long, with slender blades  $\frac{3}{16}$  of an inch wide. These blades may be covered with rubber tubing if desired. Each forceps is made to grasp the bowel beyond the point at which it is to be severed. Then the two forceps are clamped together in parallelism and the severed ends of the gut sutured. The advantages of the instrument are the possibility of union in layers, the steady approximation of

<sup>3</sup> British Medical Journal, February 28, 1903.

the ends of the bowel for anastomosis, the use of only one hand for holding the ends, the absence of any internal diaphragm when union is complete, and the availability of the independent forceps for use as intestinal clamps. [A.B.C.]

**A Case of Extensive Resection of the Ductus Choledochus and Hepaticus for Carcinoma.**—H. Kehr<sup>1</sup> reports the clinical details of a case of carcinoma of the common bile duct; the gallbladder was distended by a clear serous fluid, and its mouth obstructed by a large stone. He removed the tumor, resecting the ductus choledochus for the purpose. Finding that the stumps of the two ducts could not be united, on account of too much retraction, he closed the common duct, and directly implanted the hepatic duct into the duodenum. The surgical details of the operation are described minutely. He discusses the literature of the subject, and gives many details regarding the differential diagnosis of obstruction of the bile ducts due to carcinoma and gallstones, which he considers very difficult. His case is the first in which such an extensive operation was performed, and inasmuch as the patient recovered he thinks that radical measures should be resorted to oftener in cases of carcinoma, if only for palliative measures and to prolong life. Without operation every case is lost, but with operation some patients may be cured, and most all are helped to some extent. [E.L.]

**Adrenalin as Hemostatic in Cases of Severe Hemorrhage.**—O. Lange<sup>2</sup> opened an abscess on the thumb of a man, whom he afterward found belonged to a family of bleeders. All sorts of styptics were applied without avail, and the hematoma gradually extended along the dorsum to the middle of the forearm. Pieces of gauze soaked in adrenalin solution were then packed into the wound, and the hemorrhage stopped at once. Similar results are reported in hemorrhages in two cases of perityphlitis, one serious case of epistaxis, one of hemoptysis, and one of hematemesis. In the last two cases the adrenalin was given internally in doses of 30 drops, with the best results. He suggests its use in uterine hemorrhage. The only point against it is its expense, but as only small quantities are necessary, this is not a very important point. [E.L.]

**Mechanism of Strangulation of the Intestine.**—It is generally believed that when the intestine is caught by an adhesion or passes through a ring, strangulation is produced by the peristaltic wave pushing the intestine in from above. This is not conceded by Wilms,<sup>3</sup> especially as it is usually the lower part of the small intestine, often as far as the cecum, which lies within the strangulation. He says a small piece of intestine is caught by the fibrous band; peristalsis pushes some feces into this; peristalsis continues and through it, as well as the weight of the incarcerated loop, the intestine is pulled backward into the strangulated area, until either this is too full to receive more, or the gut is too large to pass the constriction. [E.L.]

**Behavior of Leukocytes in Suppuration, Especially in Abscesses of the Liver.**—F. Perutz<sup>2</sup> calls attention to the fact that Bornet's paper concerning leukocytosis in the diagnosis of liver abscess preceded Curschman's publication fully a year. He claims some of the honors of leukocyte investigations for this name. It is frequently a positive sign in liver abscess, and sometimes is present to a considerable degree. [E.L.]

**Importance of Early Removal of Doubtful Tumors of the Breast.**—J. C. Renton<sup>4</sup> reports five cases which come under the category of doubtful tumors of the breast. Each case is detailed at some length. They all occurred between the ages of 30 and 43. The author states that they are reported in order to illustrate the importance of early operation in any patient over 30. When the patient complains of a small hard lump the doctor may well feel some hesitancy in operating unless she has passed her thirtieth year, after which time the sooner the tumor is removed the better it will be in the vast majority of cases. A small cyst may occur in a breast, which can be dealt with by dissecting it out for microscopic examination. If malignancy is shown removal of the breast is demanded at once. It is a serious matter to recommend delay

in operation once a hard swelling has appeared in the breast. The author states that the patients upon whom he operated early are still alive, while those operated on after the disease extended to the glands are nearly all dead. [A.B.C.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### REVIEW OF LITERATURE

**Recurrent Abortion.**—The classification of recurrent abortion as given by John W. Taylor<sup>1</sup> is more rigid and severe than is usually seen. He includes under the title of recurrent abortion only those cases in which from the beginning or from some definite epoch the patient has aborted with every (succeeding) pregnancy, and with one exception only has restricted it to cases of initial or primary recurrent abortion; that is, to patients who from the beginning of their married life until the date of coming under observation have never been able to bear a living child at term. The so-called "habit" in cases of syphilis, especially when the patient is under treatment, tends to alter with each succeeding pregnancy; recurrent abortion then is a better term than habitual abortion. Of the rare forms of recurrent abortion a few are due to intraperitoneal adhesions, chronic kidney disease with albuminuria, and a deep laceration of the cervix. When all these rarer cases of recurrent abortion are accounted for, and when syphilis can be rigidly excluded, there still remains a definite group of cases of very nearly equal importance to that belonging to syphilis. The distinguishing features which bind these cases together are indications of a low vitality on the part of the mother or father or both parents, a strumous family history, and what he calls the remarkable result of an essentially "antistrumous" treatment when carried on for a long period of time or throughout the whole of the pregnancy. Twelve of the latter type of cases are tabulated. In syphilitic cases each succeeding abortion, if the patient's general condition remains satisfactory, tends to occur at a later period until the pregnancy goes to term. At this stage dead children are usually born, but finally living children may be expected. In the "strumous" class, unless something is done to improve the general health, each abortion tends to further weaken the patient, each succeeding abortion tends to occur at an earlier period, and finally in some untreated cases the power of conception is lost. [F.C.H.]

**The Surgical Treatment of Procidentia Uteri.**—The etiology of procidentia is discussed by R. Peterson,<sup>2</sup> who gives the steps in the development of this condition, including pelvic laceration or overdistention, cystocele, rectocele, and prolapse of the uterus. The principal support of the organ is said to come from the various muscles and connective tissue making up the pelvic floor. The ideal aimed at in surgical treatment of the condition is seldom attained and the retention of the uterus in nearly its normal position with prevention of the vaginal prolapse is all that can be hoped for. Operation must carry and hold the cervix backward so that the fundus of the uterus will point forward instead of backward and it must restore the anterior vaginal and bladder walls to their normal position. Removal of the uterus alone is a perfectly useless procedure, as is the simple narrowing of the upper part of the vagina or the endeavor to hold the uterus upward by a shortening of its ligaments or by attachment to the abdominal wall. Peterson sometimes amputates the cervix when it is greatly everted, elongated and enlarged. He carries upward the anterior vaginal and bladder walls by two procedures which he briefly describes. A plastic operation on the posterior vaginal wall is then performed, followed by an extensive perineorrhaphy. Only occasionally is it found necessary to remove the uterus. [A.G.E.]

**Puerperal Hyperpyrexia of Malarial Origin.**—Percy B. Spurgin<sup>1</sup> reports the case of a primipara, aged 34, craniotomy being performed upon the dead fetus. On the evening of the second day she complained of intense headache and of dull aching in both limbs following intermittent fever. She had

<sup>2</sup> The Physician and Surgeon, January, 1903.

been a resident of India for some years prior to her marriage. A diagnosis was made of tertian ague, and was clearly borne out by the temperature chart. [F.C.H.]

**Bilateral Dermoid Cysts of the Ovaries Showing Cerebellar Tissue.**—These specimens were shown at the Milwaukee Medical Society by J. M. Bffel.<sup>1</sup> The specimens were removed from a maiden school teacher. They showed the ordinary dermoid structures—hair, sebaceous glands, sweat-glands, a tube lined by columnar ciliated epithelium, some bone and cartilage, no teeth. In addition to these there was considerable glial tissue, and in one cyst was an epithelial prominence, within which was found a mass of tissue looking like the brain; upon sectioning this it was found to be an irregular mass of tissue with the exact histologic structure of a normal cerebellum—the pia mater, the molecular layer, the cells of Purkinje, the granular layer, and the white substance. All of these structures are as perfect as the ordinary section of a cerebellum can be. The finding of the cerebellar tissue in this case clears up one disputed point, viz., the presence of "specific nerve tissue" in dermoids of the ovary, which has been denied. [A.G.E.]

**The Diagnosis of Pregnancy.**—W. S. A. Griffith<sup>2</sup> observes that if a woman has amenorrhea for a period of anything under nine months and that woman is of an age to bear a child, we are wise in assuming the woman is pregnant until we have proved she is not. In a very large number of cases one can tell by examining the breasts whether the woman is pregnant with almost absolute certainty. Of all the signs which are given there are only one or two which are infallible, and certainly the activity of the breasts is not an infallible sign, but it is of the highest value, and of such value that one can form an opinion of the highest importance when the condition is recognized. He considers the evidence of the fetal heart of secondary importance. The diagnosis of pregnancy may be made easily and with absolute certainty by feeling the fetus and its movements; and in the earlier months from the history of amenorrhea, the recognition of the marked activity of the breasts, and by finding the uterus enlarged and reaching to a definite height above the pubes, allowing 1½ inches for each completed month of pregnancy. [F.C.H.]

**Primary Abdominal Pregnancy.**—A. L. Galabin<sup>3</sup> states that until the report of Witthauer's case of primary abdominal pregnancy such a condition had not been demonstrated. He reports a case which he considers presents strong presumptive evidence that primary abdominal pregnancy occurred. The patient died from hemorrhage, and a thorough examination of the pelvic viscera was made. The gestation sac was placed between the uterus and rectum, occupying the whole of the pouch of Douglas. There was a fetus 5½ cm. (2¼ in.) long, apparently at the tenth week of gestation. Both tubes and ovaries and the mesosalpinx were normal, with the exception that the right ovary contained two small cysts. Neither tube showed signs of recent dilation. A specimen was examined by a committee of the Obstetrical Society, which reported that the pregnancy was probably a primary abdominal one. It was held possible that a tubal abortion had occurred at a very early stage of gestation and that the ovum had been transferred to the bottom of the pouch of Douglas. The author states that obviously such a possibility cannot be excluded from any apparent case of primary abdominal pregnancy fetation. Other evidence of primary abdominal pregnancy was that the fetal sac consisted externally, outside of the chorion, of a membrane the outer surface of which was smooth, somewhat polished, resembling peritoneum. There was no part of such sac, however, in the ovary, and a space of nearly 2 cm. (¾ inch) of normal broad ligament intervened between the ovary and the nearest part of the placental site. [A.B.C.]

**Eclampsia of Pregnancy, with Notes on the Use of Bossi's Dilator.**—T. Arthur Helme<sup>2</sup> sums up the etiology of eclampsia as follows: There are certain cases in which eclamptic seizures following certain premonitory signs are the result of some unknown conditions associated with the pregnant state. Before the advent of convulsions it is more or less generally

agreed that when the premonitory signs are advancing in importance and the state of the urine is becoming progressively worse, that is, the urea diminishing and the albumin (if present) increasing in spite of careful treatment, it is well to forestall the eclamptic state and put an end to the pregnancy. Should eclampsia occur he advocates emptying the uterus, but not by too heroic measures regardless of injury to the maternal soft parts to control the convulsions by chloroform or morphin, and to use all measures to excite the emunctories. He details the case of a 23 year old primipara, in whom he dilated the cervix in 20 minutes with Bossi's dilator, after which the seven months fetus was delivered in 10 minutes more. The instrument, if care is taken, may be used with confidence and safety. [F.C.H.]

**Case of Dystocia Due to Uterine Myoma: Cesarean Section.**—Gilbert Kempe<sup>1</sup> details a case in which a woman was pregnant about four months and a tumor which was thought to be a fibromyoma was so impacted in the pelvis that it could not be dislodged. When the pregnancy reached term a cesarean section was done and a living baby extracted. A large, hard fibromyoma was found on the posterior surface of the uterus and cervix, bulging into and quite incarcerated in the pelvis. This had formed the obstruction to delivery. [F.C.H.]

**A Kidney in the Umbilical Cord.**—This unusual case, with a unique method of treatment, is reported by G. M. Horton.<sup>2</sup> On March 5 a primipara was delivered of a male child weighing nine pounds. A tumor the size of a hen's egg was present in the umbilical cord just outside the abdominal cavity. The cord was ligated beyond this, and the infant laid aside until the mother had been given attention. The cord over the tumor, which was supposed to be a blood-clot, was then cut with a pair of scissors, the tumor itself, which proved to be a kidney, being wounded by this procedure. When the nature of the mass was discovered the wound in the kidney was closed by two catgut sutures, and an attempt made to replace the organ in the abdominal cavity. The umbilical opening being too small, it was dilated with artery forceps until the kidney was admitted. Six catgut sutures were then placed to close the ring. No anesthetic was used, the child seeming to suffer but little pain. No urine was passed for 48 hours, but since that time the child has been doing well. [A.G.E.]

**Pregnancy Complicated by Suppurating Hydatid Cyst of the Liver.**—Richard Jones<sup>1</sup> details a case illustrative of the dangers of such a complication in parous women, more especially when suppuration and rupture of the cyst is delayed to the first few days after parturition. A diagnosis was made of suppurating hydatid cyst of the liver bursting into the chest cavity; operation was performed through the chest in the usual manner. The patient, notwithstanding the unusual circumstances of her case, stood the operation well. The cyst, however, communicated with a large bile duct, so that the flow of bile was very profuse and continuous, and the patient speedily sank from exhaustion, expiring on the fourth day after the operation. An autopsy was not obtained. [F.C.H.]

## TREATMENT

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPELMAN

## EDITORIAL COMMENT

**The Substitutes for Quinin.**—*Euquinin.*—Euquinin, the carbonic ethylester of quinin, is a white powder almost insoluble in water, but easily dissolved in alcohol and ether. When first placed in the mouth it is tasteless, but in a few minutes causes a slightly bitter taste. The following advantages are alleged for this drug: that it is tasteless, does not cause tinnitus aurium, is less prone than quinin to disturb digestion, and less irritant to the kidneys. Although there seems to be sufficient evidence that these statements have a foundation of truth, it must be confessed that some of them are more or less exaggerated. Thus, while it is far less dis-

<sup>1</sup> Wisconsin Medical Journal, April, 1903.

<sup>3</sup> British Medical Journal, March 21, 1903.

<sup>1</sup> British Medical Journal, April 11, 1903.

<sup>2</sup> Northwest Medicine, April, 1903.

agreeable than the alkaloid, equinin certainly has some bitter taste; again, while all authorities seem agreed that cinchonism is less common than with quinin, we have ourselves observed marked ringing in the ears after its use. Oberlach<sup>1</sup> and Thompson<sup>2</sup> have found it well borne by patients who cannot take quinin itself. Von Noorden<sup>3</sup> has given as high as 2 grams (30 grains) daily without any unpleasant secondary symptoms. Mori<sup>4</sup> says that the cinchonism caused by equinin will disappear in a few days, even if the use of the drug be continued. Concerning the efficacy of the drug there is no room for doubt but that it fully represents the therapeutic activities of quinin. Von Noorden<sup>5</sup> and Gray<sup>6</sup> have found it useful as an antipyretic, and Mori, Francesco,<sup>6</sup> and a host of others confirm its value in malaria. Equinin was originally recommended as a specific in whoopingcough, and its utility in this condition is vouched for by Casse<sup>7</sup> and Von Noorden. Among the other conditions in which it has been found of service may be mentioned influenza, neuralgia, rheumatic and other fevers.

Equinin may be given in capsules in doses for adults of .32 gram to 2 grams (5 to 30 grains) several times a day. Blackwood<sup>8</sup> recommends the following as a tonic in anemia with neuralgia:

Equinin . . . . .	1 dram	( 4 grams)
Iron lactate . . . . .	2 drams	( 8 grams)
Solution of arsenious acid . . . . .	.90 minims	( 6 cc.)
Compound tincture of lavender . . . . .	4 fluidrams	( 15 cc.)
Elixir of curaçoa, sufficient to make	4 fluidounces	( 120 cc.)

Mix. Dose, one teaspoonful four times daily.

**Saloquinin.**—The salicylic ester of quinin has been on the market only two years, but has already achieved for itself an important place among practical remedies. It is quite insoluble in water and therefore tasteless. For the same reason it is absorbed very slowly. According to Oberlach<sup>9</sup> saloquinin causes neither tinnitus aurium, gastric disturbances, nor irritation of the urinary tract. Fitch<sup>10</sup> believes it superior to quinin as an antiperiodic, and of especial value in malarial hematuria. Tauszk<sup>11</sup> has obtained good results in various neuralgias, and Oberlach recommends it as an antipyretic. The dose of saloquinin should be about half again that of quinin in a corresponding case. In a case of malarial hematuria Fitch gave 2.6 grams (40 grains), followed in four hours by 1.6 grams (25 grains) more. The ordinary dose is from .65 gram (10 grains) upward.

**Aristochin.**—Diquinin carbonate occurs as a white, almost tasteless powder, freely soluble in dilute hydrochloric acid. It does not dissolve in plain water. Aristochin represents 96% of quinin, and according to Von Noorden<sup>12</sup> is equivalent qualitatively and quantitatively to quinin hydrochlorate. Stursburg<sup>13</sup> has administered aristochin to children as a substitute for the natural alkaloid, mostly with pleasing results, although in one case its use in a baby of six months was followed by convulsions. He gives for a one-year-old child 0.005 gram to 0.01 gram ( $\frac{1}{2}$  grain to  $\frac{1}{4}$  grain).

**Chinaphenin.**—The combination of quinin and phenetid, known as a chinaphenin, is a tasteless powder, sparingly soluble in water but freely so in alcohol and ether. As might be expected it represents to an extent the powers of both constituents. Von Noorden<sup>14</sup> places its antipyretic action as midway between phenacetin and quinin. The same author has found it useful in whoopingcough in doses of .19 gram or .26 gram (3

grains or 4 grains), and also in neuralgia. In malaria it seems distinctly inferior to quinin. The dose for an adult is 1 gram to 2 grams (15 grains to 30 grains).

#### REVIEW OF LITERATURE.

**Treatment of Migraine.**—According to Karplus<sup>1</sup> it is necessary to make a sharp diagnosis between true migraine and migrain-like attacks of headache, this latter being a symptom of various diseases. To an incorrect diagnosis must be attributed those cases of "migraine" cured by correction of an eye lesion, regulation of the diet, etc. The true migraine should be diagnosed by the localization of the pain, the tendency to periodicity and systemic disturbances (vomiting, lassitude, etc.), and by the fact that pressure on the supraorbital nerve increases the pain. The disease is nearly always hereditary and is closely allied to other nervous disturbances, especially to epilepsy, although the occurrence of epilepsy and migraine in the same individual is exceedingly rare. Its relation to epilepsy is shown in the tendency toward periodicity of attacks and in the frequent occurrence of aura. The most common form of aura is visual and consists in various forms of scotoma. In the treatment of migraine a vegetable diet will indirectly benefit the patient by improving the general condition. Alcohol should be especially avoided. It is also important to avoid so far as possible any determining cause of the attack, such as illy ventilated rooms, overstimulation of the nervous system, excitement or overwork, and exposure to too bright light. The best preventive is a course of bromids. These should be given in doses of 3 grams (45 grains) daily for a long period of time. In cases in which the bromid treatment cannot be employed continuously if there is an aura it may be used immediately before, to prevent the oncoming of an attack. The coaltar antipyretics are recommended, such as phenacetin, pyramidon, etc. The use of drugs to control the circulation in the brain is entirely experimental, because we know but little concerning the brain circulation. Adrenalin, diuretin, or cocaine may be tried. Such treatment should be interrupted during the course of an attack. [H.C.W.]

**Effect of Lowered Oxygen Tension in Producing the Hypercythemia of Altitude.**—It cannot be said that the final explanation of the permanent hypercythemia observed at high altitudes has been reached; future investigations will no doubt modify some of its details, but for the present the theory of a true increase in the number of the erythrocytes seems the most tenable. The principal factor in the production of this change is the diminution of the barometric pressure. This is well shown by the following experiment of Regnard: A guineapig was confined for a month in a bell-jar in which a constant low pressure was maintained. To guard against any possible danger from intoxication through the animal's excretions it was transferred every day to another apparatus in which exactly the same conditions prevailed. The guineapig did not enjoy the benefit of bracing and stimulating mountain air; its appetite was rather below than above normal; it was simply subjected to a pressure approximately equivalent to the barometric pressure prevailing at the Col du St. Bernard, or at Santa Fé de Bogota, altitude 2,000 meters (6,560 feet). At the end of the month the animal's blood was found to absorb 21% (by volume) of oxygen, which very nearly represents the coefficient of absorption of the blood of llamas living near La Paz; whereas guineapigs enjoying their full liberty and placed under much better hygienic surroundings showed an absorbing power of only 14 to 17 volumes percent. Sellier, of Bordeaux, went even further, and conclusively proved that the absolute degree of pressure is without influence on the result, the important factor being the diminution in the tension of the oxygen. Three different experiments were made on birds. In the first, the birds were confined for a number of days in rarefied air; in the second, they were placed in an artificial atmosphere having an entire pressure of 76 centimeters of mercury (normal barometric pressure), but in which the oxygen tension was reduced to equal that prevailing at the Pic du Midi; in the third experiment the tension of the oxygen was normal, but the tension of the inert gas was diminished, so that the

<sup>10</sup> Internat. Medical Mag., Vol. xi, No. 4.

<sup>11</sup> Klin. therap. Woch., 1902, No. 1.

<sup>12</sup> Merck's Archives, 1903, p. 102.

<sup>13</sup> Therap. Monatsh., 1903, xvii, p. 96.

<sup>14</sup> Therap. d. Gegenwart, Vol. v, No. 1.

<sup>1</sup> Klin.-therapeutische Wochenschrift, 1903, x, 142.

total pressure was less than 76 centimeters of mercury. It was found that in the first and second experiments hypercythemia was produced, while in the third experiment this hemic reaction failed to appear. Conversely, an increase in the oxygen tension is followed by the disappearance of a certain proportion of red blood cells which have become useless for purposes of respiration. This was to have been expected *a priori*, and further experimental proof has been furnished by Doyon and Maurel, who observed a distinct diminution in the number of erythrocytes in animals subjected to the continuous action of condensed air.—Tissier, in *Cohen's System of Physiologic Therapeutics*, Vol. x.

**The Effects of Yohinbin.**—Seitz<sup>1</sup> in reporting three cases of impotence apparently cured by yohinbin gives an interesting account of its effect on a healthy man. The drug produced after one week's course no increase in the sexual desire, but apparently a more than normally strong erection. The time to ejaculation was prolonged and the coitus was followed by a peculiar headache at the base of the brain, which disappeared after some time. The amount taken was 6 milligrams ( $\frac{1}{10}$  grain) four times a day. [H.C.W.]

**Pyramidon in Typhoid Fever.**—L. Byk<sup>2</sup> treated a case of typhoid fever mainly with pyramidon in doses of  $4\frac{1}{2}$  grains (0.3 gram) twice during the night. It served to keep the temperature in check, prevented delirium, produced free perspiration, and did not depress the pulse. At no time were symptoms of collapse noted. He feels justified in recommending its use, especially in cases in which, as in his patient, the Brand method cannot be carried out satisfactorily. [E.L.]

**The Treatment of Tetanus by Injections of Brain Emulsion.**—Krokiewicz<sup>3</sup> reports four cases of traumatic tetanus treated by the injection of an emulsion made from rabbit's brain with one death. Two of the cases were of a severe type. So far 16 cases have been reported of tetanus treated with cerebral emulsion with only 3 deaths. The technic of the method is not given, although it is stated that a rabbit's whole brain may be given every alternate day or in bad cases every day. The beneficial effect is notable almost immediately after injection. [H.C.W.]

**Increase of Erythrocytes and Hemoglobin at Various Altitudes.**—Cazeaux<sup>4</sup> gives the following figures for the number of red cells at altitudes ranging between 450 and 1,800 meters—approximately 1,500 to 5,000 feet:

On the plain . . . . .	5,000,000
At 450 meters . . . . .	5,800,000
"   700 " . . . . .	5,900,000
"   950 " . . . . .	6,100,000
"  1,800 " . . . . .	7,100,000

In the case of tuberculous subjects—and it may be observed in passing that the beneficial influence of high altitudes manifests itself also in the case of anemic, alcoholic, and neurasthenic patients—the degree of hypercythemia is usually constant, while the increase in the hemoglobin does not follow a parallel course. Meisser and Schröder observed that the hemoglobin continues to increase in phthisical patients who are improving or recovering; it remains stationary or diminishes when the disease is tending toward a fatal termination; and when the progress toward recovery is arrested in subjects who had been improving, the percentage of hemoglobin rapidly falls in almost exact accord with the progress of the disease. The power of adaptation to different altitudes, within certain limits, is a general biologic law. Gaston Bonnier, in 1890, studied the phenomena of such adaptation in plants, and demonstrated the modifications that they undergo in the process. The parts under the ground accumulate an increased supply of nourishment; the stems become shorter, the leaves more abundant, greener, and richer in coloring-matter. The latter phenomenon, the increase in the chlorophyll in the external portions of the plant, on account of its analogy with the changes that occur in the hemoglobin, is the principal point to be remembered.

**An Inoperable Sarcoma Treated with Röntgen Rays.**

<sup>1</sup> Die med. Woche., December 1, 1902, p. 502.

<sup>2</sup> Deutsche medicinische Wochenschrift, January 15, 1903.

<sup>4</sup> Cited by Tissier in *Cohen's System of Physiologic Therapeutics*, Vol. x.

—Schüller<sup>1</sup> having had referred to him a recurrent sarcoma of the occiput of such extent that operation was impossible, made a trial of the Röntgen ray. The tumor covered a space the size of a hand; the posterior cervical and supraclavicular lymph glands were involved on both sides. In all 23 exposures to the rays were made, lasting from 15 to 50 minutes. The first dozen applications produced marked diminution in the size of the tumor, but further radiations were without much effect, and the patient finally died. Although the termination was unfavorable, Schüller believes the results demonstrate that the rays have an effect upon the growth. [H.C.W.]

**Salient Points in the Treatment of Catarrhal Deafness.**—S. F. Snow<sup>2</sup> considers that the most effective way of handling chronic cases of catarrhal deafness is by jets of stimulative vapor, made by passing air under pressure over a supersaturated solution of gum camphor in tincture of iodine, through the eustachian tube to the middle ear, but no good can come from such treatment if the tube is occluded by congestive membranes. No treatment for the relief of chronic catarrhal conditions will be effective if given while the body is covered by an inactive sensitive skin, causing these congestions. [F.C.H.]

**A New Treatment of Unresolved Pneumonia.**—Schüller<sup>3</sup> reports an interesting case of what was diagnosed as abscess of the lung, apparently cured by a novel mode of treatment. The history of the case was as follows: Following an attack of influenza the patient developed a right-sided pneumonia, which did not resolve. Aspiration drew off a large quantity of fetid pus. Two days later the seventh rib was resected; the lung was found firmly hepatized, but no sign of abscess cavity was revealed. After two months, the signs of consolidation having remained unaltered, a second operation was performed, and the same condition as at the first operation found. Knowing nothing better to do Schüller injected 120 cc. of a sterile physiologic salt solution into different parts of the consolidated lung. In a few days the expectoration became more profuse, the dulness less intense and vesicular murmur audible. After some time the patient made a complete recovery. The explanation given by Schüller is that the salt solution rendered the exudate more fluid allowing some of the alveoli to empty themselves, so that air could again enter the consolidated area. The movement of the air cells caused a reestablishment of the circulation which led to the removal of the remaining exudate. [H.C.W.]

**FORMULAS, ORIGINAL AND SELECTED.**

**Acute Articular Rheumatism.**—

- Salicylic acid . . . . . 2 drams ( 8.0 grams)
- Menthol . . . . . 50 grains ( 3.0 grams)
- Ichthyol . . . . . 2 drams ( 8.0 grams)
- Woolfat . . . . . 2 ounces (60.0 grams)

Apply and cover parts lightly with cotton-wool and renew night and morning.

**Muscular Rheumatism.**—

- Methyl salicylate . . . . . 3 drams (12.0 grams)
- Menthol . . . . . 20 grains ( 1.3 grams)
- Chloroform and aconite liniment (N. F.) . . . . . 3 ounces (90.0 cc.)

Rub in well every two or three hours.

**Chronic Rheumatism.**—

- Sodium iodid . . . . . 2 drams ( 8.0 grams)
- Wine of colchicum root . . . . . 4 drams (15.0 cc.)
- Sodium salicylate . . . . . 3 drams (12.0 grams)
- Ammoniated tincture of guaiacum . . . . . 2 ounces (60.0 cc.)
- Compound syrup of sarsaparilla sufficient to make . . . . . 6 fluidounces (180 cc.)

Dessertspoonful three times daily.

—Merck's Archives.

- Thiocol . . . . . 30 grains ( 2 grams)
- Sodium benzoate . . . . . 30 grains ( 2 grams)
- Tincture of aconite . . . . . 20 drops
- Syrup of poppy . . . . . 10 drams ( 37 cc.)
- Cherry-laurel water . . . . . 24 drams ( 9 cc.)
- Syrup of senega sufficient to make . . . . . 5 ounces (150 cc.)

Tablespoonful three times daily.

**Changes in the Medical Corps of the U. S. Army for the week ended May 2, 1903:**

MCCULLOUGH, Captain CHAMPEL C., JR., assistant surgeon, is detailed to accompany the party scheduled to leave Manila in the near future to make an exploration of the Mariveles Reservation, with a view to selecting a site above the 2,500-foot level for a hospital and recuperation post.

SMITH, CHARLES F., contract surgeon, is granted leave for one month from about May 1.

MONCRIEF, First Lieutenant WILLIAM H., assistant surgeon, leave granted April 9 is extended ten days.

ASHBURN, First Lieutenant PERCY M., assistant surgeon, is relieved from further duty at Fort Assiniboine and will proceed to Fort Missoula for duty.

GIRARD, Colonel JOSEPH B., assistant surgeon-general, chief surgeon department of the Missouri, will proceed to the following-named posts, in the order named, on business pertaining to the inspection of the medical and hospital departments at those posts: Fort Leavenworth, Fort Riley, Fort Reno, Fort Sill, Fort Logan H. Root, Jefferson Barracks, Fort Crook, Fort M'obrara, Fort Robinson.

MAUS, Lieutenant-Colonel LOUIS M., deputy surgeon-general, leave granted March 20 is extended one month.

ADAIR, GEORGE F., contract surgeon, is relieved from temporary duty at Fort Morgan and will proceed to Fort Wadsworth for duty.

JERAULD, F. N. C., contract surgeon, is granted leave for two months.

SMITH, CHARLES F., contract surgeon, is relieved from further duty at Fort Sheridan and will proceed to Fort Leavenworth for duty.

FRICK, Major EUCLID B., surgeon, is granted leave for ten days.

MORRIS, First Lieutenant SAMUEL J., assistant surgeon, is assigned to duty at Fort Grant.

PURNELL, First Lieutenant HARRY S., assistant surgeon, is assigned to duty at Fort Wingate.

FANNING, GEORGE J., contract surgeon, is granted leave for one month from about May 5, with permission to apply for an extension of one month.

SILER, J. F., contract surgeon, is granted leave for twenty days from about May 20.

HEPBURN, JAMES H., contract surgeon, leave granted on surgeon's certificate April 3 is extended one month on surgeon's certificate.

MCCALLUM, FRANCIS M., contract surgeon, is granted leave for two months without pay, to take effect upon the expiration of his present leave.

CARPENTER, ALDEN, contract dental surgeon, is assigned to duty at Vancouver Barracks.

BARTLETT, First Lieutenant COSAM J., assistant surgeon, having reported en route to join his station from leave, will proceed to Seattle, Wash., and await the arrival of Company I, Thirteenth Infantry, and accompany that organization en route to its station, Fort Lisicum, Alaska.

**Changes in the Medical Corps of the U. S. Navy for the week ended May 2, 1903:**

WALTON, T. C., medical director, retired, ordered to duty as senior member of a board of officers at the Naval Academy.

SMITH, G. T., surgeon, ordered to duty as a member of a board of officers at the Naval Academy.

STONE, M. V., assistant surgeon, granted sick leave for three months.

BAKER, M. W., assistant surgeon, ordered to duty as member and recorder of a board of officers at the Naval Academy.

WILLIAMS, R. B., assistant surgeon, detached from the Decatur and ordered to the Chauncey.

HOLLOWAY, J. H., assistant surgeon, detached from the Franklin and ordered home to wait orders.

GROW, E. J., passed assistant surgeon, when discharged from treatment at the Naval Hospital, Mare Island, Cal., ordered to duty at that hospital.

SMITH, C. G., assistant surgeon, detached from the Marietta and ordered to the Newport.

**Changes in the Public Health and Marine-Hospital Service for the week ended April 30, 1903:**

PETTUS, W. J., assistant surgeon-general, granted leave of absence for seven days from April 26—April 28, 1903.

BAILHACHE, PRESTON H., surgeon, granted five days' leave of absence from April 29, 1903, under provisions of paragraph 189 of the regulations.

IRWIN, FAIRFAX, surgeon, granted leave of absence for seven days from April 28—April 27, 1903.

PECKHAM, C. T., surgeon, granted leave of absence for five days from April 1, 1903, on account of sickness, under provisions of paragraph 191 of the regulations.

PARKER, H. B., passed assistant surgeon, relieved from duty in the Hygienic Laboratory, and directed to proceed to Vera Cruz, Mexico, for special temporary duty as chairman of working party of Yellow Fever Institute—April 27, 1903.

FRANCIS, EDWARD, assistant surgeon, relieved from duty in the Hygienic Laboratory, and directed to report to Passed Assistant Surgeon H. B. Parker and proceed to Jalapa, Mexico, for special temporary duty as member of working party of Yellow Fever Institute—April 27, 1903.

BARNESBY, P. N., acting assistant surgeon, granted leave of absence for two days from April 13, 1903, on account of sickness, under provisions of paragraph 191 of the regulations.

MCCONNELL, A. P., acting assistant surgeon, leave of absence for three days from April 20, 1903, granted by Bureau letter of April 16, 1903, revoked—April 28, 1903.

O'REILLY, W. J., acting assistant surgeon, granted leave of absence for twenty days from April 4—April 24, 1903.

STEARNS, H. H., acting assistant surgeon, granted leave of absence for seven days from April 15, 1903, on account of sickness, under provisions of paragraph 191 of the regulations.

WATTERS, M. H., pharmacist, granted leave of absence for eight days from May 4—April 28, 1903.

## **Ethics and the American Medical Association.**

—The report of the Committee on Ethics at the recent meeting of the House of Delegates was substantially "progress." In place of it Dr. C. A. L. Reed, that veteran reformer, moved a substitute. The chairman of the original committee seconded the motion for its consideration, and after due debate by a special committee, embracing a representative from each State, Dr. Reed's substitute was adopted with but few modifications. Let us say at once that with relatively unimportant exceptions (barring one most important omission), additions and modifications, we are decidedly in favor of what will perhaps be called this new "code," although such a name is inapplicable to it. The House of Delegates acted with splendid wisdom in adopting the main body of the substitute, and combining with it certain essential features of the report by the original committee. The report as adopted appears elsewhere in our columns. It clears the way for unity and organization of the profession in the United States, which may now march on in the new spirit of progress and practical reform to which it is predestined. The preamble of the report simply states the axiomatic truth that neither medical nor general ethics are fixed and unalterable, but are progressive and evolutionary, and that local conditions must, as a rule, govern the specific ethical statements and rules of government of medical men. As "a suggestive and advisory document," not by any means final or non-modifiable, the "Principles" should be heartily accepted by all physicians. It is democratic and in harmony with the principles upon which our general government is founded.

The relations of physicians to society are in a general way outlined in Chapters I and II. The most noteworthy statements urge the teaching of applied ethics, as related to the medical profession, as a feature of the medical curriculum, and the recognition that "physical energy, intellectual force, and moral excellence" are the necessary elements of individual character, and tend to advance ethical conduct in general. There should have been an emphasis at this place of the special medical truth that scientific research, pure truth, that love which motives original investigation and allies our calling with general science and evolution, is as conspicuous an element of character and progress as

those named. This phase comes out indirectly in the obligation of physicians to enlighten the public as to right living, to secure the enactment of laws relating to the public health, assisting in their administration, etc., and especially of promoting a better statutory regulation of the practice of medicine. We are sorry for the omission of this great truth.

The organization of the local profession is dealt with in Chapter III of the report. The basic principle of local government is accepted in full, and here, at least by implication, the finger is struck upon the ailing point of our ethical disease in the statement that the local society should consider as eligible to membership "any physician recognized as such by law and possessing a good personal and professional character, whatever may be his individual views on any question connected with the science of medicine." To that position the matter must finally be brought. The sooner the better. There is absolutely no other capable of being put in words which will bear the attack of just criticism. All "regular" physicians differ from each other as to a multitude of details regarding the science and art of medicine, and there is no logical ground for not applying for membership by sectarians because one may privately believe in certain special doctrines of "allopathy," homeopathy, eclecticism, or of any other method of cure. But this principle, admitted by us, also carries with it the obligation to accept such legal practitioners as members of our societies if they have no other disqualifications, and if they accept, as we ourselves accept, the patent corollary, that such private views as to opinions, treatment, etc., do not warrant the formation of any special "school" or title, and if there is no trading upon such distinctive specialism. For the rest the local society must form a corporate part of the State and national organizations.

**Concerning Consultations.**—The recommendations of the report on this subject are really most excellent. The only point upon which we should differ a little from it is where it says that, when asked for by the patient, the attending physician should always consent to a consultation, but "he himself ought not to ask for it except when in his judgment it is distinctly demanded for the welfare of the patient." Now we think that in all cases of doubt, and in many where no doubt may

exist, the welfare of the patient is conserved by consultations, especially if they are carried out with the tact and fine courtesy so perfectly advised in the body of the report. Particularly is this true, as so often happens nowadays, in the case of specialists. Concerning this aspect of consultations the "code" is, we think, unwisely silent. Physicians, however "general," are all more or less specialists, and every disease has a peculiar relation to certain organs of the senses, etc., or there is usually some one physician or surgeon known to the attendant who has an exceptional experience in a certain disease, or is peculiarly fitted to advise in its treatment. As to the scandal of bribe-taking and bribe-giving, or dividing fees, the report is not too severe—no words could be so—when it says that any person convicted of this corrupt practice should be denied all recognition and fellowship in the medical profession. They should be squarely turned out of our medical organizations.

As to the auxiliary professions, the "code" has capital recommendations. For the first time such a document recognizes the duties to nurses and the nursing profession, and especially that we should promote their societies and organizations. At last a needed word is said against working and training the girls to death. The prescribing for the sick by pharmacists is an old abuse which is properly discountenanced, and which will not be remedied except by thoroughgoing action of the united local profession. Selling secret nostrums is in reality prescribing, and should have been stigmatized as sharply as sophistication or substitution. The most criticisable sin of commission or of omission on the part of the document is the failure to say a word about the prescribing optician, the quack oculist who is "prescribing for the sick" without being a qualified physician. Far more harm is being done to the profession and to the world by this shameless quackery than by all the abuses of all the auxiliary professions combined, to which so much space is rightly devoted by the report. It is quite the fashion, and a most reprehensible one it is, to ignore and belittle this and smile at the "exaggerator;" it is a pity that this code substitute, however unintentionally, should have joined in this "conspiracy of silence." The matter will not down, either in this or any other way.

The causes of the recent epidemic of typhoid in Chicago, as investigated by residents of Hull House, is a grand piece of work and illustrates the practical cooperation of science and benevolence in a way that deserves all praise. The pamphlet is filled with tables, diagrams, and reports, which show that the house-to-house investigation by Misses Gernon and Howe, and by Dr. Alice Hamilton, was thoroughgoing. This is the kind of a "union of medicine and morals" which promises and prophesies great things for the future. The demonstration is perfect that the distribution of the disease-germs was largely through the agency of flies. The wind could not have been the means of scattering the germ-laden dust because of the constant rains before the time of the greatest virulence of the outbreak. The actual catching of the flies "on the spot" and their

bacteriologic investigation brought out the proof with convincing clearness.

**Records of Cases Should be Made and Preserved by Physicians.**—A physician recently tried to investigate the life and disease of a patient who for 50 years had consulted the best physicians of this country and of Europe in the hope of getting some light upon and relief from a very mysterious and severe malady. The man had been dead only a few years, and the investigation of his case had in many ways a great professional and social significance. It was highly important that every scrap of evidence should be gathered concerning his symptoms. An exhaustive search ended in the disheartening conclusion that many of the physicians and specialists consulted had not made or kept any records of the case. A number of these physicians are now living, and the sole memorandum among their books was a minute of the fees paid by the famous patient to the famous doctor. In one case the fee record was not to be found, although the mere fact of the date of the visit would have been of great importance. Scientifically and historically the fact of the fee-paying was not of the value that would have been the facts of symptomatology. Nor is it less important that case-records should be kept of the unimportant and common cases that pass under the care of the busiest practitioner. A case the details of which are not worth recording is not worth treating. Can any mind remember these particulars at subsequent visits? And when written to by other physicians under whom the patient has come for such facts, what can the earlier consultant answer? Especially if he is dead? Moreover the habit should be formed of willing to the public medical library the record-books, of course under conditions as to their use, etc., by subsequent generations. Clinical biographies will in the future play an important role in medical science, because biographic clinics will henceforth prove an important means of scientific progress.

**Child Labor, Illiteracy, etc., in the Different States.**—From the columns of our most estimable contemporary, *Charities*, we extract the following tables:

#### CHILD LABOR.

##### GROUP I.—Age Limit for Employment, 14 Years.

(A child may not be employed under the age of 14 years.)

1. *In Factories, Stores, etc.*—Connecticut, Illinois,\* Indiana,\* Massachusetts, Michigan, Minnesota,\* New Hampshire (during school hours), New York, Ohio (15 years in mines), Oregon, Texas, Virginia, Wisconsin.\*
2. *In Factories, etc.*—Colorado (except coal mines),\* Kentucky,\* Louisiana (applicable to girls), Maryland (canning industries excepted), Missouri, New Jersey, Tennessee.\*
3. *In Mines Only.*—Arkansas, Idaho, Montana, Pennsylvania, South Dakota, Utah, Washington, Wyoming.

##### GROUP II.—Age Limit for Employment, 13 Years.

*In Stores, Factories, etc.*—Pennsylvania, Rhode Island.

##### GROUP III.—Age Limit for Employment, 12 Years.

1. *In Stores, Factories, etc.*—Arkansas, California, Maine, New Hampshire.
2. *In Factories, etc.*—Louisiana (applicable to boys), North Carolina, North Dakota,† West Virginia.†
3. *Mines Only.*—Colorado (coal mines), Iowa, Kansas (coal mines), Missouri.

\* Children under 14 forbidden to work in mines.  
† Children under 14 forbidden to work in mines.

GROUP IV.—Age Limit for Employment, 10 Years.

1. *In Factories.*—Alabama, South Carolina, Vermont.
2. *In Mines.*—Alabama.

GROUP V.—Miscellaneous Age Limitations.

- Alaska.—Under 21 may not be employed in bar-rooms.  
 Florida.—Under 15 may not be employed more than 60 days without consent of legal guardian.  
 Mississippi.—Under 21 (boys), under 18 (girls); similar to Florida.  
 North Carolina.—Under 21; similar to Florida.

GROUP VI.—No Age Limit or Other Restrictions.

- Arizona, Delaware, District of Columbia, Georgia, Nevada, New Mexico, Oklahoma.

Connecticut and Massachusetts, having long set the standard of legislation for the protection and education of the working children, toward which the rest of the manufacturing States have been slowly moving, seem to have reached a limit beyond which they cannot move forward until the Middle and Southern States approach more nearly to the point reached by these enlightened pioneers.

The following table shows that a high percent of employment is concurrent with an increased percent of illiteracy and a lessened school enrolment :

States ranked according to percentage employed.	Percentage employed among applicants for insurance 10-15 years of age.	Percentage illiterate among general population 10-14 years of age, 1900.	Percentage enrolled in public schools among total population 5-18 years of age, 1900-1901.
Alabama .....	41.86	28.59	61.67
Georgia .....	27.02	22.79	65.37
Virginia .....	17.30	15.67	61.41
Rhode Island.....	14.23	1.88	66.54
Nebraska.....	13.75	0.34	87.30

“The Medical Annals of Maryland,” 1799-1899, prepared for the centennial of the Medical and Chirurgical Faculty by Eugene Fauntleroy Cordell, M.D., is a noble historical work. The study of medical history, which is at last interesting the profession more and more, is worthy of congratulation and encouragement. We see where we are and better realize what we still have to do by knowing our past and of the high-hearted struggle by our professional ancestors to rise above the dismal surroundings of early times, the “swarms of quacks,” and even their own internecine wrangles and jealousies. We are still building the temple of medical wisdom, the rough foundation stones for which they hewed with such labor and zeal. We are yet too far from “organized,” as they planned we should some time be. The charter issued to the 101 incorporators of the

Medical and Chirurgical Faculty in June, 1799, was the real beginning of medical civilization in Maryland, and through the power it conferred, especially upon its board of examiners to issue licenses, there was a beginning of the end of quackery, of newspaper advertising, and of washing the professional dirty linen before the public eye. Those who carried on this “insult to common decency, subversive of good morals,” were summarily expelled, their offenses not as now condoned, and every influence was encouraged until now the professional standards of no State are higher and purer. All Marylanders may be justly proud of their Medical and Chirurgical Faculty.

The attention of the antivivisectionists is called to the recently-arrived fad of some of their vivisection friends who are making dogs fashionably beautiful by means of surgical operations. Regular establishments, it appears, or hospitals, “for revenue only,” be it noted, are in existence for reducing the dog as nature makes him to the dog as he is desired by the vivisectionists. The following is part of the schedule of prices of the dog-artist :

Altering shape of nose .....	\$10 00
Making straight tails kinky or curly .....	5 00
Reducing thickness of tails .....	5 00
Removing or adding marks .....	5 00
Changing erect ears to drooping, and <i>vice versa</i> ..	5 00
Making a straight coat curly, and <i>vice versa</i> ..	7 50
Changing color or coat .....	7 50
Bowing bulldogs' forelegs .....	25 00
Plucking superfluous hair, per hour .....	1 00
Prinking bulldogs' faces .....	20 00

In these prices board and nursing are not included, though the after-treatment of a dog that has been operated on requires him to remain in hospital sometimes for several months. His board under these circumstances costs \$2 a week, and there is an extra charge of 50 cents a week for medicines.

The place is said to be “kept as sanitary as a hospital,” for “if we didn't the dogs we operate upon would die.” The “dangerous and painful operations” are “never performed here,” as we consider them cruel. “Breaking the tails of the pups in two places,” or “sandpapering the tail,” “loosening the teeth and making them project,” etc., are some of the “painless” operations which alone “the respectable breeder” will do. If this “breeder” were an M.D. and the “place” were called a “laboratory,” what a hard time of it they would have!

There Are More Things in Radium Than Are Dreamt of in Our Philosophy.—Physics had definitely settled down to a definite conviction as regards the development and laws of force when suddenly a substance is found that seems to upset that conviction entirely. Without apparently receiving any new accessions of energy the new element radium gives off a continual stream of energy without diminution of its own matter. Plainly a new philosophy is required, and forthwith the experts set about the work. The lesson for us is only indirect, but none the less clear; we must keep our minds open so that new facts may be observed, and more imperative still, we must be ready to profit by new discoveries, or by the rediscovery of old ones, so that our medical theories and therapeutics may avail themselves quickly of the new standpoints. The law

of the conservation of energy is not abrogated, but a larger and clearer view of it is gained. So the old laws of health and disease are not done away with, but medical truth fashions our views anew and makes us see truth in novel ways and from a more far-looking point of view. A new and yet an old beatitude of science is, Blessed are they who keep their minds open for new truth.

**Overstudy and the Nervous School-child**—such are the topics earnestly discussed by societies for the study of school problems, by school superintendents, teachers, parents, physicians, and by editorial writers. An eminent professor of pedagogics in a vehement address repeatedly demands that the will of the bad school-child shall be "broken" exactly as one "breaks a colt." This Rarey and cowboy type of child-breaker divides "the nervous child" into four classes: 1. With undergrade mind, well-nourished, destructive, and extremely violent when angered, and even homicidal. 2. The anemic, active, alert, overstrung boy, liable to sullenness and even epileptic fits when disciplined. 3. The highstrung oversensitive girl, so sensitive as almost to go insane in trying to do right. 4. The vicious, self assertive, ill-tempered boy with criminal tendencies. Such ill observation as this argues the poor diagnosis and treatment we find. In some cities the nervous child is moving parents and physicians to appeal for fewer hours in the schools and less pressure. We do not much believe in the intellect, the morals, or the pedagogics of the colt-breakers or the boy-breakers. There are better ways to break a horse or a child than to break its will, and the teacher that entertains such diabolic theories should be "broken." The noteworthy fact about the whole discussion is the utter omission from a hundred papers and editorials and discussions of the most important element of the entire matter. There are, it is true, many other factors; there is really overstudy and overpressure, but the one cause of the nervous child which is ignored, but which is as prolific a source of evil as perhaps all others combined, is eyestrain.

**Professor J. W. Runeberg.**—The northernmost university in the world is at Helsingfors, Finland, a town of about 67,000 inhabitants. For quality of work this subarctic school of learning ranks with the greatest of Old World universities. The limited material is utilized to the very best possible advantage. As an evidence of this, we refer to the Festschrift published in honor of the sixtieth birthday and the twenty-fifth anniversary of the professoriat of J. W. Runeberg,<sup>1</sup> which contains 20 articles, nearly all of marked value, by Runeberg's pupils. Some years ago the students of Dr. Homén, the pathologist of the university, issued a similar volume devoted entirely to a study of the streptococcus and of its pathogenic effects. We fear that the breaking of the Finnish national spirit by Russia will be harmful to the work of the university, which now is intellectually under German influence. We have an example of this in Dorpat, which since its Russification has not maintained its former high standard.

## AMERICAN NEWS AND NOTES.

### GENERAL.

**Leper Colony for the Philippine Islands.**—According to a recent report, plans are actively progressing for the establishment of a leper colony on the island of Culio in the Philippines. It is estimated that there are over 10,000 lepers in the archipelago and that there is a pressing necessity for the adoption of a system looking to the segregation of the lepers and the eventual extermination of the disease from the archipelago. There are at present a few hundred native inhabitants on Culio, but it is not believed that it will be necessary to remove them, as in all probability their part of the island will not be used for the colony.

**Plague** has been discovered in Callao, Peru. The authorities have closed and isolated a flour mill where the first cases were said to have originated. Forty laborers who were employed in the mill have been quarantined. The Board of Health insists that it is necessary that the mill be burned, but the British Consul and shareholders have entered a protest to the government against burning it, as the plant is estimated to be worth \$300,000. The plague was supposed to have originated from rice in the mill, which was unloaded from the ship "Serapis," which recently arrived from India. Dispatches from Pisco announce the spread of the plague at that port. Several new cases have been reported to the authorities. Active measures are being taken at both Callao and Pisco to destroy all rats.

### EASTERN STATES.

**The American Mothers' Birth Insurance Company,** which was recently incorporated in Boston, is the first organization of the sort ever incorporated in the United States. It has been formed for the purpose of paying a sickness or disability benefit upon the birth of a living child to any member. To provide insurance at cost the officers will serve without compensation other than the actual expenses incident to membership and such services.

**Massachusetts General Hospital.**—The annual report of the Massachusetts General Hospital, which was published recently, states that the total number of patients treated at the institution, exclusive of the out-patient department, amounts to 5,199, a decrease of 154 over the previous year. In the out-patient department 27,662 new patients were treated, which is 5 less than in 1901. The number treated in the accident-room was about 1,000 less, but this was probably due to the establishment of the relief station at the City Hospital. Several buildings which have been in process of construction for the past few years have been completed. A children's ward has been added to the hospital, and it is expected that the new out-patient department will be open to the public some time during the summer.

### NEW YORK.

**Scarlet Fever in Navy Yard.**—It is reported that scarlet fever has broken out upon the receiving ship "Columbia," stationed at Brooklyn Navy Yard. Three of the crew have contracted the disease within the week. The strictest quarantine will be placed on the ship. The "Columbia" has accommodations for 500 sailors only, but at present there are over 1,000 on board.

**Typhoid Epidemic at Ithaca.**—It is reported that up to the present time 955 cases with 64 deaths from typhoid fever have occurred in Ithaca. Of the total number 288 cases occurred among the Cornell students, and of these 29 terminated fatally. Dr. George Soper, who as the representative of the State Board of Health has been in Ithaca aiding the local authorities to stamp out the disease, dwells upon the necessity for a liberal expenditure of money in order that the work may be prosecuted unimpeded. He states that in view of the large amount of infectious material which has been discharged in the city this is imperative. The water has been examined repeatedly and is still polluted and impure, although it cannot be said positively that there are now any typhoid germs in it.

### PHILADELPHIA, PENNSYLVANIA, ETC.

**Kensington Hospital for Women.**—During the month of April 84 patients were under treatment. There were 40 patients in the hospital April 1, and 38 are under treatment at the present time. Seventeen abdominal sections and 77 other operations have been performed. In the dispensary there have been 67 new patients, who have made 255 visits.

**Pennsylvania Hospital.**—At the annual meeting held recently the board of managers of the Pennsylvania Hospital reported that the expenditure entailed in running the institution during the past year amounted to \$135,185, which is \$37,000 in excess of its income. A strong plea was made to the friends of the hospital to add to its permanent endowment, in order that the work might not be curtailed. During the year 40,701 persons received treatment, and of these only a comparatively small proportion paid for board and treatment.

**Cerebrospinal Meningitis at League Island.**—According to press reports, cerebrospinal meningitis has appeared among the 1,200 men aboard the receiving ships "Minneapolis" and "Puritan" at the League Island Navy Yard. Three deaths have occurred, and five other victims are still struggling with the disease. A heroic effort will be made to prevent the spread of the disease, not only by constantly watching the men, but by removing them entirely from the two ships. Thirty-five tents will be erected, and the 1,200 men will be put out to camp as soon as possible. It is thought this measure will materially lessen the further spread of the disease. The ships will be thoroughly fumigated in order to rid them of any bacteria that may have been responsible for the disease.

#### SOUTHERN STATES.

**Medical Department Instruction.**—The course of instruction in the medical department has been amended so that hereafter it will be under the supervision of the senior medical officer, and other medical and noncommissioned officers may act as instructors in the assigned subjects.

**To Revise Hospital Corps Regulations.**—A board of Army officers has been ordered to meet in Washington, D. C., May 18, to revise that part of the Army regulations referring to the hospital corps. They have been instructed to outline rules for first-aid to the injured, and to prepare a scheme and course of instruction for members of the hospital corps.

**Examination for Position of Assistant Surgeon.**—An examination of the candidates for admission to the grade of assistant surgeon in the Public Health and Marine-Hospital Service will be held June 15, 1903, at the Bureau of the Public Health and Marine-Hospital Service, Washington, D. C. Candidates must be between 22 and 30, graduates of a reputable medical college, and must furnish at least two testimonials from responsible persons as to their professional and moral character. Successful candidates will be numbered according to their attainments on examination, and will be commissioned in the same order as vacancies occur. For further information or for invitation to appear before the Board of Examiners, address Walter Wyman, Surgeon-General, Public Health and Marine-Hospital Service, Washington, D. C.

#### WESTERN STATES.

**The Dubuque Medical Society of Dubuque, Iowa,** will hold its fiftieth annual meeting June 18, 1903. An interesting program has been prepared.

**"Water Cure" Administered in Insane Asylum.**—An attendant at the Topeka (Kansas) Asylum for the Insane, in her testimony before the legislative investigation committee, stated that it was customary to administer the "water cure" to refractory patients. She swore that when a patient refused to obey orders given by the superintendent the attendants were ordered to throw a sheet over the patient's head and throw her to the floor. While attendants held the patient the superintendent poured water out of a pan into the patient's face. The pouring was continued until the patient agreed to obey orders.

**Plague Abated.**—In his report U. S. Surgeon Glennon, stationed at San Francisco, makes the following report with reference to plague in that city: The Board of Health, working with the Board of Public Works, commenced March 30 a vigorous assault against the maintenance of certain insanitary structures in Chinatown. Rear areas, alleys, and courts, which were originally intended to admit sunlight and air, have been gradually encroached upon until many of them are now entirely choked up by small wooden structures built on the sides of the houses from the top floor to basement. As a rule, these board shacks inclose water-closets, kitchens, and sleeping bunks, in many of which the plumbing is defective, their floors and roofs supporting accumulations of every conceivable sort of debris and filth. It is the purpose of the Board of Health, unless enjoined by the courts, to demolish all these "excrecences" and afterward to lime-wash the walls from roof to basement. In the work already accomplished, President Case, accompanied by Health Officer O'Brien, and Chief Sanitary Inspector Hassler, personally directed a gang of laborers in their operations. It is gratifying to all concerned that no case of plague has occurred among the Chinese population since December 11, 1902, and it is hoped that the vigorous measures for the eradication of the disease which have been enforced, and are still being enforced, will continue to show such good results.

#### CANADA.

**New Hospital for Epileptics.**—The Ontario Government has appropriated \$30,000 to erect a hospital for epileptics at Woodstock. The insane in Ontario are classified as harmless (such as epileptics), curable, and incurable. It is hoped that in time all three classes will be kept in separate buildings.

**Amendment to the Medical Practice Act.**—An amendment which was recently introduced into the New Brunswick Legislature provides that "No duly registered practitioner in that province shall be liable to any action for negligence or malpractice by reason of professional services, unless such

action is commenced within one year from the date when in the matter complaint of such professional services terminated."

## FOREIGN NEWS AND NOTES

### GENERAL.

**Contract Medical Practice in Germany.**—It is reported that the medical officers of the sick funds in Germany will strike in a body on July 1, unless their demands for more adequate remuneration be conceded. The statement is made that under the present arrangement they only receive about five cents a visit.

**Röntgen Ray Experiment.**—Lord Rayleigh's reference to Professor Blondiot's recent experiments regarding the polarizing of the Röntgen rays, suggests that the mystery regarding the true character of these curious emanations is about to be cleared up. If Professor Blondiot's results are confirmed, and the Röntgen ray proves to be polarizable, it will be classed as light whose peculiar properties are due to its very short wave length.

**Badges for Opium Smokers.**—In order to indicate the different classes of opium smokers to the officers who administer this drug under government patronage in Fukien, China, a system of badges has been placed in operation. In discussing this badge system the *Ma Po*, the Chinese daily paper of Manila, makes the following statements: "The authorities of the province of Fukien, to which nearly all of the Chinese of Manila belong, have planned to establish a government factory for the preparation of opium; and now it is reported that after the opening of this establishment all opium smokers who wish to purchase the drug must obtain from this establishment badges, which are of three classes: (1) Brass badge, which is for the government officials; (2) paper badge, which is for the gentry; and (3) wooden badge, which is for the common people. On these badges are written the names of the opium smokers, their ages, addresses, and the quantity of opium they are allowed to buy daily, which is to be decided and limited by the government officials, and which cannot be deviated from at any time. All the opium dealers who have received licenses from the government to retail the boiled or prepared opium are not permitted to sell privately any opium to those who do not have badges. According to this plan it is expected that the opium smokers will feel ashamed of wearing these badges and reform themselves generally by breaking off the evil habit."

### GREAT BRITAIN.

**The Increase in Cancer Mortality.**—According to the Registrar-General of Ireland, during the year 1901 cancer caused 2,893 deaths in Ireland, in 1900 the number was 2,717. The deaths in 1901 represent a rate of 6.5 per 10,000 of the estimated population, an increase of 0.4 per 10,000 living, as compared with the rate for 1900. The steady increase in the recorded mortality from cancer in all three parts of the United Kingdom is remarkable. In Ireland in 1864, the first year in which the registration system was in force, the rate of mortality was 2.7 per 10,000 living. In 1871 it had risen to 3.2; in 1881 to 2.7; in 1891 to 4.6; and, as already stated, in 1901 it reached 6.5. In England (including Wales), in 1864 the rate was 3.9. In 1871 it was 4.2; in 1881, 5.2; in 1891, 6.9; and in 1900 it had risen to 8.3. In Scotland in 1864 the rate was 4.3; in 1871 it was 4.4; in 1881, 5.2; in 1891, 6.8; and in 1900, 8.0. In Ireland the deathrate from cancer in 1891 was 4.6 per 10,000 of the population, and in 1900 it had risen to 6.1 per 10,000. The report closes with the following conclusions: Experience proves that in many cases cancer recurs in the same family; that frequently, when a member of a family is afflicted with the malady, other members suffer from tuberculosis; that in a number of instances, when members of a family were afflicted with cancer, other members suffered from lunacy, idiocy, or epilepsy; that in some cases the disease has occurred in persons who have been in direct contact with cancer patients; that the disease has manifested itself in individuals who have used the tobacco pipes of persons suffering from cancer of the lip; that in some instances more than one case has occurred in different families living in the same house, and successive occupants of the same house, that in a few cases the disease has appeared in different houses in the same locality about the same time; and that it frequently shows itself when conditions of residence food, etc., are bad.

### CONTINENTAL EUROPE.

**Victoria Memorial Hospital at Nice.**—The cornerstone of the new Victoria Memorial Hospital to be erected at Nice was laid May 7 with imposing ceremonies.

**Plan to Save French Babies.**—It is reported that a poly-clinic has been opened in Paris by Baron Henry D. Rothschild, who proposes to give lectures to medical students and doctors on the treatment of newborn children, among whom the mortality is so great.

**An Epidemic of Intestinal Disease Among Miners.**—It is reported that the coal mining industry in Westphalia is being seriously hampered by a sickness among the miners arising from an intestinal parasite. It is stated that about 20,000 miners are affected, and that the disease has spread so rapidly that the sickness is almost universal. Temporary barracks and isolation hospitals are being erected to prevent the spread of the disease and to enable scientific investigation.

### OBITUARIES.

**John J. Healy**, of Philadelphia, May 8, aged 54. He was graduated from the medical department of the University of Pennsylvania in 1872. He then went to Vienna to pursue a postgraduate course and after two years' work in various European hospitals returned to Philadelphia and accepted a position on the staff of St. Mary's Hospital. He was a member of the County Medical Society, and was for a long time pension examiner. Since 1899 he had been a member of the Board of Inspectors of the Eastern Penitentiary. He was a Founder of *American Medicine*.

**Herman H. Schaberg**, of Kalamazoo, Mich., April 24, aged 54. He was graduated from the Detroit College of Medicine in 1878. He was a member of the American Medical Association and the Kalamazoo Academy of Medicine. He also served as health officer and city physician of Kalamazoo.

**Emily H. Stowe**, of Toronto, Ont., died recently. She was graduated from the New York Medical College and Hospital for Women in 1867 and was the first woman physician to practise medicine in Canada. She retired from active practice in 1893.

**Hiram Long**, in Suabury, Pa., April 24, aged 71. He was graduated from the New York Medical College, New York City, in 1859. He was a surgeon during the Civil war and was several times president of the Sunbury Medical Association.

**Alvin B. Rice**, of Jamestown, N. Y., May 8. He was graduated from the Bellevue Hospital Medical College, New York City, in 1867. He was vice-president of the New York State Homeopathic Medical Society.

**William F. Wooden**, in Greensburg, Ohio, April 23, aged 45. He was graduated from the Medical College of Ohio, Cincinnati, in 1879, and was a member of the Decatur County (Ind.) Medical Society.

**Samuel Bridgman**, at Bracebridge, Ont., aged 56. He was graduated from the Queen's University, Kingston, in 1870. He had been a member of the Legislature since 1898.

**Addison C. Hinkson**, of Nevada City, Cal., died in San Francisco, April 22, aged 28. He was graduated from the College of Physicians and Surgeons of San Francisco in 1901.

**Benjamin Morris**, formerly of Martinsville, Va., died near Rangeley, Va., April 15. He was a graduate of the University of Virginia, Charlottesville.

**Rufus O. Mason**, of New York City, May 11, aged 73. He was graduated from the College of Physicians and Surgeons, New York City, in 1859.

**Stephen H. Rice**, of Memphis, Tenn., May 6. He was graduated from the medical department of the University of Pennsylvania in 1893.

**Andrew Joy**, of Evergreen, Ala., May 8. He was graduated from the medical department of the University of Alabama, Mobile, in 1872.

**William R. Davis**, in Utica, N. Y., April 19, aged 47. He was graduated from the Eclectic Medical College of New York City in 1891.

**Thomas A. Pineo**, in Brooklyn, N. Y., April 19, aged 38. He was graduated from the Long Island College Hospital, Brooklyn, in 1898.

**John I. Dyer**, of Washington, D. C., May 9, aged 76. He was graduated from the National Medical College, Washington, D. C., in 1847.

**H. T. Breckbill**, in Columbus Grove, Ohio, April 22, aged 60. He was graduated from the Puite Medical College, Cincinnati, in 1878.

**Edwin B. Reed**, at Little Tognus, Me., April 24, aged 65. He was a graduate of the University of Pennsylvania, Philadelphia.

**William W. Miller**, in Pittsburg, Pa., April 16. He was a graduate of the Western Pennsylvania Medical College, Pittsburg.

**R. B. Cotton**, of Regina, N. W. T., May 6, aged 48. He was graduated from the Toronto University, Toronto, Ont., in 1886.

**James R. Todd**, in Gridley, Cal., April 21, aged 59. He was graduated from the Kansas City Medical College in 1883.

**Edward de la Granja**, of Boston, Mass., May 9. He was graduated from the Central University of Spain in 1855.

**Charles E. Reese**, in Lowndesboro, Ala., April 25. He was graduated from the Jefferson Medical College in 1855.

**J. M. Newell**, in Rochester, N. Y., April 23, aged 82. He was graduated from the University of Buffalo in 1873.

**D. J. Grandstoff**, in Mason, Tex., April 22. He was graduated from the Louisville Medical College in 1878.

**Harold H. Haas**, an assistant surgeon in the United States Navy, died at Staunton, Va., May 5.

**Roswell E. James**, in Kalamazoo, Mich., April 23, aged 68.

**Robert M. Morgan**, in Decherd, Tenn., April 25, aged 70.

## SOCIETY REPORTS

### AMERICAN MEDICAL ASSOCIATION.

Fifty-fourth Annual Meeting, Held at New Orleans, La.,  
May 5 to 8, 1903.

[Specially reported for *American Medicine*.]

#### House of Delegates.

Owing to the fear of the difficulty of completing within the period of the meetings the entire amount of business mapped out for the House of Delegates, meetings were begun on Monday afternoon. The Monday meetings, however, were unofficial, since, in order to have the proceedings legal, certain business of the meetings must be held solely in the duly announced periods. At the first meeting the report of the Committee on the Prophylaxis of Venereal Diseases was read, and after brief discussion was referred to the Business Committee. The organization of the body was then practically completed. The Chairman of the Business Committee, HAROLD N. MOYER, stated that the evening meeting was not legal, and would require a full and unanimous vote of the House in order to legalize its proceedings. This was on motion granted, and meeting was recommended for the following afternoon, but it was decided that certain reports be considered at the present meeting. Roll-call showed 48 delegates present.

The report of the Board of Trustees was read by Dr. HAPPEL, chairman, showing the total assets of the Association to be \$131,821.16, the profits for the year 1902, \$40,140.56.

Report was made by the Committee on National Incorporation with the object of enabling the American Medical Association to meet in any State or Territory in the Union to transact and complete its business without holding an adjourned meeting in Illinois in order to ratify action taken at the annual conventions. The opinion of the counsel employed by the committee was that such national incorporation was an impossibility. The constitution and by-laws adopted at the meeting at St. Paul had no binding force until they were readopted in Illinois, but the action at Saratoga and readopted at Chicago is legal and the charter and by-laws governing the Association at present are legal since they were readopted in Illinois, where the Association was incorporated. Suggestion was made that \$50 be appropriated for the secretary of each section for postage, etc. After proposing and adopting minor changes in the button, etc., the meeting adjourned.

#### General Sessions.

In the meeting of the general sessions at 11 o'clock, Tuesday morning, the fifty-fourth annual convention was formally opened. Prayer was offered by Rev. Dr. H. G. DAVIS and Mayor CAPDEVILLE welcomed the physicians on behalf of the city, alluding in happy phrase to the work of the profession in New Orleans and Louisiana. He was followed by General LEON JASTREMSKI, who welcomed the Association on behalf of the State in the absence of Governor Heard. HENRY P. DART then spoke on behalf of the Louisiana Bar, representing the laity. He urged legislation on behalf of the Association that would regulate the relation of the physician to his patient, and spoke particularly of the great hospital system which rested upon the profession as did the ancient world upon the shoulders of Atlas. These addresses were responded to in a most happy vein by an extempore address delivered by J. A. WITHERSPOON, vice-president of the Association. The annual address of the president was then delivered by FRANK BILLINGS. It will be found in full in the issue of *American Medicine* of May 9.

#### House of Delegates.

At the first formal meeting of the House of Delegates, Tuesday afternoon, 70 responded to the roll-call. President BILLINGS made a brief address referring to the work of reorganization recommended by the Board of Trustees and adopted. He recommended the continuing in the field as reorganizer Dr. J. N. McCormack, who had done such efficient work during the past year. In view of the fact that the Rush Monument would be dedicated next year at Washington, he suggested that the next annual meeting be held there. He also referred to the disadvantages of the present system for selecting a meeting place, and advised that the committee having this matter in charge be made permanent, and that all cities desiring the Association to meet with them should make application at least three months before the date of meeting, accompanying this application with full details as to the inducements, etc. He alluded to the Section on Stomatology, which had been established after considerable labor, and was now imperiled unless some ruling should be made whereby the degree of D.D.S. would admit to affiliation with the Association. The death of Walter Reed was alluded to as a national calamity, and a plea was made for some suitable memorial by the Association.

The report of the Secretary of the Association followed. Dr. SIMMONS stated that the work of verification of membership was only partially completed; 146 members had been dropped, but the increase in the membership was material.

The Business Committee reported favorably on the reports

submitted by the Board of Trustees, regretting that national incorporation was not possible.

ELIOT HARRIS, of New York, Chairman of the Provisional Committee on National Bureau of Medicines and Foods, submitted a favorable report on the proposition, and recommended that the committee be continued and authorized to cooperate with a committee of the American Pharmaceutical Association and to confer with the government authorities.

ELIOT HARRIS, Chairman of the Committee on Revision of the Code of Medical Ethics, made a report in general terms, advocating discontinuance of the word "code" and substituting the word "principle" instead, allowing different States to formulate working rules and penalties, provided such be not in conflict with the established principles of the Association. He stated that they had decided to retain the existing code almost in its entirety, the changes being chiefly in the interests of brevity. C. A. L. REED offered a "substitute report," which he called a statement of principles which should be advisory not mandatory. After some discussion this matter was referred to a special enlarged committee consisting of the original committee with the addition of one member of the House of Delegates from each State not already represented on the committee, to meet directly after adjournment. Dr. Reed's substitute and the original report were placed under the consideration of this committee.

Section 4, Chapter 7, of the by-laws, referring to the nomination and election of officers, was changed to facilitate the work of the House of Delegates. It was adopted.

Section 1 of Article 4 of the constitution, referring to the constitution of the House of Delegates, was amended by adding the officers of the Association to the House of Delegates.

Another section, incapacitating the officers from being re-elected, was changed.

Finally all the amendments but the first, in regard to the election of officers, were referred to the Business Committee.

LEWIS S. McMURRY, Chairman of the Committee on Association Medal, asked that the committee be empowered to draw specifications for the award of the prize, which was granted.

The Committee on Senn Medal reported unanimously that none of the papers submitted had met the requirements, therefore no medal was awarded. The report was accepted.

The Committee on Rush Monument, through Chairman H. D. HOLTON, reported that all but one of the original committee named many years ago were dead. He told of the work of the committee, and said that the fund now amounted to \$15,000. Contracts had been made for the monument to be placed in Washington. It will be completed and ready for unveiling early next year. This committee asked for \$500 to defray expenses of unveiling. The report was received and referred to the Board of Trustees, with recommendation that the funds asked for be granted.

#### General Sessions.

At the second meeting of the general sessions, A. F. JONAS delivered the oration on surgery, which appears in the issue of *American Medicine* of May 9.

J. RAWSON PENNINGTON, of the Portrait Committee, stated that two portraits of ex-presidents had been prepared for the Hall of Fame, and that Edmond Souchon, president of the State Board of Health, would present that of T. G. Richardson, the first and only Louisianian to be elected president of the American Medical Association.

#### House of Delegates.

At the meeting Wednesday morning, the Committee on Medical Legislation reported on the efforts made to defeat the bill before Congress for the "regulation" of vivisection. Resolution was adopted by the House commending the efforts of the committee and deprecating further consideration of such measures by the national body.

WELCH (Baltimore) urged the importance of having a medical man on the Isthmian Canal Commission on account of the well-known unsanitary conditions prevailing. A resolution was adopted asking President Roosevelt to name a medical man as one of the members of the Commission.

The Business Committee recommended that the report of the Committee on the establishment of the National Bureau of Medicines and Foods be not adopted, because it was vague and indefinite. It was recommended that the matter be referred to the Committee on Legislation. PHILIP MILLS JONES urged immediate action because it had been pending so long already. He claimed the delay had already been great and if the present report was not adopted four years at least would elapse before anything was accomplished. FOSHAY supported the recommendation of the Business Committee, saying the report had not been presented in a form permitting its adoption. The Association was asked to appoint trustees for an institution, but there was no definition as to where this would lead. He thought a Bureau of this nature should be under the direction of the government. The report of the committee was read by MOYER. It contained no definite recommendation other than asking to be continued in office to confer with a committee of the American Pharmaceutical Association under government authorities. The report was recommitted to the original committee.

J. N. McCormack was commended for his work as organizer and urged to continue. His report on the work of reorganization followed. He said that 18 States had adopted practically a uniform constitution with phenomenal results, the increase in membership in such States being from 300% to 400%. The purpose of the movement was to secure not only systematic, but uniform work. Effort had been made in some States to organize on other lines, and unless this was discouraged it might defeat the whole plan of organization. The sum of \$500 was appropriated for expenses of Committee on Reorganization.

#### General Sessions.

At the meeting 7.30 p.m. Wednesday evening the oration in medicine was delivered by J. M. ANDERS (Philadelphia). Dr. Anders' address appears in full in *American Medicine* for May 9.

W. L. RODMAN (Philadelphia) presented a portrait of the late Dr. Hunter McGuire, of Virginia, to the Association for its Hall of Fame, with a eulogy of his life and work. By motion the Association accepted the portraits of Drs. McGuire and Richardson. A motion that every retiring president present to the Association a portrait of himself was lost.

#### House of Delegates.

At the meeting Thursday morning an appropriation of \$500 was made to meet the expenses of the Committee on Scientific Exhibits. A resolution was adopted that amendments to the constitution or by-laws be not considered unless presented at the preceding annual meeting.

The report of the Committee on Prophylaxis of Venereal Diseases was adopted. A congress will be held in St. Louis during the Louisiana Purchase Exposition, a committee of one from each State making the arrangements for the same. The Association appropriated \$500 for the expenses of the congress, and voted to ask an appropriation of \$5,000 from Congress to further the work.

Provision was made for certification by the secretary of dental and pharmaceutical graduates as associate members of the Association.

The enlarged Committee on Revision of the Code submitted a report which had been unanimously adopted by the committee. [This appears elsewhere in full.] The committee said it formulated a set of ethical principles as a guide to State associations in formulating codes and penalties to suit local conditions. Dr. REED stated that by adopting the report as given an end would be made to the controversies that had existed for many years. Upon the adoption of the report the House broke into tumultuous applause.

The Committee on Transportation and Place of Meeting recommended Atlantic City as the next place of meeting, and the report was adopted.

#### General Sessions.

WILLIAM H. WELCH (Baltimore) delivered the oration of State medicine on "Infectious Diseases" Thursday evening. This address will be given in a future number of *American Medicine*. After the delivery of Dr. Welch's address Dr. BILLINGS, in a few well-chosen words, called attention to the great work done by Dr. Welch in stimulating the profession. The three greatest discoveries of the era, the bacillus of cholera infantum, the germ of smallpox, and the theory of the transmission of yellow fever by mosquitos had all been worked out by students of Dr. Welch. Dr. Welch has fertilized more men in the profession to the honor and profit of medical science than any other man in the profession today, and his self-sacrifice and abnegation, his generosity to those working with and under him, will constitute an important element in his future fame.

#### House of Delegates.

At the meeting of the House of Delegates on Friday morning the following officers were elected: President, John H. Musser, of Philadelphia, Pa.; first vice-president, G. C. Savage, of Nashville, Tenn.; second vice-president, Isadore Dyer, New Orleans; third vice-president, C. L. Hall, Kansas City, Mo.; fourth vice-president, Geo. F. Jenkins, Iowa; treasurer, Henry P. Newman, Chicago, Ill.; secretary and editor, George H. Simmons, Chicago, Ill.; oration in surgery, W. J. Mayo, of Rochester, Minn.; oration in medicine, George Dock, Ann Arbor, Mich., and oration on State medicine, Herman M. Biggs, of New York City.

Owing to the absence of Dr. Musser, who had left the city on Thursday evening, it was resolved that the term of President Billings hold over until the beginning of the next session. It was said that this is the plan adopted by the British Medical Association and had the advantage that the president nominated for the following year had the assistance and advice for one year of the retiring president.

William H. Welch, of Baltimore; Miles F. Porter, of Fort Wayne, Ind., and M. L. Harris, of Chicago, were elected trustees. Frederick Holme Wiggan, of New York; C. B. Gillespie, of Tennessee, and D. C. Peyton, of Indiana, were elected members of the Judicial Council. The convention was declared formally adjourned at noon on Friday.

## Section on Practice of Medicine.

## FIRST SESSION.

**Continued Fever Neither Malarial Nor Typhoid.**—T. J. HAPPEL said southern practitioners have observed a continuous fever which presents none of the classic symptoms of typhoid nor malaria, except its duration, this varying from three to five weeks with an average of about four weeks. Examinations of the blood both chemically and microscopically thus far negative typhoid and malaria, but as yet affirm no other nosologic entity. The mortality is almost nil, hence no cases have come to necropsy. He has treated 100 cases and he finds a marked disproportion between the pulse and the temperature, the ratio being often inverse. One case is detailed which persisted for four weeks, there being two rises and falls of temperature in every 24 hours; quinin in large or small doses has no effect. Reference is made to too frequent neglect of bedside work and too implicit faith in the microscope. When these differ he prefers the evidence as furnished by bedside investigation. In this disease there is a frequent aching of various groups of muscles, as seen in influenza, the pulse ranges from 70 to 90, and the temperature may vary anywhere from 100° F. to 105° F. A high temperature may be present when the body surface feels cool. Is it not probable that a further classification of continued fevers may show this to be a distinct type, as has been found in the eruptive fevers?

*Discussion.*—JAMES TYSON said after an experience of 30 years he would limit rather than extend the number of continued fevers. He frequently has anomalous cases, but persistent blood examination generally proves them to be one of the common types. Ptomains in the alimentary tract may cause a fever of some duration. WITHERSPOON holds to the new fever theory. He disclaims any knowledge of the etiology but suggests possibly some form of infection in the alimentary tract. The whole clinical picture differs from that of typhoid. It begins suddenly; it has no predilection for season of year or age of patient; one attack does not confer immunity; he has found the pulse rapid as a rule; prostration is marked; fever is irregular; there are no rose-spots and no tympany; constipation is the rule; the tongue is not indicative of typhoid; there is no mental hebetude; the patient is hungry most of the time; and herpes labialis is common.

**Restorative Influences of Ozone on the Blood.**—G. LENOX CURTIS emphasized the importance of early examination of the blood on the prognosis and treatment. Not until he had abandoned the examination of dried and stained specimens and resorted to examination of blood in the fresh state did he make any real progress in diagnosing cases from blood examination. He places considerable stress on photography of blood in the fresh state, claiming this was to determine a pathologic condition of the system when no real symptoms are present, and the further claim is made that photography reveals tuberculous elements in the blood at a very early state. In regard to treating many of the incipient and latent conditions great importance is attached to oxygenation, or ozonation of the blood. This is accomplished by means of a special apparatus employed by the author, the principle being that through the agency of the electric current oxygen is converted into ozone and is caused to enter the general system. Here it possesses great power to rehabilitate the blood. F. R. WEBBER asserted that Virchow long ago taught the importance of examining blood and other tissues in the fresh state. The photographs exhibited by Curtis as illustrating pathologic conditions of the blood were mere exhibitions of artefacts and proved none of the claims of the writer. The claim that tuberculous material can be shown by photograph of the blood is wholly incorrect. The electric currents of high frequency and high potency merely influence the blood-pressure.

**Ninety Cases of Typhoid Fever: The Therapy of Fasting.**—R. M. HARBIN states that of the 90 cases 4 died; 23.8 years was the average age of the patient, and among all farmers bear the disease least well. Physicians and nurses appear to possess a somewhat relative immunity to typhoid. Typhoid constitutes more illness in the South than any diseases except tuberculosis and pneumonia. The twelfth census report shows that the mortality rate in the South from enteric fever is very high and it shows that well-water is probably the source of the infection in most of the cases. Emaciations occur regardless of the amount of food taken and a restricted diet is indicated because of the pathologic conditions. Certain severe sthenic cases are relieved better by fasting, as the active symptoms exhaust the patient more rapidly than the lack of food. Gelatin prevents too rapid emaciation and it inhibits hemorrhage. The cold, modified cold, or hot bath is more effective during fasting. The proper treatment of intestinal ulcers is rest, peristalsis favors the absorptions of toxins, and cathartics should be used only to remove undigested food. The presence of diarrhea and fasting indicate treatment by fasting. Many fasting cases run an abortive course after the amphibolic period. Many vaunted cures from specific drugs are really dietetic. In this report 45 cases were treated without a death. Of 87 whites 2 died; of colored 2 died, making a mortality rate of 4.4%. This favorable showing is ascribed to the method of treatment.

**Southern Fevers.**—WILLIAM KRAUSS reported the clinical and laboratory findings in a number of patients and pointed out the necessity of arriving at a correct diagnosis when possible. Acute estivoautumnal fever is of two types, as certain

cases illustrated. Case reports were made of each of the following: Fever associated with diarrhea; fever associated with constipation, but of typhoid type; irregular estivoautumnal fever; "postmalarial" fever; fever of cachexia; indefinite typhoids; paratyphoid; usual methods of diagnosis and their possible fallacies. A general discussion of the remainder of the fevers was given, and the advisability of applying epidemiologic rules to undiagnosed fevers and classifying them with the most dangerous then prevailing was discussed. His general conclusions were that the malarial leukocytic count is not always characteristic and only reliable when all the cells in the spread are counted; that the Widal reaction is erroneous in a small percentage of cases; that acute fevers with hyperpyrexia in midsummer are more apt to be sunstroke than "congestion"; that we should never cinchonize unless sure of our diagnosis; that a number of summer and fall fevers may elude our efforts to make a diagnosis; that a sudden chill or disturbance of temperature curve in a typhoid patient is not sufficient evidence of malarial complication; that some continued fevers are malarial, some typhoid, a few are something else, but he is opposed to the idea of any "x" fever.

**Boys' Venereal Peril.**—F. C. VALENTINE formerly advocated public lectures to young men and youths in regard to the dangers from venereal infection. Further study and observation has caused him to abandon this idea and he now believes the family physician is the one to whom such duty belongs. Venereal diseases have done their deadly work when the specialist is consulted. Ignorance in reference to the diseases of the sexual apparatus is the cause of untold misery and suffering, hence the early education of the youth by the physician would prevent much of the evil. Instruction in the public schools would be inefficient because of the usual inability of the instructor and the difference in the receptivity of the auditors. The proper time for such instruction is at puberty, and mental and physical puberty do not always coincide, hence each must be considered individually. The author submits information to give boys when they are most likely to incur the risks attendant on the acquisition of the sexual habit. If those nearest the boy deem it wise parts of the author's paper might be given him for his study. The paper concludes with an exposure of the methods employed by the advertising quacks and nostrum vendors.

*Discussion.*—J. W. WALSH emphasized the importance of such instruction as advocated by Valentine, and as an example cited the fact that in the German universities lectures on venereal diseases have for the past few years been regularly given. We are confronted by "a condition and not a theory," and to treat the matter lightly and indifferently is a great error. It is the imperative duty of American universities and colleges to impart information on venereal diseases to young men. F. W. ROBBIN insisted that a mental impression is more important to the youth than the mere knowledge. There are early periods of pubescence, from 9 to 12 years, when the father or the physician can give the youth the proper information; and a later period, about the time when the youth usually enters college, when additional information should be given and this by the physician. THEODORE PORTER said there are two dangerous periods to the boy: The one is early when at home, and the other is later when at college. At the latter place the boy is free for the first time and proper instruction is sorely needed and surely none but the physician should give it. M. M. SMITH believes the proper solution of the question lies in early and proper home-training for the youth, together with advice on the part of the family physician. FRANK JONES condemns lectures to public classes on venereal diseases, and none but a physician should impart the necessary information, this being given privately. E. S. STEVENS believed that boys should be taught at puberty the sacredness and naturalness of the sexual instinct by a physician; and now that the rules of the American Medical Association permit a counselor in each district to impart information through the public press some general information should be given especially calculated to offset the fears engendered and the false impressions imparted by quacks and charlatans. W. SHROPSHIRE thinks information should be imparted early when protection is efficient. It should be taught in the public and high schools along with physiology, a physician being the only proper person to teach either.

## SECOND SESSION.

**Treatment of Acute Dysentery.**—J. M. ANDERS divides treatment into three varieties: (1) dietetic; (2) internal remedies, and (3) topical applications. Rest in bed with proper air and regulation of diet is a most important element in the treatment of these cases. The diet should be liquid—milk and albumin-water preferred. Fats and the carbohydrates should be excluded. Internal remedies should consist of ipecac, which the writer prefers to give in small doses and give frequently rather than in large doses. Avoid vomiting during its administration by rest in bed and absolute quiet. Saline purgation should be employed only in the early stages—later it does harm. Aromatic sulfuric acid is beneficial. Opium may be necessary to relieve the pain and tenesmus and bismuth should not be forgotten. He questions the efficacy of an intestinal antiseptic, but salol may be given on general principles. Sulfur does good in many of these cases. The serum treatment has not proved successful. Among topical appli-

cations he recommends bowel irrigation with some of the astringents or with an astringent alternating with a feebly antiseptic solution. Irrigation is more efficacious in amebic dysentery than in the bacillary forms. Warm solutions are sometimes efficacious.

**Traumatic Pneumonia.**—W. T. ENGLISH defined traumatic pneumonia and stated that he would limit his paper to a discussion of concussion and contusion without penetrating wounds or fractures. He entered into a general discussion of the physical and mechanical force transmitted through the thoracic wall to the lungs and pleura within. There are normal and abnormal peculiarities in each case which resist the stress from without and that within the thoracic cavity. A great deal depends on the location of the seat of injury, the character of the vulnerating substance and the various environments and influencing factors. A general discussion of the signs, symptoms, diagnosis, prognosis and treatment was entered into, and a number of cases were reported.

**Abdominal Pain in Pleurisy and Pneumonia.**—J. B. HERRICK stated that in acute inflammation of the pleura we not infrequently have abdominal pain. This is sought to be accounted for in various ways. One is that the lower six intercostal nerves supply not only the pleura, but the abdominal muscles, hence the pain could be readily referred to the abdomen. Again, the phrenic nerve may play some part in this peculiar condition. This referred pain may give rise to the diagnosis of appendicitis, cholecystitis, etc., when the real lesion is a pleurisy or a pneumonia. The writer gave the histories of several cases in which a mistake in diagnosis had been made in some in which appendectomy had been done under a wrong apprehension. In children it appears not necessary that the lower lobes of the lung be affected to cause this referred pain, as it may occur when the pneumonia is apical.

**Discussion.**—J. N. HALL believed that a displaced liver may cause confusion between peritonitis and pleuritis. A diaphragmatic pleuritis may closely simulate peritonitis. He reported a case which had a left-sided pneumonia, yet early in the case evinced the symptoms of appendicitis. THOMAS McCRAE had seen three cases of beginning pneumonia evince the symptoms of abdominal lesions. In doubtful cases surgeons should call in the internist as consultant; it would prevent needless operation in some cases. B. W. SIBLEY and J. M. ANDERS had both seen cases of this kind, and insisted that they should be in the mind of every surgeon when dealing with an abdominal case.

**Strongyloides Intestinalis in the United States.**—M. L. PRICE gave a general history of this parasite, its discovery by Normand in 1867, its occurrence in Europe, and in sporadic cases in Brazil, Russia, Sicily, Italy, Dutch Indies, Egypt, etc. Sporadic epidemics occurred in the United States in 1896, and in the Philippine Islands in 1901. The life history of the parasite was given, together with its description and illustrations of it and its ova. It is limited in man to the intestinal canal, seldom reaching the stomach. It may occur in association with the germ of Cochin China diarrhea, and with *Uncinaria duodenale*. The parasite's occurrence in the United States has been noted by Thayer, who reported several cases. The author reported a case coming under his own observation. Attention was called to the clinical picture presented in these cases; the digestive disturbances, diarrhea, dysenteric and choleric seizures and emaciation. Death may occur from lowered vitality, asthenia and intercurrent affections. Postmortem examination shows much atrophy of the intestinal epithelium. Fasting for 24 hours followed by free administration of thymol in the author's case brought away many ova, but no parent parasite.

**Discussion.**—C. W. STILES stated that the parasite is very common in the United States. It has the same distribution as uncinaria. It should be found plentifully before a positive diagnosis is made. He doubts the efficacy of thymol in dealing with this parasite. A. J. SMITH thinks the parasite more common than is generally supposed. J. T. MOORE saw his first case in 1901. The symptoms were abdominal cramps, diarrhea, nervousness and anemia. He found the parasite in stools. His reported case will soon appear in *American Medicine*, and two other cases are soon to be reported.

**Uncinariasis in the United States—in Texas.**—A. J. SMITH confined his remarks chiefly to this parasite as occurring in Texas. The author had seen the ova of this parasite as early as 1893, but at that time was uncertain as to its character. He later found them in the stools of patients. Suspecting the rather general presence of the parasite in man he instituted a systematic examination of 88 supposedly healthy persons, and found the ova in the dejecta of eight of these—all inhabitants of Texas. It is found most commonly in the sandy districts, but not limited to these. He is of opinion that cistern water is a principal source of infection. A map showing its distribution in the State was exhibited, showing its distribution to be, for most part, along the principal water courses. The principal symptoms exhibited by the patients are abdominal pain and discomfort, varying disturbances of the bowels, marked anemia in severe cases, and almost constant eosinophilia. Malaria frequently occurs in combination with uncinariasis.

**Discussion.**—C. W. STILES stated that infection may take place through the skin, but the usual route is doubtless through the mouth. Uncinariasis as produced by the American parasite exhibits much more marked symptoms than that pro-

duced by the Old World parasite, though the former invader is more easily dislodged, because of the practical absence of the hooklets possessed by the latter. The parasite may live in the intestine for 10 years, and possibly longer. It may occur anywhere, but most observed in the sand districts. T. A. WILLIAMS, of Scotland, says the parasite is plentiful in South Africa, and was formerly thought to be malaria. C. A. SMITH said he had seen anemia so severe in some cases that hemoglobin was reduced to 10%-15%. Thymol is the most effective remedy yet tried. J. B. HERRICK insisted that we must watch for the parasite in the North, as a case had been reported in Chicago.

#### THIRD SESSION.

**Malarial Dysentery.**—W. B. BURNS disbelieved in any one organism producing dysentery. He cites many cases and conditions in which dysentery and malaria parallel each other. Most cases of dysentery respond to antimalarial treatment, and he therefore concludes they are caused by the malarial parasite. He asserts that malarial parasites are often found in the mucosa and submucosa at the necropsy of those dead of dysentery. Dysentery patients frequently reveal the malarial parasite in the blood.

**Discussion.**—J. T. MOORE seriously doubts that any form of dysentery is caused by the malarial parasite. He has seen many cases which apparently owed to malaria the incidence of the disease, but a careful investigation showed the etiology in every case to be something else. Many cases of amebic dysentery improve on quinin, but this is no evidence of malarial infection. He has tried fluid extract of chaparro armagosa in dram doses every four hours for malaria and amebic dysentery with good results.

**Clinical Diagnosis of Intestinal Parasites.**—C. W. STILES insisted on the routine practice of examining stools, urine and blood of all cases with intestinal symptoms. Stools should be examined carefully and frequently so long as doubt as to diagnosis remains. Simple methods of making microscopic spreads were given. A convenient one is to touch the wide glass slide with the little finger wet in water, then with a match-stick put a small amount of the fecal matter on the moist area and spread the same out, place on the cover-glass, and the specimen is ready for examination. Pressing fecal matter between folds of blotting-paper and searching the same for blood-stains after an interval will give information as to the presence of intestinal parasites if they be fairly plentiful; especially is this true of the hookworm. But in the latter it fails in 30% to 40% of the cases, because the cases are light and the parasites relatively few. All intestinal parasites sink in water, therefore if the stool be placed in a glass jar and agitated with water, then allowed to stand a short time and the upper liquid poured off, the parasites may be easily found after repeated washings. The microscope is the simplest and easiest means of finding the offender. There is danger of infection in dealing with but two of these parasites, viz., *tenia solium*, and with dog stools, the echinococcus. Special attention was devoted to the hookworm, and its general prevalence in the South discussed. The symptoms produced by this parasite in wellmarked cases is very characteristic. The fishlike stare of the patient's eyes, absence of hair on body of subjects infected before puberty, anemia, and stunted growth are all characteristic. In milder cases only the microscope will certainly diagnose the affection. A description and illustrations of the various intestinal parasites, together with their ova, were given.

**Amebic Dysentery at the Johns Hopkins Hospital.**—T. B. FUTCHER states that in 14 years 119 patients have been admitted to this hospital, and a general review of these cases are given. The statement is made that amebas may be found in the stools of apparently healthy persons. They are confined to the colon for the most part. Liver and pulmonary abscesses may occur, and the germ may be found in the buccal cavity, in carious teeth, etc. Little is known of the source of amebic infection. Inoculations with the germ are negative. It is probably derived in the same way as is typhoid bacillus. It is not confined to the tropics, occurs in both young and old, the very large preponderance in his reported cases being in males. The whites appear somewhat more susceptible than the blacks. Anemia exists, but there is no diminution in the red cells; there is some leukocytosis, and the hemoglobin averaged in the reported cases 63%; abscess cases 66%. Some 20.3% of the cases developed hepatic abscess. The amebas probably reach the liver by the portal circulation. Malaria was associated in five of these cases. Most of the cases occur in the third decade of life. No means of treatment appears to be entirely successful and many relapses occur.

**Clinical History and Pathology of Amebic Dysentery.**

—H. F. HARRIS discussed the necropsy findings of those dead of amebic dysentery. Emaciation is often extreme, peritonitis may have occurred, adhesions may have occurred between the walls of the intestines or between the latter and the parietal peritoneum. The wall of the gut may be very thin in some places and thick in others, thus presenting a very irregular condition as to thickness. In one-half the cases the ulcers do not extend above the transverse colon. The edges of the ulcers are undermined, and the oblong ulcer has its greatest length transverse to the axis of the bowel. The pathologic process is usually confined to the colon, but may extend to the small intestine and even the appendix. The early changes occurring

in the bowel are not well understood. He detailed the sequence of events as they occur in the puppy, as they occur after receiving an injection material containing the living amebas. He detailed the microscopic findings in and about the ulcer. Tissue damage is always well in advance of the ameba itself, so that if necrosis is caused by the germ it must occasion it by elaborating a toxin. Liver abscesses not infrequently occur; out of 90 cases there were 15 cases of hepatic abscess, 3 of which penetrated the diaphragm. The germ most likely reaches the liver by way of the portal circulation. There are three forms: (1) Very mild form; (2) moderately severe form; and (3) very severe form. The acute symptoms are not unlike other forms of southern diarrhea. Then there seems to be some improvement in 10 to 21 days, when the process often becomes chronic. It runs an irregular course and many recover soon. Bodily exercise, alcohol, etc., appears to increase the symptoms. There is often aching of the back, edema of face and feet, and lenteric dysentery.

**Summer Diarrheas of Infancy.**—J. H. M. KNOX said the study of bacteriology has revolutionized the whole aspect of summer diarrheas. Before this no pathogenic germ was known. He paid tribute to the work of Bassett and Duval in the 42 cases studied by them, in which they succeeded in finding the causal organism. The symptoms are marked by languor, diarrhea, vomiting, rise of temperature, stools fecal at first, then greenish mucus with blood stains. Tenesmus is frequently very marked. Some cases end fatally, while others recover. There is no false membrane in this diarrhea of children as is sometimes found in the adult. The mouth is the portal of entry, and water, vegetables, milk, etc., is the carrying agent.

**Tropical Dysentery.**—C. F. MASON said there are two forms: (1) A chronic, caused by the bacillus of Shiga, discovered in 1897; (2) acute, and caused by *Bacillus dysenteriae*. The latter is the type found in the United States. The inflammation in this type is confined almost entirely to the colon, and the germ may be found months after apparent recovery. It is present in all cases, and a serum has been elaborated which will secure immunity when properly given. The lesion produced consists of a catarrhal inflammation of the mucous membrane of the colon, and at times the lower part of the small intestine. It begins as small ulcers in the mucosa, and these extend into the deeper structures. The germ enters by way of the mouth, by means, doubtless of water for the most part. The incubation period is from two to three days. The onset is sudden with abdominal pain, and diarrhea with bloody mucus. There is fever, a coated tongue, and many stools. The attack usually lasts from 10 to 14 days, but may become chronic. The liver and spleen are not affected.

**Treatment of Uncinariasis.**—T. A. CLAYTON said the treatment resolves itself into three forms, viz., (1) prophylactic; (2) expulsion of the parasite; (3) combating the anemia. He was of opinion that the parasite usually enters by way of the mouth, though as has been shown, may enter through the skin. The water supply, vegetables, dust, unclean hands, etc., are the means of conveying the parasite to the mouth. Once in the alimentary canal it produces many ova, but does not multiply, the ova not reproducing in the intestine of man. It is therefore a self-limited affection, but the parent parasites may live so long (years) in the intestines as to present most serious consequences. Prophylaxis is a very unsettled question. It is known that the ova cannot live without air, and this has led to numerous suggestions for disposing of the excreta of the patients. Fasting for 24 hours, followed by thymol in 15 grain doses every two hours until four doses are taken, and this followed by a purge, is a favorite method of expelling the parasite. This should not be repeated oftener than once a week. The author experimented on a number of dogs to ascertain whether alcohol in combination with the thymol was dangerous. Alarming symptoms were produced by the combination, but this was caused by aspiration of the medicament into the lungs, producing unconsciousness and convulsions in some cases and death in a few. His conclusion was that the alcohol or brandy in itself was not dangerous except from inspiration, for the same could be given in moderate quantities hypodermically without bad effect. General treatment, such as fresh air, plenty of nutritious diet, iron, and the systemic tonics successfully combat the anemia.

**Limitations of Nonsurgical Treatment in Intestinal Obstruction.**—J. R. EASTMAN called attention to the difficulty of differentiating between mechanical and reflex ileus. In functional ileus morphia will give prompt and often permanent relief, but who can say with certainty when it is functional? Intussusception may present symptoms simulating other affections, particularly hepatic colic. The rule should be that all cases of mechanical obstruction demand the attention of the surgeon. Palliative measures seldom avail anything. The introduction per rectum of gas or water to relieve intussusception should be tried only by those with a knowledge of the technic. Such measures may be tried early, but they are not without danger and are seldom successful. Massage is dangerous and useless. The rational treatment is early surgical interference. Peritonitis may simulate and may cause intussusception; operate any way, for none can tell with certainty. Volvulus demands early operation, and any effort to reduce the condition in any other way offers small hope of success. Cysts, myomas, polypus, and neoplasms of various forms may cause intestinal obstruction, and all forms present urgent symptoms

when strangulation of the gut arises. A serious fault to find with the present status of medical practice is that cases of intestinal obstruction with the single exception of hernia are not recognized sufficiently early. When the rule of early operation in all cases of mechanical obstruction is obeyed mortality from this cause, which is now exceedingly high, will be much reduced.

**Weakness and Dilatation of the Heart Due to Chronic Nutritional Diseases.**—G. W. McCASKEY says that weakness and dilatation of the heart due to chronic changes in the myocardium is caused by various types of chronic nutritional diseases, and is of frequent occurrence in such affections. Microscopic changes may not be apparent, or we may observe interstitial myocarditis, or fatty, granular or pigmentary degeneration. We cannot expect a normal and naturally acting heart in a chronically diseased and debilitated body. Perfect metabolism and normal innervation are essential to preserve the heart muscle in its normal histologic condition. Dilatation is caused by overstrain of the cardiac muscle, and the amount of stress which the cardiac muscle can stand is relative, depending entirely upon its condition, this depending in turn upon the general body condition. Slight grades of dilatation occur in all the severer types of anemia, and are common in chronic gastrointestinal disorders. Treatment cannot be specific, but consists in removing the cause and combating by general medication and hygienic measures. The administration of constitutional remedies, improved nutrition, rest, graduated exercise, tonics, and saline carbonated baths, constitute the treatment.

**Typhoid Fever at High Altitudes.**—HALL and COOPER give a review of 600 cases in Colorado, and report a mortality rate of 14.5% after using the various methods of treatment, the tub-bath method being the favorite, and with it the mortality was slightly less. They report the various complications which occurred in their series of cases. Their conclusions are that enteric fever is practically the same in Colorado as elsewhere. Many cases called mountain fever have been found to be typhoid, and typical examples of these have had rose-spots, hemorrhages, exhibited the Widal reaction, and other evidences of a true typhoid, which they doubtless were. Hall formerly thought that typhoid in Colorado was milder than elsewhere, but a further study and investigation have convinced him this first impression was erroneous. Diarrhea appears somewhat less frequent in Colorado than elsewhere. They will continue tubbing in severe cases, avoid antipyretics, will use alcohol for the rapid, feeble pulse, and operate on perforating cases when first recognized. Five cases simulating perforation occurred, and 14 cases of actual perforation occurred.

[To be continued.]

## Section on Surgery and Anatomy.

### FIRST SESSION.

**Chairman's Address.**—JAMES E. MOORE (Minneapolis, Minn.) made a strong plea for exploratory celiotomy in obscure abdominal affections. The moral responsibility of the surgeon is much greater than formerly, and exploratory operations are more frequently indicated now that the importance of the surgical diseases of the stomach, gallbladder and pancreas is generally recognized. Moore believes that the mortality of operation for typhoid perforation need not exceed 25% in competent hands, and may be less if the operation is early. If the patient is in bad condition local anesthesia under cocain may be employed, but this Moore believes is seldom necessary. He has operated in three cases with one death occurring the third day after operation. One cause for high mortality is the neglect of medical men to call in a surgeon early. In future he believes the mortality will be greatly reduced. Exploratory operations are frequently indicated for chronic peritonitis, generally caused by inflammatory diseases of the appendix, gallbladder or pelvic organs. He prefers the right rectus incision for exploration and denounces indiscriminate exploratory operations; on the other hand, to refuse to operate when other means of diagnosis have failed is frequently to sacrifice human life to prejudice.

**Suppression of Urine: Report of Case Enduring Eight Days Relieved by Decapsulation of the Kidneys.**—H. J. WHITACRE (Cincinnati). The case of a woman of 40 is reported who had been in perfect health previously. Her illness began with attempt at criminal abortion, which she tried to bring about first by taking drugs, the exact character of which is not known, and afterward by introduction of a catheter. Following the abortion suppression of urine occurred. During the first 24 hours a few ounces of bloody urine was voided. Intravenous injections of salt solution, 60 ounces, were given every six hours, and the patient was given hot-air baths of 25 minutes' duration without any very decided effect on her general condition. A few drops of urine were obtained by catheterization which contained red and white blood cells but no casts. The condition of suppression lasted about eight days, then after consultation with other physicians, all usual medical measures having failed, it was decided to try the effect of decapsulation of the kidney. A lumbar incision was made over the right kidney; the kidney was found very much reddened and congested, and had a mottled appearance. Exploration was made for stone without anything being found. On incising the capsule of the kidney the cortex bulged as the brain does fre-

quently on incising the dura. The capsule was stripped off and the cortex was found so friable that it was lacerated by the slightest touch. The first 24 hours after operation the patient voided 21 ounces of urine; her condition decidedly improved; the quantity of urine gradually increased until she was passing 60 ounces, and a complete recovery followed. She is now quite well and attending to her usual duties nine weeks after the operation. The cause of the suppression in this case is attributed to the vasomotor constriction of the capillaries from the emenagogs or to reflexes. It was certainly not a symptom of acute nephritis. In such cases of suppression of urine the cause is either obstruction of the ureter or suspended kidney function. Obstruction could be excluded in this case. Medical treatment should be tried in such cases until the symptoms become imperative, then Whitacre believes decapsulation is indicated, for the condition probably arises from compression of kidney substance from venous stasis. Suppression is a condition frequently arising after operations. While it may be a symptom and not a disease, the condition menaces life, and if not treated frequently kills the patient.

**Fat Necrosis of the Kidney.**—J. R. GUTHRIE (Dubuque, Iowa). The case of a young woman aged 32 was reported. Her family and past history were quite negative. On admission to the hospital her condition was negative on examination with the exception of a large mass which could be felt in the region of the right kidney, almost filling the hypochondrium. A lumbar incision was made exposing the kidney. The kidney was seized with forceps and drawn up into the wound, and a considerable quantity of oily liquid resembling iodoform emulsion was evacuated. The kidney substance was found to have almost entirely disappeared. The sac which formed the remnant of the kidney was stitched into the wound and the patient made a perfect recovery. On a search through literature Guthrie has been unable to find any record of a case entirely like this. A somewhat similar case was reported by E. W. Cushing, of Boston; but in his case the oily material seemed to have been formed by disintegration of the fat surrounding the kidney, and it emptied by breaking into the pelvis of the kidney. The opinions of a number of authorities as to the cause of such conditions were reported at some length.

**Surgical Treatment of Nephritis.**—ALEXANDER HUGH FERGUSON (Chicago). In a paper by this title read in 1889 and published March 11 of that year in the *Journal of the American Medical Association*, Ferguson reported the first case of decapsulation of the kidney of which he has any knowledge. About one month later Edebohls, of New York, published his paper on this subject, and apparently entirely overlooked Ferguson's previous paper. In his original communication Ferguson reported two cases of decapsulation of the kidney, with a report of examination of tissue removed from the kidneys by Professor Klebs, which showed interstitial inflammatory changes. Ferguson believes that he is entitled to priority for having first performed this operation with a definite purpose in view, although Reginald Harrison had operated upon three cases, performing nephrotomy in cases of nephritis, with a mistaken diagnosis of stone in the kidney or some other condition. Ferguson's first decapsulation was performed not for nephritis, but for floating kidney, in 1896. His two other cases with definite diagnosis of nephritis were fully reported in 1899. Brief reports were given of several cases which Ferguson has since operated upon with considerable success and with complete symptomatic relief.

**Discussion.**—BEVAN (Chicago), in discussing Whitacre's case, called attention to the paper which he read recently before the Chicago Medical Society reporting several cases of anuria, upon some of which he had operated. In these cases of suppression he believes that nephrotomy is indicated in preference to decapsulation. The operation can be readily performed under cocaine or nitrous oxid gas anesthesia. The operation can be done rapidly, not more than eight minutes being required. It gives free drainage and entirely relieves the congestion, which Bevan believes is the cause of suppression in these cases. JEPSON (Iowa) believes that decapsulation is most likely to do good in hemorrhagic cases, and specially when the hemorrhage is beneath the capsule. He believes that the question is still not definitely settled whether decapsulation is a justifiable operation, and if so, how it is best accomplished. GIBBONS (Scranton, Pa.) mentioned several cases in which he performed decapsulation of the kidney with relief of the symptoms. He believes that Edebohls should be credited with priority for first performing this operation for Bright's disease. GUIERAS (New York) believes that the operation for chronic Bright's disease is still in its infancy. The benefit in these cases has been attributed by some to the increased circulation through adhesions of the kidney to the surrounding structures, but experiments by Johnson, of San Francisco, have shown that there is little, if any, improvement in the circulatory conditions after decapsulation. WINSLOW (Baltimore) reported a case of nephritis in which the symptoms were entirely relieved by decapsulation of the kidney. FERGUSON advocates returning the kidney not to its fatty capsule, but placing it so that it shall come in contact with muscular tissue; fat is not a vascular tissue, and improvement in circulation cannot be expected if the kidney is left in contact with fat. There seems to be no reason why collateral circulation should not be established in adhesions to the kidney in the same way that this occurs in cases of intraabdominal adhesions.

**Indications for Cholecystectomy.**—B. B. DAVIS (Omaha). In his last 28 cases of cholecystostomy pain recurred after operation in 6 cases. This seems to indicate that only about one patient in 5 is permanently relieved by this operation. In 3 cases biliary fistula persisted for many months, and for this reason a second operation was necessary for the removal of the gallbladder. The experience of surgeons in general indicates that symptoms recur in less than 1% of the cases after cholecystectomy, while the proportion is certainly as great as 17% after cholecystostomy; the advantages of cholecystectomy in these cases are: that the healing is more prompt; the source of infection is entirely removed; after trouble from adhesions is avoided; a useless organ, for such the gallbladder as well as the appendix must be considered, is removed, and a constant source of danger from secondary troubles is avoided. The risk of the operation in uncomplicated cases is slightly if any greater than after cholecystostomy; drainage is as easy and recovery is rapid.

**The Call for Exploratory Operations in the Gallbladder Region.**—F. A. DUNSMOOR (Minneapolis). Considering the slight dangers of abdominal incision Dunsmoor believes that exploration for symptoms referred to the upper part of the abdomen should be more frequently resorted to. Trouble in the region of the gallbladder is the most frequent cause of these symptoms, and from clinical symptoms alone gallstones and other pathologic conditions are as often overlooked as found. Several cases were reported in support of this position.

**Discussion.**—MAYO (Rochester, Minn.): In many of the cases mentioned by Dunsmoor the symptoms were such as to indicate that they would be relieved only by operation, and Mayo entirely agrees as to the necessity for exploratory celiotomy in such cases. He also agrees with Davis as to the desirability of removing the gallbladder if this can be safely accomplished. It is not always safe, however, in the case of patients who are very fat or in cases in which degenerative changes are going on in important organs. Personally he does not feel justified in removing the gallbladder in all cases. The cause of death after these operations is usually from cessation of liver function. This is most likely to occur if the gallbladder is removed in cases in which it contains bile and the cystic duct is open. In such cases cholecystostomy is generally sufficient; in any case bile should be drained to the surface. MURPHY (Chicago) believes that the most common cause for return of symptoms after gallbladder operations is from remaining stone or from flexions of the duct. Both of these factors are the result of imperfect operations. It is extremely important to examine very thoroughly for stone and to take great care in the separation of adhesions, which are the most common cause of flexions of the duct. In many cases in which the gallbladder is infected no more than is absolutely necessary should be done. This is usually the simple drainage of the gallbladder. OCHSNER (Chicago): The diagnosis of gastritis is made in many cases of gallstones, from the reason that the pain is located in the region of the stomach. Exploratory operation would show the real cause of the trouble in these cases. With increasing experience nearly all surgeons more frequently perform cholecystectomy. After the abdomen is open in exploratory operation a very careful examination should be made of the common, cystic, and hepatic ducts as well as the gallbladder. Cholecystostomy is much the safer operation in the hands of surgeons of only moderate experience, and Ochsner considers cholecystectomy safer as a secondary than as a primary operation. GIBBONS (Scranton, Pa.) finds that patients can be relieved of their symptoms by cholecystostomy and does not see the necessity of resorting to a more dangerous operation when a safer operation will do. DAVIS, in closing, expressed the belief that all small and contracted gallbladders with obliteration of the cystic duct should be removed. Cholecystectomy is least needed in simple, uncomplicated cases.

#### SECOND SESSION.

**A Contribution to the Surgery of Gastric Ulcer.**—VAN BUREN KNOTT (Sioux City, Iowa) called attention to the importance of adhesions resulting from gastric ulcer. In about 80% of these cases the adhesions are to the posterior wall of the stomach near the pylorus. Broad bands are frequently formed by stretching of these adhesions. The symptoms caused are usually from interference with drainage because of stenosis of the pylorus. Symptoms may be entirely lacking or may be so severe as to endanger life from malnutrition. The diagnosis is frequently impossible without exploratory operation. Pain in the right hypochondrium and constant vomiting are among the more important symptoms. Knott calls attention to the importance of placing the patient in the knee-chest position in the diagnosis of these cases. This causes tugging on posterior adhesions if they are present. With the symptoms of pain and vomiting there is usually a history of gastric ulcer, possibly of local peritonitis. There is sometimes an area of resistance and possibly an inflammatory mass may be felt. By inflating the stomach and outlining it by percussion its form is frequently found to be irregular. The treatment advocated was exploratory operation in doubtful cases and freeing of adhesions unless too extensive. Several cases of this kind in which operation was successfully performed were reported.

**Surgical Conception of Pyloric Obstruction.**—H. D. NILES (Salt Lake City) believes that 90% of gastric troubles

are caused either by ulcer, late adhesions following it or by carcinoma. These conditions are not removable by medical measures. Operation in such cases is not attended with the dangers which were formerly supposed. The operation for gastric carcinoma he believes to be favorable in early cases, for carcinoma of the stomach is slower to involve glands than carcinoma of the uterus or breast. Gastrectomy is seldom indicated in these cases. Carcinoma does not involve the region of the fundus until very late. It often has its starting point in cicatricial tissue of healing ulcers. Niles believes that he has been able to trace the origin of several cases to this cause. In all doubtful cases of stomach trouble with symptoms of pyloric obstruction, exploratory celiotomy was indicated. Many lives are yearly sacrificed from neglect of early exploratory operation. The symptoms in such cases are usually such as demand surgical treatment. The surgeon in dealing with such cases would best limit himself to a few recognized operations in which he has gained some experience. It is important not to undertake to do too much, nor to select too long operations. The duodenum is too short to attach to the stomach after excision of the pylorus in most cases and the upper part of the jejunum should be chosen for anastomosis. Niles generally employs Murphy's button but in certain cases suture is preferable. It is very important that general practitioners of medicine should be impressed with the necessity for early diagnosis in these cases and this is frequently only possible by exploratory celiotomy. With early operation the mortality should be much reduced.

**The Surgery of the Stomach.**—A. J. OCHSNER (Chicago) said that with wider experience surgeons in general are impressed with the importance of surgical intervention in an increasing number of cases. The diagnosis in these cases is often difficult without exploratory operation. Our operative technic has been so much perfected of late that such exploratory operations entail little danger and their value is established when so many permanent cures can be obtained. Ochsner compared the palliative operations of gastroenterostomy, etc., to the interval operation in appendicitis. If such an interval operation is performed in cases of gastric ulcer more radical operation for gastric carcinoma is frequently unnecessary. In gastroenterostomy if the opening be made in the lowest part of the stomach, as suggested by Mayo, pernicious vomiting is prevented. It is a matter of indifference whether a mechanical means or suture is employed in the operation. Ochsner has made use of McGraw's elastic ligature method in nine cases with favorable results. In performing gastroenterostomy it is better to close the pylorus if it is still open. Otherwise the gastroenterostomy opening is likely to contract. The operations for enlarging the pylorus have been mostly unsuccessful. Finney's pyloroplasty operation promises well, but its value is not yet entirely established. Ochsner has used this operation in one case with a good result. Shortening the gastrohepatic ligament to aid in drainage of the stomach has not given him good results. Complicated operations in the treatment of carcinoma are never necessary. In cases of benign stenosis gastroenterostomy gives the most favorable results if just enough stomach tissue is included in the stitches, if the anastomosis is made at the lowest point of the stomach and without tension. Ochsner has performed 79 operations on the stomach, including 9 pylorotomies, with 3 deaths. In one case death was accidental and not the result of the operation. In the second case the patient was in a weakened condition and gastroenterostomy would have been preferable. In the third case death was due to loosening of the Murphy button. As a preparation for operation he advises gastric lavage. After the operation the patient should be fed by the rectum for two weeks. Patients suffering from nonmalignant affections are greatly benefited by operation in every case.

**Discussion.**—ANDREWS (Chicago) believes that practically all the cases of disturbance of gastric digestion belong to the surgeon. Most of them are the immediate or remote results of gastric ulcer. There is no more reason why that gastric ulcers should not be treated surgically than an ulcer of the leg or any other part of the body. The presence of gastric ulcer, he believes, indicates operation in every case. Operation is also indicated in cases of chronic indigestion. The anemic, hysteric dyspeptics are nearly all cured by efficient drainage of the stomach. Gastric disturbances are usually not a series of disorders but a number of different stages of gastric ulcer. He agrees with Niles that most of the cases of carcinoma have their origin in an ulcer of the stomach. Other conditions are caused by adhesions or inflammatory thickening from ulcer. MAYO (Rochester, Minn.) believes that most of the cases of gastric trouble arise from gastric ulcer and its complications. The ulcer is most commonly situated in the region of the pylorus, and is frequently so small that it is impossible to find it. Operations on the ulcer itself are hence impossible, and the rational procedure is to drain the stomach at its lowest point. In carcinoma of the stomach the glands which are affected are situated in the gastrohepatic omentum, and hence in these cases all of the lesser curvature and the omentum should be removed. RODMAN (Philadelphia) believes that the time will soon come when all gastric ulcers will be treated surgically, before complications arise. The greater number of carcinomas of the stomach arise in ulcers of the stomach. In operating Rodman prefers v. Hacker's method of posterior gastroenterostomy, but believes whatever method is used pernicious vomiting some-

times follows. CORDIER (Kansas City, Mo.) says the pathologic condition in these cases frequently precludes excision of the gastric ulcer, and gastroenterostomy is the operation of choice. The quickest operation possible should be performed in these cases. He prefers to use the Murphy button and the anterior operation. The photograph of a specimen was exhibited in which gastroenterostomy had been performed seven years previously, the patient dying from pneumonia. BEVAN (Chicago) called attention to the fact that papers on appendicitis, gallbladder surgery and typhoid perforation, subjects belonging properly to the Surgical Section, were being read in the Section on Gynecology and Obstetrics, and asked that a committee be appointed to consult with the officers of that section and to request them to limit their discussions in the future to subjects connected with obstetrics and diseases of women. NILES, in closing, called attention to the fact that gastroenterostomy is helpful in treating all cases of gastric ulcer, both those which are evident at the time of operation and those so small that they cannot be seen. Excision is impossible in these cases.

**The Single Cuff Method of Circular Enterorrhaphy: A New Method.**—O. BEVERLY CAMPBELL (St. Joseph, Mo.), by means of drawings, demonstrated a method of intestinal anastomosis, the important points of which were in turning back a cuff of the serosa and muscular coat of the intestine, excising the part covered by this cuff, suturing the ends of the intestine, folding the cuff over the sutured area and stitching in place. By considerable experimental work he has found this method easy, rapid, safe, and followed by no postoperative complications. He has been able to perform the operation in from five to eight minutes. He reported the pathologic findings in two cases in which he had operated by this method, one an adenocarcinoma of the sigmoid flexure of the colon, the second a case of tuberculous peritonitis with intestinal perforation.

**Intestinal Resection, with Report of 15 Cases, 9 with the Button and 6 with Suture.**—JAMES H. DUNN (Minneapolis) is of opinion that in doing intestinal anastomosis the operator should be master of two methods—a good mechanical method and a good suture method. The Murphy button Dunn finds on the whole the most satisfactory of the mechanical methods of anastomosis, but anastomosis by the button is not applicable to all cases. For anastomosis of the large intestine the button is not well suited, because of the thickness of the wall of the intestine, the solid contents of the intestine which tend to plug the opening in the button, the poor peristalsis, the poor circulation in the large intestine, and the thick epiplocae, which are often a hindrance in performing the operation. The suture methods are applicable to all cases, though Dunn prefers the button in anastomosis of the small intestine, because of the rapidity in operating. He considers Connell's method of anastomosis the best of the suture methods. End-to-end suture he believes is preferable to the lateral methods of anastomosis, as we obtain nearer the normal condition of the intestine by this method of suture. He employs the continuous Connell suture and finds it rapid and safe. A brief report was given of the 15 cases in which Dunn had found intestinal anastomosis necessary.

**Discussion.**—JONAS (Omaha) agreed with Dunn as to the use of the Murphy button and the Connell suture, being the preferable methods of intestinal anastomosis. WALKER (Detroit) formerly used the Murphy button almost exclusively. He has performed anastomosis by Connell's method in six cases with three deaths. He has used McGraw's elastic ligature method in 17 cases, the immediate results being successful in all. He finds the operation rapid, it precludes sepsis, it is simple and he has found no immediate trouble with the method. MURPHY (Chicago) believes that the most common cause of failure in intestinal anastomosis is that the condition of impaired vitality or bad condition of the proximal end of the intestine is not recognized and excision is not carried far enough into good intestine. FERGUSON (Chicago) emphasized the importance of experimental suture on animals for those who desire to perform intestinal anastomosis. Without such experience no operator is justified in undertaking the operation.

[To be continued.]

## Section on Obstetrics and Diseases of Women.

### FIRST SESSION.

**Chairman's Address: The Trend of Gynecological Work Today.**—A. PALMER DUDLEY: There is shown a marked tendency toward conservatism in operative work. A quarter of a century ago conservative surgery upon the uterine appendages was unknown. To the students of the star actors of a quarter of a century ago must be given the credit of making the effort to rescue womankind from enthusiastic aspirants for surgical honors who could only see radical removal of all in their path as the road to success. How many thousands of suffering, misguided women have offered up their pelvic organs as a sacrifice only to find that they had changed one condition of suffering for another equally as disagreeable. Yet these sacrifices are resulting in ultimate good. During this period the use of electricity as a method of treatment was of short duration. Conservatism of whatever nature was for a time lost sight of. It was not until the nerve specialists called

attention to the fact that we were sowing the wind and reaping the whirlwind; that many of us realized what we were doing for these poor women—prematurely endowing them with hot flashes, the rapid taking on of fat, the loss of their generative function, and regrets for their unsexing. Dr. Dudley tries to save only what he thinks will perform its function normally. In all, he has operated upon 269 cases in this way and without a death until the last week of 1902, when he lost two from septic peritonitis, introduced by the hands of a septic house surgeon. In doing conservative surgery upon the tubes and ovaries the first thing to do is to put the inside of the uterus into condition to become healthy. Plastic work may also be necessary. In deciding what to do the age, social position, domestic relations, the after-effects of radical work, and the dangers to which the patient is subjected should be determining factors. Dr. Dudley does the plastic work first. He removes small fibroids from the uterus, in one case as many as 16, and leaves the appendages. He opens a hydrosalpinx, washes out the tube and drops it back. If a tube is occluded at the uterine end (not as the result of sepsis from abortion or gonorrhoea) he does not hesitate to open it and wash it out. He leaves whatever healthy tissue may be found in a cystic ovary. A dermoid cyst requires, however, the most radical treatment. If requested to do so he would open the abdomen to determine the cause of sterility. After resecting an ovary he closes the wound with fine silk, ordinary floss silk No. 00, using a very fine cambric needle. The surgeon who now removes organs that could possibly be saved is open to the criticism of not being a conscientious man. Of 269 patients from whom he has removed portions of tubes and ovaries, coupled with various other procedures, Dr. Dudley has so far been able to trace 43 pregnancies. Many of the 269 cases have been lost sight of. In a case of salpingitis the fibrinated extremity is closed, dilated, and club shaped. The tip should be opened with scissors, the contents evacuated, the tube washed out with an antiseptic solution. The tube should be gently probed and if the probe passes into the uterus we will know that the tube is patent. There is then no excuse for removing the tube, but with fine silk, the probe still in place, you suture all around the tip of the tube, sewing the mucous membrane to the peritoneum. Hematosalpinx and hydrosalpinx are similarly treated. In pyosalpinx, if the pus is septic, it is well to precede the opening of the tube by its injection with 1:1,000 mercuric chlorid solution, its withdrawal and repeated injection. The tube may be afterward treated as suggested above. Ventrosuspension is often essential in conservative surgery upon the tubes. As soon as the patient comes out of the ether she should have a saline. The patient should be moved from one side to the other to prevent adhesions. The bowels should move at the end of 24 hours, the intestinal canal being the best drainage tube. Do not give morphia. No food should be allowed until after the bowels have moved. Then begin with milk and vichy. Keep the patient in bed 14 to 16 days. If ventrosuspension has been done the stitches should remain in for 21 days. During and for two days subsequent to the first menstruation the patient should be kept in bed. The results of many operators, the material secured by correspondence, were given. In 860 operations reported but 9 patients died. In 435 cases in which complete results are given the operation was successful in 396 and unsuccessful in 39 (10% failures; 1% mortality). There is but a slight preponderance of tubal and ovarian disease on the left side. The totals comprise 754 conservative and 522 radical operations upon the ovaries. The excess of conservative intervention is bound to increase in the future. As to tubal operations, there were 265 extirpations and 179 partial operations. As regards results, the general outcome of the operation and the preservation of sex must be considered. The primary mortality is quite insignificant, and as regards ultimate success, the tables show not over 10% of failures. There is positive proof that at least 10% of the patients became pregnant, and there is every reason to believe that this does not represent the whole number.

#### Appendicitis from the Standpoint of the Gynecologist.

—H. P. NEWMAN (Chicago) said that appendicitis is not usually difficult to diagnose. Even the laity are alert in recognizing its premonitory symptoms. I report the case of a young girl of 16, nervous, anemic who had attacks of pain in the lower abdomen associated with the menstrual period. Her father, a physician, brought her to me for treatment of some gynecologic condition from which he believed her to be suffering. Appendicitis was diagnosed. The patient was taken to a surgeon, who diagnosed and operated for pelvic disease. The condition found was catarrhal appendicitis, the appendix being slightly attached at its distal end to the right ovary. The result of operation was complete relief. This is one of many cases in which the diagnosis is obscure. Disease of the appendix as well as of other abdominal viscera may produce functional disturbance of the female pelvic organs, or may give rise to disease in these parts. The abdomen should be examined in all obscure pelvic troubles, and in opening the abdomen for pelvic disease the appendix should always be examined. If catarrhal, adherent or containing concretions it should be removed. It is not enough to break up adhesions. Any localized peritonitis, particularly appendicular, may be an active factor in the production of intestinal obstruction. Intraabdominal strangulated hernia has occurred after the lapse of years as a direct result of early appendicitis. In operating for intestinal obstruction in the female look for adhesions to the pelvic as well as to the

abdominal viscera. In removing the appendix the invaginating operation should be done or some equally effective method used for protection against adhesions.

*Discussion.*—E. W. REYNOLDS (Boston) said there are many obscure cases in which there are pain and tenderness upon the right side and in which nothing can be made out by physical examination and in which the symptomatology alone must be depended upon for diagnosis. A group of symptoms, including right-sided pain and tenderness, indigestion, flatulency, and headache, point strongly to appendicitis. In abdominal operation the surgeon should remove every abnormal appendix; but we are apt to be too radical, and the subject is at present one for study, not for decision. The ilio-lumbar ligament should be studied in this connection. B. M. RICKETS (Cincinnati) thinks it timely to consider the subject of appendicitis complicating disease of the right tube and ovary, and to say that the diagnosis can always be made by putting it strongly, and it is putting it broadly to say that the appendix should always be removed when the abdomen is opened. It is, however, a step in the right direction. WATHEN (Louisville) thinks that appendicitis is frequently related to disease of the ovaries and tubes. He had lately, in eight cases of pelvic inflammation, found the appendix adherent and involved and had removed it. MICHALD (New Orleans) expressed his difficulty in making a differential diagnosis between right salpingitis and appendicitis. It is important to differentiate, for appendicitis endangers the patient's life. He offered these points for consideration. In chronic appendicitis the greatest intensity of pain is elicited by pressure upon the abdominal walls in salpingitis by pressure in the vagina. The seat of greatest tumefaction is likewise determined. MANTON (Detroit) thinks that connections between the appendix and right-sided disease can usually be made out by a delicate tactus eruditus. For several years he has made a habit of having appendices removed, examined microscopically, and has usually found them diseased even when not appearing so macroscopically. CARSTENS (Detroit) believes that in acute salpingitis the uterus is fixed. In appendicitis it is not fixed. In the former there is no rigidity or tenderness over McBurney's point. If the patient complains of pain over McBurney's point and there is rigidity in that area the appendix is the offending organ. BOVÉE (Washington) believes Dr. Carstens to be too radical in asserting that pain and rigidity at McBurney's point are positive signs of appendicitis. They may lead to error in diagnosis. Though he usually, in laparotomy, removes the appendix, there are cases, such as ruptured ectopic gestation, when time cannot be given to examination of the appendix. NEWMAN, in closing the discussion, asserted that one purpose in the presentation of the subject was to make operators more alert in diagnosis. The appendix makes ravages not to be passed by lightly. Appendices should not be left if pathology is present. The presence of appendicitis in infected ovarian cysts he believes common, the infection occurring from continuity.

*Gastric Ulcer: Some Clinical, Pathologic, and Surgical Phases.*—A. N. CORDIER (Kansas City, Mo.) said that on the posterior wall of the lesser curvature near the pylorus is the favorite site of ulcer. In a large series of fatal chronic cases 20% resulted from hemorrhage. The death-rate from hemorrhage in acute cases is 50%. In cirrhosis of the liver ulcers are of frequent occurrence, and are especially prone to bleed. Inflammatory adhesions and cicatrices prevent the normal functions of the stomach, fermentation of food results, and dilation is inevitable. In deep ulceration, nature often so agglutinates adjacent organs as to prevent, in perforation, the spilling of the stomach contents into the peritoneal cavity, otherwise death results quickly. Anterior perforations of the stomach are the most fatal ones, because of the lack of inflammatory adhesions at this area. The ingestion of food usually produces pain. During menstruation the pain is increased. Vomiting, sometimes present, is not so frequent as is generally supposed, and when it occurs is not usually accompanied by nausea. The vomitus usually contains an excess of hydrochloric acid. Vomiting is a dangerous complication, leading to starvation, hemorrhage, and rupture. About 10% of all gastric cancers have their origin, according to Lebert, in a benign ulcer. Accepting this statement as true, we have a strong argument in favor of any procedure for the early cure of all benign ulcers of the stomach. Eight years ago Cordier laid stress upon the importance of making the opening in the stomach in a position that would act as a drainage opening. The medicinal management of 50% of these cases is quite satisfactory, but there are a class of cases the medicinal management of which is a total failure. I confine my remarks to the management of the class where a fair line of medicinal management has failed. The prime object to be sought in the healing of a gastric ulcer is to maintain the health standard by proper nutrition, removing all sources of irritation possible, giving the parts rest. Certain rebellious cases become strictly surgical ones. A gastroenterostomy meets most of the indications in such cases. By selecting a dependent portion of the stomach for anastomosis the organ will empty itself by gravity both of food and the strongly acid secretions. If efforts at vomiting occur the stomach empties itself into the bowel. The motility of the organ is limited by this procedure and the ulcer given rest. The putrefaction of retained food and distention of the stomach are prevented, thus permitting contraction of the edge of the ulcer.

*Discussion.*—CARSTENS (Detroit) believes in gastroenterostomy for obstruction for causes other than gastric ulcer. CLARK (Philadelphia) raised the two questions, namely, how long a case should continue under medical care, and how, in operating, the ulcer could best be found? Clark leaves the case to the judgment of a skilled medical man. To find the ulcer the speaker believes in an exploratory gastrotomy, by transverse incision between the two curvatures. Excision of the ulcer may be done through the wound. CORDIER, in closing, advised against operation during hemorrhage. In grave cases rapid operation is essential; therefore the advantage of using the Murphy button, opening being made in the bottom of the stomach for drainage, thus avoiding fermentation and vomiting.

[To be continued.]

## Section on Sanitary Science and Hygiene.

### FIRST SESSION.

#### Address of Chairman.—H. W. BRACKEN (Minneapolis):

A question has been made whether the section should have recognition by the American Medical Association? This can only be answered in the affirmative. The speaker defined the functions of the section. He believes that discussions on preventive medicine and special diseases should be conducted by the section on "Practice of Medicine." The medical men of this section should be affiliated with the medical section. He urged the necessity of purely sanitary science, and the necessity that the chairman keep in touch with the medical section. The papers read before the medical section should not conflict with those of the Section on Sanitary Science.

**Cooperation Methods for Improving the Usefulness of Statistical Classification of Causes of Death.**—L. C. WILBUR (Lansing, Mich.). The speaker defined the necessity of classification, stating that the present classifications were too narrow. He thought probably no ideal classification was possible, and defined special limitations, showing the desirability of uniformity. He urges the general adoption of international classification as the first step toward improvement. There are many unsettled points, especially as to deaths, for which two or more causes are assigned. The lack of uniform classification affects mortality statistics. The nomenclature used by physicians in reporting deaths is too vague, and it is often difficult to decide under which disease to check death in recording same when there is a complication of diseases. To correct this he suggests getting rating for each disease from the profession, striking an average and publishing pamphlets accordingly, this pamphlet to be kept in every registration office. The help of every physician and user of vital statistics is necessary for this reform. Dr. Wilbur does not think it should be developed to such an extent as to be a mere mechanical process in recording statistics, but should be presided over by a medical man. He urged cooperation of special committees of the Conference of the Boards of Health, of the American Public Health Association, of the United States Census Bureau, and of the Marine-Hospital and Public Health Service. He also advocated the appointment of a committee from the American Medical Association to cooperate also for uniformity in classification. The entire medical profession should be urged to express its opinion, as sanitarians cannot accomplish the desired effect alone. Improvement in precision of statement by the physician who makes out original certificate is necessary for more exactness.

*Discussion.*—J. S. FULTON (Baltimore) said the difficulty is that sanitarians do not like to go to work on vital statistics. He compares present system to the system which would exist if the entire United States post office system were to be disturbed. Physicians lay too much stress on value of vital statistics and depend too much upon them. Present classification is merely mechanical. Thus we lose many causes of death from the fact that there is no space to enter disease. A draft of the international classification should be sent around to specialists for opinions as to rating of each title. Fulton does not think the international classification is ideal. It is a question if it can be made available for clerks. In 10 years statistics will be improved by adoption of international classification. WILBUR: By looking in pamphlet, clerk can find exact rating of disease and can enter it accordingly. SWARTS (Providence) thinks clerks could not be sure of rating, and on second reading would be apt to change rating. He is not sure if plan will be beneficial, but can tell in 10 years.

*Resolutions* were unanimously adopted by the section to be referred to House of Delegates urging the appointment of a permanent committee of five from the American Medical Association to cooperate with a like committee from the American Public Health Association and from the Marine-Hospital Service to help the Census Office in bringing about more uniformity in registration of deaths. Resolutions were also adopted congratulating Congress upon its activity in the matter.

**Relation of Physicians to Correct Registration of Vital Statistics.**—W. A. KING (Washington, D. C.) considers this subject especially interesting to this section, as the members are responsible for reports. He advises that data be collected according to definite system, requiring registration of each death previous to interment. At present this must be accomplished by uniform passage of laws by cities and coun-

ties. Registration should be complete and accurate. Success depends more upon hard and persistent work than upon sentiment. Any improvement in accuracy of recording statistics of causes of death can be accomplished only by well organized movement. After giving an outline of the work of the Census Office he stated that the Census Office proposes to furnish every practising physician with a copy of statistical tables published by the Bureau. He advised medical schools to adopt instruction in vital statistics, and proposed enlistment of lay people in encouraging the Census Bureau. He gave a brief outline of Circular No. 71, published by Census Office, containing a plan to be adopted in registering deaths, also a brief outline of international classification with remarks thereon, copies of which are being distributed by the Bureau. Dr. Wilbur has done much toward adoption of uniform plan. The general adoption of the classification (international) will do much toward bringing about uniformity. All persons using this are urged to file criticisms. The test is to be in 1910. Census Bureau requested Congress to adopt resolutions leading to uniformity in death statistics. Following this a circular was sent to each Governor of a State, to each society, etc., urging good registration by prohibiting burial until registration; also uniform slips for death certificates fixing responsibility upon local registrar. Criticisms are asked for, and replies so far indicate that the majority of the Governors are in favor of pressing law. Societies, he thinks, should urge along this line, and each member should take upon himself the duty. The value of vital statistics depends solely upon the lucidity and uniformity with which physicians report. The value of statistics depends upon accuracy. So far there has been much ignorance of what is wanted. Bureau sent out circulars explaining what physicians should do. It is not to be expected that causes of death can always be known. Complete returns, of course, should be regarded as essential, for legal reasons. The physician also should record experiences in individual cases systematically. In this respect registration becomes only a step in progress. Circular No. 303 gives digest of previous circulars and instructions to medical colleges. The paper closed by proposing to send out circulars to educate the profession in this line. The adoption of the international classification with manual or pamphlet is deemed essential to uniformity in vital statistics. It is the desire of the Census Bureau that the annual reports should be of great benefit and should be made as accurate as possible. The annual report is now in progress. Census reports have been generally distributed through members of Congress. In this system persons could not get them who wanted them, and those who did not want them did so. Circulars were sent to all registration officers notifying them that they could get them, and such was the demand that the third edition is now in process of publication. The speaker hopes that the American Medical Association will urge the adoption of uniformity.

*Discussion.*—EGBERT (Philadelphia) said he had notified all physicians to be uniform, and had accepted the suggestions promoted by Dr. King. The great difficulty will be in rural districts. Only 14% of rural districts are registered, and these mostly in New England. Philadelphia has an average of 450 deaths weekly, and should not have trouble in securing uniformity. In Philadelphia the births are ascertained by the city, and it should be easy to educate along the lines proposed. He does not think that the average physician appreciates the importance of this matter. The Census reports are the best method of impressing this. A. WILLIAMS (Edinburgh) thinks it will be hard to get good statistics from Texas, as the Legislature is not educated along that line. In that State there are no good laws regulating the practice of medicine even. WILBUR: In regard to country districts, in Middleton they have registration offices in all districts, and report each month, never later than two months. If any items are omitted they make corrections and send circulars to the registration clerk to see the undertaker and report the following month; and if he does not do so 25 cents is deducted from the registration fee. They also urge him not to accept incomplete reports. Thus they are being educated rapidly, but the great fault is that incumbents of the office change too often. Sending of pamphlets to physicians is most important. Registrars are apt to change, but should have, moreover, both physicians and registrar to follow up reports. Cost of each certificate of death 25 cents, and this the only fee. He exempts cities of over 10,000 in population with salaried employes. J. N. HURTY (Indianapolis) has followed the system of Michigan in following up each report which is lacking. He finds the great difficulty is to find the real cause of death. For a short while he allowed physicians to enter cause as "unknown" when uncertain, but found that almost all certificates came in as unknown, and had to abolish the rule. He cited a case of gross error on the part of a prominent physician in a certificate of death, and spoke of the frequency of such errors. Teachers of hygiene should impress the importance of vital statistics. He also follows up reports which are in error. He does not think the clause in Dr. King's plan of registration previous to burial as especially hard on inhabitants of rural districts, and does not think it can be carried out. It should be done as in Indiana, where if such happens the coroner disinters the body and holds the undertaker responsible. J. S. FULTON (Baltimore) believes what is wanted is due appreciation on the part of State and city of the importance of vital statistics. Allegheny and Pittsburg are the sixth city in the United States in deaths from typhoid. This comes from rural districts.

Therefore, the community itself should be made to appreciate what great importance there is in rural registration. No registration is good unless it includes registration of entire State.

[To be continued.]

### Section on Diseases of Children.

#### FIRST SESSION.

**Address of the Chairman: The Development and Care of Children.**—JOHN C. COOK (Chicago) pointed out the difference between the heart, the lungs, and the nervous system in children and adults, and the need for conserving the energy of the child during the period of development. He then discussed the child labor question at some length, pointing out the more glaring defects of existing State laws. It was not the labor but the environment which during the period of development injuriously affected the character. The least that the medical profession should do in the premises was to see that the children who must work be supplied with sufficient fresh air and the surroundings are sanitary. The speaker earnestly recommended that each State have a commission of five, at least two of whom should be physicians, and that this commission should control all matters of education and labor. This commission should be appointed by the supreme judges of the State and should, in turn, nominate inspectors, thus forever removing the question of child labor from petty politics and contract labor.

**Anatomic and Physiologic Correspondence of Child and Adult.**—WILLIAM T. ECKLEY (Chicago), in reading this paper, curtailed it somewhat because part of it traversed much the same ground as had been covered in the address of the chairman. He said that the child possessed mental and physical qualities of heredity only, while the adult possessed the same qualities modified by the activity of the body and mind. Continuous stimulation tended to produce exhaustion and should be avoided. From this the author argued that adult doses in comparison with doses suitable for a child represented not increased vigor but the wane of receptivity. Idiosyncrasy was the survival in the adult of the normal susceptibility of stimulation in the child, and this raised the question as to whether the physician was justified in beginning treatment with adult doses of powerful drugs. The author's answer to this question was in the negative and was based upon the belief that idiosyncratic rights should be respected.

**Is the Study of Pediatrics Worth the Attention It Gets, and Does It Get the Attention It Deserves?**—C. F. WAHRER (Fort Madison, Iowa) said there were few places outside of metropolitan cities which could afford full scope to the pediatrician, and hence the diseases of children should receive more study from the profession at large, the more so as about one-half of general practice was made up of the diseases of children and adolescents. It was a good field for the young practitioner, as it served as an introduction to family practice.

**Discussion.**—W. F. BOGESS (Louisville, Ky.) emphasized the fact that the diseases of children constituted an individual study. Teachers should impress upon their students the most optimistic views concerning the management of the diseases of childhood, because it was a not uncommon experience in this field that seemingly desperate cases could be guided to a successful issue.

**Acute Suppurative Cervical Adenitis of Infancy.**—THOMAS S. SOUTHWORTH (New York) took the ground that this was an affection peculiar to infancy, and that it was the result of the absorption through the lymphatics of infectious matter from the nasopharynx. The child's head was usually thrown over toward the opposite shoulder, the glandular mass was tender and there were fever and malaise. In making the differential diagnosis, it should be remembered that tuberculous adenitis rarely occurred before the fourth year, and was essentially a chronic affection. Attention was directed to the frequency with which suppuration occurred in these cases of acute cervical adenitis under the usual treatment. The general surgical rule that free exit should be given for all pus accumulations found a notable exception here, for incision should be delayed until pointing had occurred, and then the opening made should not be more than a quarter of an inch in length. The evacuation of the pus should be favored by gentle pressure, and then a drainage-tube measuring  $\frac{3}{16}$  of an inch in diameter and  $1\frac{1}{2}$  inches in length should be inserted. This tube should be rapidly shortened so that it could be wholly removed after three or four days. This method secured rapid healing and the best cosmetic results. He had obtained only negative results from attempts at aborting the adenitis by the use of such remedies as iodine and ichthyol. His own practice now was to give tablets containing small doses of aconite, belladonna and camphor, and in addition one or two grains of potassium chlorate at intervals of two or three hours. This last remedy was almost a specific in the pharyngeal inflammations of childhood. The most important part of the treatment was the cleansing of the nose and nasopharynx by means of Dobell's or Seiler's solution poured into the nose with a teaspoon every three hours. This abortive treatment had proved singularly effective in his hands.

**Discussion.**—ALFRED C. COTTON (Chicago) said that in the families in which he had established the use of the nasal toilet there had not been in the past five years one case of suppurative

cervical adenitis. CHARLES G. KERLEY (New York) agreed with the reader of the paper that only a small incision was necessary, and emphasized the necessity for using a drainage-tube if one would avoid rapid closure of the wound and a repetition of the incision. There was a more distinct localization of the process in simple acute cervical adenitis than in the tuberculous form. He knew of no better internal remedy in these cases than potassium chlorate. Nasal cleansing was certainly useful, but the danger of inflaming the eustachian tube and middle-ear was great. He preferred the simple installation into the nose of albolene suitably medicated. R. B. GILBERT (Louisville, Ky.) spoke of cervical adenitis arising from injury to the scalp and of the value of full and frequently repeated doses of iodid of potassium as an abortive measure. C. F. WAHRER (Fort Madison, Iowa) referred to the mechanical injury likely to be done to the middle-ear by the pressure exerted by the gas evolved from a strong solution of hydrogen dioxide. JAMES G. MASTIN (Chicago) also spoke in favor of the internal use of potassium chlorate, but objected to cleansing the nose by any process which allowed of the use of force. He had found normal salt solution superior to albolene or other oily preparations. LEAVELL (Louisville) agreed with the last speaker as to the superiority of normal salt solution. SOUTHWORTH, in closing the discussion, said that he had been pleased to learn of the general unanimity of opinion in favor of the internal use of chlorate of potash in these cases. He had always employed it cautiously and with some anxiety concerning its possible beneficial influence on the kidneys. He had found potassium iodid chiefly of service in those cases which were either syphilitic or presented a persistent induration.

[To be continued.]

### Section on Nervous and Mental Diseases.

#### FIRST SESSION.

**Neurologic Progress and Prospects.**—F. W. LANGDON (Cincinnati), chairman, stated that during the past year the progress of neurologic medicine had been satisfactory, though not marked by brilliancy of achievement. No supreme discovery or demonstration approaching in importance that of the neuron had been announced. Yet a steady advance had been kept up along the "firing line," and the skirmishers, represented by the workers in research laboratories, had penetrated farther than ever into the territory of the hitherto unknown with noticeable advantage to the position and strength of the "main army."

**Trend of Modern Psychiatry and Its Relation to General Medicine.**—JOHN PUNTON (Kansas City) stated that prior to the address of Dr. S. Weir Mitchell, of Philadelphia, made some years ago, in which he severely criticised the prevailing methods of the officials of insane asylums as well as the management and treatment of the insane, little was actually being done of a truly scientific nature (excepting in a few noteworthy instances) by those who had charge of the various State insane hospitals to enlighten the general medical profession concerning the true nature and character of insanity. Dr. Mitchell's bold and fearless address, however, had the desired effect of arousing the alienist from his lethargic slumber to a condition of extreme zeal and scientific activity. The amalgamation of the American Psychological Association with the Congress of Physicians and Surgeons was a step in advance and illustrated the trend of modern psychiatry. Psychiatry had as yet a great work before it as well as a rich field for conquest in exposing the various fads and frauds of the day and substituting in their stead scientific truths as revealed in the practical observation and experience of those who are working in this field of neurology. He also called attention to the advantage of admitting certain cases of acute insanity into special wards of the general hospital.

**Discussion.**—F. SAVARY PEARCE (Philadelphia) was in accord with the suggestion made by Dr. Punton that certain selected cases of acute insanity should be sent to the general hospital instead of the insane asylum, but for that purpose a special ward should be provided. In some cases of acute insanity, the patient's family were the very ones who insisted upon immediate removal to an asylum. The public must be educated up to the view that acute insanity was not infrequently a curable disease. D. W. BROWER (Chicago) said he was an earnest advocate of the establishment of psychopathic wards in general hospitals, but this was not always attainable. The establishment and maintenance of such a ward in a general hospital was a very expensive matter. Even under the most favorable circumstances, only selected cases of acute insanity could be thus treated. R. H. COOK (Oxford, Ohio) thought it would be a mistake to set aside a certain ward in a general hospital for insanity cases. If the insane hospital was a proper place for the treatment of cases of chronic insanity, it was also a proper place for the care of the acute cases. Undoubtedly in the newer insane asylums better provision would be made for the care of the acutely insane. J. H. MCBRIDE (Los Angeles, Cal.) said that in regard to the curability of insanity, his experience could be essentially summarized in the statement of a certain French alienist, who said that of 10 insane patients 5 would recover from the first attack and 5 would not recover. Of the 5 who recovered, 2 certainly and probably 3 would relapse. The other 2 (or possibly

3) would remain well. This gave a probable recovery rate of 20% or 30%. RICHARD DEWEY (Wauwatosa, Wis.) said insanity was so complex a condition that it was difficult to draw definite lines or make sweeping assertions. Many persons were insane, in the ordinary sense of the term, who could be treated advantageously in a general hospital, but there were other cases for whom that method was entirely inadmissible. Many patients were noisy or had suicidal tendencies, and for such special provision was necessary. Another point was that insane patients required a great deal of freedom out of doors, and hospitals in which they are taken care of should be built with that object in view. ALBERT E. STERNE (Indianapolis) said that no alienist could foresee, in any given case of insanity, even of the mildest type, what the duration of the psychosis would be. Not infrequently the seemingly mild cases, which we would like to send to the general hospital, were the very ones that grew steadily worse, and sometimes took weeks, months, and even years to recover. No general hospital, run on general lines, could possibly take care of these patients for any great length of time. The acute cases could best be taken care of in separate detention or observation hospitals. WILLIAM J. HERDMAN (Ann Arbor, Mich.) said that when Dr. Mitchell criticised the officials of insane asylums some years ago, he scarcely did justice to what was being done at that time. Many of the asylum officials were greatly handicapped by the condition under which they were obliged to work. In the progress that had taken place within the past few years in the care of the insane, the alienist had done his part, and done it well. Provision should be made in the general hospital for the care of acute cases of insanity. The early treatment of such patients was very important. He suggested the feasibility of establishing reception hospitals, either in connection with private institutions or otherwise, where the acutely insane could be kept under observation until the true character of their malady was ascertained. G. W. McCASKEY (Fort Wayne, Ind.) said that his experience with the treatment of acute insanity cases in general hospitals had not been satisfactory. The number of recoveries among such cases he thought was less than 20%.

**A Contribution to the Study of Visual Disturbances in Brain Injury.**—WILLIAM E. GAMBLE (Chicago) reported a case of bullet-wound of the brain, with resulting eye-symptoms, which suggested the following conclusions: (1) That a cortical lesion of the size of a .32-caliber bullet, involving the greater part (posteriorly) of the third and fourth left temporal convolutions, and injuring the extreme anterior end of the inferior occipital convolution, and a subcortical lesion penetrating the middle occipital convolution at the same level, produced verbal amnesia, especially for names and objects seen and having been seen, particularly those which have proper names, and for names of colors; (2) that verbal amnesia is a result of a lesion in the cortex of the third and fourth temporal convolutions, and injury to the cortex at the anterior end of the inferior occipital convolution; (3) that the amnesic color-blindness and alexia result from a subcortical lesion in the left middle occipital convolution; (4) that the reacquirement of these functions in a man 28 years of age is a slow and tedious process, and education of the specialized though undeveloped cells of the right hemisphere requires years for even its partial accomplishment; (5) that injury to the optic radiations of Gratiolet may produce negative scotoma, contrary to the teaching that such a lesion produces positive scotoma; (6) premature atrophy of the optic discs occurs in lesions of the left temporooccipital region.

**Discussion.**—H. T. PERSHING (Denver) said that while Dr. Gamble had worked out his theory with admirable care, he could not entirely subscribe to his deductions. In a case like this, in which the autopsy findings were wanting, it was a little precarious to infer the existence of a lesion from an attempted reproduction of it on the cadaver of another person. He was inclined to believe that the case was one of subcortical visual aphasia. H. T. PATRICK (Chicago) said that from the symptoms given he did not think the course of the projectile, as traced by Dr. Gamble, was necessarily the correct one. Instead of invoking the aid of theories that were as yet unproved, he thought it would be simpler to accept the explanation that the bullet, in its course, went a little deeper, so as to account for the sensory and motor disturbances in the right lower extremity. Furthermore, in the recent studies of dynamics, Horsley and others have shown that the injury of a projectile passing through the brain was not accurately represented by the course of the bullet. The force of the projectile and its explosive action were important factors, both as regarded the immediate injury and the subsequent reparative process. W. T. ECKLEY (Chicago) discussed the paper from an anatomic standpoint. He stated that in the case reported by Dr. Gamble, the patient could see and recognize things seen; he could hear and recognize things heard; he could smell and recognize things smelled; he could taste and recognize things tasted; therefore the respective sensory and memory centers of vision, audition, olfaction, and gustation were unimpaired. The patient, however, could not express in words visual, auditory, olfactory, and gustatory memories. Therefore there must have been interruption in the long association fibers connecting the cortical memory centers of these special senses with the motor speech center, and the injury must have been to the radiating fibers in the occipital

lobe, where the superior longitudinal fasciculus turns forward into the temporal lobe. In view of the symptoms, visual, auditory, olfactory, and gustatory aphasia was not the easiest explanation to be found in the assumption of a common naming center, interposed somewhere between the motor speech center and the cortical memory center previously mentioned.

**A Clinical Study of Epilepsy.**—J. G. BILLER (Cherokee, Iowa) referred to the difficulty in recognizing the early symptoms of epilepsy, and the frequency with which they were overlooked. The importance of heredity as an aid to diagnosis should not be disregarded. The advantage of early diagnosis and the application of proper treatment was emphasized. The speaker said that in treating epilepsy we cannot be too careful in the examination of our patient, and especially regarding habits, history, the peculiarity of the attack, and any relationship that may exist between the patient's habits and the attacks. The important point was to treat the patient and not the epilepsy. The treatment should aim at one thing in particular, namely, to increase the vigor and health of the entire system. Assimilation and elimination should be carefully looked after. He had seen what he believed to be very disastrous results from the promiscuous prescribing of bromids, especially in young children; he had observed such patients degenerate both mentally and physically so rapidly that it was impossible to attribute it to anything but the large doses of this drug. While we may get good results from the use of bromids in adults, and in some cases in children, he had yet to see any case of epilepsy that had been permanently benefited by this treatment; he had seen many cases where the attacks were diminished and even interrupted for a considerable period, but they had always returned and the patient was left in a worse condition than before.

**Pathology of Inebriety.**—T. D. CROTHERS (Hartford, Conn.) summarized his views as follows: 1. In all cases of inebriety there are marked changes in the capillary and vascular systems of the brain. The walls of the vessels show fibrinous deposits and scleroses. The nerve-cells and dendrites are altered and retracted, and in some instances prematurely destroyed. 2. The liver, kidneys, and heart show diminution or enlargement, with fibrous and fatty deposits. Both the organic and functional activities are changed, and sclerotic states are present. 3. Pathologic changes are apparent in the paralysis of the sense organs and the higher psychic functions of the brain. These conditions are so common following the use of alcohol—sometimes its moderate use, but always when taken in excess—as to constitute a distinct pathology traced directly to alcohol as the most prominent cause. 4. The recent researches in the chemico-physiologic action of alcohol on the heart, bloodvessels, and nerve-cells and fibers show a paralyzing and eroding action that cannot be mistaken for any other cause.

[To be continued.]

## Section of Laryngology and Otology.

FIRST SESSION.

The address of the chairman expressed a plea for naming operations and other procedures from their typical anatomic characteristics rather than after the men who invented or introduced them.

**Report of Cases Showing Instrument and Technic in Cure of Deaf-mutism.**—MAURY M. STAPLER (Macon, Ga.) stated that of 20 cases treated, 6 gave good results; others were more or less improved. The instrument consists of a rubber tube having four branches. To this tube is fitted air-tight an ordinary aspirating pump; the tips of the branches are held air-tight, one in each nostril and in the external auditory canals. The technic consists in having patient swallow when the pump rarifies the air in the external auditory canals and middle-ears, reached through the eustachian tubes. This rarefaction removes the pressure of the foot-plate of the stapes on the oval window. The tubes can be attached to a compressed air-tank and middle-ear and eustachian tubes treated with medicated air in this way.

**Discussion.**—JOACHIM (New Orleans) saw some analogy between Dr. Stapler's device and that of Lucae, which is well known. COBB asked what proportion of cases of deaf-mutism have trouble with auditory nerve. P. HAMMOND could not give a definite answer on the spur of the moment. He said few cases showed any reaction of auditory nerve under treatment. CLARKSBRO (Rome, Ga.) said only about 5% of so-called deaf-mutes are absolutely deaf according to the literature. He thought the method of educating the small fragment of hearing power present in a case gave but slight lasting results. ROBERT C. MYLES preferred gentle passive movement of the drum membrane in cases of ankylosis of the ossicles, as in chronic catarrhal conditions of the middle-ear. C. M. COBB (Boston, Mass.) thought cases of deaf-mutism should be classified and considered as to treatment according to the cause. Some could be improved; others gave little or no result. DE ROALDES (New Orleans) agreed with Dr. Cobb, and said we should be cautious in passing judgment on these cases, especially those of acquired deaf-mutism. He referred to Koenig's system of testing hearing, and said the subject should be given thorough study and experimentation in a scientific way by those competent. SNOWE (Syracuse, N. Y.) believed vaporization of middle-ear by compressed air would give as good results as

any method after removal of all abnormalities in nose and nasopharynx.

**Membranous Pharyngitis.**—JOHN McREYNOLDS (Dallas, Texas) showed the patient to the section, and called on R. C. MYLES (New York) to speak on the case, as he had seen it a short time since. Dr. Myles said he had had a bacteriologist to examine a specimen of the membrane and he reported the presence of Friedländer's bacillus; but as this bacillus is found independent of this condition, Myles attached no importance to the report and thought it more likely of atrophic origin. B. R. SHURLEY (Detroit) asked for symptoms of a case, which were given by McReynolds. In closing, McReynolds said he agreed with Dr. Myles that organisms present played but a small part in causation.

**Nasal Polypus: Origin and Treatment.**—CHAS. H. BAKER (Bay City, Mich.) thought the origin largely due to sinus disease and that the best treatment was by use of the cold snare.

*Discussion.*—R. C. MYLES (New York) considered nasal polypus a dropsy of the nasal mucosa, due to venous pressure. He believed the removal of the middle turbinate body the best radical method of treatment. LOEB (St. Louis) liked the electrocautery snare, but thought the middle turbinate should be removed, at least eventually. MINOR (Detroit) thought turbinectomy rather too radical. He liked cureting of under surface of middle turbinate as a preliminary measure. COBB (Boston) did not believe adenotomy, no matter how thoroughly done, would cure purulent rhinitis. SCHEPPGREGG (New Orleans) exhibited a specially made snare, stronger than the one in common use, which he had used in hard, fibrous polypi with success. In conclusion, BAKER said the cold snare was more easily insinuated over polypus than the more delicately wired electrocautery snare. He also exhibited a snare used by himself with success, in which the cannula slipped forward upon the wire loop, instead of the loop being drawn back into the cannula, as in usual snares.

MYLES (New York) moved that the next paper on the list, that of SCHEPPGREGG (New Orleans), on diphtheria of the nose, be read by title and published in the next issue of the *Journal of the American Medical Association*, and in its stead the doctor speak informally on the use of the x-ray. The motion was carried. SCHEPPGREGG spoke particularly of its use in malignant tumors and lupus. He said the x-ray should be given a fair trial in treating these conditions. Static or coil machines were found equally good, the static possibly to be preferred by some on account of making less noise. In course of his talk he referred to a case which he recently reported cured, one of carcinoma of the larynx. He said that the growth had recurred, however, after three months, so could not be considered cured.

#### SECOND SESSION.

**Some Observations on the Removal of Diseased Tonsils.**—CHAS. M. ROBERTSON (Chicago) showed special scissors for the operation devised by himself and demonstrated a method applicable to small adherent tonsils on some half-dozen patients at the New Orleans Eye, Ear, Nose, and Throat Hospital before the entire section.

It was resolved that the retiring chairman of the section be one of the delegates to the House of Delegates, and that he choose the other member from the floor.

**The Necessity of an Early Diagnosis and Treatment in Acute Suppurative Affections of the Middle-ear.**—FRANK G. BOYD (Fort Worth, Texas) touched on the surgical anatomy of the region, urged thorough paracentesis of membrana tympani, and made a plea for an early diagnosis and treatment of acute suppurative conditions of the middle-ear.

*Discussion.*—HOMER DUPUY (New Orleans) spoke of a good local anesthetic solution for paracentesis. Formula: Anilin oil, absolute alcohol, 50 parts; cocain hydrochlorate, 18 to 20 parts. He has used this some 800 times at the New Orleans Eye, Ear, Nose, and Throat Hospital with good results. ELLETT (Memphis) liked equal parts of cocain, menthol and carbolic acid. KUYK (Richmond, Va.) thought anilin oil mixture should be used with caution. HARMON SMITH (New York) liked anilin solution or nitrous oxid. J. F. BARNHILL liked anilin solution, but had had some unpleasant results from its use. Some cases, however, unquestionably demand a general anesthetic. SCHEPPGREGG (New Orleans) considered carbolic acid a dangerous agent when used in middle-ear; liked ethyl bromid as a general anesthetic.

C. A. THIGPEN (Montgomery, Ala.) reported a case of empyema of the frontal sinus.

SCHEPPGREGG (New Orleans) reported and showed to the section a case of tuberculous laryngitis.

Thigpen's case of frontal sinusitis presents an anomaly in the form of absence of posterior wall with pressure on the brain, producing mental symptoms.

*Discussion.*—GORDON KING (New Orleans) urged the necessity of radical measures in treating cases of chronic sinusitis by thorough cureting and packing of the cavity to bring about obliteration of the cavity. Paraffin may be injected if necessary, or the Kuntz method (cutaneousperiosteal flap method) may be employed to bring about the same result. Better still is the Lucke modification of the Kuntz operation. FREER (Chicago) called attention to Killion's operation for complete obliteration of the frontal sinus, considered by him the most

radical and perfect operation known. INGALLS (Chicago) reported the cure of a case of chronic frontal sinusitis by injection of protargol.

*Discussion* of Robertson's paper: BARNHILL prefers the snare to the scissors method, as quicker and less painful. INGALLS (Chicago) prefers separating hook (for the anterior pillar of fauces) and cold wire snare in children, and the tonsillotome in adults. Contrary to most operators, he advocated entire removal of the gland, leaving no stump. R. C. MYLES said the method used should depend on anatomic or pathologic characteristics of the case. Thorough extirpation is important.

#### THIRD SESSION.

**Paraffin Injected Subcutaneously for the Correction of Nasal and Other Deformities.**—HARMON SMITH (New York) employs a metal-barreled syringe of 90 minims capacity. The piston can be screwed down, thus giving desirably slow injection. Showed a couple of syringes loaded with paraffin, with a melting point of 110° F. (really a combination of paraffin and petroleum jelly). Both syringes had been carried by the doctor in his pocket for several hours before he read his paper, yet the paraffin contained in them was easily ejected from the needle (which was warmed) in a semisolid state. After paraffin is injected under the skin he sprayed the part with ether, causing immediate cooling.

*Discussion.*—MYLES (New York) advised thorough loosening of subcutaneous tissue before injection to allow of better molding of the paraffin. In conclusion, SMITH said he would only warn surgeons to beware of hyperinjection. It is better to have the patient return in a few days for second injection than try to correct the entire deformity at once.

**The Special Influence of High Altitudes on the Nose and Throat.**—S. E. SOLLY (Colorado Springs) dealt mainly with regions above 4,500 feet.

R. C. MYLES (New York) read a paper entitled a general consideration of the diseases of the ethmoid cells. Some very interesting specimens, normal and pathologic, belonging to Dr. O. Joachim, of New Orleans, as well as some new forceps and other ethmoid instruments, were shown the section. In all this class of operations the cardinal principle was drainage.

**Nontuberculous Hemorrhages of the Air Passages.**—L. F. PAGE (Indianapolis). He also reported several cases, illustrating his paper.

**The Resection Operation for the Correction of Deflections of the Nasal Septum.**—OTTO T. FREER (Chicago) presented this with drawings illustrating various stages of the operation, together with some original instruments.

[To be continued.]

#### Section of Materia Medica, Pharmacy, and Therapeutics.

##### FIRST SESSION.

**Chairman's Address.**—SOLOMON SOLIS COHEN: Therapeutics has a number of definite principles, under each of which many facts may be grouped. Discoveries of error among the subordinate data do not invalidate the principles. Medicine must be studied as a department of biology; biology as a department of cosmology; cosmology seeks to establish not merely facts, but general laws governing the action and interaction of matter and energy, while its special departments treat of the special manifestations of universal energy and their special laws. It is needful to attain as definite a knowledge as possible of the physical and chemical processes of life, normal and abnormal, for thus only can we learn to preserve the one and to remedy the other; also the means at our command are largely physical and chemical, and must therefore be studied both from the viewpoint of physics and chemistry and from that of their effect upon life processes. The functions of therapeutics is to preserve and restore health, to prevent and remedy disease. It must be remembered that these are both vital phenomena, and the transition from one to the other is a vital process. Hence recovery is not something brought about by drugs or other agents, but a vital process due to the essential powers of living matter. It is not in mere chemical composition or in physical structure that dead cells and organisms differ from live ones, but in vital activity, and the plasticity and mobility that this imposes upon structure and chemical constitution. It has an autogenous tendency to maintain this activity against the antagonistic action of the environment, by inhibition or modification of the ordinary chemical and physical reactions and the substitution of vital defensive reactions. The least highly vitalized portions of the body, as the bones, are the most susceptible to mechanical violence, but even broken living bones and broken living twigs will try to restore their continuity, as dead bones and dead twigs will not and cannot. Mr. Spencer defines life as a continual adjustment of internal relations and external relations. This is shown as well in the production of antitoxin and bacteriolysins in infected animals and in the development of antilysins by the infecting microbes. Unusual vital phenomena are not necessarily to be interfered with, their tendency may be salutary rather than morbid, they may be part of the defensive reaction by which life is preserved. The therapist must know whether febrile heat tends to the prolongation or to the curtailment of life in a given case before he decides whether or not he will attempt to reduce it. He must also know what

other effects will follow from its reduction, and what additional effects, desirable or otherwise, will result from each of the various measures by which it may be reduced. Under all circumstances, however, it must be kept in mind that neither morbid agents nor remedial measures add anything to the powers possessed by the body. They alter, they evoke the natural actions and reactions—the vital processes of disease and recovery; but it is the living body that determines the nature of the disease process—it is the living body that determines the nature of the process of recovery; and our therapeutic measures must be guided by the natural vital defensive processes, to evoke, to stimulate, to assist; never to oppose, never to risk interference.

**Is Pharmacologic Action Determined by Chemical Structure or by Physical Characters?**—ARTHUR R. CUSHNY (Ann Arbor) said that so close a relation exists between the two that experimental pharmacology should renew the old alliance could the effects of drugs in the organism be coordinated with their molecular constitution. The answer was in the affirmative. Some believe and hope that the action of a drug may be deducted from its structure alone. The quest of drugs not to be pursued in the haphazard way of the past. The formula of ethyl alcohol ( $\text{C}_2\text{H}_5\text{OH}$ ) indicates its relationship to ethane ( $\text{C}_2\text{H}_6$ ). If formula was unknown it would be impossible to infer whether it would be soluble in water, or how volatile it would prove to be. The volatility of ether and chloroform determines their use as anesthetics. These physical factors are important. There is doubt whether the pharmacological effects are due to the formation of chemical combinations in the tissues or to the presence of drugs as uncombined foreign bodies in the cells and fluids. An example is the comparison of the effects of methane and methyl alcohol. The experiments of Kronka have suggested that the depressant qualities of this series are determined by some physical factor which is always present. When chloroform is no longer inhaled molecules in nerve cells slowly return to the plasma. A substance must be soluble (partially) in water or blood-plasma in order to be hypnotic. Another set of reactions which appear to rest upon the difference in physical properties is offered by the action of the salts and alkalies in the bowel. The sulphites, phosphites, tartrates, citrates, and the alkalies possess cathartic properties, while the chlorids, bromids, iodids and nitrites do not. The theory that pharmacologic action is correlated with the formation of chemical compounds has received a new lease on life. It is a wellknown fact that certain drugs act only in presence of other bodies which are inert.

**Relationship Between the Pharmacologic Action of Drugs and Their Therapeutic Indications.**—M. VEJUE TYROD (Boston) thinks that the use of drugs has been based on past experience. *Materia medica* has existed since the early part of the Christian era. Bitter drugs were considered dry, and acid drugs cold. Metallic combinations were introduced by German alchemists. Syphilis was successfully combated with inunctions and vapors of mercury. Cinchona was imported from India and used in treatment of fevers. Ipecac was imported from Brazil. From time of Hippocrates to the nineteenth century numerous drugs were introduced and various diseases treated by new and old remedies. Homeopathy was first introduced because of the toxic effects of drugs from their action not being known. The theory of obtaining information by observation is a good one, but must be used cautiously. One cause of the varied effects of drugs is from the use of the crude preparations. Chemistry was early placed on solid foundation and promptly made great strides. Experimental pharmacy was introduced with unlooked for results, Pasteur's experiments and discoveries are due to it. Few drugs have been found to act on cause of disease. Main strength in drugs is in their strengthening functions which are decreased and diminishing those which are increased. None of the anesthetics have ever been shown to have a direct action on heart, therefore are undesirable.

**Research Problems of Pharmacology.**—(Read by the chairman) TORALD SOLLMAN (Cleveland). The object of pharmacology is to supply basis for rational therapeutics. Prejudice against laboratory experiments has practically disappeared. It is necessary to study profoundly this most delicate question, and combine rational therapeutics with bedside experience, and it is important that we do not even know wherein the members of the pharmacologic group—such as the digitalis group, the bitters, the cathartics—differ from each other. It is also important to study the therapeutic and poisonous actions of aconite, alcohol, antipyretics, antiseptics, arsenic, caffeine, cathartics, cholagoges, dietaries, digitalis, digestive ferments, diuretics, ergot, gelatin (as hemostatic), hydrastis, iodids, iron, mercury, quinin, strychnin, saline infusions, etc. These should be investigated by laboratory experiments, and also carefully diagnosed cases at the bedside. It is necessary for hospitals to have a man who can attend to scientific research alone, and he could be greatly aided by older practitioners and clinicians. We know less about the mechanism of tolerance of drugs than in the case of bacterial toxins. No doubt that the action of a drug depends on its constitution. The pharmacologist and clinician should work together to ascertain the effect of these modifications. The time of drugs to be derived from the organic kingdom is still very distant. This offers an alluring field for scientifically trained pharma-

ceutical chemists. Dr. Sollman suggested that committees be appointed who would report yearly on such observations that could be made. There would be no difficulty for physicians who live near a center if they give a few hours each day to scientific research; one cause for failure is the choice of problems, which are too great. The present medical curriculum is too extensive to allow a student to do any research.

#### SECOND SESSION.

**Mercury.**—LAURA HOUSE BRANSON (Iowa City, Ia.) laid stress on the different forms of mercury and their application, and gave examples of extreme doses given from time to time. As much as one pound has been administered at a dose. Small doses are gradually getting the upper hand. She then reviewed the age, condition and disease of patient as regards dosage. Two grains of calomel has caused death, and medicinal doses have caused abortion, but 20 grains have been given with no ill effects. The hypodermic injection is not the best or safest form of administration. After reviewing the symptoms of its toxic effect, she said that mercury is eliminated by all secretions as an albuminate. It is accumulated by increasing doses. She then spoke of its various uses as purgative, antiseptic, germicide, and disinfectant, and gave various forms most applicable in different diseases. External applications may produce toxic symptoms by its accumulation as well as its internal administration. She gave the test for determining presence in system, and spoke of its incompatibility and gave instances.

**Discussion.**—OSBORNE had a suspicion that we will realize that the alteratives are the drugs which modify the secretions. He reviewed symptoms of tertiary syphilis and compared them to the condition caused by atrophy of the thyroid gland. It is his belief that mercury stimulates the thyroid gland. He does not like the minimum and maximum dose as given in *materia medica*; thought that the smallest dose should depend on the patient, and the maximum dose on the effect desired. ROBINSON had found a very unusual effect of mercury on the formation of the teeth when given to children even in the smallest doses. The pound doses spoken of were given in part for their effect from weight and not for systemic effects. TOMPKINS said he had found great variance in the idiosyncrasy to mercury and gave instances of a case in which the patient was poisoned by a small dose. SOLIS COHEN said he believed there was only one maximum and one minimum dose—namely, enough to do the work, and spoke of the peculiar susceptibility of different persons.

**The Limitations of Antidiabetic Diet.**—ARTHUR R. ELLIOTT (Chicago) said we have not reached a point where we can by any known drug or treatment cure the disease. Heretofore we have been bent on getting rid of the sugar in the urine without regard to the condition of the patient. More stress should be laid on the medical education of men in regard to the subject. Clinicians divide cases into two classes—mild and severe. The condition can be greatly controlled by diet, which must not only try to maintain weight, but should try to add to body energy. Substitutes must be found for carbohydrates, and the author suggested oils and fats. Proteids constitute the only class on which we can rely for heat-production in such cases, but they must be used with oils and fats. It is better to try to modify the glycosuria on a mixed diet than by a total abstinence. We should try to modify diet so as to supply the system and uphold it. Absolute diet can only be followed for a few months.

**Discussion.**—BATTES was much impressed by reference to medical education on the subject. CROFTAN thought that as much importance should be placed in quantity and quality, and in weights and measures as pertaining to glycosuria, as was placed in the measurements, etc., of drugs. He thought the antidiabetic diet necessary for the successful treatment of the disease. OSBORNE believed the dietetic treatment to be vicious. The physician must be careful about reducing the carbohydrates and sugars. Diabetes is often a condition and not a disease. MOONEY (Ala.) reported a case of complete anesthesia of foot in case of diabetes. The patient was put on dietetic treatment. The speaker laid stress on the condition of the intestinal tract. Had never seen a case which had developed before puberty and favorably, many cases in the aged ran for years. SOLIS COHEN could not agree on all extreme views brought out by discussion, but agreed with author as to importance of dietetic treatment. He gave instance of two cases—one which did well while he consumed large quantities of sugar and one which could not take the carbohydrates. WEBSTER (Chicago) believed many cases thought to be diabetes were really acute pancreatitis due to typhoid. ELLIOTT, in closing, said he had never seen a case in the negro. He believed that too much attention was focused on the glycosuria.

#### THIRD SESSION.

**The Absorption of Iron from the Alimentary Canal.**—WINFIELD S. HALL (Chicago) spoke of the quantitative experiments for iron in the body, and gave proofs of the absorption of iron. Its absorption may be affirmed by results of experiments on the excretion. He then gave tables showing how iron is absorbed, and in what proportion. He wished to prove that the absorption of iron is positive. Half-grown animals have more iron proportionately than those full-grown. The mere fact that iron is in the excretion proves that it is absorbed from the alimentary canal.

**Demonstrated Pathologic Effects of Alcohol.**—T. D. CROTHERS (Hartford, Conn.) said a new field is opened for the study of alcohol. For a long time study has been made with instruments of precision by the author; only healthy subjects are available. Examinations should be made daily to test the senses. After administration of alcohol the vision is markedly affected in distance and color, the hearing is diminished, certain sounds lost completely, voice several keys higher, touch diminished. There is a hyperesthetic condition of skin, which is lost after a time. Salts and acids could not be recognized by smell, and odors are confused. Taste and smell are both depressed, and muscular fatigue is marked. The action on the heart shows two periods: first, short acceleration; second, prolonged depression. The effect on the memory is marked; there is difficulty in repeating words and sentences. Alcohol in ounce doses is distinctly a paralysis, and has effect at an early period.

**The Legitimate Therapeutic Use of Alcohol.**—O. T. OSBORNE (New Haven) discussed the symptoms of a dose of alcohol, and said it is used more freely than its action warrants. Its local use is to stop secretion and as a preventive. It acts as a stimulant to the heart by increasing the blood-pressure through vasomotor centers. He then discussed the contraindication of alcohol. In heart failure, alcohol causes a reflex action (stimulant) through the mucous membrane of throat and stomach. In proper doses, alcohol has a progressive, beneficial effect. If overdoses are given, it will be necessary to increase the dose, which is vicious treatment. In sthenic fevers nitroglycerin has given as good results as alcohol. He then discussed alcohol as a valuable hypnotic, digestive agent, prophylactic, and stimulant.

**Discussion.**—MUSSEY (Philadelphia) said he had used less alcohol in the past few years than in previous years, and was gradually giving it up, as he considered it a dangerous drug. He uses it in streptococcus infection very freely, also in typhoid. He uses it more as a food than for its stimulating qualities. ROBINSON thought that many physicians used alcohol more than they realized. In puerperal septicemia he considered alcohol more valuable than any other drug. With regard to its antidotal qualities, it had the same action in the body as on it. HALBERG said that the sulfates were the chemical antidote to carbolic acid, but alcohol had an action which nothing else produced, and which was increased when camphor was used. CROTHERS, in closing, said the point had been reached in the psychologic studies where the facts were known, and they could say whether or not alcohol was tonic, and could demonstrate these facts.

**The Therapeutic Value of Spinal Puncture for the Cerebral Symptoms of Typhoid Fever.**—J. H. MUSSEY (Philadelphia) gave report of cases of typhoid fever with alcoholic meningitis relieved by spinal puncture, and cites other cases with symptoms known as typhoid meningismus with some rigidity of neck. Three out of four cases recovered, and he considered that spinal puncture was responsible for one case.

**Discussion.**—ROBINSON stated that the opinion in Germany was that the spinal puncture had a diagnostic value, but was of no value therapeutically. OSBORNE wished to know when Dr. Mussey considers the best time for puncture. MUSSEY, in closing, said when the symptoms which the French call typhoid meningismus appears he considers it the time for puncture, also when cerebral symptoms demanded leeching. He related a case of otitis media with convulsion, which was relieved by spinal puncture before the abscess burst.

**Intestinal Antiseptics: Their Use and Limitations.**—J. A. STORCK (New Orleans): The aromatic series must be used with care. Creasote is safer than carbolic acid. He discussed the different drugs and their position as intestinal antiseptics, saying he thought tannic acid one of the best. He laid stress on the use of salicylic acid in the treatment of dysentery and enteritis. The peroxid series has proved to be among the best germicidal agents. The sodium series is best for troubles situated in the higher intestine. The aluminum series is serviceable in cases of tuberculous ulcer when the antiseptic is not to be absorbed. Quinin is the best drug in amebic dysentery. Calomel should be used when an elementary antiseptic is desired.

**Discussion.**—OSBORNE prefers salol to all other intestinal antiseptics. He thinks we cannot afford to impair action of the kidneys while using such antiseptics. Care should be taken to have one which is nonirritating and nontoxic. BUTLER had found acetozone most efficient, but preferred guaiacol benzoate. ROBINSON stated that most physicians thought creasote to be the same as carbolic acid, because coal tar creasote had been used instead of the beechwood creasote. SOLIS COHEN thought that the sulfur group was the best series for intestinal antiseptics and ichthylol the best of their class. KUSTER recommended zinc sulfocarbolate. He had used it with great success.

#### FOURTH SESSION.

**Exercise as a Mode of Treatment in Heart Disease.**—N. S. DAVIS, JR. (Chicago) reviewed shortly the history of exercise treatment, treating specially of massage, Swedish gymnastics, mountain climbing, and resisting exercises. He then compared the heart to the voluntary muscles of the body and reviewed study of action of muscular exercise on the heart. He is of opinion that the effect of exercise is due to the amount of blood drawn into muscles, causing a depletion of blood to the

heart. Muscular effort must be slight, but numerous muscles must be used. The heart is strengthened in the same way as the muscles. Exercises should be graduated. Massage and resisting exercises come first. Hill climbing causes deep breathing which brings about improvement. DAVIS defined the exercises best adapted for different affections of heart; he believes that diseases of the mitral valve respond more readily than those of the aortic.

**Discussion.**—TOMPKINS thought results depended on how much industry the patient put into it. Every one with heart trouble had a "weak link" in his makeup. Many physicians overlooked these diseases. He suggested that iron be used for all cases with heart complications. SOLIS COHEN thought that all functions should be made as equal as possible, making the depressed function come up to the highest point. DAVIS, closing, said he realized that exercise should be taken in moderation. Patients should be warned against exercises which would be harmful. He did not mean that drugs should not be used in connection with exercise.

**The Limitations in the Use of Aconite and Veratrum Viride.**—W. B. HILL (Milwaukee) quoted numerous men who valued aconite as an antipyretic as well as other uses. Both of these are old drugs, and have been in use many years. It is necessary to preserve the energy of patient in order to ensure recovery. The use of aconite and veratrum viride has supplanted bloodletting. Dr. Hill then gave the indications for their use, stating that one should not apply drugs solely for the reduction of temperature. Both drugs have in a measure been supplanted by new remedies, which are considered safer.

**Discussion.**—WEAVER said that both drugs are heart depressors and therefore the indications for their use are very limited. Physicians have paid too little attention to the muscles of the heart. When a patient has a weak heart and these drugs are used we cannot be surprised at grave results. MOODY did not consider that the action of the drugs, aconite and veratrum viride, were identical. He thought also their use was very seldom desirable. TOMPKINS valued both drugs and had obtained good results with them, but he realized that both had done a great amount of damage. CHAMBERLAIN objected to the classification of veratrum viride and aconite as identical in their effects. HILL, closing, said he did not mean to class the two as identical, although in many ways they were very similar. He did not wish to take up all the uses of the drugs. The successful use of a drug stamps it as good.

#### Section on Pathology and Physiology.

##### FIRST SESSION.

**Contributions from the Hygienic Laboratory of the University of Michigan.**—VICTOR C. VAUGHAN (Ann Arbor) demonstrated how he obtained the different products or protamins as he terms them with which the experiments have been made, the five papers following dealing upon these. The pure culture is poured upon the agar, and after ten days' incubation the growth is scraped from the surface. The germ substance is then extracted by means of alcohol and difute acids, dried, then powdered—at least 70% of this is pure bacteria. From these split-up substances a pigment is obtained which dyes silk cloth.

**The Chemistry of B. Coli Communis.**—MARY F. LEACH, in her experiments to determine whether or not the proteid constituents of these cells yield hexon bases, found bodies which closely resembles hexon bases. The paper gave a thorough review of literature, and detailed the work of the past year. She favors Kossel's contention as to the structure of the proteid molecule.

**The Chemistry of B. Typhosus.**—MARY WHEELER states that in her experiments she demonstrates that the cellular substances of the germ elaborates a soluble toxin, while the toxicity of the colon bacillus is due entirely to its intracellular substance. The paper gave details of a number of experiments.

**The Toxicity of the Intracellular Substances of B. Typhosus.**—LOUIS M. GELSTON stated that (a) the toxicity is in inverse proportion to the virulence of the culture according to the experiments of Gelston upon guineapigs on which the dilute culture proved more virulent than the concentrated; (b) its toxicity is increased when treated with a  $\frac{1}{10}$ % to 1% solution of sulfuric acid. It is reduced when treated with physiologic salt solution—with sulfuric acid and then with alcohol poisonous substances have been obtained which are even more poisonous than the mother cells; (c) small amount of germ substances injected into guineapig repeated once produces a condition in which the serum of the animal gives the Widal reaction; (d) he induces a certain immunity to the guineapig by using subcutaneous injection of the germ substance. Only subcutaneous injections should be employed, as intraabdominal injections of 1-50,000 have killed the animal.

**The Anthrax Toxin.**—J. W. VAUGHN, in his experiments with the germ substance of *B. anthracis*, proved that by vaccination with the protamin from the bacterium upon animals immunity seems to be impossible; so far, inoculation or vaccination with dead substances renders the animal more susceptible to the living germ.

**A Preliminary Chemical Study of the Hepatic Cells of**

the Ox.—FRANK SPENCER and FREDERICK MUNSON, in their experiments upon animals with the protamin obtained by treating hepatic cells with dilute acids, proved the toxicity of this product upon the animals. The work has an important bearing upon the subject of autointoxication.

**Multiple Periosteal Sarcomas of the Cranium, with Involvement of Retroperitoneal Lymph-nodes and Attending Severe Anemia.**—WALTER L. BIERRING (Iowa City, Iowa) stated that in this case the autopsy revealed seven apparently primary sarcomatous nodules arising from the different parts of cranial periosteum, the frontal, parietal, and occipital bones being involved, the nodules involving both inner and outer plates of the cranium. Metastasis was confined to the liver and retroperitoneal lymph-nodes; blood count revealed a state of pernicious anemia; sections of nodules revealed infiltration of small round cells.

## SECOND SESSION.

**Studies of Antirennene.**—JOSEPH MCFARLAND (Philadelphia). The investigation showed the rapidity with which animals injected with rennet furnish an antibody inhibiting its action, which antibody occurs in blood and tissue juices. It acts directly and chemically on the rennet, and for this action a definite length of time and exposure to a definite temperature are essential; that the reaction takes place according to the law of multiples, and therefore that the antirennene is of the same nature as the other antibodies, especially antitoxins. All quantities above  $\frac{1}{10}$ % inhibited the coagulation of milk.

**The Protoplasmic Activity of the Renal Epithelium as Determined by the Elimination of Pigments Injected Into the Circulation.**—W. S. CARTER (Galveston, Tex.). In his experiments with the different pigments injected into normal animals he showed that these pigments are being thrown off by the excretory apparatus. Several dyes were used for these experiments and all had the same results. He cut the cord so as to lessen the flow, pressed the ureter so as to cause a dilation in the uriniferous tubules and pelvis. The pigments were deposited on the cells but not reabsorbed, showing conclusively that the renal epithelium acts as an excretory apparatus and not as an absorptive.

**The Apparent Immunizing Value of Attenuated Tubercle Bacilli.**—E. A. DE SCHWEINITZ (Washington, D. C.). Experiments begun in 1894. Used tuberculin and attenuated human tubercle bacilli to produce immunity to bovine virus in cattle. Some instances of apparent positive protection. Others not so favorable, but in general it may be said that these attenuated human bacilli seem to increase resistance of cattle to bovine tubercle bacilli.

**The Successful Treatment of Streptococci Infection of the Lungs with Antistreptococci Serum.**—FOSS (Phoenix, Ariz.). No record of successful treatment of streptococci infection of the lungs is on record. The doctor gives clinical cases showing remarkably successful results by the use of anti-streptococci serum. The ultimate recovery of the cases depends upon the amount of recuperative power in the individual case. A large percentage of otherwise incurable cases are cured by this treatment, which eliminates the streptococci. The cases mentioned cover a period of over a year, showing that the effect of the treatment is permanent. It is not given except before an absolute diagnosis of streptococci infection is made.

**Precision in Determination of Human Parasites.**—H. B. WARD (Lincoln, Neb.) Up to the present time investigations have been conducted only in Europe, but have been done of late. The paper deals on the necessity of accurate identification of the human parasite, also of the eggs obtained from sputum, urine, feces, etc., on account of the mistakes generally made by the profession in taking even banana fibers, paper, and vegetable matter for human parasites.

**Condition of the Endometrium in Cases of Uterine Myomata.**—THOMAS S. CULLEN (Baltimore). As a rule the cervical mucosa shows no change. Occasionally cervical polypi are present or the cervical glands dilated. Endometritis is occasionally found with inflammatory changes in adnexa. Adenocarcinoma of the corpus is frequently associated with this condition while any of the foregoing may exist; in most instances the changes are entirely mechanical. If myomata are subperitoneal or intraligamentary, the mucosa is usually normal. When a nodule impinges on the cavity, the mucosa becomes stretched until there is nothing but the surface epithelium covering the nodule, but the mucosa in the depressions remains unaltered or becomes thicker, producing polyps or distortion of mucosa. It is a general rule when the fallopian tubes are normal and no sloughing submucous myoma is present that the uterine mucosa is perfectly normal or shows simple mechanical changes. Myomectomy can be done in such cases, opening up, if necessary, a large part of the uterine cavity with little danger of infection. But if the tubes are adherent or sloughing submucous myomas exist, complete removal of uterus is indicated, the sloughing submucous nodule being previously removed. These results are based on the examination of nearly 1,000 cases.

**Neuroglia and the Ependymal Epithelium of Teratoid Tumors.**—HENRY A. CHRISTIAN (Boston) spoke of the methods used, and material studied, of the occurrence of neuroglia in teratoid tumors; of its relation to other elements. He also called attention to its resemblance to the central nervous system and at times to the structure in gliosis and gliomas. It

is also sometimes present in cysts lined by epithelium of ependymal origin; in these cells certain characteristically staining rolls or dots may be considered as evidence of this origin.

**A Case of Gigantism and Leontiasis Ossea.**—(With lantern demonstration.) Dr. LECOUNT, for Dr. BASSOE (Chicago). The growth of bones was compensated by hyperplasia of the muscles, the one-sixth of the space of the frontal skull-cap was filled with bony substance which at the time of autopsy was filled with nodular deposits.

## THIRD SESSION.

**A Case of Short-limbed Dwarfism.**—L. HEKTOEN (Chicago). The case was that of a man, aged 45. The skeleton showed extensive curvature of spinal column, convoluted and twisted long bones with enlarged extremities and deformed pelvis. The skull contained about 110 Wormian bones. Of the diseases that may produce dwarfism, diseases of the cartilage and osteoporosis probably rank first.

**The Influence of Consanguinity on the Organs of Special Sense.**—L. W. DEAN (Iowa City, Iowa). The doctor only took into consideration the eye. In his three years of observation in this line he relates that 44% of the cases that came under his treatment were for diseases of the eye. No other causes could be traced but the influence of consanguinity.

**The Cultivation of Trypanosoma lewisii.**—F. G. NOVY and W. J. MCNEAL (Ann Arbor) have taken the flagellate hematozoan of the rat for their experiments, and planting the organism on a culture of agar and rabbit's blood, taken aseptically, have demonstrated the possibility of growing this organism in the test-tube for the period of over a year, the virulence of the culture being the same as when freshly planted. This may be considered as the first successful pure cultivation of an organism.

## Section on Cutaneous Medicine and Surgery.

## FIRST SESSION.

**The Modern Conception of Eczema.**—The chairman, JOHN A. FORDYCE (New York), referred at length to the various inflammatory affections of the skin usually included under the eczemas, such as seborrheic dermatitis and the various types of infective eczematoid dermatitis. He did not think it possible in many instances to differentiate clinically or histologically the dermatitis caused by chemical or microbe irritants from that type presumably caused by some general disturbance. He thought that such general conditions as indigestion, gout, anemia, neurasthenia, etc., lowered the powers of existence of the tissues and thereby rendered them more susceptible to the exciting cause of the disease. He referred to Bockhart's experiments with the filtered chemical products of bouillon cultures of the staphylococcus and believed with him that these toxins were concerned in the production of many of our more common types of the disease.

**Discussion.**—JOSEPH ZEISLER was inclined to the view that eczemas were parasitic in nature and should be treated along those lines. BULKLEY (New York) agreed with Fordyce, especially the fact that indigestion, gout, etc., lowered the powers of resistance of the tissues, rendering them a prey to disease. He thought in many cases it was the sole cause of eczema. He cited several cases in which internal treatment was alone sufficient to cure.

**Results of Radiotherapy and Clinical Conclusions.**—H. R. VARNEY (Detroit) reported having treated 50 cases of epithelioma of the face and hands with good success. He thought that when the lesions were extensive the light should be preceded by some surgical procedure as cureting, etc. Of these cases 19 were cured. In lupus, acne, scleroderma, psoriasis, keloid, hypertrichosis, and the pitting following smallpox his results varied. In lupus the results were very good. In acne the results were good, but more especially was this so when some erythema had been induced. His case of scleroderma was much improved. Psoriasis was always improved. Keloid not materially affected. In hypertrichosis the light was effective, but it required a long time, and the patient was liable to the usual accidents. Accordingly he did not recommend it. The pitting of smallpox was materially benefited.

**Discussion.**—DUNCAN reported a case of ichthyosis involving the extremities in which the x-ray had been used with apparently good effect, as shown by photographs. ROUSSEL suggested the use of oxygen for accelerating the action of the x-ray in parasitic affections. This may be obtained by the static breeze or the oxygen gas. In his experience it was of material help. JOSEPH ZEISLER suggested that more attention be paid to permanency of results in this field.

**The Treatment of Syphilis by Injections.**—M. S. HEIDINGSFELD (Cincinnati) realized that the subject was not new, but he thought the injection method was the best if irritating menstrums were avoided. He suggested the use of a mixture of mercury with lanolin, equal parts. Of this about 10 minims was administered about three times a week. He believed that only portion of this would undergo immediate absorption; the balance would act, so to speak, as a reserve to be absorbed later.

**Fibroma Molluscum.**—HENRY G. ANTHONY (Chicago) thought that pigmentation was an essential feature of the dis-

ease. Pigmentation was of two kinds: large plaque variety, varying in size to a half-dollar piece, single or multiple, characterized by distinct outlines, observed in whites and negroes. These pigmentations usually look like nevi. He contends that they are an essential part of fibroma molluscum, which is a developmental defect. Other variety is the freckled form. This form is rare. Fibroma molluscum may manifest itself by appearance of tumors alone, by appearance of tumors with pigmentation, and by appearance of pigmentation alone. The disease may appear at any time of life following acute disease. Should this acute illness be tuberculosis of the lung, the pigmentations would be assigned to tuberculosis of the suprarenal capsules, with a diagnosis of Addison's disease accompanied by nodules in the skin would follow. If, on postmortem examination, nothing would be found, the pigmentations would be assigned to arsenic.

[To be continued]

### Section on Ophthalmology.

#### FIRST SESSION.

Two members of the Executive Committee being absent the Chair appointed Drs. Geo. E. de Schweinitz and Harold Gifford to serve during the session, Dr. Frank Allport being the member present.

On motion of EDWARD JACKSON (Denver), the section voted that the Executive Committee act as Nominating Committee, as had been done in former years.

**Address of the Chairman.**—JOHN E. WEEKS (New York) believed the Section on Ophthalmology to be the representative body of ophthalmologists in the United States; that its membership was wider than that of any other society. As a part of a great association it had collateral support and was founded upon a constitution and governed by by-laws sufficiently broad and liberal to permit of indefinite expansion. He considered that the method of officering the section provided against the danger of the domination of cliques and of the continuation of officers through courtesy or otherwise that might endanger its activity. He thought the possibilities of the section were great and that all should endeavor to cause these possibilities to be realized by lending their influence to the production of work of the highest order. The inducements to become identified with the section were greater than those offered by any other association of ophthalmologists in this country, some of them being contact with representative colleagues from all parts of the United States; the assurance of large attendance; the publication of accepted papers and the discussions in a journal having a larger circulation than any other medical paper in the United States, as well as the publication of the papers and discussions in a bound volume at a nominal cost. He thought it scarcely necessary to mention the recent advances in ophthalmology as they would be presented in better form and more in extenso by the members. Some lines of research that promised much could be mentioned: as the effect of the x-ray and of the Finzen ray on neoplasms, detached retina, deep inflammatory processes and suppurative processes. The study of the bacteriology of the eye had not yet been exhausted. There were still some acute processes of apparently bacterial origin, as Parinaud's conjunctivitis, trachoma and some of the suppurative diseases of the cornea. The question of the value of subconjunctival, intraorbital, and intrabulbar injections, too, were as yet in a chaotic state. An exhaustive paper on orbital neoplasms, embracing a careful study of modern methods, would be heartily welcomed by all ophthalmologists.

**Vernal Conjunctivitis.**—WILLIAM CAMPBELL POSEY (Philadelphia) outlined the history of the generally accepted picture of the disease known as vernal conjunctivitis and of the differential diagnosis, and spoke of the frequency, physical characteristics, and distribution in the United States, based on answers to circular letters to ophthalmic surgeons in all parts of the country, and gave his observations regarding the pathology, etiology, and treatment.

**Discussion.**—JOHN E. WEEKS (New York) said the disease was one that had interested him a great deal, and to which he had given much study. It was his observation that the cases occurred among the well-to-do in a proportionately larger percentage than in those whose hygienic surroundings were less favorable. A striking example of the disease, he thought, was the variability in the length of time during which it persists. There seemed to be no particular predisposition, the disease occurring equally as often in the robust as in those of poor nutrition. He had been able as yet to find no proof of contagion, though he had observed it affecting several children in the same family. It differed from trachoma in that the retrolarsal fold never presented vegetations. In the treatment he had found mild measures to serve best—bathing the eyes with a warm solution of boric acid, 1% to 1½%, twice a day and the use of the yellow oxid ointment once daily. He considered that the use of cocain was not beneficial. HENRY DICKSON BRUNS (New Orleans) called attention to the relation of the disease to phlyctenular ophthalmia, and referred to the frequency of that disease in the negro race. He believed the phlyctenular ring appearing around the cornea was a phlyctenular phenomenon. HENRY GRADLE (Chicago) considered the changes of a progressive nature increasing from year to year, a history dating back more than one year being sufficient to establish a

diagnosis. The disease resembled in some respects hay-fever, though he had not seen hay-fever existing with the disease. As a rule, the retrolarsal folds were not involved, but there were exceptions. The cornea was invariably exempt. He had obtained the best results with adrenalin. HIRAM WOODS (Baltimore) thought the type of the disease seen in Baltimore corresponded with that described by Dr. Bruns. He had seen only two cases with corneal complications. There was no pain or photophobia, but the typical annular ring.

**Subtropical Trachoma.**—RUFIN A. WRIGHT (Mobile, Ala.) considered trachoma chiefly in its clinical aspect, basing his consideration of the disease upon the following hypotheses: That it is a distinct disease characterized by a granular and hypertrophic condition of the palpebral conjunctiva and its transition folds. It tends to progress in a fixed manner, varying only in degree. Certain complications and sequels mark its course. It is contagious and a distinct disease from follicular conjunctivitis. It is capable of being modified by proper treatment. He was of the opinion that the type of the disease in the South was milder in form and less frequent in serious complications. As to racial immunity his experience had been negative. He had never seen a case of true trachoma in the negro. The State Boards of Health had not inaugurated any system of inspection or exclusion of cases from the schools. He advocated the use of a recent remedy, copper citrate, claiming for it that it produces absorption of the granulations; that it is less irritating and readily used at home in the form of an ointment of 3% to 10% in white vaselin.

**Discussion.**—DUNN (Cairo) thought the treatment might be divided, in that used before the appearance of the granulations and that used after. He thought the disease might be aborted early by germicidal remedies. After the appearance of the granulations nothing compared with the use of the roller forceps. PFINGST (Louisville) thought there was considerable misconception as to the nature of genuine trachoma, and that many of the cases so-called were not trachoma. He congratulated the author of the paper upon his success with the new remedy, but thought the number of cases so treated too small to base definite conclusions upon. GIFFORD (Omaha) spoke of the difficulty of securing the drug. The few cases in which he had tried it were in line with the results obtained by Dr. Wright. HARLAN (Baltimore) reported the case of three Russians detained in Baltimore for trachoma, in which the symptoms subsided and disappeared entirely after an attack of measles; the father, who had had measles before, having to undergo a protracted course of treatment.

**Experimental Study on Some Methods of Combating Postoperative Infection of the Anterior Segment of the Globe.**—E. C. ELLET (Memphis, Tenn.) referred to the experiments of Ostwalt in introducing iodoform into the anterior chamber of the rabbit's eye and later injecting a culture of the staphylococcus, by which purulent inflammation was prevented, and to Romer's report of its use in three cases. The author carried out a series of seven experiments along these lines, using iodoform rods made with gelatin, containing 50% iodoform, and came to the following conclusions: Iodoform used in three cases of streptococcus infection; one failure, two successes. In two cases of staphylococcus infection, two successes. He also referred to one clinical case, cataract extraction followed by infection, in which the iodoform was introduced in the form of powder, no cones being available, result being failure. Method: peripheral incision made in cornea, the rod caught at one end with forceps and pushed into the chamber completely. The author concludes that the method has a field of usefulness, with no possibility of harm. Must be used early, certainly not later than the second day.

**Discussion.**—EDW. A. SHUMWAY (Philadelphia) thought the best way of introducing the iodoform was by means of these rods and that the best results might perhaps be secured by cauterizing the wound and then introducing them. It was not possible to keep the powdered drug from being washed away out of the anterior chamber. He thought it of great importance to first evacuate the opaque lens center and to use vigorous internal medication, sodium salicylate in large doses having proved of great value. FRANK ALLPORT (Chicago) had experienced great difficulty in securing the discs or rods. He had used some left him by Dr. Haab last year, but had been unable to have them properly made. One difficulty was to make the rods aseptic. Efforts to sterilize them resulted in making them difficult to handle. He had used them a number of times and obtained good results. GEO. E. DE SCHWEINITZ (Philadelphia) said the sterilization of the iodoform, which, of course, was not a sterile product, could be accomplished by washing the powder in sterile solutions of mercuric chloride. He spoke of the pain, severe in character, on the night following the introduction of the rods, necessitating the use of hypodermics of morphia. CLAIBORNE (New York) referred to some experiments which Dr. Colburn and himself were carrying out with the use of formalin. They had experimented upon rabbits, using formalin 1 to 5,000. One injected in the capsule of Tenon recovered; one with injection into vitreous went straight to destruction. In order to secure a very virulent growth of the streptococci they passed it through a second growth. With injections of this growth the eyes went to rapid destruction. He thought if any light could be thrown upon the subject it was greatly to be commended. HALE (Chicago) thought the use of the cautery with the introduction of the

iodoform would be contraindicated, as it would not tend to the preservation of the eyeball. He was not convinced that much had been accomplished practically when the eyeball had been saved but without vision. It was a successful surgical procedure, but of little benefit to the patient.

**Ocular Complications of Bright's Disease.**—LOUIS STRICKER (Cincinnati) thought the eyes became involved as a result of the general systemic conditions of Bright's disease, which conditions were the result of faulty kidney excretion, leading to retention of urea and other excrementitious substances in the blood, which substances are either poisons or lead to the formation of toxins, producing degenerative changes in the vessels. In the eye it was the vascular system, the choroidal and retinal vessels and its nervous expansion, the optic nerve and retina most frequently involved. The hemorrhages were due to the combined influence of arterial degeneration and increased arterial pressure. Of 16 cases, 5 were optic neuritis; 3 neuroretinitis; 2 neuroretinitis hemorrhagica; 2 of neuroretinitis and choroiditis; 1 venous thrombosis; 2 uremic amaurosis; 1 keratitis, in all probability a general uveitis. The writer concludes that the ocular complications of Bright's should lead to systemic examination; that the idea that one must find the characteristic picture is a mistake; only a small percentage of cases develop ocular symptoms, but if larger number of cases were examined more would be found to have ocular lesions; the complications are the result of altered nutrition, or toxemia, and chronic uremia; that disease of the eye coming on in the course of Bright's is of the gravest import; in acute Bright's the condition is of a more hopeful character; estimate of the urea quantity is the barometer; in the Bright's of pregnancy with ocular complications a low urea quantity should be the sign for immediate interference; that excrementitious substances retained are responsible for the inflammatory changes.

**Albuminuric Retinitis and Decapsulation of the Kidney.**—GEO. F. SUKER (Chicago) said the object of the paper was to elicit the interest of the members in determining whether or not decapsulation could be accepted as a curative measure for the intraocular complications. The conclusions to be drawn from the operations were not encouraging. The death rate for nephritis with fundus complications is very high. The writer concludes: that the operation so far offers no hope in cases of bilateral interstitial nephritis with retinal complications; that any improvement in the eye ground is temporary; that the operation may be of service in unilateral nephritis with fundus lesions; that the mortality rate for albuminuric retinitis has not been lessened by the operation; the retinal complications are an index to the severity of the kidney involvement; in nearly all cases of chronic nephritis cardiac involvement is present; as yet the medical treatment yields as good results as the operative.

**Discussion.**—HENRY BRUNS (New Orleans) agreed with Dr. Stricker that the proportion of urea excreted is of greater significance than the presence of albumin. He thought the general practitioner somewhat slow in recognizing this fact and making use of it. That whether the urea is the offending agent or not we can not say positively, but when there is a lessened excretion of this element the patient suffers. GREENWOOD (Boston) thought the cases should be considered from the standpoint of arterial degeneration rather than from the standpoint of kidney disease. JACKSON (Denver) said there could be no question of agreement with Dr. Stricker that albumin is not the factor, but that defective elimination of urea is much more important. The ocular lesions depended upon the condition of the general vascular system. He had never seen a typical case without involvement of the vessels generally. DE SCHWEINITZ (Philadelphia) believed there were two varieties: one depending upon toxic influences, whatever they may be; and the other not a complication of nephritis, but of degeneration of the vascular system. There were types, however, of retinal lesions associated with diffuse nephritis when the vessels throughout the general system were not yet in a state of degeneration. GRIFFIN (Ann Arbor) reported a case occurring in a patient whose only symptom was reduced vision, and who died in six months after the examination.

[To be continued.]

### Section on Stomatology.

#### FIRST SESSION.

**Chairman's Address.**—M. L. RHEIN (New York) called the attention of the dentists to the fact that a very small minority of them practise preventive dentistry, which is the only means of guaranteeing the preservation of sound teeth. He made the recommendation that there be established in connection with training-schools for nurses schools for dental nurses, whose duty it should be to do the ordinary cleansing of the teeth under the direction of the dentist himself. There was great need of such women in hospitals and infirmaries, where the teaching of cleanliness of the mouth would be of great service in the lifting up of the unfortunate classes where these were the only means of health at their disposal.

**The Vasomotor System of the Pulp.**—EUGENE S. TALBOT (Chicago) said that Stephen Hale discovered in 1733 that small arteries changed their caliber; that the action of drugs on some caused them to contract, while others dilated them.

Talbot has collected 4,000 teeth, of which number 2,000 were selected and cracked in such a manner as to show the pulp. He then showed different slides taken from different pulps of teeth which were placed in Mueller's fluid and stained.

**Discussion.**—W. H. FLETCHER (Cincinnati) commended the paper particularly because the study of nerve distribution in the pulp has been neglected. He hopes that the reason why it is so delicate in its sensitive tendency may be discovered. T. CONSTANT (Scarborough, Eng.) was principally impressed by the large number of nonmedullated fibers shown in the slides. From clinical reasons the so-called odontoblasts have very little to do with the formation of dentine. G. S. EAMES (Boston) said the exhaustion of the nervous system controls the blood supply, therefore in a subacute inflammatory condition with one whose nervous system has been exhausted we may reach a chronic inflammatory condition of the pulp. TALBOT: Decay of teeth takes place much quicker in degenerates. I have worked for 30 years in this line and my paper covers four years of work. Modern stains enable the terminal branches of nerves to be well shown, which could not have been demonstrated 20 years ago.

#### SECOND SESSION.

**Orthodontic Facial Orthomorphia.**—W. E. WALKER (New Orleans) detailed an entirely new treatment of protrusion of the lower jaw, whereby he effected some remarkable cures. The lecture was illustrated by some 10 plaster casts of his patients in various stages of treatment. The first was that of a youth of 19 who had been always informed that the only remedy for the defect was a surgical operation removing a section from each side of the jaw. Walker diagnosed the case not so much protrusion of the lower jaw as arrested development of the upper jaw. He showed casts of the face taken before regulating and presented cast representing the patient as he appears today. The result is remarkably good. The treatment in this case consisted largely in the use of an appliance much resembling a baseball mask, and which is to be worn at night. Its object is to move the teeth forward, using the chin and forehead as anchorage. The molars form sufficient anchorage to place an appliance to hold during the day what was gained at night.

**Discussion.**—E. S. TALBOT said that Aristotle first clearly defined the principle of sacrifice of the part for the benefit of the whole. Some parts of the human body illustrate this truth. They are passing away for the benefit of the whole. The little toe, the floating ribs and the appendix are evidences of this fact, but chief instances occur in the face, jaws, and teeth, which are becoming smaller to allow for development of the brain. Charles V of Spain, the worst of all the monarchs of that ill-ruled country, owed his disposition to dyspepsia. Two hundred years after his death his skeleton was examined and it was found that the teeth of his lower jaw protruded beyond those of the upper jaw so that he could not properly masticate his food.

#### THIRD SESSION.

The symposium on the dental pulp was completed by essays by Dr. T. E. Constant, of England; Dr. J. Choquet, of Paris; Dr. Causch, of Brighton, England, and Dr. Talbot, secretary of the section.

Some histologic facts contradictory to the theory of odontoblasts, by Dr. Michael Morgenstein, of Strasburg, Germany; an article by Dr. Oskar Romer, of Strasburg, entitled pulp hypertrophy of the teeth, and by Dr. Fletcher, on the tolerance of foreign bodies by the tissues, were read by title.

**Officers Elected.**—George F. Eames, of Boston, chairman; E. S. Talbot, secretary; M. L. Rhein, of New York; R. R. Andrews, of Harvard University, and A. H. Peck, of Chicago, executive committee.

**Therapeutic Use of the Röntgen Rays in the Oral Cavity.**—GEORGE F. EAMES (Boston) illustrated his paper by exhibiting a novel apparatus of his own design which allowed the use of the rays in the mouth. He stated that the therapeutic and chemical effects were accidentally discovered. He believes that they act by the decomposition of the tissues and the liberation of oxygen. The essayist has used it extensively in treating neuralgia to good effect, but has found that when applied to the human body an excess of uric acid is produced. The x-rays do not destroy germ life by direct action any more than does the sun's rays; the bactericidal effect of both is due to ionization or electrolysis. The factors to be considered in x-raying are: The potential of the ray; the resistance of the tissue to the ray; the intensity of the radiation. The effect of the x-rays on malignant growths is summarized as follows: Relief from excruciating pain; establishment of the process of repair; reduction in size of newgrowth; removal of odor if present; cessation of discharge; softening and disintegration of lymphatic nodes; disappearance of lymphatic enlargements not submitted to treatment and often quite distant; improvement in the general health; cure up to date of a certain number of malignant growths. These changes suggest that x-ray vibration acting on cancer cells tends to stimulate many to maturity at the same time breaking down the weaker ones, which are absorbed by the lymphatics and enter the circulation, producing the autointoxication so frequently observed; the number of cells reaching maturity and those undergoing destruction depending upon the intensity of the reaction established.

THE SURGICAL TREATMENT OF PRURITUS VULVÆ, WITH THE REPORT OF A CASE CURED BY RESECTION OF THE GENITOCRURAL, ILIOINGUINAL, INFERIOR PUDENDAL AND SUPERFICIAL PERINEAL NERVES.<sup>1</sup>

BY

BARTON COOKE HIRST, M.D.,

of Philadelphia.

The treatment of idiopathic pruritus vulvæ is among the unsolved problems of gynecology. The number and variety of remedial measures suggested attest the unsatisfactory results of the treatment heretofore employed. The surgical treatment seems to promise better than the application of drugs, electricity, subcutaneous normal salt solution injections, the x-rays, and general systemic treatment, which are the remedies ordinarily prescribed.

There are two surgical procedures available for the treatment of pruritus vulvæ. One is the operation first proposed by Schroeder, exsecting the portion of the labia affected, by an inverted V-shaped incision, bringing the elastic skin of the vulva over the denuded area and joining it to the mucous membrane of the introitus. This operation has not invariably been successful. The pruritus has reappeared in the same position as before, which was really to be expected, if idiopathic pruritus is a functional disease of the sensory nerves supplying the part. A resection of the nerves supplying the vulva is the other of the two operations for pruritus vulvæ. Priority for this operation is often ascribed to Sir James Y. Simpson, but he himself credits Dr. Burns, of Glasgow, with being the first to recognize "neuralgia and hyperesthesia of the vulva," and to cut the pudic nerve for it. Burns' incision for this purpose could not possibly have touched the pudic nerve. The Simpson modification of the Burns operation by a subcutaneous section of the nerve was even less likely to injure it. This proposition of Burns and Simpson has been revived from time to time, but it cannot yet be said to be a well-defined procedure with a well-considered and effectual technic. The pudic nerve has really been resected in some of the later operations, but the disadvantages of this resection are that there is danger of depriving the sphincter ani of its innervation, and so producing incontinence of gas and feces, and of not depriving the vulva of its sensory nerve supply which is contributed by the inferior pudendal, the ilioinguinal and the genital branch of the genitocrural nerve, as well as by the two perineal branches of the pudic and the nerve of the dorsum of the clitoris. The mere resection of the pudic nerve, therefore, cannot be expected to remedy a pruritus vulvæ. The only method certain to accomplish the desired result is to cut off all the sensory nerve supply to the part. This can be accomplished by making four incisions: two in the groins as for an Alexander operation, and two on the buttocks parallel with the ascending ramus of the ischium beginning just above the tuberosity and extending upward about two inches. By the groin incision the genital branch of the genitocrural and the ilioinguinal nerves can readily be exposed by a careful dissection. It may be necessary to open the inguinal canal by incising the deep fascia. After the nerves are isolated they are divided and as long a distal piece as possible is extracted by catching the nerve in the grip of a hemostat or a tissue forceps, making traction on it and twisting it.

The inferior pudendal nerve is readily isolated where it crosses the ramus of the ischium, about an inch above the tuberosity. The perineal branches of the pudic are not so easy to discover, but a careful dissection should

display them in the upper outer portion of the ischio-rectal fossa; or, in the case of the posterior superficial perineal branch, on the fascia to the inner side of the ischial ramus. If the clitoris is involved, its dorsal nerve must be resected just above the bifurcation of the pudic nerve into its two branches, the perineal and the nerve of the dorsum of the clitoris. It is found under the inferior layer of the triangular ligament, alongside the inner surface of the ascending ramus of the ischium to the outer side of the pudic artery.

After their exposure the nerves are treated in the same way as the ilioinguinal and the genitocrural, by resection and extraction of their distal portions.

It is too early as yet to decide what the ultimate outcome of this operation will be in a number of cases, but it seems reasonable to expect a greater certainty in results than has hitherto been obtainable by any treatment for pruritus.

The writer has recently cured an intractable case with the characteristic history of having consulted several specialists and general practitioners without relief.<sup>1</sup>

In addition to the question as to the success of this treatment in curing pruritus, it is important to obtain information as to the effect of the anesthesia of the vulva upon the future condition of the parts. There is some reason to fear atrophic changes and the development of kraurosis vulvæ as a secondary result of the resection of the nerves for pruritus. If this disadvantage is found to attach to the operation in the future, one must hesitate to recommend it unreservedly. It will be interesting also to observe the frequency of epithelioma after this surgical procedure. If kraurosis should be a consequence, and epithelioma develop in association with it, as it occasionally does, there will be still graver reason for hesitating to resort to it.

These are questions for the future to decide, and it was in the hope of eliciting an expression of opinion and of hearing the results of experience from our fellow members that this paper was presented to the Society. The writer hopes to hear an expression of opinion on four interesting points in connection with the subject:

1. Which is the better of the two surgical treatments of pruritus vulvæ, exsection of the affected skin, or resection of the sensory nerve supply?
2. What is the best surgical technic for isolating and resecting the sensory nerves supplying the vulva?
3. What has been the permanent result of this operative procedure in the experience of the members who have performed it or have had the opportunity of watching cases afterward?
4. If a cure of the pruritus can be expected, is there a likelihood, or has any one clinical evidence to present, of the development of kraurosis vulvæ, and possibly of an associated epithelioma?

**Yellow Fever in Mexico.**—For the second time the yellow fever invaded the city of Orizaba, commencing at the end of August last, but notwithstanding the virulence of the first cases the epidemic terminated at the beginning of December, thanks to the experience acquired during the first irruption of the disease and the firm and timely measures taken by the authorities of the State of Vera Cruz, the efficacy of isolation and disinfection being once more demonstrated. The Executive sent to Orizaba a delegate, who, in concert with the local authorities, enforced the necessary measures to prevent the epidemic from spreading beyond the city in question.

**Standard for Admission to Medical Colleges.**—The endowed medical colleges of the North won a victory at the Association of American Medical Colleges held recently in New Orleans, La., in the adoption of an amended report of the committee to which the matter of requirements for admission had been referred. The report as adopted requires four full years of work in the high school, or its equivalent, for eligibility to admission in a medical college. This is believed to mean the final exclusion from admission in the medical colleges of all applicants who have not had a college education. Two-thirds of the medical colleges in the country are not endowed.—[*Press report.*]

<sup>1</sup>Since writing the above another patient has been operated on. In this patient the nerve of the dorsum of the clitoris was resected.

<sup>1</sup>Read before the Philadelphia County Medical Society, April 8.

**CONGENITAL DISLOCATION OF THE HIP: REPORT OF A BLOODLESS REPOSITION, FOLLOWED BY DEATH, WITH AN ANALYSIS OF TWENTY-THREE CASES IN PROCESS OF TREATMENT.**

BY

H. AUGUSTUS WILSON, A.M., M.D.,  
of Philadelphia.

Clinical Professor of Orthopedic Surgery in the Jefferson Medical College.

AND

J. TORRANCE RUGH, A.B., M.D.,  
of Philadelphia.

Demonstrator of Orthopedic Surgery in the Jefferson Medical College.

**PATHOLOGIC REPORT BY**

W. M. L. COPLIN, M.D.,

Professor of Pathology and Bacteriology in the Jefferson Medical College.

The clinics held by Professor Adolf Lorenz on December 11 and 12, 1902, at the Jefferson Medical College Hospital and the widespread accounts of his methods and skill naturally attracted many people to his bloodless methods of reduction of congenital dislocation of the hip. Many patients were brought for treatment by the noncutting method that were beyond the age limit set by Lorenz and often positively refused to have even subcutaneous tenotomy performed. This will explain the fact that patients beyond the age of 7 were operated upon by the bloodless method that were considered too old for that method, and yet at least three cases were found to present conditions that rendered the reduction much easier than in some of the younger children.

All of the patients that have been operated upon at the Jefferson Hospital during and since the Lorenz clinics are in process of treatment, as six months from the time of operation have not yet elapsed. It is proper to speak of them at this time only as to the reduction and later when their plaster casts are removed the results can be determined.

of the orthopedic department, and 2 done outside of the hospital by Dr. Rugh. The details as practised by Lorenz have been most critically carried out. It was deemed unwise to attempt the least departure from the methods which Lorenz with his vast experience and consummate skill had demonstrated before a most critical audience of 700 medical men. That we lacked his ability was, of course, to be expected, but each of us became more and more convinced with each case that in suitable cases great force was unnecessary when skilful manipulations were employed. The very great force that is sometimes spoken of in connection with this method is employed only in those older patients in whom use has developed strong and resistant muscles and fibrous materials in relations with the hip or when unsuccessful attempts have been made at reduction.

Professor Lorenz found the reduction to be accomplished with ease in the first four hips, notwithstanding that one of the patients was 9 years of age. The next one, aged 4, proved to be extremely difficult, and taxed Dr. Lorenz's skill and strength almost to the limit, but finally yielded and demonstrated a satisfactory reduction.

The last patient, aged 4, with double dislocation, had been placed under ether to be in readiness, but could not be operated upon because of the difficulties encountered in the former case. The child had been under ether for 35 minutes before it was decided to postpone reduction in her case. She made a satisfactory return to consciousness. The day following she was again etherized, and Dr. Lorenz reduced both hips. She went to the ward in good condition at 6 p.m.

The following notes are given by Dr. P. H. Moore, the house surgeon. The phenomena were also witnessed by Dr. Wilson:

At 9.15 p.m. the right hand was observed to begin to move in an indefinite, convulsive manner, and the patient rapidly passed into a state of stupor; the eyes became fixed, pupils dilated and did not respond to light; the tongue protruded, and froth-like saliva dribbled from the mouth. The face was markedly pallid and cold. Breathing was somewhat slower than normal and labored. Occasionally the lower jaw moved slightly, but there was no biting of the tongue. The pulse was not rapid, but decidedly weak. Later it became rapid, and could not be counted owing to arm movements. The right leg was several degrees lower in temperature than the left, and offered almost no resistance to manipulation. In three-quarters of an hour the stupor began to lessen; respiration became more nearly normal. A slight flush came to the cheeks, the tongue retracted, and the muscles of the face showed some twitching movements. The right hand underwent convulsive movements, the head was turned violently from side to side; there were mild clonic convulsions of the muscles of the back, and speech, slowly restored, became coherent. In about 1½ hours the condition was practically the same as before the attack. The child did not sleep. At 12.30 (same night) there was a much briefer attack, showing some of the above phenomena in modified form. Restless sleep until morning. There was no recurrence, and no resulting paralysis. The child was languid.

Professor Lorenz, in a personal communication, said (after reading the above record of the phenomena) that he had never had a case in which convulsions followed the operation, and he considered shock and trauma as the cause of this case.

K. C. The radiograph was relied upon, and it showed the condition of the acetabulum and the head of the femur to be favorable. There had been a cutting operation performed two years previously, and it was stated that this was for the evacuation of an abscess. The head of the bone seemed to be easily pulled down to Nélaton's line before the reduction was attempted. It was discovered later, during the manipulations, that there was no head to the femur, and we inferred that it had been removed at the operation referred to. It was found to be impossible to obtain any information as to what was really done, although careful inquiries were instituted. The hospital where the child was operated upon was under a staff that was not in affiliation with members of the American Medical Association.

The members of the orthopedic department who assisted Dr. Lorenz on December 11 and 12 were H. Augustus Wilson, J. Torrance Rugh, F. E. Dolson, T. D. Taggart, with G. J. Schwartz etherizer, supplemented by Dr. Frederick Müller and D. D. Ashley. The 23 hips operated upon include 8 done by Lorenz and the above-named assistants, 13 done conjointly by the staff

majus developed about 10 hours after reduction of the hip, which necessitated catheterization for 24 hours, but it then subsided and normal functions were reestablished.

With these few exceptions the patients all progressed favorably, and after remaining quietly in bed for from three to four days, were permitted to sit up, and were usually sent out of the hospital within a week from the time of operation. They were kept under observation by physicians in attendance upon the families and reports were made to the Jefferson Hospital from time to time.

In not one case has there been any evidence of paralysis or other nerve disturbance. Pain on attempting to use the leg operated upon has generally persisted for two to four days, and after that was only present when the hamstring tendons were stretched in those cases in which some flexion of the knee persisted. This, however, soon subsided, and freedom from pain or annoyances of any kind has been the condition in all cases excepting only the inconvenience of the plaster cast and the position in which it held the leg. It was a matter of great interest to see how quickly the children learned to adapt themselves to the posture of the affected leg, and to use it in walking where only one hip had been replaced.

We were surprised to see how little attention Lorenz paid to the very carefully prepared skiagrams that accompanied each of the 20 cases submitted to his inspection and selection for his clinics on December 11 and 12. His reliance on clinical inspection of the case, the thorough manner in which he determined the existing conditions and the prospects for reduction, impressed every one with his rapidity and certainty of action and decision.

Subsequent experience has convinced us that the well recognized possibility of variously interpreting radiograms renders their use of much less real value than would naturally be supposed.

It cannot be disputed that aid can be obtained from a careful study of a radiogram in direct connection with the analysis of the clinical phenomena, but the latter are to be relied upon for definite facts as to the condition of those factors about the joint other than bone which play equally important parts in resistance to reduction. In the case of M. I., which Professor Lorenz found the most difficult of all to reduce, the radiograph showed a most favorable condition, and was therefore most misleading. The same thing has been found in several other cases, notably in E. K., age 10 years, and the radiograph indicated unfavorable conditions for the bloodless method, which was attempted only as a preliminary measure in order to prepare him for a cutting operation to be performed later in accordance with the teaching of Lorenz. Reduction, however, was accomplished by us with far greater ease and certainty than in many of the other cases.

[To be continued.]

## HEART SHOWING CHRONIC TUBERCULOSIS OF THE PERICARDIUM, WITH INVOLVEMENT OF THE MYOCARDIUM.<sup>1</sup>

BY

A. G. ELLIS, M.D., B.Sc.,  
of Philadelphia.

Demonstrator of Morbid Anatomy, Jefferson Medical College, Philadelphia; Director of Laboratory, Friends' Asylum for the Insane, Frankford; Assistant Pathologist, Philadelphia Hospital.

(From the Laboratories of the Jefferson Medical College Hospital.)

The specimen was obtained at autopsy from the body of a male negro, aged 24, who died in October, 1902. In March of that year he had an attack of pneumonia, from which he never fully recovered, the succeeding symptoms being pain in the chest, cough, copious expectoration, night sweats, and progressive weakness. He was admitted to the hospital August 15, 1902. The

notes state that the action of the heart was then rapid, but there was no murmur. The pulse was weak. The upper portion of the left lung was flat on percussion, this flatness changing on August 25 to high-pitched tympanitic resonance. Repeated examinations of the sputum for tubercle bacilli were negative until August 27, when they were demonstrated to be present. A note on October 6 states that the heart was not displaced and that the sounds were normal. On October 14 the patient died suddenly while in the dining-room.

Autopsy showed the mediastinal tissues to be studded with variously-sized grayish or yellowish nodules, some

Chronic, adhesive, indurative and caseous tuberculous mediastino-pericarditis. Heart and adjacent mediastinal structures. (Four-ninths natural size.) A, trachea slightly distorted by pressure; B, left bronchus, compressed by enlarged peribronchial lymph-nodes; C, aorta; the arch is displaced to the right; the middle of the arch is elongated largely at the expense of the descending portion; it is probable that a large part, but certainly not all, of this distortion is postmortem. D, one of several caseous lymph-nodes on the mediastinal aspect of the pericardium; some of these nodules are indistinguishable from caseous masses that have arisen in the pericardial synechia. E, area of caseous tuberculosis occupying fissure between the left auricle and corresponding ventricle. F, caseous mediastinal (peritracheal) lymph-nodes. G, thickened and adherent parietal layer of the pericardium; H, thickened visceral layer of the pericardium (epicardium); the space between F and G is occupied by firm, greyish, slightly hyaline fibrous tissue in which are embedded many caseous areas. I, caseous mass extending into the myocardium; even in this short incision, through the lateral wall of the left ventricle, several points of myocardial invasion can be seen.

of which had caseous centers. The heart and the mediastinal tissues formed practically one large adherent nodular mass. Both pleuras were universally adherent. In freeing adhesions upon the left side, the lung, which was markedly caseous and contained many cavities, was extensively torn. The pericardium is universally adherent, the external surface being studded with yellowish nodules, varying from 0.2 to 2 cm. in diameter. In a number of places these nodules extend into the heart muscle, in some instances to a depth of more than a centimeter. The involvement of the heart is greatest in the left ventricle, but is quite extensive in

<sup>1</sup>Read at the Philadelphia Pathological Society, March 12, 1903.

the right. The liver, spleen, pancreas and kidneys contain miliary tubercles.

Microscopic examination shows the adhesions uniting the two layers of the pericardium to be formed of granulation and fibrous tissues in which are disseminated areas of caseation. At many points the visceral pericardium has disappeared, and the heart muscle shows invasion by lymphoid cells or even granulation and fibrous tissues. Sections from a dozen blocks have been examined, but in none of them have structures bearing any resemblance to an anatomic tubercle or a giant cell been found. A very few tubercle bacilli were found in one section.

Tuberculous pericarditis is not a notably infrequent condition, this specimen being presented because of the extent rather than the nature of the lesion. In 1,048 autopsies Wells<sup>1</sup> found tuberculous pericarditis ten times and Baginsky reports fifteen cases in 4,500 autopsies. Robinson<sup>2</sup> reports two cases, and fully discusses diagnosis and treatment. Riesman<sup>3</sup> reports a case of primary tuberculosis of the pericardium, and states that the primary form is rare, the most frequent source of infection being a tuberculous mediastinal or bronchial lymph gland, which was in all probability the source in this instance. To Riesman's article is appended a full bibliography. Sabin<sup>4</sup> reports a case in which recovery followed repeatedappings of the pericardium and the right pleura. Tubercle bacilli were found in the pericardial, but not in the pleural, effusion. Robinson states that tuberculosis as found in the pericardium is generally either of the miliary form or cheesy masses, though in certain instances there is no evidence of tuberculous deposit in the adhesions present. The myocardium may be affected at the same time as the pericardium, the former coming primarily, as a rule, from the latter. The caseous form penetrates deeper and may perforate the cardiac wall. Myocardial tuberculosis, however, is rare, Anders<sup>5</sup> collecting from literature but 71 cases, to which he adds one of his own. He states that Valentin found 7 cases of myocardial tuberculosis in 3,203 autopsies, and Sangalli 2 cases in autopsies upon 796 tuberculous patients. With the statement of Wells, corroborated by Osler, that "tubercular pericarditis is generally unaccompanied by any symptoms referable to the heart, and is almost always an autopsy finding," Robinson is inclined to differ. It may be of interest to note in this connection that Ferrand and Rathery<sup>6</sup> report a case of tuberculous vegetative endocarditis following primary tuberculosis of the spleen. Tubercle bacilli were found in the vegetations and in clotted blood in the heart. The question of adhesive mediastinopericarditis arises in this connection, but its consideration is beyond the scope of this brief paper. A careful clinical study of a case in which this condition, presumably tuberculous in origin, was diagnosed, has been recently published by Gibson, Bullmore, and Conder.<sup>7</sup> They compare their case with those of Harris,<sup>8</sup> whose exhaustive work is based on a study of 25 cases.

**American Pork Admitted to Turkey.**—Minister Leishman, at Pera, has cabled the State Department that the prohibition of American pork in Turkey, which has been in effect for five years, has been removed, and orders have been issued permitting entry, after the customary inspection.

**Cholera in Manila.**—The disease is reported to be steadily increasing throughout the Philippine Islands. The deaths in Manila average 20 weekly. The health authorities are taking every precaution against the spread of the disease, giving special attention to preventing a contamination of the water-supply.

## SARCOMA OF THE THUMB: REPORT OF TWO CASES.

BY

WILLIAM B. TRIMBLE, M.D.,

of New York City.

Instructor in Clinical Surgery, New York University (University and Bellevue); Chief of the University Clinic, Surgical Division; Assistant at the New York Skin and Cancer Hospital.

With Pathologic Examination

BY

GEO. REESE SATTERLEE, M.D.,

of New York City.

Instructor in Histology, University and Bellevue Hospital Medical College.

Because of the comparative rarity as regards location, I desire to report two cases of sarcoma of the thumb, the two patients having presented themselves within an interval of but four days.

In searching for information on the subject, a perfect sea of literature on sarcoma was encountered, and finally, after continued investigation, three cases of thumb sarcoma were found recorded in Mr. J. Bland Sutton's excellent and latest work on tumors; one case reported by Ferguson,<sup>1</sup> in a man aged 36; one by Hutchinson,<sup>2</sup> in a woman of 60; one by Bowlby,<sup>3</sup> in a woman of 55.

Nunn has reported a case of sarcoma of the fifth finger in a woman, and Lediard, one of the index finger also in a woman. In this country Dr. W. B. Coley had a patient with a sarcoma of the hand<sup>4</sup> and Dr. A. G. Gerster one of fibrosarcoma of the finger.<sup>5</sup> Sutherland, of London, has a case on record of epithelioma involving the metacarpal bone of the thumb; and several cases of cysts, lipomas, etc., of the fingers have also been recorded by Stabb Duboy and others, but in the language of Mr. Kipling, "that's another story."

The diagnosis was made chiefly by exclusion. On first inspection it seemed probable that the trouble might be either the ravages of syphilis or tuberculosis, or a malignant growth. The first was excluded by the therapeutic test, the second by the history of the patient and by close observation of the clinical appearance of the condition. This left the diagnosis one of malignant growth, which was afterward confirmed by the microscope. The result of the microscopic examination proved one case to be a giant-celled sarcoma, which is said to be the least malignant form, and the other a melanosarcoma, probably the most malignant kind.

**CASE I.**—A female, aged 39, presented herself about July 17, 1901. Family history negative; specific history negative. While washing windows two months previous she run a splinter under the thumb nail. A part of it was removed at the time by a neighboring druggist, a portion of the decayed wood remaining; suppuration followed and the nail came away, exhibiting a small ulcerated surface; the ulceration becoming gradually worse, and finding no relief, she sought medical advice. When first seen the thumb presented the appearance of a miniature bass-drum stick, the growth on the end being about the size of an English walnut. It was fungoid in appearance, greatly resembling exuberant granulation tissue. On the palmar surface of the distal phalanx the skin was healthy, the tumor being confined, in the main, to the dorsum. The tissues seemed to have proliferated very rapidly; so much so that the fungous mass turned on itself and overlapped the healthy skin on the dorsum, extending a little beyond the first joint. The tumor was about one inch and a quarter in length and one inch broad. The thumb was dressed antiseptically and the patient put on mercury and the iodids for four weeks, after which period no beneficial result was perceptible. Microscopic examination proved the case one of giant-celled sarcoma.

Amputation was advised and consented to. The operation was done under ether, and the ordinary oval or racket incision employed. The head of the metacarpal bone was removed to make the hand look better. The recovery was uneventful. A longitudinal section was made through the amputated thumb, which shows the growth coming from the periosteum.

**Microscopic Examination.**—The sections removed before and after amputation show the same picture; both were removed from the dorsum of the tumor.

Sections are made up of large round-cells; they contain proportionately large nuclei and are separated from each other by a scant amount of stroma. About the periphery are a number of round or oblong cells of large size which contain several

nuclei situated at the center of each cell. These cells are found only along the borders of the growth. The tissue is abundantly supplied with newly-formed bloodvessels. Pigmentation is absent. (See Fig. 1, Case I.)

vious to the present visit he noticed that his nail split slightly to one side of its middle, and in a short time it came off altogether. A small spot slightly pigmented was noticed in the film of skin over the nail-bed, which soon ulcerated through,

Case I.

Fig. 1.

Case II.

The tumor is a giant-celled sarcoma, probably less malignant than that in Case II.

Three weeks later microscopic examination of exuberant granulation tissue which had formed on the stump of the amputation wound showed no evidence of malignancy. [G.R.S.]

encroaching upon the adjacent skin. At the first examination the thumb showed a large fungous, spongy mass involving the whole of the distal phalanx, and extending beyond the first joint on the dorsum, in fact, half way to the second joint. The growth was about three inches long by two inches broad. It was exceedingly vascular, the removal of the dressings causing profuse hemorrhage. Here and there on the ulcerated surface were little patches of epidermis, as if they had been grafted on. On the dorsum the appearance was one of sloughing exuberant granulation, but on the palmar surface the ulcerated part was very dark, a deep black in some parts. The line between the diseased and healthy skin was of a dirty yellow color and the healthy part was excoriated from the discharge. A number of skin lesions were also observed on the back of both hands, dark red and scaly in character, which were probably specific in nature.

The thumb was dressed antiseptically and the patient put on syphilitic treatment for four weeks, during which time all the cutaneous lesions disappeared.

Microscopic examination revealed the fact that the growth was a melanosarcoma. Amputation was advised and the patient disappeared for fully a month. He afterward returned and consented to operation. In the meanwhile the growth had extended considerably, more on the dorsal than on the palmar surface. Operation was performed with the same incision as in Case I, only about one-third of the metacarpal had to be sacrificed to get healthy flaps. The lower end of the incision suppurated and two stitches were removed for drainage; for several days a dirty, pinkish sanious discharge exuded through this opening. It ceased finally, and the patient went on to recovery without further hindrance.

*Microscopic Examination.*—Section taken from the center of the tumor before operation.

At first sight the growth resembles carcinoma of the alveolar type. At the periphery there are numerous newly-formed bloodvessels and the tissue is infiltrated with leukocytes. Trabeculae of fibrous tissue extend down from the granulation tissue on the outside. Between the trabeculae are numerous large round cells, the nuclei of which fill up most of the cell body. In some places the nuclei contain pigment. Among the cells is a moderate amount of connective tissue stroma and a few leukocytes. Near the periphery are a few large cells which contain several irregularly arranged nuclei. The sections removed from the sloughing ulcerations on dorsum after amputation show a condition similar to the one previously described. Sections removed from the blackened area on the palmar surface show a mixed cell-growth with a considerable amount of pigment and high vascularity.

In Fig. 1, Case II, which is a sketch of sections from the first

Fig. 2. A.—Case I. B.—Case II.

CASE II.—A male, aged 43, presented himself about July 19, 1901. Family history negative. His wife died of "cancer of breast." He gives a history of a chancre 25 years ago, but does not remember any eruption following. Six months pre-

piece, some of the cells have fallen out in the manipulation of the specimen.

The tumor is a giant-celled melanosarcoma, probably originating from the bone, although none of the sections examined showed this definitely. It is a growth of great malignancy and of rapid formation. [G.R.S.]

In order to be sure of careful investigation both patients were put on increasing doses of "mixed treatment" for a month, during which time two microscopic examinations were made of each thumb. The specific treatment had no appreciable effect, and every report from the laboratory said unmistakably sarcoma.

A point to be taken into consideration is that both specimens showed giant cells; and as giant-cell sarcomas are frequently maroon colored on section it occurred to me that the second case might be only an ordinary giant-celled sarcoma. More proof in this direction is the fact that the man's urine contained no pigment, and his lymphatics were not implicated. Be that as it may, Dr. Satterlee assures me, after repeated examinations, that the growth is undoubtedly one of the melanotic variety. No section was made of the man's thumb, in order to have the tumor intact for inspection.

According to Bland-Sutton, primary melanosarcoma of the skin happens most frequently in pigmented moles, next in frequency comes the pigmented skin of the genitals, and the rarest form of all occurs in or near the nail of a finger or toe. These growths began as a pigmented spot in the nail matrix. In neither of the patients were the lymphatics involved at or previous to the time of operation. I removed the man's thumb under very adverse circumstances, and as said before in this history, a certain amount of suppuration took place, and two of the stitches were removed to secure proper drainage. This point may awaken some interest and possibly may be of some benefit to the man, as Dr. Wyeth of this city has reported a case in which a large sarcoma of the abdominal wall was only partially removed, suppuration ensued, and the patient made a good recovery, no recurrence having taken place after 10 years.

A photograph of each thumb has been made and a microscopic drawing from each case is also shown.

### SERIOUS INFECTION FOLLOWING PUNCTURE, LACERATION, OR CONTUSION OF THE FINGER OR TOE.

BY

THOS. H. MANLEY, M.D., PH.D.,

of New York City.

Visiting Surgeon to Harlem and Metropolitan Hospitals, New York.

I have been peculiarly struck by the large number of very grave cases of "white erysipelas" or widespread and intensely acute phlegmonous inflammation, following comparatively trivial injury in all instances, which came under my observation in dispensary and hospital practice during last December and January. The infection was of a most virulent type, spreading rapidly up the forearm from wounds of the fingers.

In one instance a hearty, vigorous man sustained a puncture in the pulp of his index finger from a penknife. He gave the matter little attention until four days later, when inflammatory changes extended up into the hand; four days subsequent to this he declined the drastic resources of surgery appropriate for less dangerous cases. A week later when septicemia was present an amputation at the shoulder-joint was offered as his only hope, but he died the same night with nothing being done.

An important question in connection with this class of cases relates to the causes in operation which initiate

these grave pathologic changes. Are they purely local and solely dependent on the virulence of some specific germ or toxic substance forced into the tissues at the time of accident? They evidently are not; the microbe is certainly on the ground, but the way must be prepared for it.

We note that this class of cases occurs, by all odds, more frequently in the winter and spring seasons, and that in some years such cases occur in greater numbers than others, at about the time when carbuncle, felon, and their next of kin, erysipelas, are most in evidence.

The late Sir James Paget, in writing on infection at autopsies, expressed his belief that the state of the system of the poisoned individual was, without doubt, a factor; that the degree of tolerance or immunity from time to time varied. Early and active treatment can stamp out the lethal element in operation, in every instance, as delay, or lack of skill or nerve, means very serious consequences to the afflicted.

Let us first fasten the fact in our mind that the early changes are always local, that the lymph ganglions constitute powerful defenses against systemic invasion, and that when toxic absorption, by the circulation, is in small doses it will be neutralized by the plasma or oxidized in the pulmonary organs.

The first tissues seized on by the lethal elements in operation here, are the cutaneous and connective, precisely the same as we find in genuine erysipelas; and clinically, it only differs from it in the absence of the lobster redness and metastatic invasion. Lymphangitis is always well pronounced; but the real mischief only begins when the vascular supply is compromised. Vasomotor paralysis is always an early phenomenon, and however a case may terminate, the pathologic feature is slow to yield.

The surface and subcutaneous veins are the seat of inflammatory changes, and hence there is a widespread stasis in the capillaries and vesicles. This stagnant state permits of serous effusion and widespread edema. The tissues are in a condition of incipient asphyxia; the agonizing distress of the patient at this stage is nature's monitor of danger; it is the cry of the terminal nerve filaments for fresh blood. Let us beware, then, of the free use of narcotics at this juncture. From the capillaries there is a propagation backward into the arteries of septic invasion, and once their intima is seized on marked changes spread rapidly toward the body, embolic occlusion of the main trunks preceding. The enormously distended, engorged limb, in advanced cases, is supersaturated by a most virulent substance; the blood-vessels, notably the veins, are overcharged with the putrid products of infective changes. By a salutary provision of the economy their walls are paralyzed and their contents motionless, still, and stagnant.

An insight into the pathology clearly suggests the line of attack: it must be local, *i. e.*, applied to the limb involved, or its appendage when we are only assured that its vitality is intact. Nothing less than the free use of the scalpel will suffice; the limb must be freely exsanguinated in the areas of the greatest distention; the tissues must be disinfected; and here, in my opinion, comes in one of the most valuable discoveries of modern times, the Powell-Phelps mode of directly charging the tissues with pure carbolic acid, to be displaced and neutralized by strong alcohol.

In one of my own cases that seemed to carry a forlorn hope, through two very large incisions, carried down to the bone shafts, and after freely dividing the muscle-sheaths, four ounces of pure phenic acid was injected; then, after a moment, squeezed out and followed by pure alcohol. The local and systemic changes resulting were most salutary. After this is done, the very warm emollient dressings, heat and moisture, free drainage, and rest are ordered.

After operation—for this is a radical surgical procedure—the patient is in a state bordering on collapse.

For this opium is invaluable, the pure resin, in pill or powder; hot drinks, coffee, tea, fresh beef juice, soups, milk and eggs. After the temperature falls small doses of calomel, quinin, Huxham's tincture of cinchona, or other bitter tonic may be given with advantage.

Recovery is slow; in some cases there has been most destructive waste of muscle, with widespread, intermuscular deposits of inflammation, so that in various groups of muscles there follows diminished contractile energy. The appendages—the fingers, the hand and wrist—over a long period remain stiff and weak; in some rare instances this impairment in the function of the limb remains permanent.

## THE USES AND ABUSES OF THE URETHRAL SOUND.

BY

J. HENRY DOWD, M.D.,

of Buffalo, N. Y.

Considering the steady advancement made in all branches of medical science during the past few years it may seem a loss of time to write of such a trivial matter as the use of the male urethral sound. At the outset it may be stated that it is not my intention to bring out anything new or startling regarding an instrument that has been used for centuries, but rather by some undisputed facts to try and convince my readers that many of the sought for but unobtained results, also the complications which so frequently follow, are not due directly to the use of the sound, but to the condition of the mucous membrane at the time the instrument was used. No other instrument known to surgery will give the same happy results as will the sound when it is used at the proper time and in cases indicating it. It cannot be denied that no matter how intelligently used irritation will follow, more or less in degree with the already existing pathologic condition present. From this it must be evident that the use of the sound when there is a general inflammation from the meatus to the internal sphincter, even though it be of a chronic nature, must surely be followed by more disturbance than if the condition was localized. The steel sound is the very best instrument for promoting absorption of inflammatory deposit impinging upon and surrounding a dilatable tube, but the great question why do not more favorable results follow its use may be answered: It is not used at a time when it and nothing else will give the desired results. For instance, in the case of acute urethritis, if the discharge has not ceased in from four to six weeks, even though it be the first infection, the patient is told he has a stricture and treatment by sound is begun, resulting in 99% of the cases in exaggerating the condition and in a goodly number being the direct cause of epididymitis, prostatitis, vesiculitis, etc., often becoming chronic and making an invalid of the patient for months or years, and in some instances the patients never recover.

When the prostate is involved the inflammation is usually of the follicular variety and there is no doubt that at this time we have the first seed of hypertrophy. When dilation of the urethra is necessary, except in those cases in which there has never been infection, either simple or specific, pus is always present. Although the patient may urinate just previous to sounding, if the canal were examined pus would be found adhering to the walls; this is especially true when the inflammation is of a very chronic nature such as exists in front of or behind a stricture, or when granulations are present. When such a condition is present it must be evident that when a sound, or for that matter any instrument, is passed through the canal that has not been previously flushed, the adherent debris will be carried forward, being forced into the numerous follicles along the canal and in the prostate. Gonococci may not be found in the pus, but streptococci and staphylococci are demonstrable

in every case, and these are capable of producing inflammation, although it will be of a milder character than by the former.

Some general rules for use of the steel sound follow:

1. When the urethra has been involved by inflammation, specific, or otherwise, no instrument, and especially the steel sound, should be used until the urine is clear excepting for shreds or floating particles. (Prostatic plugs.)
2. The urethra should in all cases be flushed with an antiseptic solution (formaldehyd, 1-3,000) before the passage of any instrument. Following its withdrawal an astringent should be used, preferably silver nitrate 1-10,000.
3. A sound should never be passed for at least three months following acute gonorrhoeal infection, and then only when the urine is as in No. 1.
4. When dilation of a stricture will answer, sounds are increased in size according to the tissue forming the pathologic growth and its location. True gonorrhoeal strictures of the deep urethra may be dilated five or six numbers at each sitting, up to 18 or 20 F.; following this two or three numbers should be the rule.
5. In case of traumatic or gonorrhoeal stricture in the pendulous urethra, or when the sound is followed by marked irritation, etc., cutting gives the best result.
6. When the contraction seems not to dilate without too much force, weekly treatments being followed by considerable irritation, making the interval 10 to 14 days is generally followed by the most gratifying results.
7. Stricture can be permanently eradicated. This occurs when after dilating the circular muscles of the canal to their fullest extent, without rupturing, no bloody string is found in the washings after four to six dilations which have varied from one to four months apart.

### THE DUTIES AND RESPONSIBILITIES OF TRUSTEES OF PUBLIC MEDICAL INSTITUTIONS.

The Presidential Address at the Sixth Congress of American Physicians and Surgeons, Washington, May 12, 1903.

BY

W. W. KEEN, M.D., LL.D., F.R.C.S. (Hon.),  
of Philadelphia.

Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia.

The value of occasional and stated gatherings of the principal leaders of medical thought in the various special departments is acknowledged by all. Certainly those who have attended this Congress, now held for the sixth time, have felt its broadening influence. We are all apt to become narrow when we are devoted heart and soul to one specialty, be it medicine, surgery, physiology, ophthalmology, or any other. When we meet nearly all of the more prominent men in cognate interrelated branches of medicine in Washington every third year, we are sure to find that there are as interesting and as important questions in other specialties as there are in our own; and, moreover, we are sure to find that there are men of as acute intelligence, wide reading, and original thought in other than our own departments whom it is our pleasure to meet, and whose acquaintance becomes not only valuable for what we find them to be, but because of the stimulus that they give to our own thoughts.

Ordinarily the Presidential address has been devoted to some special professional topic. My first idea was to select such a subject for tonight, but as I was absent from the country when I received the very highly appreciated notice of my selection, I asked the members of the executive committee for suggestions, being sure that their united judgment would be better than my own. I was very glad when they proposed

the topic upon which I shall address you, partly because it is different from the usual type of such addresses, and partly because it seems to me appropriate to the present time. I shall, therefore, give the time at my disposal to presenting to you some thoughts on "The Duties and Responsibilities of Trustees of Public Medical Institutions."

Before entering upon my topic I beg to state explicitly that what I may say is offered in no spirit of unfriendly criticism, but only by way of friendly suggestion. I have been too long and too intimately associated with scores of such trustees not to know that they are almost without exception generous, self-sacrificing, giving of their time and money and thoughtful care without stint and often sacrificing personal convenience and comfort for the good of the college or hospital which they so faithfully serve. Anxious to discharge their trust to the best of their ability, I am sure they will accept these suggestions, the fruit of 40 years of personal service as a teacher and a hospital surgeon, in the same friendly spirit in which they are offered.

There are two such classes of institutions to be considered: (1) Medical colleges, and (2) Hospitals, whether they be connected with medical schools or not.

There is, it is true, a third class of trustees for a wholly new kind of medical institution which has arisen as a modern Minerva Medica, born full-armed for the fray. Of this class we have as yet but a single example—the Rockefeller Institute for Medical Research. Akin to it are laboratories for special investigations such as the two Cancer Laboratories in Buffalo and Boston. But the Rockefeller Institute is so recent, and its scope at present necessarily so undetermined, that I would not venture to consider the duties of these trustees, and I am sure their responsibilities are adequately felt by them. Moreover, their admirable selection of a Director for the institution is the best pledge of a future wise administration. I heartily congratulate the Profession and America upon the establishment of so peculiarly useful an institution. Its founder has wisely left its work unhampered saving as to its general purpose, and the whole world, and especially the United States, will soon be his debtor for researches and discoveries that will abridge or even abolish some diseases, shorten sickness, prolong life, and add enormously to the sum of human happiness. Could any man of wealth by any possible earthly gift win for himself a higher reward or a happier recollection when he faces the future world?

Though not a medical institution, I cannot refrain also at this point from expressing not only for myself, but for you, our hearty appreciation of what the Carnegie Institution has done for medicine in the reestablishment of the *Index Medicus*. This publication is essentially and peculiarly American in origin, but its usefulness is worldwide. It aids alike an author in Japan or in India, in Europe or America. It is one of the best and wisest undertakings of this lusty educational giant. But to ensure the permanent publication of the *Index Medicus* the profession must show that it really values this generous gift. Unless the *Index* finds a hearty support in the profession abroad and especially at home, we can hardly expect the continued publication of this unique and invaluable publication. May I earnestly ask, therefore, of this audience of the chief medical authors of the United States that each one will demonstrate his appreciation by an immediate subscription to the *Index Medicus*.

There are some matters common both to the medical college and the hospital which may be considered together. The most important of all these is the cordial and hearty cooperation of the medical men connected with the college or hospital and the boards of trustees. In order to ensure this the members of each body must be acquainted with each other. I have known of instances in which if a professor in the medical school ventured to suggest any changes as to its management, or even to state his opinion as to the qualifications of a candidate for a vacant professorship, his suggestions were resented as an interference instead of being welcomed as a means of valuable information. I take it for granted that we should not offer such suggestions after the fashion of a partisan either of a man or a measure, for the advancement of a friend or to the disadvantage of an enemy, but solely for the good of the institution with which we are connected. He who would endeavor to foist a friend

upon an institution *because* he is his friend, and in spite of the fact that a rival is the abler man and better fitted for the position, is just as false to his duty, to his college, or to his hospital, as the trustee who would vote for the less desirable man on the ground of personal friendship, or of association in some society, church or other similar body. Of all these influences that arising from membership in the same religious body is, I fear, the most frequent and yet most absolutely indefensible. What one's theological opinions are has no more to do with his qualifications for a professional or hospital appointment than his opinions on protection as against free trade, or whether Bacon or Shakespeare wrote Hamlet.

I have always honored one of a board of trustees, who was an old personal friend of my father's and who had known me from boyhood, yet who in my early professional career, when I asked for his vote for an important hospital appointment, had the manly courage to tell me that he thought a rival, who was older and more experienced, was the better man for the place and that he should, accordingly, vote for him and not for me. I confess it was at the time a bitter disappointment to me, but I never had so high an opinion of my father's friend as after he denied me his vote.

There should be in my opinion but two questions asked in considering the election of either a professor or a hospital physician or surgeon. First, which one of the candidates for the place has the best qualifications from the medical point of view? This should include not only his scientific knowledge, but his ability practically to impart or to apply that knowledge. Secondly, are his personal qualifications and character such as to make him a desirable incumbent of the position. It must be remembered that a man may be scientifically and practically an extremely able man, but of such a quarrelsome disposition or the unfortunate possessor of some other similar personal disqualification as to make him a most undesirable member of a staff. The personal equation may be quite as important as the scientific qualification. Of course his personal moral character should be above reproach. To place a drunkard or a libertine in a position of so much responsibility and influence is to abuse a trust. No patient should be confided to the care of such a man and still more no such man should be made an instructor of young men, upon whom his influence would be most disastrous.

It is often extremely difficult for a layman to reach a correct conclusion as to the qualifications of medical men for college or hospital appointments, because of the confident, yet conflicting statements of their friends. But there is apt to be a certain clear partisanship in such statements which betrays the purpose of the speaker. Especially will this be so if he advocates the election of A or B on the lower grounds of friendship, social position, or for other similar motives. The man who is advocating the best man because he is the best man has the stamp of sincerity upon every word.

Perhaps the most striking example I can adduce of such an unfortunate misjudgment is Dr. S. Weir Mitchell, who was denied a professorship in both the medical institutions of his native city, thus depriving them of the most brilliant medical genius that America has produced within my personal recollection. For him it is now a matter of indifference, and for American literature it has been a gain. But for medicine, and especially for physiology, it was an immense loss. Both of his rivals were estimable, worthy gentlemen who held an honorable position in the profession, it is true, but Mitchell is a genius. "Eclipse was first; the rest were nowhere."

One of the best methods of bringing the medical board and the board of trustees into more intimate contact would be to have the dean or a committee of the faculty, or, in a hospital, if the staff is not too large, the whole staff invited to the meetings of the board. Here I can speak from personal experience. At the Orthopedic Hospital and Infirmary for Nervous Diseases in Philadelphia there are three surgeons and three physicians. These members of the medical staff are invited to meet with the board of managers at each monthly meeting, excepting the annual meeting, when the medical staff is elected. They are free to express their opinions on any topic relating to the management of the hospital to which their judgment may contribute something of value, but when a decision is taken they have no vote. It is purely in an advisory

capacity and for the purpose of giving and receiving information that they are present. The plan works exceedingly well. When economy is necessary in the hospital the staff is fully acquainted with the fact and can cooperate with the trustees; when expenses have run up from carelessness in the wasteful use of dressings or appliances, a halt is called; when, alas, very rarely, the treasurer is all smiles, and plans for the extension of the hospital, or the installation of some new addition to the plant is contemplated, their knowledge as to the necessity, for instance, of a hydrotherapeutic or an x-ray plant, or a new operating-room is of the greatest possible value. Nothing but good, in my opinion, can come from such personal cooperation.

One of the difficult questions which boards of trustees have to face is whether there shall be a fixed age at which a college professor or a hospital physician or surgeon shall retire from the active duties of his post. I firmly believe that they should fix such a retiring age in the interest of the students and the patients. As age advances a man's opinions and his practice become "as petrified as his arteries." He is incapable of constant study, of adding to his knowledge or of keeping up with the feverish strides of medicine. He ought then to be relieved of his cares and his duties. If no rule exists he is allowed to continue his inefficient or even disastrous work, or by some harsh suggestion is compelled to give place to another more competent man. A rule is a condition accepted when he is appointed, and just as in the army and navy, when an officer reaches 64 or 62 years of age he is retired on reduced pay, and because it is a rule he does not feel hurt or humiliated; so in a college or a hospital, when time and the rule bring us to the period when we must gracefully retire, no one's reputation is injured or his feelings lacerated.

I have ascertained that the following rules are in force in some of the larger institutions:

At Harvard the age when a professor may request to be retired is 60, provided he has been in the service of the university for 20 years, with a reduced pay ranging from one-third to two-thirds of his salary. At 66 he may be retired by the President and Fellows partly or wholly. The details of the plan are admirably arranged.

At Chicago, while no plan is yet in force, largely, I presume, because of its recent establishment on the present basis, such a plan will soon be made operative.

At Columbia the retiring age, after 15 years of service, is 65, either at the request of the professor or upon motion of the trustees, and on half pay.

At Yale the retiring age is 65 after 25 years of service and on half pay, but the retirement is not compulsory. It will probably be made compulsory before long.

At Cornell the retiring age is 70, but the Pension Fund will not be available until 1914. The retiring pension will then be \$1,500.

At the University of Pennsylvania and at Johns Hopkins no retiring age is fixed.

The only hospitals I know of in which a retiring age is fixed are the Massachusetts General Hospital and the Boston City Hospital. At the former the compulsory retiring age of the surgeons is 63, and of the physicians 65. At the Boston City Hospital the visiting surgeons are retired at 65, but the physicians, gynecologists, and all the other medical officers continue in service indefinitely—a very curious anomaly.

These varying, but in the main identical provisions when any exist, show the trend of thought and practice. They generally apply to the medical department, except that in case a professor is engaged in the practice of his profession and so has a private income the provision for continuing a portion of his salary does not apply. This is right and fair. Of course, in all hospitals where there are no salaries, no provision as to reduced salary would obtain.

The point I wish to emphasize is, however, that the age limit (which in my opinion should be 65) should be compulsory and so not be invidious in any given case. It will be objected that not a few men are in full intellectual and physical vigor at 65, and it will be a detriment to the institution to lose their services when their ripe experience and admirable teaching are most desirable. I admit it. But for every one

such case of harm done by compelling a man to stop, there are a score of instances of men who are doing vast injury by their inefficiency. Moreover, in the very few cases in which it might be allowable, as boards of trustees make rules they can unmake them, and in special cases they could pay a graceful compliment and preserve to the institution their exceptional men by extending the limit to 70. In no case can I think it wise to go beyond this limit.

In some of the universities I have quoted a sabbatical year of rest or study is allowed a professor. He is put upon half pay and his place is filled by a temporary substitute, who receives the other half of his salary. I believe that in present conditions this should not be applied to medical faculties, for nearly all of the professors are in active practice and take sufficiently long summer holidays. These latter are often spent in observation and study abroad—a most useful and remunerative employment of a holiday—and serve the purpose of the sabbatical year for men whose entire time is given to their teaching. In hospitals it certainly should not apply.

One of the recurring questions in hospital and college management is whether there should be a certain number of doctors on the board. I know that there is a wide diversity of opinion upon this point. My own belief is that a small proportion of well chosen medical men is a distinct advantage in such boards of trustees. I have said a "small proportion," for it should not be, I think, larger than probably 20%; and I also said "well chosen;" that is, they should be men of large mental caliber and executive ability. It should be distinctly understood, if not indeed absolutely expressed, in institutions in large cities at least, that any physician or surgeon placed upon such a board should never be eligible, even by resignation from the board, for a position on the faculty or the medical staff. In small towns the lack of suitable persons for hospital trustees and members of the hospital staff might make it desirable not to institute such a rule.

Moreover, such medical men should be selected for trustees as by their mental training, social relations, and personal character would be, so far as it is possible for human nature to realize such a position, absolutely free from influences arising from personal jealousy or professional bias. If it were a social club it would be perfectly proper to vote against a man because he is personally distasteful, but where it is a scientific body responsible for the education of large numbers of young men and for the care of still larger numbers of hospital patients among the poor, even if a candidate were personally unfriendly I should vote for his election if he were the man best fitted for the place.

Turning now to the duties and responsibilities peculiar to trustees of hospitals, let me point out the objects of a hospital.

First, the care and the cure of the sick and injured; secondly, the education of medical men and medical students; and thirdly, the promotion of knowledge, which, in turn, will inure all over the world to the more speedy and certain cure of the sick and injured, and so be of the greatest benefit to humanity.

In order to accomplish these three purposes, it is necessary that the hospital shall have sufficient funds to purchase ground, erect buildings, and provide a thorough material equipment. It is a great pleasure to me, as to you also, to note that throughout the length and breadth of the land the medical and surgical staff never tax the always inadequate resources of hospitals for any remuneration. They serve without pay, they give ungrudgingly and freely day and night, to the poor often for many years, their time and skill, without ever a thought of any money reward. Their reward comes from increased knowledge and skill, and the daily blessing invoked of heaven, often lisped in children's prayers or breathed in mothers' benisons which pass not unheeded by the Recording Angel.

But, as I have pointed out elsewhere, instead of receiving any pay, they give to hospitals. The mere money value of this daily gift of the profession to the poor amounts to an enormous sum. The value of the professional services of the staff of the Jefferson Medical College Hospital, a single hospital in a single city, on a moderate basis of fees, I found was more than half a million dollars annually. The millions upon millions of money given in that most self-sacrificing form—personal service—by the entire profession all over the United

States, and I might add with still further pride, all over the world, is simply incalculable. The Gideon Grays and Weellum MacLures are not found only in Scotland or at the countryside. They are even more plentiful in the slums of our great cities giving of their time, their skill, and what is more, their hearts, their lives, themselves to the service of humanity.

Trustees sometimes seem to take it for granted that their duties are ended when they have done two things: begged or given and safely invested the necessary funds, and then elected the staff. To my mind their duties do not by any means end at this point. They should see to it that the resources of the hospital are utilized to the utmost in doing the largest good.

Let us see now how the objects of a hospital, as I have stated them, can be realized. The first object is the care and cure of the patients. But the cure of any individual patient is not the "be all and the end all" of a hospital. His cure must be a means of larger vision to the doctor, who will thus be better fitted to care for future similar cases. Even his death, if he cannot be cured, should minister to the increasing knowledge and skill of the doctor so that he may be able to snatch future victory from present defeat.

The second—the training of doctors and students—is frequently carried out, but sometimes even objected to. There are three classes of doctors who are trained by a hospital: first, the staff of the hospital itself. I have lived through the period of the establishment of hospitals in many of the smaller cities and towns, and in some cases even villages in this country, for it was a rare thing in my early professional life for any except the larger cities to have hospitals. The moment that a hospital is established with its medical and surgical staff, that moment a new era has dawned on the *community* in which the hospital is established. More careful methods are introduced, greater cleanliness is observed, hygienic conditions are bettered, laboratory methods are inevitably introduced in time. Even if the old timers who graduated years before our modern laboratory methods were adopted do not care for them or cannot use them, the young fellows who come fresh from our medical schools and serve as residents, and even the nurses graduated from our training-schools, finally shame the older ones into better ways and greater exactness, not only in the hospital, but in their private work as well.

As a consequence of the establishment of these hospitals and the added skill and training of the local physicians and surgeons the character of the consultations of the physicians and surgeons of our great medical centers has been greatly modified. The really simple cases, such as hydrocele and small tumors (and even large ones), clubfoot, harelip, etc., which used to be sent to city consultants, are now successfully operated on by the local surgeons and only the more difficult, serious, or complicated cases are sent to the cities. This is a great advantage to the patient, whose good is the first consideration, and to the local medical men; and though seemingly a serious loss to the city consultant, it is in the end an advantage, as he must prove his better metal in the higher scientific fields and be, as well as seem to be, the better man.

Moreover, the trustees of every hospital should see to it that a good library and laboratory are provided. Insensibly the staff will read more and more. A single restless progressive spirit, even though it be a young interne, calling attention to this case and to that, in one journal or another, will compel the rest of the staff to read in spite of themselves. It is absolutely clear that a laboratory with modern equipment for bacteriological, pathological, and chemical research in its examination of tumors, of the urine, the sputum, the feces, the blood, the pus, and other fluids from wounds, etc., is a necessity in every hospital. Even many of our smaller hospitals are equipped with microscope and reagents if not with a complete bacteriological outfit, which nowadays is inexpensive and imperative. All of this raises the intellectual and professional standard of the staff. I venture to say that no town of 20,000 people can afford to be without its hospital for the sake of its *own citizens*, utterly irrespective of the good it does to the poor who are treated in its wards. It must be established in the interest of the *well-to-do citizens* and their families so that they may secure better equipped doctors for themselves as well as for the patients in their hospital. Self-interest, therefore, will

compel every community to establish its hospital, even if charitable motives had no influence.

Again, the trustees of all hospitals of any size should establish a training-school for nurses. Only those who, like myself, have lived in the period before such training-schools were established, can appreciate the vast improvement effected in a hospital by this change. To replace the former ignorant, untrained attendants by "trained nurses whose jaunty caps and pretty uniforms and often winsome faces almost make one half wish to be sick, and when one is sick, half loath to be well," is not only a boon to the patients but to the doctors as well. The intelligent, well-trained nurse, who is on the alert to observe every important change of symptoms and who will keep accurate bedside notes, is the doctor's right hand. Not a few patients who would otherwise lose heart and hope are, one may say, lured back to health and happiness by the tactful attentions and restful but efficient care of such a nurse. The community of the well-to-do also are benefited, because the hospital provides them with skilled nurses in their homes when they are so unfortunate as to be compelled to remain there instead of going to the hospital.

The old repugnance to entering a hospital when sick or when an operation is demanded is rapidly fading away. The immense advantages of a good hospital over the most luxurious home are now acknowledged on all hands. The poorest patient in a hospital is better cared for, his case more carefully investigated by bacteriological, chemical, and clinical methods in a hospital than are the well-to-do in their own homes. Indeed, wise surgeons, except in cases of emergency, now very properly refuse to do operations in homes instead of in hospitals. In many instances lives that would be lost in homes are saved in hospitals, where the many and complex modern appliances for every surgical emergency are provided.

The hospitals in direct or indirect connection with medical schools, however, do a far larger work than merely the training of its own staff of doctors. They train three other classes of doctors: First, the undergraduates who are aspiring to the degree; secondly, graduate physicians who spend a certain amount of time in the hospitals either as internes or as temporary students refurbishing their professional knowledge; and thirdly, experts in certain branches of medicine and surgery.

The undergraduates are taught first in the general clinics, where to some extent they learn both by didactic instruction and by seeing the patients, hearing their histories, and witnessing the institution of proper treatment by prescription, by regimen, or if necessary, by surgical operation. This is of great value, particularly in the more important cases, and especially, for I speak now as a surgeon, in important operations. It is often objected that students see nothing in large clinics. To some extent this holds good; but no student can look on at an operation when the jugular vein or the lateral sinus is torn, the pleural cavity opened, the bowel lacerated, or other of the great emergencies of surgery occur and fail to be impressed by the coolness of the operator, the carefully explained methods adopted for remedying the mischief, and the various devices used by him to save life, all of which hereafter will be used when similar emergencies may occur.

Yet far more important than the public clinics are the smaller clinics held with classes of 10 to 20 men each, when under an experienced teacher the absolute work of the clinic is divided among the various students in turn, watching the pulse and the respiration, giving an anesthetic, assisting actively at operations, percussing the chest, palpating the abdomen, determining inequalities of the surface or the varying density of underlying organs. Here is the real forum in which our modern medical student acquires his skill. In many cases visits in the ward itself are made, and to a small group around the bedside the physician or surgeon will point out the phenomena to be recorded, the need for the examination of the blood, the results of bacteriological cultures, the facts discovered by the microscope, or the chemical reagent. By the Socratic method also he will reveal to the student the imperfection of his knowledge, call out—educate—his powers of observation, of reasoning; stimulate his thought, and give him an impetus which will last throughout life. Who that has "walked the hospitals" with a Skoda, a Trousseau, a Nélaton, a Da Costa, or a Mitchell can ever forget their teaching?

It is sometimes objected by those who are not familiar with the actual facts, and especially by trustees, that this method of actual bedside instruction does harm to the sick. I speak after an experience of nearly 40 years as a surgeon to a half dozen hospitals and can confidently say that I have never known a *single patient* injured or his chances of recovery lessened by such teaching. Of course, the physician or surgeon uses common sense. He would not allow a number of men to palpate the abdomen of a patient with peritonitis, or move an acutely inflamed joint, nor would the physician allow a patient with pneumonia to have the chest unduly exposed, or a typhoid fever patient disturbed if his condition was such that it would be inadvisable. But such cases are the exception. In fact, many of you are familiar with patients who have responded to repeated percussion by members of such a class by prompt recovery, attributed by the patient to the supposed medication of percussion. Moreover, it is by this actual practice only that the student acquires the necessary skill in the use of modern instruments of precision, such as the stethoscope, the laryngoscope, the esthesiometer, the sphygmomanometer, the various specula. Here he learns when to make blood counts, how to take histories, arrive at the actual facts by skilful cross-questioning, note the varying symptoms and physical signs of a case, determine the need for laboratory investigations, all under the guidance of skilled observers, who will point out his errors, encourage his queries, and stimulate his thought.

Moreover, trustees may overlook one important advantage of a teaching hospital. Who will be least slovenly and careless in his duties, he who prescribes in the solitude of the sick chamber, and operates with two or three assistants only, or he whose every movement is eagerly watched by hundreds of eyes, alert to detect every false step, the omission of an important clinical laboratory investigation, the neglect of the careful examination of the back as well as of the front of the chest, the failure to detect any important physical sign or symptom? Who will be most certain to keep up with the progress of medical science, he who works alone with no one to discover his ignorance; or he who is surrounded by a lot of bright young fellows who have read the last *Lancet*, or the newest *Annals of Surgery*, and can trip him up if he is not abreast of the times? I always feel at the Jefferson Hospital as if I were on the run with a pack of lively dogs at my heels. I cannot afford to have the youngsters familiar with operations, means of investigations or newer methods of treatment of which I am ignorant. I must perforce study, read, catalogue, and remember; or give place to others who will. Students are the best whip and spur I know.

Of the value of training graduates in postgraduate work I need scarcely speak to this audience at least. The doctor who graduated 5, 10, or 15 years ago comes to our great centers of medical education and renews his youth at the fountain of knowledge. He learns the use of all the new instruments, sees new methods of operation, new methods of treatment, new means of diagnosis, and goes home an enormously better equipped man.

The trustees should see that the staff does not become fossilized by following the same ancient local methods from year to year, but should encourage them to visit other hospitals, see other men operate, hear other men discourse on the latest methods of investigation, and then import into their own hospitals all the good found elsewhere. I learn a deal by such frequent visits to the clinics of my brother surgeons, and if one who has grown gray in the service can thus learn, surely the younger men can do so. When we are too old to learn we are too old to remain on a hospital staff.

I do not know anything which has more impressed upon me the enormously rapid progress which surgery is making than a recent experience. I was absent from this country for almost a year and a half. In that time circumstances were such that I saw almost no medical journals and but few doctors. I have been home now eight months and even with incessant work I have not yet caught up, so rapid has been the progress of surgery in this short time. Had I been absent for five years verily I should have been a "back number," and never could have caught up at all.

In his very excellent Presidential address before the Asso-

ciation of American Physicians in 1901, Professor Welch made a plea for hospitals to afford "the requisite opportunities to young men who aim at the higher careers in clinical medicine and surgery." He called attention to the fact that in our bacteriological, pathological, and anatomical laboratories the opportunities, though still too few, were reasonably good, and in a few places exceptionally good, for the training of young men for positions as teachers of anatomy, pathology, and bacteriology. Any young man in these departments who by good hard work makes for himself a name is fairly sure, before long, of being called to some important post as a professor, director of a laboratory, or some similar position. But the opportunities for work in clinical medicine and clinical surgery are far more restricted, since opportunities for both the exercise of their clinical skill are less frequently open to them and the opportunities of combined physiological, pathological, bacteriological and anatomical research along with their clinical work is but scantily provided for. This plea is reinforced by the recent paper of Sir Michael Foster (*Nineteenth Century*, January, 1901, p. 57). These special graduates, bright young men, determined to devote themselves to one or another department of medicine or surgery, are the men who bring honor to the school at which they obtain their training, and are invaluable to the community. They are the future Jenners, Pasteurs, Virchows, Listers, DaCostas and Grosses, and our hospitals should provide for these exceptional men exceptional facilities.

The third object of a hospital is the promotion of knowledge, and so, fourthly, the good of humanity. Physicians and surgeons engaged only in private practice do not generally keep notes of their cases, and rarely publish important contributions to knowledge. I find in 100 books taken consecutively in my library that 85 were written by hospital men and only 15 by authors not connected with any hospital so far as was indicated on the title page.

In order that proper investigations may go on, trustees should enforce a permanent record of all the cases treated in the hospital, properly indexed, from which the staff may derive their data for papers and books. Each large hospital should have its pathological resident as well as the clinical residents in the various wards, so that postmortem records shall be well kept, pathological, bacteriological and chemical investigations of the various secretions, or blood counts, etc., shall be properly made and permanently recorded in such a manner as to be accessible.

It is too often the case that trustees, as I have said, regard their duties and responsibilities at an end when they have taken care of the funds and elected the staff. They may say that after all this is their real duty, and that all that I have advocated is medical and surgical, and the responsibility for it should devolve on the staff and not on the trustees. I do not take so narrow a view of the duties of trustees. When they have elected a physician or surgeon, if he neglects his duty, it is their business to displace him and fill his place with another man who will attend to his duty, and the duties that I have indicated pertaining to the increase of knowledge as well as of its diffusion are quite as much within their province as it is to see that the funds are invested to the best advantage. The intellectual funds as well as the invested funds must bring in good dividends.

If trustees and staff work together for such a purpose and in such a manner, they will create an ideal hospital which will do more good to the patients than any other type of hospital. It will attract the best physicians and surgeons in every community, will acquire the best reputation, not only local, but it well may be national, and do the most for the good of science and the benefit of humanity.

It may be said that this is an unduly strenuous view of the duties of trustees, that in our father's day and in our own earlier lives no such conditions existed or were contemplated. "I need hardly ask a body like this," said President Roosevelt in addressing the Methodists assembled in council, "to remember that the greatness of the fathers becomes to the children a shameful thing if they use it only as an excuse for inaction instead of as a spur to effort for noble aims. . . . The instruments with which, and the surroundings in which we work have changed immeasurably from what they were in the

days when the rough backwoods preachers ministered to the moral and spiritual needs of their rough backwoods congregations. But if we are to succeed, the spirit in which we do our work must be the same as the spirit in which they did theirs."

Moreover, we must remember that "the world-field into which all nations are coming in free competition by the historical movement to which all narrower policies must sooner or later yield, will be commanded by those races which, in addition to native energy and sagacity, bring the resources of scientific investigation and of thorough education." The international race for the leadership of the world is just as strenuous and intense in medicine as it is in commerce. If we are going to join the race and win the prize there must be the highest development of American education at the top. The best men must be pushed to the front, and ample opportunities for growth, for investigation and for original research must be provided. Never has there been so large an opportunity for the man of large ideas, complete education and indomitable energy and purpose as there is today. The world is waiting, looking, longing for him, and will cry "Make room" for him when he is found.

In the hands of the trustees of our colleges and hospitals are the money and the opportunity for developing such men. If the right spirit pervades both trustees and medical faculties and hospital staffs, then it will be but a short time before America will lead the world in medicine as well as she now does in commerce.

Will the profession rise to the level of their great opportunity? Yea, verily they will! Never yet have they been wanting when the emergency arose; not only the emergency of labor, but also the emergency of danger.

In Russia the common soldier counts for little. Yet in Vladikavkaz (where the Dariel Pass—the old *Portæ Caspiæ* of Herodotus—leading from the Caucasus joins the railroad from Baku on the Caspian to Moscow) is a monument to a common soldier. At the last battle in which the Russians won the victory over Schamyl which gave them undisputed sway over the Caucasus, this soldier blew up a mine and won the day at the cost of his own life. It was ordered that his name should never be erased from the list of his company. At every roll-call when his name is reached, the solemn answer is given, "Died in the service of his country."

In our hospitals lurk the deadly breath of diphtheria, the fatal virus of bubonic plague, of cholera, of yellow fever, of typhus fever, and the ever present danger of blood poisoning. I have known of brother physicians who have died victims to each one of these scourges. Yet who has ever known one of our guild to shrink when danger smote him on the right hand and the left and death barred the way? As brave as the Russian soldier, ready to risk life, and, if need be, to lose it, these martyrs to duty shall never have their names stricken off the honor list, and at the last roll-call the solemn reply shall be, "Died in the service of humanity."

## PRINCIPLES OF MEDICAL ETHICS OF THE AMERICAN MEDICAL ASSOCIATION.

The American Medical Association promulgates, as a suggestion and advisory document, the following:

### Chapter I.—The Duties of Physicians to Their Patients.

SECTION 1.—Physicians should not only be ever ready to obey the calls of the sick and injured, but should be mindful of the high character of their mission and of the responsibilities they must incur in the discharge of momentous duties. In their ministrations they should never forget that the comfort, the health, and the lives of those entrusted to their care depend on skill, attention, and fidelity. In deportment they should unite tenderness, cheerfulness, and firmness, and thus inspire all sufferers with gratitude, respect, and confidence. These observances are the more sacred because, generally, the only tribunal to adjudge penalties for unkindness, carelessness or neglect is their own conscience.

SEC. 2.—Every patient committed to the charge of a physician should be treated with attention and humanity, and reasonable indulgence should be granted to the caprices of the sick.

Secrecy and delicacy should be strictly observed; and the familiar and confidential intercourse to which physicians are admitted in their professional visits should be guarded with the most scrupulous fidelity and honor.

SEC. 3.—The obligation of secrecy extends beyond the period of professional services; none of the privacies of individual or domestic life, no infirmity of disposition or flaw of character observed during medical attendance should ever be divulged by physicians, except when imperatively required by the laws of the State. The force of the obligation of secrecy is so great that physicians have been protected in its observance by courts of justice.

SEC. 4.—Frequent visits to the sick are often requisite, since they enable the physician to arrive at a more perfect knowledge of the disease and to meet promptly every change which may occur. Unnecessary visits are to be avoided, as they give undue anxiety to the patient; but to secure the patient against irritating suspense and disappointment the regular and periodical visits of the physician should be made as nearly as possible at the hour when they may be reasonably expected by the patient.

SEC. 5.—Ordinarily, the physician should not be forward to make gloomy prognostications, but should not fail on proper occasions to give timely notice of dangerous manifestations to the friends of the patient, and even to the patient if absolutely necessary. This notice, however, is at times so peculiarly alarming when given by the physician that its deliverance may often be preferably assigned to another person of good judgment.

SEC. 6.—The physician should be a minister of hope and comfort to the sick, since life may be lengthened or shortened not only by the acts, but by the words or manner of the physician, whose solemn duty is to avoid all utterances and actions having a tendency to discourage and depress the patient.

SEC. 7.—The medical attendant ought not to abandon a patient because deemed incurable, for continued attention may be highly useful to the sufferer and comforting to the relatives, even in the last period of the fatal malady by alleviating pain and by soothing mental anguish.

SEC. 8.—The opportunity which a physician has of promoting and strengthening the good resolutions of patients suffering under the consequences of evil conduct ought never to be neglected. Good counsels, or even remonstrances, will give satisfaction, not offense, if they be tactfully proffered and evince a genuine love of virtue, accompanied by a sincere interest in the welfare of the person to whom they are addressed.

### Chapter II.—The Duties of Physicians to Each Other and to the Profession at Large.

#### ARTICLE I.—DUTIES FOR THE SUPPORT OF PROFESSIONAL CHARACTER.

SECTION 1.—Every one on entering the profession, and thereby becoming entitled to full professional fellowship, incur an obligation to uphold its dignity and honor, to exalt its standing and to extend the bounds of its usefulness. It is inconsistent with the principles of medical science, and it is incompatible with honorable standing in the profession for physicians to designate their practice as based upon an exclusive dogma or a sectarian system of medicine.

SEC. 2.—The physician should observe strictly such laws as are instituted for the government of the members of the profession; should honor the fraternity as a body; should endeavor to promote the science and art of medicine and should entertain a due respect for those seniors who by their labors have contributed to its advancement.

SEC. 3.—Every physician should identify himself with the organized body of his profession as represented in the community in which he resides. The organization of local or county medical societies where they do not exist should be effected so far as practicable. Such county societies constituting, as they do, the chief element of strength in the organization of the profession, should have the active support of their members, and should be made instruments for the cultivation of fellowship, for the exchange of professional experience, for the advancement of medical knowledge, for the maintenance of ethical standards, and for the promotion in general of the interests of the profession and the welfare of the public.

SEC. 4.—All county medical societies thus organized ought to place themselves in affiliation with their respective State associations, and these in turn with the American Medical Association.

SEC. 5.—There is no profession from the members of which greater purity of character and a higher standard of moral excellence are required than the medical; and to attain such eminence is a duty every physician owes alike to the profession and to patients. It is due to the patients, as without it their respect and confidence cannot be commanded; and to the profession because no scientific attainments can compensate for the want of correct moral principles.

SEC. 6.—It is incumbent on physicians to be temperate in all things, for the practice of medicine requires the unremitting exercise of a clear and vigorous understanding; and in emergencies—for which no physician should be unprepared—a steady hand, an acute eye, and an unclouded mind are essential to the welfare, and even to the life, of a human being.

SEC. 7.—It is incompatible with honorable standing in the profession to resort to public advertisements or private cards inviting the attention of persons affected with particular diseases; to promise radical cures; to publish cases or operations in the daily prints, or to suffer such publications to be made; to invite laymen (other than relatives who may desire to be at hand) to be present at operations; to boast of cures and remedies; to adduce certificates of skill and success, or to employ any of the other methods of charlatans.

SEC. 8.—It is equally derogatory to professional character for physicians to hold patents for any surgical instruments or medicines; to accept rebates on prescriptions or surgical appliances; to assist unqualified persons to evade legal restrictions governing the practice of medicine; to dispense or promote the use of secret medicines, for if such nostrums are of real efficacy any concealment regarding them is inconsistent with beneficence and professional liberality, and if mystery alone give them public notoriety, such craft implies either disgraceful ignorance or fraudulent avarice. It is highly reprehensible for physicians to give certificates attesting the efficacy of secret medicines, or other substances used therapeutically.

#### ARTICLE II.—PROFESSIONAL SERVICES OF PHYSICIANS TO EACH OTHER.

SECTION 1.—Physicians should not, as a general rule, undertake the treatment of themselves, nor of members of their family. In such circumstances they are peculiarly dependent on each other; therefore, kind offices and professional aid should always be cheerfully and gratuitously afforded. These visits ought not, however, to be obtrusively made, as they may give rise to embarrassment or interfere with that free choice on which such confidence depends.

SEC. 2.—All practising physicians and their immediate family dependents are entitled to the gratuitous services of any one or more of the physicians residing near them.

SEC. 3.—When a physician is summoned, from a distance, to the bedside of a colleague in easy financial circumstances, a compensation proportionate to traveling expenses and to the pecuniary loss entailed by absence from the accustomed field of professional labor should be made by the patient or relatives.

SEC. 4.—When more than one physician is attending another, one of the number should take charge of the case, otherwise the concert of thought and action so essential to wise treatment cannot be assured.

SEC. 5.—The affairs of life, the pursuit of health and the various accidents and contingencies to which a physician is peculiarly exposed sometimes require the temporary withdrawal of this physician from daily professional labor and the appointment of a colleague to act for a specified time. The colleague's compliance is an act of courtesy which should always be performed with the utmost consideration for the interest and character of the family physician.

#### ARTICLE III.—THE DUTIES OF PHYSICIANS IN REGARD TO CONSULTATIONS.

SECTION 1.—The broadest dictates of humanity should be obeyed by physicians whenever and wherever their services are needed to meet the emergencies of disease or accident.

SEC. 2.—Consultations should be promoted in difficult cases, as they contribute to confidence and more enlarged views of practice.

SEC. 3.—The utmost punctuality should be observed in the visits of physicians when they are to hold consultations, and this is generally practicable, for society has been so considerate as to allow the plea of a professional engagement to take precedence over all others.

SEC. 4.—As professional engagements may sometimes cause delay in attendance the physician who first arrives should wait for a reasonable time, after which the consultation should be considered as postponed to a new appointment.

SEC. 5.—In consultations no insincerity, rivalry, or envy should be indulged; candor, probity and all due respect should be observed toward the physician in charge of the case.

SEC. 6.—No statement or discussion of the case should take place before the patient or friends, except in the presence of all the physicians attending, or by their common consent; and no opinions or prognostications should be delivered which are not the result of previous deliberation and concurrence.

SEC. 7.—No decision should restrain the attending physician from making such subsequent variations in the mode of treatment as any unexpected change in the character of the case may demand. But at the next consultation reasons for the variations should be stated. The same privilege, with its obligation, belongs to the consultant when sent for in an emergency during the absence of the family physician.

SEC. 8.—The attending physician, at any time, may prescribe for the patient; not so the consultant, when alone, except in a case of emergency or when called from a considerable distance. In the first instance the consultant should do what is needed, and in the second should do no more than make an examination of the patient and leave a written opinion, under seal, to be delivered to the attending physician.

SEC. 9.—All discussions in consultation should be held as confidential. Neither by words nor by manner should any of the participants in a consultation assert or intimate that any part of the treatment pursued did not receive his assent.

SEC. 10.—It may happen that two physicians cannot agree in their views of the nature of a case and of the treatment to be pursued. In the event of such disagreement, a third physician should, if practicable, be called in. None but the rarest and most exceptional circumstances would justify the consultant in taking charge of the case. He should not do so merely upon the solicitation of the patient or friends.

SEC. 11.—A physician who is called in consultation should observe the most honorable and scrupulous regard for the character and standing of the attending physician, whose conduct of the case should be justified so far as can be, consistently with a conscientious regard for truth, and no hint or insinuation should be thrown out which could impair the confidence reposed in the attending physician.

#### ARTICLE IV.—DUTIES OF PHYSICIANS IN CASES OF INTERFERENCE.

SECTION 1.—Medicine being a liberal profession, those admitted to its ranks should found their expectations of practice especially on the character and the extent of their medical education.

SEC. 2.—The physician, in his intercourse with a patient, under the care of another physician, should observe the strictest caution and reserve; should give no disingenuous hints relative to the nature and treatment of the patient's disorder, nor should the course of conduct of the physician directly or indirectly tend to diminish the trust reposed in the attending physician.

SEC. 3.—The same circumspection should be observed when, from motives of business or friendship, a physician is prompted to visit a person who is under the direction of another physician. Indeed, such visits should be avoided, except under peculiar circumstances; and when they are made, no inquiries should be instituted relative to the nature of the disease, or the remedies employed, but the topics of conversation should be as foreign to the case as circumstances will admit.

SEC. 4.—A physician ought not to take charge of, or prescribe for, a patient who has recently been under the care of another physician, in the same illness, except in case of a sud-

den emergency, or in consultation with the physician previously in attendance, or when that physician has relinquished the case or has been dismissed in due form.

SEC. 5.—The physician acting in conformity with the preceding section should not make damaging insinuations regarding the practice previously adopted, and indeed should justify it if consistent with truth and probity; for it often happens that patients become dissatisfied when they are not immediately relieved, and as many diseases are naturally protracted, the seeming want of success in the first stage of treatment affords no evidence of a lack of professional knowledge or skill.

SEC. 6.—When a physician is called to an urgent case, because the family attendant is not at hand, unless assistance in consultation is desired the former should resign the care of the patient immediately on the arrival of the family physician.

SEC. 7.—It often happens, in cases of sudden illness, and of accidents and injuries, owing to the alarm and anxiety of friends, that several physicians are simultaneously summoned. Under these circumstances, courtesy should assign the patient to the first who arrives and who, if necessary, may invoke the aid of some of those present. In such a case, however, the acting physician should request that the family physician be called, and should withdraw unless requested to continue in attendance.

SEC. 8.—Whenever a physician is called to the patient of another physician during the enforced absence of that physician, the case should be relinquished on the return of the other.

SEC. 9.—A physician, while visiting a sick person in the country, may be asked to see another physician's patient because of a sudden aggravation of the disease. On such an occasion the immediate needs of the patient should be attended to and the case relinquished on the arrival of the attending physician.

SEC. 10.—When a physician who has been engaged to attend an obstetric case is absent and another is sent for, delivery being accomplished during the vicarious attendance, the acting physician is entitled to the professional fee, but must resign the case on the arrival of the physician first engaged.

#### ARTICLE V.—DIFFERENCES BETWEEN PHYSICIANS.

SECTION 1.—Diversity of opinion and opposition of interest may, in the medical as in other professions, sometimes occasion controversy and even contention. Whenever such unfortunate cases occur and can not be immediately adjusted, they should be referred to the arbitration of a sufficient number of impartial physicians.

SEC. 2.—A peculiar reserve must be maintained by physicians toward the public in regard to some professional questions, and as there exist many points in medical ethics and etiquette through which the feelings of physicians may be painfully assailed in their intercourse, and which can not be understood or appreciated by general society, neither the subject-matter of their differences nor the adjudication of the arbitrators should be made public.

#### ARTICLE VI.—COMPENSATION.

SECTION 1.—By the members of no profession are eleemosynary services more freely dispensed than by the medical, but justice requires that some limits should be placed to their performance. Poverty, mutual professional obligations, and certain of the public duties named in Sections 1 and 2 of Chapter III, should always be recognized as presenting valid claims for gratuitous services; but neither institutions endowed by the public or by the rich, or by societies for mutual benefit, for life insurance or for analogous purposes, nor any profession or occupation, can be admitted to possess such privilege.

SEC. 2.—It can not be justly expected of physicians to furnish certificates of inability to serve on juries, or to perform militia duty; or to testify to the state of health of persons wishing to insure their lives, obtain pensions or the like, without a pecuniary acknowledgment. But to persons in indigent circumstances such services should always be cheerfully and freely accorded.

SEC. 3.—Some general rules should be adopted by the physicians in every town or district relative to the minimum pecuniary acknowledgment from their patients; and it should be

deemed a point of honor to adhere to these rules with as much uniformity as varying circumstances will admit.

SEC. 4.—It is derogatory to professional character for physicians to pay or offer to pay commissions to any person whatsoever who may recommend to them patients requiring general or special treatment or surgical operations. It is equally derogatory to professional character for physicians to solicit or to receive such commissions.

#### Chapter III.—The Duties of the Profession to the Public.

SECTION 1.—As good citizens it is the duty of physicians to be very vigilant for the welfare of the community, and to bear their part in sustaining its laws, institutions and burdens; especially should they be ready to cooperate with the proper authorities in the administration and the observance of sanitary laws and regulations, and they should also be ever ready to give counsel to the public in relation to subjects especially appertaining to their profession, as on questions of sanitary policy, public hygiene and legal medicine.

SEC. 2.—It is the province of physicians to enlighten the public in regard to quarantine regulations; to the location, arrangement and dietaries of hospitals, asylums, schools, prisons and similar institutions; in regard to measures for the prevention of epidemic and contagious diseases; and when pestilence prevails it is their duty to face the danger, and to continue their labors for the alleviation of the suffering people, even at the risk of their own lives.

SEC. 3.—Physicians, when called on by legally constituted authorities, should always be ready to enlighten inquests and courts of justice on subjects strictly medical, such as involve questions relating to sanity, legitimacy, murder by poison or other violent means, and various other subjects embraced in the science of medical jurisprudence. It is but just, however, for them to expect due compensation for their services.

SEC. 4.—It is the duty of physicians, who are frequent witnesses of the great wrongs committed by charlatans, and of the injury to health and even destruction of life caused by the use of their treatment, to enlighten the public on these subjects, and to make known the injuries sustained by the unwary from the devices and pretensions of artful impostors.

SEC. 5.—It is the duty of physicians to recognize and by legitimate patronage to promote the profession of pharmacy, upon the skill and efficiency of which depends the reliability of remedies, but any pharmacist, who, although educated in his own profession, is not a qualified physician, and who assumes to prescribe for the sick, ought not to receive such countenance and support. Any druggist or pharmacist who dispenses deteriorated or sophisticated drugs or who substitutes one remedy for another designated in a prescription, ought thereby to forfeit the recognition and influence of physicians.

**Pure Water for Buffalo.**—The New York Legislature has passed a bill granting to the city of Buffalo the privilege of issuing bonds to the value of \$500,000 for the purpose of improving the water-supply.

**Site Chosen for Tuberculosis Camp.**—President Lederle, of the New York City Board of Health, has announced that he will establish the tuberculosis camp on North Brother's Island. Efforts to make a selection from other localities have met violent opposition from those living in the neighborhood. An examination of the atmospheric conditions of North Brother's Island has shown that it is suitable for such a camp.

**Uniform Disinfection.**—A uniform plan of disinfection has been established by the State Boards of Health of Louisiana and Texas governing quarantine matters in New Orleans and Galveston. The resolutions were adopted at a meeting of the boards recently and read: "The Galveston regulations governing disinfection at Havana and other Cuban ports are hereby reconsidered and rescinded and the following substituted: 'Pyrethrum powder shall be burned in the living quarters at Havana immediately before the departure of the vessel. Baggage of passengers shall be sealed and signed in Havana by joint medical inspectors, and each passenger to have a certificate signed by the inspectors. Certificate to show temperature at time of inspection, hour to be noted. Thorough disinfection of living quarters, baggage (and holds when no perishable cargo) upon arrival at quarantine station. Noninfected vessels from Cuban ports other than Havana (so long as reported free of yellow fever) shall be given pratique after thorough disinfection at quarantine station.'"

1, 2, 3.—See *American Medicine*, Vol. V, No. 19.

4.—**Blood-pressure in Typhoid Perforation.**—G. W. Crile reports five cases in which there was a marked rise after perforation, these cases assuming the level attending peritonitis from other causes. The highest point reached was 208 mm. [H.M.]

## Boston Medical and Surgical Journal.

[May 7, 1903. [Vol. CXLVIII, No. 19.]

1. Brachial Paralysis; Post-narcotic. F. J. COTTON and S. W. ALLEN.
2. Pyronin-methyl Green: A Brilliant Double Stain for Cells and Bacteria. WILLIAM F. WHITNEY.
3. X-light in Anthropometrical Signalment. WILLIAM ROLLINS.

1.—**Post-anesthetic Brachial Paralysis.**—F. J. Cotton and S. W. Allen report four cases which have come under their observation. All were typical cases of post-anesthetic paralysis. The writers believe such cases to be much more frequent than the scanty literature would suggest. They were able to find but 30 cases reported. The type they would define is that in which paralysis of a part or the whole of the brachial plexus has evidently resulted during anesthesia. They excluded those cases in which the paralysis is of central or referred origin, or those due to direct pressure on the peripheral nerve-trunks, from pressure of the body on the arm in lateral postures, from pressure of the edge of a table on the musculospinal nerve, from the pressure of leg-holders or the edge of a Trendelenburg table on the perifeal nerves, or from too efficient application of a tourniquet. They emphasize the following points: Paralysis of part or all the muscles supplied by the brachial plexus with some sensory involvement is not very uncommon after narcosis, though rarely mentioned. Its cause is not toxic but mechanic. It occurs only when the arms are long held above the head or lie in abduction—never if they lie flexed on the chest. The mechanism is a pressure on the nerve-roots, probably between the clavicle and the muscles over the transverse processes of the cervical vertebrae, or from stretching over the head of the humerus in abduction. The trouble is essentially functional without known lesions. The lost function returns in part very early. Total recovery is often long delayed, but apparently is to be counted on. The possibility of the accident should be impressed on students, on house officers, and on all of us. [A.B.C.]

2.—**Pyronin-methyl Green.**—W. F. Whitney emphasizes the great general utility of this stain, which was first brought forward by Pappenheim. One percent solutions of pyronin and methyl green in distilled water are made separately and mixed, four parts of the former to one of the latter. This stains nuclei bluish green, the bodies of the neutrophile leukocytes are unstained, while those of the lymphocytes, mast cells, endothelial and epithelial cells have varying shades of purple by which they can be distinguished from each other. Bacteria contrast with these by their brilliant red. He describes also methods of bringing out the red corpuscles, of examining fresh cells and frozen sections. [H.M.]

3.—**X-light in Anthropometric Signalment.**—W. Rollins believes the time will come when law will require every adult to be signalized. Value attaches only to accuracy, and x-light photographs of the bones double the accuracy with which measurements can be taken and make more measurements possible, thus allowing at least four times as many persons to be identified as at present. The writer alludes to an apparatus for the work which he designed and has described elsewhere. [H.M.]

## New York Medical Journal.

[May 2, 1903. [Vol. LXXVII, No. 18.]

1. The Tendo-Achillis Shortened for the Restoration of the Function of the Calf: Lost as the Result of a Previous Tenotomy. RUSSELL A. HIBBS.
2. A Case of Nevus of the Scalp and Nose Treated by Hot Water Injections. FREDERIC GRIFFITH.
3. The Treatment of Gastric and Duodenal Hemorrhages. MAX EINHORN.
4. The Uses of Suprarenal Extract in Nose and Throat Diseases. BEAMAN DOUGLASS.
5. The Operative Treatment of Stenosis of the Larynx Following Intubation and Tracheotomy: Report and Exhibition of Cases. ARTHUR B. DUEL.
6. An Anastomosis Ring. WILLIAM L. KELLER.
7. Suprascrotal Operation for Varicocele, with Ligature of the Spermatic Artery. E. STYLES POTTER.

1.—**Shortening of the Tendo-Achillis.**—R. A. Hibbs reports three cases in which the tendo-Achillis was shortened for the restoration of the function of the calf, lost as a result of a previous tenotomy. In the first case the action of the calf group of muscles has been so remarkably restored that it can be safely expected eventually to perform practically its normal function. In the second case the action of the calf has been restored to some extent. In the third case there has been no appreciable improvement. In these three cases the structure filling in the gap between the ends of the old tendon had elongated, and was dissimilar to the normal tendon in every important particular, especially in not being nonstretchable. The author says that the facts revealed by the operation for shortening the tendon in these cases may be considered unmistakable evidence that the subcutaneous division of the tendo-Achillis is not always so successful as it has long been considered to be; that while in some cases the healing process seems to reproduce a structure sufficiently strong to perform the function of tendon, in others exactly similar it does not do so. He believes that the conditions necessary in order that the healing process may be entirely satisfactory are: 1. The preservation of the sheath. 2. The preservation of the continuity of the tendon. [C.A.O.]

2.—**Hot Water Injections for Nevus.**—Frederic Griffith reports a case of nevus of the scalp and nose in a child of 7 months, successfully treated by hot water injections. From 10 to 60 drops at a temperature of from 180° F. to 200° F. was injected at intervals of three or four days. Further growth ceased after the first injection, and shrinkage, with flattening of the surface of the mark to the level of the surrounding skin took place. [C.A.O.]

3.—**Gastric and Duodenal Hemorrhages.**—Absolute rest in bed, total abstinence from food and drink, and the administration of opiates (subcutaneously or per rectum), will serve to lessen the peristalsis of the stomach and small intestine and favor the healing process. During the first three to five days following the hemorrhage rectal alimentation must be the only mode of nourishing the patient. Saline solution will supplement the amount of fluid required. An ice-bag over the upper part of the abdomen is of service and ergot is a useful remedy. Gelatin may be employed per os, or subcutaneously. In the latter instance a 2% gelatin solution may be used, injecting about 100 cc. at a time, preferably in the gluteal region. Max Einhorn prefers this method in order to avoid gastric peristalsis. In giving gelatin by the mouth, simple calf's foot jelly may be administered. Adrenalin has been used by some authors with good results. The author also reports some experiments on rabbits to show the value of adrenalin in checking hemorrhage. [C.A.O.]

4.—**Suprarenal Extract.**—Beaman Douglass gives a review of the uses of suprarenal extract in nose and throat diseases. It is of inestimable value in reducing hemorrhage during nasal operations. The nose should be packed after the operation to guard against hemorrhage. In acute catarrhal con-

ditions of the respiratory tract, when there is much congestion, soreness and the general accompanying symptoms of this condition, suprarenal gland is of great use. Here it should be used not only locally, but also internally, either alone or in combination with other remedies, for the purpose of combating constitutional symptoms. It may be given with phenacetin, Dover's powder, quinin, and aconite, and should be taken each hour until the effect is produced, after which every two or three hours will maintain the condition which has been established. Used in this way it is valuable in the treatment of acute catarrhal laryngitis, hay-fever, hay-asthma, coryza, conditions of relaxation of the erectile tissue of the turbinates, chronic nasal congestion, and in some cases it seems to modify the quantity and quality of nasal discharge. Considerable diminution in the size of newgrowths may be obtained by the use of suprarenal locally or by injection into the tumor. The author prefers to use the simple dried suprarenal gland of the pig. The most convenient solution is made by adding 30 grams of dried suprarenal gland to 1 ounce of water that has just been freshly boiled and allowed to cool until it is just warm. It may then be filtered. The most reliable preparation of suprarenal gland is adrenalin chlorid. To each half ounce of a 4% solution of cocain about 20 minims of solution of adrenalin chlorid 1-1,000 are added. For septal work a 7% cocain solution is used, and the suprarenal strength doubled. [C.A.O.]

5.—**Stenosis of the Larynx.**—A. B. Duell discusses the operative treatment of stenosis of the larynx following intubation and tracheotomy, and reports three cases. He finds that about 1% of all patients intubated for acute laryngeal stenosis will "retain" the tube. The cause of the retention is due, in the majority of cases, to chronic inflammation of the intralaryngeal mucous membrane and hypertrophy of the subglottic tissues, and is not, as has been generally supposed, the result of granulation, ulceration, or cicatricial bands. Autoextubation in these cases is the rule, and adds greatly to the danger when an experienced intubator is not at hand. As a result of this a large number of such patients are tracheotomized for safety. When high tracheotomies are done cicatricial bands are almost certain to form in the trachea or lower part of the larynx above the tracheotomy wounds. The points in treatment emphasized are: (1) The largest sized tube possible should be inserted, under an anesthetic. In case of contraction rapid dilation should be done by beginning with the small sizes and working up to the large special tube, which is to be left in place. This special tube should be as large as can be inserted, and the constriction below the neck only  $\frac{1}{32}$  inch smaller than the retaining swell; (2) this tube should be left in, undisturbed, for six weeks at least. It should then be removed, and if a cure has not been accomplished it should be replaced for six weeks longer. [C.A.O.]

6.—**An anastomosis ring** is described and graphically presented by W. L. Keller. It is made of aluminum and is divided into three segments and grooved externally to accommodate the ends of the divided intestine. In this groove is placed a spring which holds the serous coats of the intestinal ends in apposition. The three segments are held together by catgut sutures, which, after intestinal union has taken place, absorb or disintegrate, allowing the ring to fall apart. As the segments become free from the bowel by pressure necrosis and sloughing they pass out in the intestinal stream. Almost the normal lumen of the bowel is maintained when the ring is in position. [C.A.O.]

7.—**Suprascrotal Operation for Varicocele.**—In the operation described by E. S. Potter the incision begins at the external abdominal ring and proceeds downward for about  $1\frac{1}{2}$  inches, directly over the course of the cord, ending just above the scrotal tissue. The tissues are divided down to the cord, then the cord, the vas, artery, nerves, and pampiniform plexus are drawn through the incision, and the vas and nerve separated, the veins, artery, and connective tissue ligated above and below, and the intervening portion removed. The ligatures are left long, then a ligature is passed through the stumps and tied, which brings the two stumps in perfect apposition. Then the remaining long ends of the ligatures are tied, which brings the point of contact in perfect end-to-end apposition and acts as a natural suspensory for the previously dragging testis.

The cord is then returned and the external wound closed. Excellent results are claimed for this operation. Three cases are reported. [C.A.O.]

4. Intussusception: Report of a Case Reduced by Operation. GEORGE TULLY VAUGHAN.

1.—**Resemblances of Malignant Endocarditis to Typhoid and Paratyphoid Infections.**—H. L. Elsner finds that the typhoid type of infectious malignant endocarditis has rarely been diagnosticated during life, and that the detection of the focus from which infection sprang presents great difficulties. Infection is probably secondary, the organism not always the same, and can be determined only by painstaking bacteriologic study of the blood. Because paracolon infections are associated with typhoid symptoms, together with absence of the Widal reaction, the resemblances between them and malignant endocarditis offer many obstacles to positive early differentiation. The latter is almost always fatal. Endocarditis is rare as a complication of typhoid fever, and with evidences of the former we may assume the case is not typhoid. In the presence of murmurs with infection, petechiæ, disturbed circulation, infarcts, leukocytosis and negative Widal reaction, we may strongly suspect malignant endocarditis. For positive diagnosis we must have physical signs referable to the heart, and these generally appear before death, although the endocardium may be plastered with vegetations without giving rise to any symptoms. Transitory or even lasting paralyses in the midst of acute general infections are exceptional save in those diseases associated with embolic detachment and consecutive tissue change. Typhoid may be excluded if there are repeated chills; also if with a chill there are leukocytosis and symptoms of infection. In primary typhoid we may be sure of secondary infection if chills persist. Malignant endocarditis has less morning remission of temperature, the pulse is more rapid and softer, and is more likely to become irregular than in typhoid. [H.M.]

2.—**Nephrorrhaphy for Intermittent Hydronephrosis.**—J. W. Bovée, after a general review of the literature on the subject and a discussion of the causes of hydronephrosis, states that in the way of treatment nothing can be more rational than the employment of some means to prevent renal displacement. Various bandages have been used for this purpose, with but little success. Nephrorrhaphy is the remedy which should be employed in nearly all cases. In many cases this affords permanent relief. Two cases are reported: One was a widow of 46 who had suffered at various intervals for the past nine years with attacks of intense pain in the right side, lasting for a number of hours, and showing every evidence of hydronephrosis. Examination revealed the right kidney movable and at the pelvic brim. Operation was performed, the kidney delivered through an incision in the loin, its capsule split and sutured to the muscles of the back. The patient made a good recovery and has had no return of the symptoms. The second case was a married woman of 21. Since the birth of her only child three years ago she had suffered from intermittent severe pain in the right side, and at such times a pyramidal mass could be felt slightly to the right and above the umbilicus. She was examined in one of these attacks and mobility of the kidney could be definitely made out. The mass was elevated and held in position with a bandage, with almost immediate relief from pain, and on the following day no tumor formation could be made out, though by this time the mobility of the kidney was perfectly apparent. Nephrorrhaphy was performed as in the preceding case, with entire relief of the symptoms. The author states that the principle underlying the indication for nephropexy is simply a mechanical one. By fixing the kidney the ureter is straightened and prevented from gland-kinking and thus producing obstruction to the outflow of the kidney's secretion. [A.B.C.]

3.—**Extraperitoneal Ligation of External Iliac for**

**Femoral Aneurysm.**—Wm. B. Crawford reports the case. A negro man of 38, with alcoholic and syphilitic history, fell and struck the left thigh on the upright end of a heavy piece of timber. He suffered from slight pain, but 12 days later the injured thigh began to swell, and there was intermittent pain. Relief was obtained by assuming the recumbent posture. A physician was called, who found a tumefaction in the region of the injury, and believing there was an abscess, made a slight incision, but encountering a free flow of blood he applied a compress and bandage and sent the patient to a hospital. Examined by the author, aneurysm was diagnosed. The pulsating tumor extended from Poupart's ligament to the junction of the upper and middle thirds of the thigh. The usual physical signs of aneurysm were present, and the patient's arteries were thickened and sclerosed. Operation was performed. An incision  $3\frac{1}{2}$  inches long was made at the usual site for appendiceal operation. The peritoneum was retracted, the artery exposed and ligated with silk. The after-treatment consisted in elevation of the thigh, continuous application of heat with the Tufnell treatment. Pulsation was felt in the posterior tibial artery on the third day, and the foot and leg remained cold for five days, and not until 12 days had elapsed was the temperature of the left leg equal to that of the right. Three weeks after operation the tumor had decreased one-half, and no pulsation could be felt. The patient was discharged but with instructions to remain in bed for two weeks and continue potassium iodid. The tumor mass gradually and almost completely subsided, and the patient is otherwise well. [A.B.C.]

**4.—Intussusception.**—G. T. Vaughan states that in his study of 1,000 operations for acute intestinal obstruction Gibson found that intussusception was the cause in 187 cases, thus holding a place second only in point of frequency to hernia, which occurred in 354 of the cases. It is estimated that more than one-half of the cases occur in children under 10 years and more than one-third in infants under one year, and Wiggins found it three times as frequent in males as in females. The rational treatment of intussusception is laparotomy. The earlier the better. Hydrostatic pressure may be tried during the first 12 hours, but this method failed in three-fourths of the cases reported by Wiggins. Without operation the mortality is variously estimated at from 60% to 90%; with operation only 32%, and the author is of opinion that if operation is performed within the first 12 hours the mortality will not exceed 5%. He reports a case occurring in a white male, aged 5. Owing to the uncertainty of the symptom-complex operation was not performed until the third day, and intussusception of the ileocecal variety was found, but this was reduced without difficulty and the child made an uneventful recovery. [A.B.C.]

### Philadelphia Medical Journal.

May 9, 1903. [Vol. XI, No. 19.]

1. Report of a Case of Suturing the Omentum to the Abdominal Wall (Talma) for the Relief of Ascites Due to Cirrhosis of the Liver, 21 Months After Operation. THOMAS R. NEILSON.
2. A Case of Cirrhosis of the Liver With Ascites. W. W. KEEN and H. M. FISHER.
3. Novelties in the Physical Treatment of Skin Diseases. L. FREUND.
4. The Importance of Repair of Small Cervical Lacerations. JAMES HAWLEY BURTENSHAW.
5. Toxic Amblyopia from Wood Alcohol. J. W. SHERER.
6. A Note on Traumatic Syringomyelia, With Report of a Case Presenting Sensory Disturbances Affecting One Limb, and Trophic Changes of the Subcutaneous Tissue of the Entire Limb. ALFRED GORDON.

**1.—Talma's Operation.**—Thomas R. Neilson details the case of a man of 51, in whom the omentum was sutured to the abdominal wall for the relief of ascites due to cirrhosis of the liver. During the past ten years the patient has imbibed freely of alcohol. Tapping had been resorted to on three occasions previous to operating. There was complete freedom from abdominal symptoms following the operation which was performed 21 months ago, and at no time since has there been the slightest evidence of return of the ascites. In addition to the operation the patient received tincture of digitalis in small doses, infusion of juniper for a few days, a mixture of sodium phosphate, sodium sulfate and sodium bicarbonate, and lastly Basham's mixture with strychnin. [F.C.H.]

**2.—A Case of Cirrhosis of the Liver with Ascites.**—W. W. Keen and H. M. Fisher detail the case of a man of 32, in

whom operation was performed eight weeks after the first occurrence of ascites, with subsidence of the ascites six months after the operation, and nonrecurrence in two years. At the time of operation two gallons of fluid were removed from the abdominal cavity. The omentum was shrunken, but showed no evidence of malignant disease. The upper surfaces of the liver and diaphragm were rubbed with a gauze sponge, the spleen and its corresponding parietal peritoneum were treated in the same manner, also the anterior surface of the omentum and the corresponding portion of the anterior abdominal wall. The omentum was sutured to the anterior abdominal wall with celluloid thread, and four of the silkwormgut sutures used to close the abdominal incision "picked up" the omentum as further security. For a few months after the operation the ascites was very little influenced; about five months subsequent to the surgical procedure the collateral circulation was established and since then there has been no recurrence. [F.C.H.]

**3.—Novelties in the Physical Treatment of Skin Diseases.**—L. Freund believes that the dermatologists have taken precedence over the other branches of physical therapy, and that dermatology may look back with pride upon the excellent results achieved. He details some experiments to show the inaccuracies of some of the claims made by a few French observers for the radiochromometer and spintometer. Other experiments of interest to x-ray workers are detailed. [F.C.H.]

**4.—The Importance of Repair of Small Cervical Lacerations.**—J. H. Burtenshaw details a series of cases to prove that not every cervical laceration requires a surgical operation for its cure, but that due significance is not attached to the smaller lacerations which, in many instances, are the unrecognized causes not only of local morbid conditions, but of general systemic ones as well. An additional reason, and a most important one for the repair of a torn cervix, lies in the fact that, beyond question, malignant degeneration is much more liable to occur in such a cervix than one that is normal. There can be no difference of opinion as to the necessity of repair of a laceration, whether unilateral or bilateral, of such degree as to cause eversion of the lips of the cervix. [F.C.H.]

**5.—Toxic Amblyopia from Wood Alcohol.**—J. W. Sherer details the case of a Swede of 32, with a reference to four others who drank a mixture, the basis of which was wood alcohol. Two of the patients died, one within 48 hours, the other within 72 hours. He firmly believes that the earliest lesion in toxic amblyopia is to be found in the ganglion cells of the retina, and that consecutively the nerve-fibers break down. The fact that the vision in chronic toxic amblyopia may be markedly improved by amyl nitrite, rest, good hygiene, etc., to decline just as markedly under reversed conditions, points decisively to a nuclear, not to a neuritic, source of the trouble. Reasoning deductively from the treatment which has been proposed for toxic amblyopia in general, he would suggest strychnin, potassium iodid, mercury bichlorid, and nitroglycerin for the treatment of amblyopia due to wood alcohol. [F.C.H.]

**6.—A Note on Traumatic Syringomyelia.**—Alfred Gordon details the case of a woman of 40, suffering from a traumatic syringomyelia presenting sensory disturbances affecting one limb (the left), and trophic changes of the subcutaneous tissue of the entire limb. He believes that all the cases presenting the classic dissociation with or without muscular atrophy should be classed as syringomyelia, provided they do not present symptoms of other systemic diseases of the cord. Whether there is a gliosis or a cavity formed in place of an old hemorrhagic focus, or only a disintegration of the nervous tissue in the cord, affecting the sensory fibers so that either of these affections give rise to the sensory dissociation, all of them should be called syringomyelia. He concludes as follow: In view of the fact that the sensory disturbances in the case are those of syringomyelia in its most typical form, that the trophic changes are in the strictest relation with the area of distribution of the sensory dissociation, that the affection is in the upper extremity, that hematomeles foci after trauma in a number of cases were followed by cavity formation or only by a stage of necrosis, and that the symptoms in the patient made their appearance shortly after the trauma, for all these reasons it is justifiable to classify this case as one of a posttraumatic syringomyelia.

The peculiarity of the case consists in the fact that the symptoms are unilateral and limited to one extremity, and that the trophic changes of the subcutaneous tissue cover the entire affected extremity. The latter condition makes the case unique, as all the cases reported with similar condition presented trophic disturbances only of one portion of the limb. [F.C.H.]

### CLINICAL MEDICINE

DAVID RIESMAN

A. O. J. KELLY

#### REVIEW OF LITERATURE

**Socalled Functional Aortic Insufficiency in the Atheroma of Hodgson's Disease.**—M. Barjon<sup>1</sup> reports two cases. Each patient exhibited during life a double aortic murmur, with all the symptoms of insufficiency of the aortic valves. Autopsy showed that these valves were healthy and closed perfectly. The aorta in each case, however, was found to be highly atheromatous, with its ascending part cylindrically dilated to an extraordinary extent, exhibiting the condition described under the name of Hodgson's disease. In previously reported cases the murmurs have been explained in various ways to be due to a functional insufficiency of the aortic valves. This appears to Barjon to be unnecessary. The systolic murmur is produced by the blood passing through a comparatively narrow orifice into the enormous cavity beyond. The diastolic murmur is due to a reflux of blood from the large arteries into the aneurysmal sac. The clinical diagnosis between this condition and true aortic insufficiency seems difficult, if not impossible. [B.K.]

**Congenital Defect of the Pectoral Muscle.**—Lengsfelder<sup>2</sup> reports the case of a man in whom the costosternal and abdominal portions of the pectoralis major were absent; the clavicular portion was hypertrophied. Concerning the pectoralis minor nothing could be definitely made out. The condition was evidently congenital. The clinical interest of this and other similar cases is that such patients usually on account of deficient ventilation of the right lung are predisposed to pulmonary disease. The patient in question suffered repeatedly with inflammation of pleura and lungs, which had led to formation of pleural adhesions and pulmonary sclerosis. [E.L.]

**Undulant Fever.**—An unusually interesting and readable article on the above subject is contributed by F. J. A. Dalton,<sup>3</sup> who prefers this name to the more common one of Malta, or Mediterranean fever, because the disease undoubtedly occurs in other localities. Among the latter are India, North and South Africa, South America, and China. Dalton has reached the conclusions that the disease is air-borne, that the organism is very widely diffused in the localities where the fever is endemic, and that it has to be taken into the healthy individual in large numbers to produce its characteristic effects. Under ordinary circumstances the disease is not infectious. Of the symptoms the most important is pyrexia, after which is placed affections of the nervous system. The importance and frequency of the neuritis has not been sufficiently noted in the literature of the disease. On the other hand, Dalton takes exception to the statements of most writers, particularly Hughes, regarding the high frequency of joint effusion. In his experience this complication has occurred in less than 1% of the cases. Cardiac failure is the great complication to be guarded against. The agglutination test is the reliable means of diagnosis. The real treatment of undulant fever consists in keeping the patient in such a condition that he will avoid many of the symptoms of the disease, especially the anemia, the cardiac weakness, and the neuritis. [A.G.E.]

**Value of Functional Diagnosis.**—Krauss<sup>4</sup> discusses the recent methods of studying the functions of the heart, lungs, kidneys and general metabolism. He passes upon the value of orthodlography, tachography, cyrtometry, stethography, sphygmography, sphygmochromography, cryoscopy, relationship between electrolytes and nonelectrolytes of the urine, the determination of sulfur excretions, etc. [E.L.]

### GENERAL SURGERY

A. B. CRAIG

MARTIN B. TINKER

C. A. ORR

#### REVIEW OF LITERATURE

**Radical Cure of Inguinal Hernia in Early Infancy.**—B. H. Nicholson<sup>1</sup> is of the opinion that the factor which militates most strongly against operation for inguinal hernia during infancy is the difficulty of preserving an aseptic condition of the wound. He advocates operation, and prefers the method used by Bassini, the two points of chief importance in the operation being that the scrotum shall not be opened and that the aponeurosis of the external oblique shall be cut through, thus exposing the whole length of the inguinal canal and making it easy to ligate and sever the sac flush with the peritoneal cavity. In congenital hernia it is best to isolate the vas at the neck of the sac only for a short distance, sufficient for the sac to be divided or transfixed. It is better not to meddle with the distal end of the sac in the scrotum, as the testicle is easily damaged, and a twist in the vas, which is but feebly vascular, is sufficient to cause death of the organ. Hemorrhage must be absolutely controlled. The wound is closed in the usual way. A collodion dressing is applied, and over this a dressing of sterile gauze. Then a plaster-of-paris spica is applied, beginning below the knee. The spica is removed on the sixth day. The important part of the operation is to prevent the dressings from being saturated with urine. The penis is therefore inserted in a wide rubber tube, the tubing being attached by four interrupted stitches to the skin at the base of the organ, and is then carried into a receptacle in the cot, and thus the urine is conveyed entirely away from the dressing. In hospital practice he believes dressings are of little use. [A.B.C.]

**Concerning the Socalled Physiologic Salt Solution.**—F. Engelmann's<sup>2</sup> investigations demonstrate that neither the 0.6% nor any other salt solution except the 0.9% solution must be considered as isotonic with human blood-serum. In all cases in which formerly on account of false suppositions the use of solutions varying from 0.5% to 0.75% have been recommended (whether at the sick bed as infusion, or in the laboratory as preserving fluid) the 0.9% solution should be employed. [E.L.]

**Fat Embolism Following Straightening of the Limbs.**—J. Preindsberger<sup>3</sup> reports a case occurring in a girl of 17, with bilateral genu valgum. The knees were straightened, under anesthesia, by means of Lorenz's osteoclasts, the operation being accomplished with very little difficulty. Two days later the patient was suddenly seized with dyspnea, pain in the epigastrium, nausea, and rapid pulse. There was slightly impaired resonance at the base of both lungs, with weakened breath sounds and fine rales. A few hours later she suddenly collapsed and died. Autopsy showed some signs of traumatism in the bones around the left knee-joint, and also fat emboli in the pulmonary arteries and capillaries. Death is attributed to the latter lesions. [B.K.]

**Experiences Concerning Bülow's Aspiration Drainage in the Treatment of Empyema.**—Oloff<sup>4</sup> operated on 15 children with empyema according to Bülow's method. This consists in the introduction of a small trocar into the pleural cavity through one of the intercostal spaces. A rubber drainage tube is passed into the abscess cavity through a canula, and fastened to the chest wall. The syphon tube, one end of which is in a vessel containing an antiseptic fluid, is connected with the drain by means of a glass link, and the pus drawn off in this manner. About the fifteenth day the condition is usually so far improved as to permit the substitution of a simple drain. Of the 15 patients, 7 were cured, 1 improved, 2 unimproved, and 5 died of lung or heart complications. It is important to study carefully the cases before deciding on the method of operation. Old sacculated empyemas, multiple and gangrenous abscesses, cavities containing tough, stringy pus or such as require rapid evacuation should be treated by resection, but in all other cases Bülow's procedure is preferable to the graver operation. **GYNECOLOGY AND OBSTETRICS**

WILMER KRUSEN

FRANK C. HAMMOND

**REVIEW OF LITERATURE**

**Ovariectomy During Pregnancy.**—Willi Thomass<sup>1</sup> performed ovariectomy in the fourth month of pregnancy upon a patient wishing the operation because of severe pains and great suffering. There was no "strict" indication for undertaking the operation, and previous to it there was not the slightest sign of impending abortion. Since the existence of the tumor the patient had passed through four normal deliveries and one abortion. Two days after the ovariectomy abortion followed, though the fetus was completely normal in form and constitution. The operation was abdominal celiotomy and presented unforeseen difficulties in the way of numerous and strong adhesions only separable by knife or scissors. However, all manipulation of the uterus was avoided by the abdominal method. The woman passed through the abortion and its results in great danger, but her recovery was rapid and complete. [w.k.]

**Parotitis Following Operations on the Female Genital Organs.**—M. Condamin<sup>2</sup> has reported to the Société de Chirurgie de Lyon a case in which parotitis followed a curetment of the uterus. The operation was done for persistent hemorrhage after the expulsion of a hydatidiform mole. The patient complained of dryness of the mouth for several days after the operation. On the fourth day the temperature began to rise, and the left parotid gland began to swell. The genital tract was normal. The swelling increased for five days and then subsided. The right gland was not at all affected. The complication is explained by a close nervous connection, through the sympathetic system, between the genital organs and the salivary glands. The reverse process to that occurring in this case is a wellknown phenomenon. A diminution of salivary secretion was produced reflexly by the operation, and this condition favored the penetration of microorganisms from the mouth to the interior of the gland. [b.k.]

**Congenital Goiter.**—W. E. Fothergill<sup>3</sup> reports a case of fetal hyperplasia of the thyroid. This was based upon a case in which the mother had been given potassium chlorate during pregnancy. The child was born alive, but death occurred within an hour. The thyroid gland was uniformly enlarged, and weighed 25 grams, the normal weight being 1½ grams. The author mentions the fact that Hewetson and MacDonald have each reported cases of congenital goiter after potassium chlorate had been administered to the mother during gestation. [A.B.C.]

**Operative Treatment of Uterine Carcinoma.**—Gustav Klein<sup>4</sup> gives a concise review of this subject. He states the three fundamental bases of cancer are hereditary disposition, local disposition of the tissues, and the unknown quantity or exciting cause. Since the cause is unknown, there is no general prophylaxis; but as carcinoma of the portio or cervix may result from old lacerations, the early repair of lacerations may be considered a preventive measure. All irritation from pessaries should be avoided as contributing causes. Klein does not believe in hereditary carcinoma, but thinks the infection may be facilitated by endemic conditions, individual predisposition, or deficiency of resisting power. In discussing results of treatment, three things must be considered: whether operable, operation mortality, and absolute healing statistics. He gives the proportion of operable cancer by various methods as varying from about 30% to 50%. The percentage depends largely upon the primary situation of the cancer, being highest in primary carcinoma of the body. The operation mortality he summarizes as varying from 7% in simple vaginal total extirpation to 20% in abdominal total extirpation. Absolute healing, that is freedom from recurrence for five years after operation, is about 10% to 13%. Klein claims that uterine cancer can be cured in practice only by operation and not by any temporizing measures. [w.k.]

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPLEMAN

**EDITORIAL COMMENT**

**On the Value of Pepsin.**—Among the delusions which interested manufacturers encourage among physicians there is perhaps none to which we cling with a more pathetic credulity than that of the value of pepsin as a digestant in cases of gastric dyspepsia. It is in vain that it has been pointed out that it is the fermenting starches, which are not at all affected by pepsin, that give rise to the unpleasant symptoms; it is in vain that it has been shown that pepsin is almost never absent from the stomach, the digestive failure being due to lack of hydrochloric acid. If a "pepsinite" is asked how he expects two grains of pepsin to do any great amount of digestion he points with a childlike pride to the fact that the United States Pharmacopeia requires that pepsin shall digest 3,000 times its weight of egg albumen, ignoring entirely the fact that the test allows six hours for the digestion, and that just about one specimen in a thousand comes up to the pharmacopeial standard. Recently it has been pointed out by the Laboratory of the Delaware State Board of Health<sup>1</sup> that the solution of the precipitated albumen, as required by the United States Pharmacopeia, does not necessarily indicate the complete digestion of the egg, since the acid albumen produced by the HCl is soluble. Assays made of various brands of pepsin show that there is no uniformity in strength, even of different samples from the same firm. The investigation is so instructive that we give a few results obtained by this method of assay upon four of the best known brands of pepsin, marked 1:3,000:

Pepsin A .....	1:560
Pepsin B .....	1:1,052
Pepsin C .....	1:1,209
Pepsin D .....	1:1,253

If pepsin is of value in the treatment of diseases of the stomach, and we believe that in many cases it is, it probably is not by virtue of any digestive power, but perhaps through some sedative effect on irritated mucous membranes.

**REVIEW OF LITERATURE**

**The Influence of Drugs on the Glycosuria of Diabetes.**—M. Kaufmann<sup>2</sup> gives an exhaustive study of the literature and his own investigations concerning the various drugs used in diabetes mellitus. He finds the following drugs worthless, or nearly so: Chloral, piperazin, iodine preparations, arsenic, quinin, methylene-blue, myrtillus, linseed tea, bean-shell tea, alkalies, calcium salts, uranium salts, ammonium salts, pancreas extract, liver extract, cocain, pilocarpin, ergotin. The secret preparations—glycosolvol, saccharosolvol, and antimellin—are also of no value. Antipyrin, carbolic acid, and corrosive sublimate have some influence, but should not be used on account of deleterious effects on the human body, especially with prolonged use. Potassium bromid and the Carlsbad waters are of value in a few cases. The drugs having definite influence on the intensity of the glycosuria are opium, salicylic acid and its derivatives, salol and aspirin, and to a limited extent, jambul. Opium should be employed only in severe cases when diet alone has no effect on the progress of the disease. The salicylic acid preparations are of value only in mild or moderately severe cases of glycosuria, especially when treatment by diet still allows a small residue of sugar in the urine. Jambul is also useful in some mild cases, but fails altogether in others. [b.k.]

**Dangers in Anesthesia.**—Cardie<sup>3</sup> believes that fear can exercise a great effect on the way in which an anesthetic is borne. The effect it produces is comparable that of violent exertion. Under these circumstances chloroform is very dangerous, especially in the early part of the anesthesia. He

<sup>1</sup> American Journal of Pharmacy, 1903, lxxv, 42.

<sup>2</sup> Zeitschrift für klin. Med., Bd. xlviii, pp. 260 and 436.

<sup>3</sup> Treatment, March, 1903, No. vii, page 1.

regards this fear as a potent factor in the production of shock. Another condition increasing the danger of anesthesia is the lymphatic diathesis, which is characterized by persistent thymus, enlarged lymph-glands, adenoid growths in the nasopharynx and sometimes by enlarged spleen. [H.C.W.]

## THE PUBLIC SERVICE

**Health Reports.**—The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended May 9, 1903:

### Changes in the Medical Corps of the U. S. Army for the week ended May 9, 1903:

KIRKPATRICK, Captain THOMAS J., assistant surgeon, will report to the commanding general, department of Luzon, for assignment to duty.

LEWIS, Captain WILLIAM F., assistant surgeon, will proceed to Zamboanga, Island of Mindanao, for assignment to duty.

MUNSON, Captain EDWARD L., assistant surgeon, will report to the civil governor of the Philippine Islands for duty to assist the commissioner of public health.

SPILMAN, ROBERT S., contract surgeon, now in Manila, P. I., is relieved from duty in the department of Luzon, and will proceed to Zamboanga, Island of Mindanao, for duty.

HANSEN, MORRIS J., contract surgeon, is granted leave for two months with permission to visit Japan, to become available about May 1.

O'NEIL, JOSEPH A., contract surgeon, will report to the commanding general, department of Luzon, for assignment to duty.

MCODORY, ROBERT J., contract surgeon, leave granted April 10 is extended one month.

WHEELER, LEWIS H., contract surgeon, leave granted March 19 is extended one month.

SMITH, CHARLES F., contract surgeon, is granted leave for ten days.

PERLEY, Major HARRY O., is granted leave for four months, from about June 1, with permission to go beyond sea.

CRAMPTON, Major LOUIS W., surgeon, is relieved from duty at Fort Adams and will proceed to St. Louis, Mo., and assume charge of the medical supply depot in that city, relieving Major Harry O. Perley, surgeon, to enable him to take advantage of leave.

A board of officers to consist of Major Charles F. Mason, surgeon; Captain Francis A. Winter, assistant surgeon; Captain Frederick P. Reynolds, assistant surgeon, is appointed to meet at the office of the surgeon-general of the army May 13 for the following purposes: To revise the drill regulations and outline for first aid for the hospital corps; to recommend a course of instruction for the companies of instruction, hospital corps; to prepare a scheme of instruction for the hospital corps detachments; to consider the desirability of a side arm for members of the hospital corps, and to recommend one if found desirable.

CLAYTON, Captain JERE B., assistant surgeon, is relieved from duty at Vancouver Barracks and will, upon the opening of navigation on the Yukon River, proceed to Fort Egbert, Alaska, to relieve Contract Surgeon C. A. Treuholtz, who will proceed to Vancouver Barracks, Washington, for temporary duty.

MILLER, EDGAR W., contract surgeon, is granted leave for one month.

POWELL, DWIGHT C., contract surgeon, is granted leave for one month.

HARVEY, Lieutenant-Colonel PHILIP F., deputy surgeon-general, is granted leave for one month.

BROWN, HENRY L., contract surgeon, is granted leave for twenty-one days.

ENDERS, WILLIAM J., contract surgeon, is granted leave for ten days, from about May 17.

STONE, Captain JOHN H., and EDWARDS, First Lieutenant JAMES F., assistant surgeons, now on duty at Fort Leavenworth, are detailed as assistants to the instructor in the department of hygiene at the General Service and Staff College.

### Changes in the Medical Corps of the U. S. Navy for the week ended May 9, 1903:

LEWIS, D. O., surgeon, detached from the Pensacola and granted sick leave for three months—May 2.

SHAW, H., assistant surgeon, ordered to the Yankee—May 2.

COCKE, P. L., acting assistant surgeon, detached from the Naval Academy and ordered to the Chesapeake—May 2.

MICHEL, R. H., assistant surgeon, ordered to the Wisconsin—May 4.

STRINE, H. F., TRAYNOR, P. J., NEILSON, J. L., MUNSON, F. M., BACHMAN, E. A., assistant surgeons, ordered to the Asiatic station, via Solace, May 15—May 4.

BERRYHILL, T. A., surgeon, detached from the navy yard, Pensacola, Fla., and ordered to the Baltimore—May 6.

ARNOLD, W. F., surgeon, detached from Port Isabela, P. I., and ordered to Naval Hospital, Yokohama, Japan—May 6.

MCCLANAHAN, E. K., assistant surgeon, detached from the naval station, Polloc, P. I., and ordered to the Oregon—May 6.

BACKUS, J. W., assistant surgeon, detached from the Princeton and ordered to the Helena—May 6.

DUNN, H. A., assistant surgeon, detached from the naval station, Cavite, P. I., and ordered to the naval station, Olongapo—May 6.

HOYT, R. E., assistant surgeon, ordered to the Texas—May 7.

JENNNESS, B. T., assistant surgeon, ordered to the Indiana—May 7.

### Changes in the Public Health and Marine-Hospital Service for the week ended May 7, 1903:

NYDEGGER, J. A., passed assistant surgeon, bureau order of April 21, 1903, directing Passed Assistant Surgeon Nydegger to proceed to Gulf Quarantine and assume command of the service at that port, revoked—May 2, 1903.

FOSTER, M. H., passed assistant surgeon, granted leave of absence for two days—May 4, 1903.

KERR, J. W., assistant surgeon, granted leave of absence for two days from May 7—May 6, 1903.

BALLARD, J. C., acting assistant surgeon, granted leave of absence for twenty days from April 23—May 2, 1903.

FRARY, T. C., acting assistant surgeon, granted leave of absence for one day—May 5, 1903.

GRACE, J. G., acting assistant surgeon, granted leave of absence for nine weeks—May 2, 1903.

MARR, H., acting assistant surgeon, granted leave of absence for thirty days from May 10—May 2, 1903.

WOODS, C. H., pharmacist, department letter granting Pharmacist Woods leave of absence for twenty days, amended so as to be for nineteen days—May 2, 1903.

HOLT, E. M., pharmacist, granted leave of absence for thirty days from May 5—May 2, 1903.

### Promotion.

C. W. STEPHENSON, pharmacist of the third class, promoted to be pharmacist of the second class, effective April 1, 1903.

PUBLISHED WEEKLY AT 1321 WALNUT STREET PHILADELPHIA BY THE AMERICAN-MEDICINE PUBLISHING COMPANY

VOL. V, No. 21.

MAY 23, 1903.

\$5.00 YEARLY.

**State Supervision of State-aided Private Charitable Institutions.**—The Pennsylvania newspapers of the past week have been publishing the column-long lists of the millions parceled out to the private charitable institutions by the State Legislature. In one sense it is a demonstration of praiseworthy benevolence on the part of the people of the Commonwealth, but in another it is melancholy reading. For the indiscrimination and lack of control to which it bears even more striking witness is a sorry proof of the absence both of sound morality and clear business sense. The Pennsylvania plan—such is the name by which history will stigmatize it—wholly disregards the fundamental principles of State aid, viz., supervision and control over the disbursement of money given for charitable purposes, to see that the objects for which it is given are fulfilled, and the elimination of partisan politics from the management of the institutions and placing them on a scientific basis. The State that has no effective State Board of Control, nor any Advisory Board of State Charities, has no right to spend the taxpayers' money in the support of its charitable institutions.

**The Extinction of Rabies.**—A few years ago hundreds of cases of rabid dogs were annually reported in Great Britain. There is not a single case reported in the first three months of this year in the whole country. The government wisely took up the treatment by prevention, ordered all dogs to be muzzled, formulated drastic rules to prevent the importation of dogs with the disease, and saw to it that tramp, lost, and vagabond dogs were disposed of. Now that hydrophobia has disappeared the muzzle order has been withdrawn. In Norway, Sweden, Holland, Switzerland, and Denmark hydrophobia is now unknown. Why is it that in our country the disease is so common? In New York City there have been twelve fatal human cases in the last six months. The reason is believed to be threefold: First, because it is under local instead of Federal control, and an effective national quarantine is almost impossible. Second, three-quarters of the States in the Union have neither quarantine nor muzzle laws for dogs exposed to the contagion of rabies. Third, and most important of all, because the patient, who in nine cases out of ten is the victim of the community's carelessness and not his own, has to pay the fee for Pasteur treatment, instead of the

guilty community paying it. In New York City the dogs are at last to be restrained, and if the whole country could be brought under the same wise rules to prevent the spread of this infectious disease there would soon be no more need here of the Pasteur institutes and treatment by that method than there is in England. An incidental demonstration of the fallacy of the now extinct denier of the existence of the real disease is offered in the fact that panics and "pseudorabies" have also disappeared in England. The contention of the reactionaries, it will be remembered, was that rabies and hydrophobia was epilepsy or the disease was imagined, either by the dogs, the human patients, or by the spectators. The English method seems to have been as effective against the simulated as against the real disease. Hence the silence of the antihydrophobics.

**Another diploma-selling and book-selling institution** is flooding the profession with its literature. There are something less than a dozen enclosures in the envelope, not forgetting the half-filled-in postal order for the cash desired. It is a hospital which appeals to the diploma hunter, and the price is only \$15.00 for the certificate if it is of the quality on "heavy Royal linen paper," the imitation article costing \$20.00; but the genuine sheepskin can be had for \$25.00. Five dollars in advance is required with the application. In addition you will get a real Red Cross button for your coat lapel, and still another gratis inducement is the president's great book how to get half a million dollars by the practice of medicine, as the president himself has done. We came near forgetting the beautiful pocket membership ticket. And the president is also A.M., M.D., LL.D.—only outdone by the vice-president, who has a still longer tail to his name, being also D.D.S., and Ph.D. The *praefectus potestatis medicorum*, or "president of the staff," is also an LL.D. and a man of national fame. The capital stock is \$250,000 and Christianity is especially commended. The morals of this concern are illustrated by the following quotations:

The whole course of a successful professional career resolves itself into one of diplomacy, associated with indispensable professional capacity.

Our certificate of membership (see fac-simile) is artistically designed and executed in the highest style of the lithographers' art; neatly framed and hung on the walls of your reception-room, it imparts confidence to all visitors and patients, and is

a much stronger drawing card than an ordinary diploma, as it indicates a higher attainment.

We will agree to pay you a cash commission of 50% of all surgical fees, and 25% of all medical fees received from patients you bring or send to us. This, of course, will be held strictly private and confidential. Your professional interests as well as our own demand this.

We have a large number of the best Chicago surgeons and specialists in all branches on our staff; therefore, you are assured, etc.

The men who support and profit by this sort of thing are the worst enemies the profession has, because they encourage antimedicine, and both the justified and unjustified contempt of the lay world, bringing the whole profession into disgrace. The new substitute for the Code of Ethics says that the divider of fees should be denied all recognition and fellowship in the medical profession. Are these mere empty words?

**Interstate Reciprocity.**—In his otherwise most admirable presidential address before the American Medical Association, it seems surprising that Dr. Billings should have spoken favorably of the impossible scheme for a National Board of Medical Examiners, and that the feasible and actual plan of reciprocity between the States was not commended or even alluded to, and yet that is the only legal and practical method of meeting the difficulty. The profession should not only not ignore, but should heartily cooperate to put life into this method of bringing about reciprocity. There seems to be a strange disinclination to call the child by its right name. This may be due to a hidden and mistaken feeling that interstate reciprocity means somehow or other a lowering of the standard. Uniformity of educational qualification is the foundation of true reciprocity; equal qualification should alone entitle to reciprocity. The strength of the reciprocity term is in the fact that States not allowed the measure are under standard, and the sole cure lies in bringing them up to a proper grade. There is no improvement except by comparison, and true reciprocity not only invites but forces official comparison. The American Confederation of Reciprocating, Examining and Licensing Boards demands two wise qualifications:

I. That a certificate of registration showing that an examination has been made by the proper board of any State, on which an average grade of not less than 75% was awarded, the holder thereof having been at the time of said examination the legal possessor of a diploma from a medical college in good standing in the State where reciprocal registration is sought, may be accepted, in lieu of examination, as evidence of qualification. Provided, that in case the scope of the said examination was less than that prescribed by the State in which registration is sought, the applicant may be required to submit to a supplemental examination by the board thereof in such subjects as have not been covered.

II. That a certificate of registration, or license issued by the proper board of any State, may be accepted as evidence of qualification for reciprocal registration in any other State. Provided, that the holder thereof was, at the time of such registration, the legal possessor of a diploma issued by a medical college in good standing in the State in which reciprocal registration is sought, and that the date thereof was prior to the legal requirement of the examination test in such State.

“The Sanitary Regulation of Barber Shops” was the subject of an excellent paper by Dr. W. E.

Hart, of Elyria, Ohio, read at the January meeting of the local and State Boards of Health of Ohio.<sup>1</sup> The statement was made that in 1900 there were 3,400 children refused admission to the schools of New York City because of parasitic affections of the head, and of these over 800 were because of ringworm of the scalp. Dr. Hart had a lively personal interest in the subject, as he had contracted barbers' itch from the use by a barber of unsterilized “clippers.” Cases of syphilis have arisen from the application of alum stick by barbers. The barbers of Chicago have formed a union, raised prices, and petitioned to be placed under the protection of the City Health Department. They wished to abolish “the five-cent shop.” To ensure the requisite cleanliness of the barber shops, Dr. Hart recommends: 1. Education of the barber. 2. Protect him by suitable legislation. 3. Enforce the rules and regulations recommended by boards of health. Running hot water for sterilizing all instruments is the prime requisite. Successful water-heaters, and special formaldehyd cabinets are now on the market and their use should be made obligatory.

At a meeting of the Board of Health of Boston, in 1900, the following regulations were adopted, and posted in all the city barber shops:

The place of business, together with all furniture, shall be kept at all times in a cleanly condition.

Mugs, shaving brushes and razors shall be sterilized by immersion in boiling water after every use thereof.

A separate clean towel shall be used for each person.

Alum or other material used to stop the flow of blood shall be so used only in powdered form and applied on a towel.

The use of powder-puffs is prohibited.

The use of sponges is prohibited.

The barber shall cleanse his hands thoroughly immediately after serving every customer.

No person shall be allowed to use any barber shop as a dormitory.

Every barber shop shall be provided with running hot and cold water.

**Medicine and pedagogics** are inevitably becoming more and more interrelated and a good illustration is the appointment of a committee of the Section on Nervous and Mental Diseases of the American Medical Association to consider and report on the health of school children. Presented by Dr. William J. Herdman, the resolutions were as follow:

*Resolved*, That we, the members of the Section on Nervous and Mental Diseases of the American Medical Association, are deeply conscious of the vital importance of the methods of education and school environment on the development of youth, and are of the opinion that the time has arrived for the harmonious and helpful cooperation of educators and physicians in the work of education. In view of this belief on our part, be it further

*Resolved*, That we appoint a committee from our membership at this meeting whose duty it shall be:

First, to collect during the coming year such exact information as may be accumulated both in this country and in Europe upon the school methods in their relation to the physical and mental welfare of youth.

Second, to confer with leading educators everywhere with the view of eliciting information and opinions upon the subject and of securing cooperation in efforts for improvement of methods.

Third, to report to the section at its next annual meeting the results of their investigations, and formulate a plan for

<sup>1</sup> Ohio Sanitary Bulletin, February-March, 1903.

future and vigorous prosecution of such reforms as we may decide from their report are clearly needed.

The committee appointed is composed of W. J. Herdman, of Ann Arbor; T. A. Williams, of Texas; J. H. McBride, of Pasadena, Cal.; Hugh T. Patrick, of Chicago; F. Savary Pearce, of Philadelphia. This able committee have it in their power to do a great service, and their work should be prosecuted with zeal and thoroughness.

The requirements for admission to medical colleges adopted at the recent meeting of the Association of American Medical Colleges constitute a noteworthy advance. According to the accepted report of the committee, no college shall be a member of the association that does not require of each student for admission either a diploma from a high school or State normal school, obtained after attendance upon a four years' course of instruction, preceded by not less than a six years' course of study in primary and intermediate schools; or a degree of B.S. or B.A. or other equivalent from an approved university, college or academy; or examination upon (a) English grammar, rhetoric and composition, the equivalent of two years of high school work in this branch; (b) algebra, to quadratics; (c) Latin, one year high school work; (d) physics, one year of high school work; (e) United States history, one year of high school work, and seven additional branches of the students' choice from a large number of electives. A student may be allowed to enter upon his medical work conditioned in not more than two branches (one year's work in each), but these conditions must be removed by satisfactory examination before he is allowed to enter upon the second year of his medical course. Candidates for the degree of Doctor of Medicine shall have attended four years of study of not less than seven months each and at least twelve calendar months shall intervene between the beginning of any course and the beginning of the preceding course. Time credits may be given to students who have the necessary entrance requirements and who are graduates or students of recognized colleges of homeopathic or eclectic medicine for such courses of instruction of the required duration as they have successfully filled, excepting in the course of the fourth year, provided they pass satisfactory examinations in materia medica and therapeutics. No time credit or advanced standing shall be given to any student holding a baccalaureate degree or a degree in pharmacy, dentistry or veterinary surgery; but credit for work done may be given a student, he being then permitted to take equivalent electives, which the school shall provide. On and after July 1, 1905, each of the four years of the medical course shall be separate and distinct from the arts and scientific department of a university or college, and no student shall be permitted to be a matriculate in another department of a university or college. One year's work in any subject of a high school or academic course is defined to mean a series of daily recitations of forty-five minutes or more in time for each week of a school year of not less than thirty-six weeks. With this placing of the standard there will remain the long struggle to bring the members of the association up to an actual and not a

theoretic obedience, and the securing and retaining as members those colleges at present bound by history and policy to the lower grades of qualification.

**Surgery Gone Clean Daft.**—In a leading editorial of a prominent medical journal we read:

Who will say that Mayo, that master of American surgery, is not a true prophet when he proclaimed that "We as externists shall soon be able to say to the internist, 'Send to us your intractable cases of neurasthenia, of hysteria, of confirmed gastric irritability and dyspepsia and we will at the end of a simple and virtually safe operation hand you the excised ulcer which you were unable to cure, and which was the causative factor in the condition.'" When that time comes, and come it will, the surgery of the stomach will have reached its goal.

The corollary of all this for the general practitioner is that he should make up his mind that those of his patients who have vague gastric symptoms which do not respond to rational internal treatment may not be longer left to their own devices. Such people usually have ulcers of the stomach or duodenum. Unless the practitioner wishes to take upon himself the responsibility of leaving within that patient what is now recognized as the paramount cause of malignant disease as well as many other incurable conditions he will consult a surgeon and advise his patients to submit to a harmless exploratory investigation, which, in an increasing number of cases, will end in absolute relief by operation.

Amazed disgust cannot find words strong enough to designate properly the folly of such advice. If ever the general practitioner so far loses his head as to be guilty of such criminal nonsense, he will find an outraged professional and public sentiment which will give him and his crazy surgical colleague short shrift.

**The Power for Good of City Health Boards.**—The grand work of Dr. Munn, of Denver; Dr. Reynolds, of Chicago; Dr. Wende, of Buffalo, and others, has been followed by the most noteworthy reorganization of the service by Dr. Lederle, of New York City. In linking the profession with the public life, in educating the masses to help in the eradication and prevention of disease, boards of health have a vast power, equaled by no other, in uplifting and effecting the progress of civilization. Far behind other cities in this respect, Philadelphia has now at last an opportunity of revolutionizing her sanitary government, and physicians and public are eagerly looking forward to the grand possibility of realizing the long delayed measures for placing the city's health business on a scientific and unselfish basis. Director Martin has one of the grandest opportunities ever put before a man. He has appointed a splendid board of advisers, promises freedom from bad politics, and a crusade of education which, if zealously and thoroughly carried out, will reduce the deathrate and redeem the city from medical barbarism.

**Badges for Opium Smokers and Others**—A government monopoly and a factory for the preparation of opium has been established at Fukien, China. Hereafter all opium smokers who wish to purchase the drug must obtain from this establishment badges which are of three classes, viz.: (1) Brass badge, which is for the government officials; (2) paper badge, which is for the gentry, and (3) wooden badge, which is for the common people. On these badges are written the names of the

opium smokers, their ages, their addresses, and the quantity of opium they are allowed to buy daily, which is to be decided and limited by the government officials, and which cannot be deviated from at any time. The interest of Americans for this news consists in the fact that from the province of Fukien come most of the Chinese of the Philippines. The *Manila Times* even thinks such a method of controlling the opium abuse in our new dependency should be adopted by our government. One smiles to think of a purely democratic government undertaking such a direct ordering of the lives of its rulers, the common citizens. For if the use of opium and opium-using citizens are to be thus ordered, the principle must be carried out with logical consistency. The users of cocain, morphin, and alcohol must also have their badges, and must be compelled to wear them conspicuously on their breasts, a new kind of distinction—crosses, buttons, pins, badges, ribbons, and insignia galore for every sort of crime and evil habit. How the breasts of some of our fellow-citizens would be covered with blazing tokens, not "for merit," for demerit. The legends on them would be illuminative of the ways of our social and political life, when our drug-users, patent medicine guzzlers, our gamblers, Senators, drinkers, and our advertising doctors, the eddyites, etc., should all be properly badged!

**Progress is Slow!**—and this fact is illustrated by a letter received at one of our hospitals "within sight of Philadelphia" in reference to a patient. It reads as follows:

EDITORIAL ECHOES

**Medical Unity in New York.**—The action of the House of Delegates as regards the Code was distinctly expressive of the sentiment of the medical profession of the country. Local conditions in the State of New York were not taken into consideration. There was no question of expediency. What was done by the House of Delegates was manifestly that which in its judgment was best for the profession, without reference to incidental or extraneous considerations. The final result could not have been better devised to solve the problems awaiting adjustment in the State of New York, as well as the problems of medical organization of our entire country.—[*Buffalo Medical Journal.*]

AMERICAN NEWS AND NOTES.

GENERAL.

**Leper Will Not be Removed.**—The residents of Savannah, Ga., requested the officials of the War Department to remove the soldier who is afflicted with leprosy and confined at the military station at Tybee to the Sapolo quarantine station. Reply has been made that this request cannot be acceded to. He will be kept at Tybee, it is said, because of the contagiousness of the disease. He is thoroughly isolated, to prevent the disease being communicated to others.

**Football Players Rarely Hurt.**—Professor Dexter, of Illinois University, who has collected a large array of figures, states that in 10 years 210,334 students have been enrolled, and 22,766, or 10.8%, have played football. Of these 654 have been sufficiently injured to cause absence from class, and three have been killed. Thus far in the last 10 years one man out of every 2,846 players has been injured. He summarizes his data as follow: "One student in 10 in America plays football. About one in 35 players is injured badly enough to cause loss of time in class. The number of college men who are permanently injured is very small. Opinions of college officers as regards the value of the game is 27.3 to 1 in favor of football. Accident insurance statistics indicate that many other sports are more dangerous than football."

**The People Should Elect Doctors Only as Governors.**—A press dispatch says that by his knowledge of surgery Governor Garvin, of Rhode Island, saved the life of a boy recently. The Governor had gone to Andersonville, Ga., to attend the dedication of the monument erected by his State in memory of the Rhode Island soldiers who died in Andersonville prison. Just as the Governor was concluding his address the horses attached to the carriage containing the family of E. W. Callaway, of Americus, ran away. The occupants were thrown out and young Edwin Callaway's leg was broken, and the jagged bone severed an artery. The little fellow was fast bleeding to death when Governor Garvin heard of it. He tied the severed artery and set the broken leg. But why were there no members of the profession present at the dedication? All the doctors cannot be Governors!

**Malaria.**—Much malarial fever exists among the troops at certain military stations in the Philippines, and a general order has been issued directing the precautions to be taken against its further spread, through protection against the mosquito and the destruction of the latter wherever practicable. It is reported that an army surgeon at a post where both American and native troops were stationed made systematic blood examinations of all the men of the Filipino organizations and found the malarial parasite present in the peripheral circulation in 19% of apparently healthy men, who presented no clinical symptoms whatever of the disease. He concludes from this that the native possesses a certain resistance to the malarial toxin, and that the existence of such latent infections is a strong factor in the spread of malarial fevers of a severe type among the American soldiers stationed with native troops.—[*Boston Medical and Surgical Journal.*]

**Bubonic Plague.**—In combating bubonic plague in Manila a bounty was paid for all rats turned over to the health authorities, and stations were established at convenient points throughout the city, where they were received. Each rat was tagged with the street and number of the building or lot from which it came, was then dropped in a strong antiseptic solution and eventually sent to the biologic laboratory where a bacteriologic examination was made for plague. During the first two weeks of January, 1901, 1.3% of the rats examined were found infected. This proportion steadily increased and reached 2.3% in October of the same year. At this time numerous rats were found dead of the plague in the infected districts. Buildings from which plague rats were taken were treated exactly as were those where the disease attacked the human occupant. This method of combating the disease is believed by the board of health to have been one of the most substantial factors in enabling the authorities to combat successfully the plague epidemic in Manila.

**Hospital Benefactions.**—SPRINGFIELD, MASS.: The late Richard W. Rice, of this city, bequeathed \$100,000 to the Hampden Homeopathic Hospital, and \$1,000 to the Home for Aged Men. PHILADELPHIA: The will of the late Hiram Woods, of this city, mentions 65 charities as beneficiaries to share in \$77,000. Among these are the Philadelphia Dispensary, \$500; Pennsylvania Hospital, \$2,000; Insane Department of the Pennsylvania Hospital, \$1,000; St. Joseph's Hospital, \$1,000; St. Timothy's Hospital, \$500; Jewish Hospital, \$1,000; and the German, Hahnemann, Jefferson, the Episcopal Hospitals, and Bethany Dispensary, each \$2,000. BOSTON, MASS.: By the will of the late Adolph Openhym, of this city, \$5,000 each is left to the Mount Sinal Hospital and the Montefiore Hospital and Home for Chronic Invalids.—The latter institution has also just received a gift from S. R. Guggenheim of 500 shares of the preferred stock of the American Smelting and Refining Company, having a par value of \$100 a share.—The late Samuel D. Babcock bequeathed \$20,000 to St. Luke's Hospital.

## NEW YORK.

**No Patent Medicines to Children.**—Governor Odell, of New York, has signed a bill making it a misdemeanor to distribute samples of drugs or patent medicines in such a way that children may get them.

**Public Safety Proclamation.**—Governor Odell has signed a bill abolishing the requirement of public safety proclamation in case of epidemic or public emergency. This was done to avert the necessity of influencing the public mind in case of smallpox and other perils prejudicial to public health.

**Pollution of Public Waters.**—Governor Odell has signed a bill prohibiting the pollution of public waters by commercial establishments or others in a manner detrimental to public health. The State Health Department is given jurisdiction and is to issue permits for the discharge of materials from factories into streams.

**To Disinter 10,000 Bodies.**—The Aqueduct Commissioners of New York are carrying out the contract to remove 10,000 bodies from three cemeteries on the Croton division of the Croton reservoir. This is for the purpose of preventing pollution of New York City's watershed. The entire work must be completed by October 1, 1904.

**Child Labor Bill Signed.**—Governor Odell has signed the bill which limits the work of any child between the ages of 14 and 16 years employed in any mercantile or business office, restaurant or apartment house to nine hours a day. Such child must present an employment certificate issued by the health commissioner or the chief executive of the health department of the city or town in which the child lives. The bill will not become operative before October 1.

**Appropriations.**—Governor Odell, of New York, has signed bills providing for the following appropriations: \$2,000 for the expenses of a commission to confer with a New Jersey commission on the construction of a sewer from that State emptying into New York bay; \$870,000 for repairs and improvements to the State Insane Hospitals; \$50,000 for the purchase of a site for a new State hospital for the insane in the north-eastern part of the State; \$2,700 for improvement to the Syracuse Institution for Feeble-minded Children; \$115,000 for the construction of a tuberculosis hospital at Ray Brook.

**Few Mosquitos on Vessels.**—Assistant Surgeon Grubbs, in charge of the government quarantine station, has inspected 82 vessels arriving from ports where the stegomyia is prevalent, and of these vessels 65 had no mosquitos on board during the voyage. The doctor's conclusions are that mosquitos can come aboard a vessel under favorable conditions when the vessel is not more than 15 miles from shore; the stegomyia can be carried from Mexican or West Indian ports to those of our Gulf States; they can board a vessel lying at anchor for a mile or less from shore, being conveyed by the open lighters used or flying aboard, and that a vessel moored a short distance from land may become infected with yellow fever.

**State Bacteriologist Publicly Censured.**—Dr. Follen Cabot, New York City's bacteriologist, has been ordered publicly censured and a record thereof to be placed upon the minutes of the Department of Health, by Dr. Ernest J. Lederle, president of the board. Dr. Cabot's offense, it is stated, consisted in accepting a fee for treating a woman for rabies who had applied to him in his official capacity. It is stated that the victim came from the country and was informed by Dr. Cabot that the cost for the virus would be \$50 and that there would be an additional fee. The allegation is that the doctor presented a bill for \$105. The question arises whether Dr. Cabot could accept a fee for work done under the department, especially in view of the fact that he had not asked permission to treat the patient privately.

## PHILADELPHIA, PENNSYLVANIA, ETC.

**To Abate the Smoke Nuisance.**—An ordinance which has been introduced in the Philadelphia Councils regulates the use of bituminous or soft coal in the city and prohibits the burning thereof unless the place where it is used is properly equipped with smoke consumers. The measure, which becomes effective July 1, provides that a fine of \$50 be imposed for violations.

**Eddyites Refused a Charter.**—The Supreme Court of Pennsylvania recently rendered a decision confirming the findings of the lower court in regard to its refusal to grant a charter to the eddyites. The Supreme Court held that the State regulates the practice of medicine, and requires certain qualifications in its practitioners, while according to the eddyite teaching, no knowledge of anatomy, physiology, or pathology is required to treat disease, the fundamental principle of the eddyite teaching being that disease has no real existence. It was, therefore, held that the courts cannot furnish a charter sanctioning methods and practice at variance with the statutes, with public welfare, and with sound common sense.

## SOUTHERN STATES.

**Olfactory Crusade.**—The *Baltimore News* is authority for the following: "Unless Mayor Howell interferes by veto, Atlanta will soon have an ordinance which will bar from street cars persons who carry odors. By 'odors' the Council means those scents which emanate from persons who work in factories, especially those devoted to the manufacture of guano, of which there are many located in Atlanta. But the ordinance is so broadly framed that the car conductor will have power to eject any person from whom emanates a smell offensive to any other passenger. The working people are demanding that it be vetoed."

**Progressive Pharmacists.**—At a recent State convention of pharmacists in New Orleans a number of measures were instituted to place the pharmaceutical profession on a higher plane and to instil greater confidence on the part of the medical profession and the public in general. A committee was appointed to investigate the adulterations and deteriorations of drugs and the sale of the same. A resolution was passed authorizing the committee to notify offending druggists upon the first offense, reprimand upon the second offense, and to report to the police authorities upon the third offense. This will surely secure a higher standard of preparations and greater care on the part of pharmacists and inure to the benefit of the public and the physician. It was recommended by the association that no pharmacists be allowed to practise in the State without previously passing an examination and being officially registered by the Board of Pharmacy, the custom heretofore having been to allow a pharmacist to practise in the State without an examination in case the board should not be in session. A higher standard of pharmaceutical education was demanded.

## WESTERN STATES.

**The Smoke Nuisance.**—It appears that Chicago will suffer from the smoke nuisance this year as it has done in the past, as the new ordinance cannot become operative for lack of funds. A petition has been made for \$1,200 for carrying out the provisions of the ordinance. It appears that this cannot be granted.

**Illegal Butterin Factory.**—It is stated that a factory which was manufacturing illegal butterin has been seized in Chicago, with the complete manufacturer's outfit and a thousand pounds of butterin. The seizure was made by the revenue agent. Men operating the factory had purchased uncolored oleomargarin, upon which there is a tax of  $\frac{1}{2}$  cent a pound. They were selling the product as creamery butter at 25 cents a pound.

**Nurses Attack Correspondence Schools.**—At the closing session of the Illinois State Association of Graduate Nurses a righteous attack was made upon those so-called schools in nursing which profess to teach by correspondence and by any other means, except actual contact with patients in hospitals. Such institutions were condemned, and an appeal was made to the public and to physicians to sustain the graduate nurses in their position.

**Separate Schools Demanded for Crippled Children.**—The Board of Education of Chicago is contemplating a plan to build separate schools for crippled children, who under present conditions are obliged to climb stairs, and in many instances are subjected to the continual ridicule of their more fortunate playmates. The erection of three separate schools, one for each side of the city, is declared to be an imperative necessity. It is estimated that these buildings will cost \$45,000.

**Health of Chicago.**—According to the Bulletin of the Chicago Health Department there were 2,628 deaths recorded for the month of April. This represented only partly the amount of sickness during the month. It is announced that not since the year following the great fire of 1871, when the larger proportion of the population was crowded together in hastily improvised barracks, or in quarters far beyond their normal capacity, and when thousands came to the city bringing with them all manner of disease, has there been such a prevalence of the graver maladies. The 756 deaths for April, 1872, represented an annual mortality rate of 25.20 per 1,000, while the rate of the past April represents only 16.96 per 1,000. There were 604 deaths caused by pneumonia and only 233 by pulmonary tuberculosis. This is an excess of 113.4% of pneumonia over tuberculosis deaths, and although the deaths from tuberculosis have increased 30.4% over those of April, 1902, the deaths from pneumonia have increased 41.1%. The Health Commissioner again urges that the greatest care should be taken to collect and destroy the sputum of pneumonia patients. Four deaths are reported as due to the exertion of long standing in the taxpayers' line. During the two weeks ended May 2, there were 20 deaths from diphtheria, but only six cultures showing the diphtheria bacilli were sent to the laboratory. This indicates a neglect by physicians of an essential means of diagnosis. Investigation of these deaths shows that they were either due to mistaken diagnosis or to dilatory or imperfect administration of antitoxin. Only two typhoid reactions were found in the laboratory during the week. The bacillus of influenza still predominates in the cultures sent to the laboratory.

## FOREIGN NEWS AND NOTES

## GENERAL.

**Widows of Doctors Remembered.**—In his last will Dr. Ladislaus Jascinski, a leading physician of Lemberg, Galicia, bequeathed £13,000 to a fund for assisting widows of doctors, and ordained at the same time that not more than eight shillings should be spent on his funeral. His numerous orders and medals of distinction he had given away the day before his death to a hostler and a postman.

**Many Die from Plague.**—An exchange states that 33,000 persons are dying each week of plague in India, according to a report from Consul-General Patterson, at Calcutta. On account of the opposition of the native population to the enforcement of laws of sanitation, it is difficult to prevent the spread of the disease. In Calcutta the deaths have been confined to the native quarter, and no cases have occurred in the European quarters, where the laws of sanitation are enforced.

## GREAT BRITAIN.

**The Blind Receive Their Sight.**—It is stated that a man 30 years old and blind from birth has had his sight restored by an operation for cataract at a Glasgow ophthalmic institution. The first thing the patient actually perceived was the face of the surgeon. The first time he saw yellow it made him feel sick; the first sight of red gave him pleasure.

**Artists Poisoned.**—Artists in London are making complaint that the new solid Rafaelli oil colors are deleterious to health. It is asserted that numerous cases of blood-poisoning have been due to this cause, and that the use of these paints caused W. Padgett's death. It is stated by way of explanation, however, that the Rafaelli paint contains neither more nor less poisonous material than the ordinary oil colors, and that the cases of poisoning have been due to neglect on the part of those using them. No painter should think of using his unprotected hands to rub the oil colors into the canvas, as has been done with the Rafaelli sticks.

## CONTINENTAL EUROPE.

**Adulteration of Wine.**—A prominent manufacturer of wines in Berlin has been found guilty of adulterating his manufactured product and sentenced to pay a fine or be imprisoned. Witnesses from among his employes testified that he used tannic acid, gelatin, and isinglass mingled with Greek wines of the cheapest grade.

**Rabies.**—The Council of Hygiene for the Seine Department has made its report on rabies for the year 1902: 1,600 persons were treated in the Pasteur Institute against 1,321 in the previous year; but 3 deaths occurred as against 12 in 1901 and 10 in 1900; and 472 animals were reported as suffering from rabies in 1902 as against 846 in 1901. The Council states that the conditions with reference to rabies were never more favorable.

**Germans to Combat the New Disease.**—From Berlin comes the news that the investigations which have been carried on by the government relative to the tropical worm disease which has attacked 20,000 miners of Westphalia, have shown that only those who are shut out from the sunlight are affected. The disease frequently proves fatal. One hundred and fifty doctors especially trained have been appointed by the government to combat the condition.

## OBITUARIES.

**Eben J. Cutler**, at Cleveland, Ohio, April 28, aged 65. He was graduated from the Cleveland Medical College in 1866. He was a lecturer on surgical pathology and minor surgery in the Cleveland Medical College, and he served two terms as a member of the health board.

**Lucius C. Herrick**, in Cleveland, Ohio, April 30, aged 63. He was graduated from the University of Vermont, Burlington, in 1864. He served as an assistant surgeon during the Civil war.

**D. S. Chamberlain**, of Lyons, N. Y., aged 65. He served as surgeon during the Civil war, and afterward assumed charge of the Soldiers' Hospital at Syracuse.

**Samuel G. Dearborn**, of Nashua, N. H., May 3, aged 76. He was graduated from the Dartmouth Medical College, Hanover, in 1850.

**W. L. Funderburg**, of Gadsden, Ala., May 12. He was graduated from the Southern Medical College, Atlanta, Ga., in 1883.

**M. T. Alexander**, of Apalachicola, Fla., May 8. He was graduated from the Jefferson Medical College, Philadelphia, in 1877.

**Edwin Ellis**, of Ashland, Wis., May 3, aged 78. He was graduated from the New York University in 1846.

**Archibald Taylor**, of New York City, died at Somerville, N. J., May 12, aged 42.

**Samuel A. Gayley**, of Philadelphia, died at Kensington, Md., May 15, aged 80.

**William Johnstone**, of Washington, D. C., May 7, aged 50.

**Solomon H. Holbrook**, of Salem, Mass., May 13, aged 70.

## SOCIETY REPORTS

## SIXTH TRIENNIAL CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

Held in Washington, May 12, 13 and 14, 1903.

[Specially reported for *American Medicine*.]

## Sessions of the Congress.

## FIRST SESSION.

The president, W. W. Keen, was in the chair, and made an announcement in reference to the Major Reed memorial.

## Symposium on the Pancreas and Pancreatic Diseases.

E. L. OPIE (Baltimore) read a paper on the anatomy and histology of the pancreas. This will appear in a future issue of *American Medicine*.

**The Physiology and Physiologic Chemistry of the Pancreas.**—R. H. CHITTENDEN (New Haven) referred to the many abnormalities that occur when the pancreas has been extirpated. Bodies more or less toxic are formed, and he believes that the cells of the pancreas had several more peculiarities of composition than one realized. He referred to the synthetic action of the pancreatic ferments upon glucose, and claims that diet had much to do with the formation of enzymes. He believes also that the pancreatic juices were very much modified by food, and that there were many deviations from the ordinary metabolic processes of the body when the pancreas was extirpated.

**Etiology and Pathologic Anatomy of the Pancreas.**—SIMON FLEXNER (Philadelphia) spoke of the relationship existing between inflammations and degenerations of the pancreas and diabetes. Commenting upon the production experimentally of hemorrhagic pancreatitis, he stated that certain forms of injury had been quite successful along this line. The nearest approach in the artificial production of hemorrhagic pancreatitis in man had been made by injections of natural gastric juice into the ducts of Santorini, inflammatory symptoms appearing with great rapidity. Demonstrable necrotic lesions appeared in the pancreatic cells in from four to six hours, but it is doubtful, in his opinion, whether the natural gastric juice of man ever gets into the pancreas and produces hemorrhagic pancreatitis. He did not believe that gangrenous pancreatitis is of itself a disease, but believed it to be a secondary condition grafted upon a hemorrhagic pancreatitis. He divided suppurative pancreatitis into two forms, first, where the abscesses are small and localized, and second, where they are large and diffuse. As regards spots of fat necrosis, they are frequently surrounded by a zone of hemorrhage, and their relation to the pancreas has long been suspected, although they probably depend upon the presence of pancreatic juice. He considers that fat necrosis occurs, not only where the pancreas is in a state of acute inflammation, but also in cases of chronic inflammation.

**Symptomatology and Diagnosis of Pancreatic Diseases.**—REGINALD H. FITZ (Boston). This paper will appear in a future issue of *American Medicine*.

**Injuries and Inflammatory Processes of the Pancreas.**—JOHN VON MIKULICZ-RADECKI (Breslau) laid considerable stress upon the topographic relations of this organ. He mentioned two methods of exposing the pancreas, first, transperitoneally, and secondly, retroperitoneally. He believed that operations upon the pancreas were more dangerous than those upon any other abdominal organ, due to the fact that the general condition of the patient is usually so low. He collected 80 cases of operations, of which 41 were fatal. Of the 80, 37 were drained. In operating he prefers to make the incision in the median line and showed by statistics that all cases of pancreatic injuries not operated upon died, while of those operated upon, many recovered. He urged early operation in these cases, claiming that far better results were secured than by waiting until abscesses formed. He believed that most cases die in the acute stage, and that the subacute is most favorable for operation. He mentioned four points in favor of early operation, but believed that the operation in all cases should begin as an exploratory incision.

**Cysts, etc., of the Pancreas.**—ROSWELL PARK (Buffalo) approved of Robson's six divisions of pancreatic disease. He mentioned two cases of obstruction of the pancreas by lumbricoid worms, and stated that he believed hydatid cysts of the pancreas were extremely rare. He believed also that injury has more to do with pseudocysts than with the true pancreatic cyst, the symptoms of the latter being mainly those of pressure. Fat in the stools and glycosuria in these cases is very suggestive. Differential diagnosis of pancreatic cysts must be made from at least 13 different kinds of cysts. The place of the incision depends upon where the tumor presents. Referring to drainage, he believed that this was often a life-saving remedy, and should be done posteriorly. In some cases he had observed that the discharge from the fistula increased when the patient became excited. He believed that cancer was most common at the head of the organ, and spoke of some which attained a great size. He considers that medicinal treatment must be sympto-

matic, but claimed to have gotten good results from operating, reporting eight recoveries out of 16 cases. He referred briefly to tuberculosis and syphilis of the pancreas, and advised operation when in doubt.

**Discussion.**—CHARLES C. STOCKTON (Buffalo) discussed these papers; he stated that the question of diabetes in association with pancreatitis did not seem to be by any means settled, as there still seemed some reason for believing that diabetes may exist without ascertainable disease of the pancreas. One point upon which he laid considerable stress was polyuria. In his experience there are many cases in which there is relatively a large amount of sugar without corresponding increase in the quantity of urine, while in other cases there will be considerable urine with very little sugar. He mentioned a case which had been operated upon for a cyst of the pancreas, in which glycosuria appeared a short time afterward. A year later this was considerably increased, and a few years afterward developed into a distinct diabetes. He mentioned the fact that physiologists have found that the secretion of the stomach acts as a normal stimulant to the secretion of pancreatic juice, and that if the stomach secretion is diminished the secretion of the pancreas will also be, but clinically this is not the case. Where there is a disturbance of gastric juice the intestinal digestion will be disturbed to some extent. He concluded by asking for a little delay in accepting the classification which had been suggested by Dr. Robson, although it had been favored by Professor Mikulicz and Dr. Park. HERBERT U. WILLIAMS agreed very largely with what Dr. Stockton had said, and commented upon the fact that in some respects our knowledge of pancreatitis and fat necrosis is very unique. He insisted upon the importance of fat necrosis in diagnosis, and considered that this information was easily obtained by the use of the microscope. He attached considerable importance to this information, and urged the wide circulation of its value. He dwelt briefly upon the experiments of Dr. Wells, and in referring to hemorrhagic pancreatitis mentioned the fact that it was long ago suggested that the action of the pancreatic juice upon the bloodvessels might account for the hemorrhage in at least some cases. He made reference to his recent experience in endeavoring to prepare the Kaiserling preparations for two specimens. His results were extremely poor, and the color did not materialize, which in his opinion may possibly have been due to the action of the pancreatic juice. He agreed with Dr. Flexner as to the causation of acute pancreatitis, and added traumatism to the list of causes, as well as catarrh extending from the duodenum or the bile ducts. He mentioned that one often finds areas of fat necrosis at autopsies, and that sometimes these areas are associated with areas of hemorrhage. MAURICE H. RICHARDSON (Boston) said that acute lesions of the pancreas are very unusual. In 7,000 laparotomies at the Massachusetts General Hospital but six cases have been operated upon for acute pancreatic lesions; all fatal. The disease is as fatal even though operated upon early as it ever was, though death ensues later. In Richardson's two acute cases death followed after four weeks' drainage, the pancreas sloughing and escaping piecemeal. The lesion seems essentially fatal in infections apparently total. Patients surviving long enough for well defined and protected abscesses have a better chance. Three hospital cases have survived. In several laparotomies Richardson has seen throughout the abdomen evidence of old healed, disseminated, fat necrosis without abnormalities in the pancreas. In operative wounds of the pancreas no bad results had followed. These wounds accompanied resection of the pylorus and operations involving the pancreas, but the number is small. The aseptic lesions of the pancreas have apparently a small mortality after operation. Five patients with cysts have all survived drainage, and one infant recovered from total extirpation of a large cyst supposed to be pancreatic. In the other cysts there was discharge of pancreatic fluid for years. Cancer of the pancreas has been the indirect cause of death in many explorations and cholecystotomies for jaundice. Patients with jaundice and cholelithiasis associated with benign enlargements of the pancreas have, after removal of gallstones and drainage through the gallbladder, wholly and permanently recovered. By far the larger number of operations affecting the pancreas have been of this kind in Dr. Richardson's experience. In none of these cases was there any evidence, except by palpation, of pancreatic disease, for all have recovered. To this condition the perhaps unjustified term "chronic pancreatitis" has been used. For the successful surgical treatment of acute pancreatic affections, if successful treatment is ever possible, much more must be known of the very earliest symptoms of these affections. B. S. A. MOYNIHAN (England) agreed with most of what the previous speakers had said, and claimed to have operated on 15 cases of chronic pancreatitis, of which all recovered. One of the cases was particularly interesting on account of the marked polyuria, amounting to 80 or 90 ounces daily—no sugar; more than half of the gland was affected. He drained the gallbladder for some time and then did a cholecystenterostomy. The patient progressed satisfactorily, but five months ago he developed glycosuria, and is now dying of diabetes. The second case was also very interesting, and was one in which the diagnosis had been made of chronic pancreatitis, and in which a calculus was found in the pancreatic duct. On opening the abdomen he removed the stone, which was found to be composed of calcium carbonate. He believed that this was the first occasion in which

pancreatic stone was diagnosed and found on operation. He admitted having had a small amount of experience with acute pancreatitis, and had only been able to find seven or eight cases, two of which were associated with cholelithiasis. One recovered without operation, but the other died.

[To be continued.]

## AMERICAN SURGICAL ASSOCIATION.

[Specially reported for *American Medicine*.]

**The Contributions of Surgery to Internal Medicine: The Presidential Address.**—MAURICE H. RICHARDSON (Boston) spoke of the great opportunities which surgical exploration had afforded in the study of internal diseases, especially in their earliest stages. He had been impressed by the importance of noting accurately all variations from the normal, not only as shown in the lesion for which the operation was undertaken, but in the condition of contiguous structures. Laparotomies should demonstrate not only the exact cause of previously existing symptoms, but, so far as possible, they should explain symptoms developing after convalescence and depending upon abnormalities of viscera other than those operated upon. Surgery affords in many diseases the only opportunity for exact observation. In the frequently fatal lesions the conditions are more accurately described during life than after death; in the lesions of small mortality existing conditions can be described only during life. The great multiplication of laparotomies has not only added enormously to our knowledge of internal diseases, but it has increased our skill in the interpretation of symptoms. Surgery is the *control* of diagnosis. It has taught us to be cautious, to doubt positive opinions, both as to present conditions and as to future possibilities. Surgery has shown time and again its efficacy in apparently inoperable cases as well as its impotence in the apparently operable. By broadening the field of operative treatment surgery has encroached upon medicine. But if it has shown the inefficacy of medical treatment in one class of cases it has also shown the inefficacy of surgical in another class and it has added greatly to the scientific accuracy with which medical treatment may be directed. Surgery has, furthermore, given extraordinary opportunities to the physician for the study of internal processes, both normal and abnormal, so that his deductions may now be based upon facts rather than upon theories. In conclusion, Dr. Richardson said: "The surgeon, then, in his opportunities for observation and study, has contributed vastly to our knowledge of internal disease, especially in its early stages. His explorations demonstrate truth and control opinions; they perfect observations, and, in showing the value of deductions, teach their weight; they prove the interdependence of symptoms upon lesions, and of lesions upon symptoms; they demonstrate the falsity of some inferences and the truth of others. Accumulated experience will show these things so clearly that in time the diagnosis of the clinician will approach the accuracy of scientific demonstration. In therapeutics surgery has shown what surgery can do and what it cannot do, as well as what medicine can and cannot do. Surgery will show still more clearly its own limitations, as well as the limitations of clinical medicine. Working together it seems not impossible that in the near future there will be no borderland between them. It will then have been demonstrated that internal diseases, even some of those now regarded as hopeless, will, by surgical or by medical therapeutics, or by both, be delegated to that class of brilliant achievement to which now belong appendicitis, gallstones, and internal hemorrhage."

**The Toilet of the Peritoneum in Appendicitis.**—GEORGE R. FOWLER (Brooklyn). This will appear in a future issue of *American Medicine*.

**Operations Upon the Stomach, with Special Reference to the Toilet of the Peritoneum.**—A. VAN DER VEER (Albany) felt that much of the success in operations in this region was due to the care exercised in this direction. The abdominal contents should be handled as little as possible; traumatism should be avoided, and the peritoneum should not be soiled with secretions from the mucous surfaces, which are fruitful sources of infection. The importance of drainage, especially in operations on the posterior portion of the stomach, was emphasized.

**Toilet of the Peritoneum in Tuberculous Peritonitis.**—A. OCHSNER (Chicago) after giving a careful review of the literature and his personal experience upon the subject summed up as follows: 1. In the absence of ascitic fluid in the peritoneal cavity, the diseased tissues may be removed with safety if the section is made entirely in healthy tissue. 2. In the presence of ascitic fluid the latter should be evacuated and the abdominal cavity drained. 3. Great care should be exercised in making the intraabdominal examination not to cause any abrasions. 4. Adhesions should not be disturbed. 5. The less the tissues are manipulated, the better will be the results. 6. Manipulations of the infected pelvic organs—uterus, ovaries, fallopian tubes—is less harmful than manipulation of the infected intestines.

**Septic Phlebitis of the Roots of the Portal Vein, and on Pylephlebitis, Together with Some Remarks on the So-called Peritoneal Sepsis.**—ARPAD A. GERSTER (New

York) went very fully into the literature on the subject and reported several cases. He believed the important points in diagnosis were: 1. The presence or precedence of an infectious process involving the abdominal contents. 2. The presence of pyemia. 3. The implication of the liver. The prognosis, while very bad, is not always absolutely hopeless, but early diagnosis and prompt operation are the only safeguards.

**Toilet of the Peritoneum in Typhoid Operations.**—R. H. HARTE (Philadelphia) stated that owing to the desperate condition of the patient, it is necessary that the operation be rapid and thorough, both as to the complete elimination of the septic and extraneous matter and the closure of the wound. He laid particular stress upon the advantages of thorough irrigation and drainage, preferably by means of a large piece of gauze carried well down in the pelvis over which is placed a liberal gauze dressing. The operation should be followed by douching with normal salt solution, and excision of the ulcer is not advisable in most cases on account of the prolongation of the operation.

**The Toilet of the Peritoneum in Appendicitis.**—S. H. WEEKS (Portland, Me.) stated that the method pursued must be according to the individual case, if no pus is present drainage need not be established. Where there is a circumscribed abscess, care should be taken not to infect the general peritoneal cavity by forcible irrigation. The wounds and pus cavities should be thoroughly cleansed with gauze pads wet with sterile salt solution and hydrogen dioxid, and the abscess cavity packed with sterile gauze. In that class of cases where the infection has permeated the whole abdominal cavity, the contents must be thorough cleansed and drainage established.

**Toilet of the Peritoneum in Gunshot Wounds of the Stomach and Intestines.**—GEORGE TULLY VAUGHN (Washington, D. C.) emphasized the absolute necessity for drainage and thorough cleansing of the abdominal contents. He divided the cases into two classes: 1. Those without peritonitis: (a) Without extravasation of visceral contents; (b) with extravasation of visceral contents; (c) with considerable blood in the peritoneal cavity or incomplete hemostasis. 2. Those with peritonitis: (a) Local peritonitis; (b) general peritonitis.

**Treatment of the Peritoneum in Spreading and Diffuse Peritonitis.**—JOSEPH A. BLAKE (New York) considered the purulent form of the disease under the following classifications: 1. Cases of abscess in which there is a localized collection of pus with limiting adhesions. 2. Cases with spreading peritonitis, in which there is no limitation of the process by adhesions or gravitation, but in which the limits are ascertainable. 3. Cases of general peritonitis, in which no parts of the peritoneum, possibly excepting the lesser sac, can be demonstrated as free from the invasion. The treatment which has given the best results in his experience is as follows: 1. Early operation. 2. Lavage of the peritoneum with large quantities of saline solution. 3. Closing of the peritoneal cavity without drainage, unless the latter is absolutely indicated by the presence of nonabsorbable amounts of necrotic material. Appended to the paper was the report of a large number of cases.

**Discussion.**—JOHN C. MUNRO (Boston) referred particularly to Gerster's paper, and laid stress upon the chill as being a very important symptom. The uniform enlargement of the liver was dwelt upon, and also the tendency of the condition to become chronic. He claimed that the appetite is ravenous in most cases and the emaciation tremendous, although the sensorium is rarely clouded. Irregular jaundice was looked upon as an important symptom, and one very often overlooked by the average practitioner. Lymphangitis, it was claimed, is often associated with other symptoms, although frequently is present by itself. In the author's opinion, subphrenic abscesses are more apt to be secondary to liver abscesses, although they may come from the retroperitoneal lymphangitis, and sometimes by direct extension from the liver. GERSTER, in closing, referred to two cases which were mentioned in his paper, in each of which the phlebitis was particularly demonstrated. They were cases of appendicitis, and in each case he searched for the veins and turned out the thrombi. The veins containing the cylindrical masses are the thrombosed veins, and are frequently present in places that are not being explored. He looked upon this procedure as a part of the peritoneal toilet in appendicitis, and considered that it should be attended to whenever possible.

**Simplified and Improved Operation for Trigeminal Neuralgia by Intracranial Neurectomy, with Interposition of Rubber Tissue, and Without Resection of the Gasserian Ganglion.**—ROBERT ABBE (New York) after noting the well recognized dangers of ganglion resection, viz., hemorrhage, prolonged operation, damage to brain substance by retractors, secondary abscesses and infected meningitis, quoted Lexer's statistics of 33 deaths from 201 cases collected from all literature, of which 17 died from the operative procedure and the others from above mentioned causes, in several of which the cerebral damage was shown postmortem. After having operated for many years by the usual intracranial method, with 1 death from shock, he had adopted a modified method in 8 cases during the past 7 years, which he regarded as a distinct improvement. Satisfied from study of the nerves removed extensively anterior to the base of the skull that the disease is, in almost all cases, an inflammation of the nerves infected in the bony channels adjacent to the antrum and teeth, he regards the temporary cure by nerve resection within the skull as

proving that ganglion resection is uncalled for. The recurrence being unquestionably due to reunion, he prevents that by interposing a small piece of sterile rubber tissue between the ganglion and the outlets of the second and third branches, which are all he ever resects. He has used this method in eight cases with the same excellent results as in ganglion resection. Numerous experiments on rubber tissue implanted on the brain of rabbits, as well as outside the dura mater and in various other places, showed that it always remains sterile and is never changed in texture. Therefore it remains as a permanent barrier to reunion in the human subjects in all of which it has remained for varying periods up to seven years, the first patient being still absolutely free from pain and having been formerly one of the most inveterate cases of "tic." The operation was further simplified by preliminary ligation of the external carotid artery in the last three cases, with resulting freedom from hemorrhage and reduction in time of operation fully one-half. The complete operation consists in ligation of the external carotid in the neck; a straight incision from just behind the middle of the zygomatic arch; upward and slightly forward in the temporal fossa; splitting the temporal muscle and scraping it widely from the bone; enlarging to one and a half inches a small trephine opening, and lifting the brain and dura mater from the middle fossa; exposing and resecting a half inch of the second and third branches in front of the gasserian ganglion; spreading a rubber tissue strip an inch and a half long over the openings and pressing it down on the bone until all bleeding stops; letting the ganglion settle down on the tissue and closing the wound.

**Discussion.**—GEORGE R. FOWLER (Brooklyn), referring to the preliminary hemostasis, mentioned a method introduced by himself some years ago of ligation of the external carotid which materially lessened hemorrhage in operations for intracranial work. He spoke favorably of the Abbe method, although out of two cases in which he had employed it only one did remarkably well, and the other just the opposite. However, he was able to account satisfactorily for the failure in the second case, as the tapes around the carotid artery were allowed to press upon the jugular vein. GEO. E. BREWER (New York) mentioned one case in which he employed the Abbe method, with only a fair degree of success so far as hemostasis was concerned, but the intolerable neuralgia from which the patient suffered for years was completely cured. His experience in ligation of the external carotid has been that the hemorrhage was venous and very hard to control. He believes that in nearly every case it is due to some tributary of the cavernous sinus, and it has not seemed to him that external ligation would control such a hemorrhage as easily as it would from a meningeal artery. ABBE, in closing, stated that as some of the most inveterate cases had been cured by his method he was satisfied that the disease was not in the ganglion. He laid stress upon the fact that an examination of the nerve before it has been handled at all will often show spots of inflammation along the sheath, and it has seemed to him that these were the original sites of the neuralgia, from which the disease worked its way back to the ganglion.

**Single Ulcer of the Urinary Bladder Nontuberculous and Nonmalignant, with Report of Cases.**—GEORGE E. ARMSTRONG (Montreal, Canada) reported the case of a man, aged 21, without venereal history and of temperate habits, in whom the attack came on suddenly without known cause, accompanied by the following symptoms: (1) Pain at the end of the penis about the corona and on the dorsum, just before micturition, and generally so severe as to necessitate the administration of morphia; (2) frequent micturition, and (3) loss of expulsive power. The patient died eight months after the onset, operation having been performed in the meantime, and autopsy showed acute miliary tuberculosis of both lungs, the left adrenal, spleen, kidneys, left ureter, and kidneys and bladder. The second case occurred in a boy, 12 years of age, and was cured by injections of silver nitrate. He went fully into the literature on the subject, and stated that he believed the three chief causes of single ulcer of the bladder to be infection, thrombosis, and syphilis. The chief symptoms are pain, frequency of micturition, and presence of small quantities of blood in the urine. The prognosis is good if recognized early, and he believed operation gave as good chances of relief as for ulcer in the stomach.

**Discussion.**—WILLIAM L. ESTES (Bethlehem, Pa.) desired to add another case to those reported by Armstrong. The patient was a man of 50, who was operated upon with the idea that he was suffering from septic peritonitis, but instead an ulcer of the bladder was found closely resembling an ulcer of the stomach. The result of the operation was that the man made a good recovery.

**A Case of Enchondroma of the Spinal Column.**—H. R. WHARTON (Philadelphia) reported the case of a man who suddenly felt something give way while lifting a casting, necessitating stopping work for several months, and a year after the injury a tumor developed at the junction of the vertebra with the sacrum, gradually increasing in size and involving several of the lumbar vertebra. The tumor was excised and two weeks after the operation the patient left the hospital and made a good recovery. He gave a report of the pathologist upon the substance of the tumor and a careful review of the literature upon the subject.

[To be continued.]

## AMERICAN GYNECOLOGICAL SOCIETY.

[Specially reported for *American Medicine*.]

## FIRST SESSION.

**Treatment in Cases of Pregnancy Complicated with Fibroid Tumor.**—HENRY C. COE (New York) said that fibroid tumors complicate labor because they interfere in the normal development of the pregnant uterus, may cause distressing symptoms and jeopardize the life of the fetus and mother. Each case must be studied separately and treated according to indications, and these interpreted according to the experience and bias of the surgeon. There are three "semesters" of pregnancy: 1. Up to the fourth month. Here empty the uterus if the tumor is a large interstitial fibroid or a broad-ligament tumor, or if situated in the lower uterine segment, or if an impacted intrapelvic growth. If small tumors are believed to promise danger remove them through the vaginal route if possible, though this will probably terminate the pregnancy. Subserous and pedunculated tumors may be removed by enucleation through the abdominal route. Impacted growths should be freed, under anesthesia, and kept free until the distending uterus will keep them out of the pelvis. 2. From the fourth to the seventh month. The location, size and variety of the tumor are important. Pain and pressure-symptoms are indications for treatment. If there are large interstitial growths we may empty the uterus but the danger of hemorrhage is greater than if done earlier. We may enucleate by the abdominal route. It is a question whether we should remove small multiple growths or wait till the child is viable. In some cases it is wiser to keep the patient under observation, trusting to her safe delivery at term. 3. After the sixth month. We should endeavor to obtain a viable fetus if the mother's life is not actually jeopardized. If growths are subserous, not too large and favorably situated she can probably be safely delivered at term. After the eighth month the Porro-Cesarean, or a complete hysterectomy, be done, *i. e.*, before term. His conclusions are that conservatism should be the rule in these cases, as in other gynecologic procedures, but not carried to extremes. We should discuss marriage and a subsequent risk of pregnancy with women who have fibroids. The time for conservative surgery is often before there is an opportunity for pregnancy. In general, if a fibroid tumor is to be regarded as a menace to life before pregnancy the condition is still more grave after pregnancy. It is the duty of gynecologists to ward off the danger.

**Myomectomy or Hysterectomy.**—JOSEPH T. JOHNSON said the conditions calling for such a decision are fortunately rare. Few, if any, have had sufficient experience with such cases as to enable them to speak with authority. He has had experience in but two cases. In one he did a vaginal hysterectomy when the fetus was in the fifth month, recovery of the prospective mother was uneventful; in the other he did a myomectomy on a uterus four months pregnant, and the woman was normally delivered five months later. Our aim should be to conserve the uterus if possible with safety to the mother, and whether hysterectomy or myomectomy shall be done depends on the conditions which each individual case presents. We are doing more myomectomies than formerly. Every case is a law unto itself. Many pass through the danger period safely, but when complications arise they are serious. Entire danger does not end with delivery—subinvolution may be complicated. Medical and electrical treatment are useless. If surgical treatment is resorted to in subserous and interstitial growths, it should be myomectomy. Many operations have been reported on the pregnant uterus without disturbing the fetus. Properly done, this is a relative safe procedure.

**Pregnancy and Labor Complicated by Myomas.**—GEORGE T. HARRISON quoted, without approval, Hofmeier as saying that myomas have little or no influence on fertility and sterility. The speaker was of opinion that conception is often rendered difficult and at times impossible by the presence of these growths. If conception has occurred and the tumors are small they may do no harm; if large, they are more dangerous and may cause abortion or complicate delivery, or malnutrition and even gangrene. The diagnosis may be difficult if the fibroid be large and soft, and pregnancy occurring late in life it may cause serious pressure-symptoms. Myomas may cause serious complications in pregnancy, labor, and the puerperal period, but this is of infrequent occurrence. The subserous variety usually produce no trouble, unless pedunculated and twisted. An interstitial myoma, if situated near the cervix, may offer serious obstruction to labor, and if multiple may markedly impair the contractile power of the uterine muscle. No rule, however general, can be laid down for treatment. Each case must be studied and interpreted separately. Treatment must in the main be expectant. All the conditions must be watched carefully when myomas are known to be present, and the attendant be governed accordingly.

**Discussion.**—J. CLIFTON EDGAR, with intimate knowledge in some 17,000 confinement cases, had not known of dystocia occurring in more than half-dozen as a result of uterine fibroid growths. He is of opinion that the dangers from this complication are exaggerated. He knew of three cesarean sections for the relief of dystocia from fibroids, and in each case the mother died.

**Bisection of Tumors and Uterus in Abdominal Hysterectomy.**—GEORGE H. NOBLE said the operation of hysterectomy when dealing with a large fibroid uterus is difficult for want of space in which to work. The best way to avoid this difficulty is to bisect both uterus and tumor after raising the uterus out of the pelvis with strong forceps. The tumor can be quickly enucleated after turning the two halves of the uterus to one side, which halves can now be removed and the vessels ligated. The tissues in the pelvis are treated in the usual way after hysterectomy. We can do both panhysterectomy and supravaginal hysterectomy in this same general way. The advantages of this method are: Saving of time, prevention of hemorrhage, increased working space, easy manipulation, accessibility to blood supply in the deep pelvis, freedom from liability of injury to ureters and uterine arteries.

**Discussion.**—W. R. PRYOR said the bars to removal of these growths are asymmetry and distortion of the anatomy of the parts. Mobility is established by bisection of tumor and uterus and symmetry is secured by rolling out or enucleating the fibroids. He then always has a complete hysterectomy; this leaves no dead space.

**Relation and Correlation Between Gynecologic and Nervous Affections.**—CHAUNCEY D. PALMER enumerated a number of nervous affections often associated with pelvic diseases of women. Hysteria is often so associated, but more than 50% of the cases are unassociated with such pelvic diseases, and yet the continued presence of the latter often does produce the former. Chorea may accompany pregnancy, but it more often appears about the menstrual epoch in young girls. Various diseases of the ovary, such as prolapse, cirrhosis, cystic changes, etc., may be, at least so far as we can ascertain, the cause of hysteria and other nervous affections. Too many pelvic operations have been resorted to for the cure of nervous symptoms. The sexual organs play a very small part in nervous disorders of women. Exception may be made in dysmenorrhea, which may cause many nervous symptoms among young women, though not a few of these are psychic rather than pathologic in origin. A spasmodic type does exist, but treatment should not be by gynecologic operation.

**Discussion.**—HARRIS related the history of a young married woman, who, when pregnancy occurred, became morose, melancholic, and suicidal. The symptoms all disappeared after the birth of the child. During the second pregnancy, two years later, the same symptoms recurred, again to disappear after labor. At the request of her husband and self the tubes were sealed to prevent subsequent pregnancy. J. D. EMMERT stated his belief that habitual hysteria in the female is always dependent upon, or at least associated with, a lesion in the genital apparatus, and it almost always disappears with correction of the condition; especially is this true of lesions of the cervix. FORD said neurasthenia was sometimes assigned to pelvic disease. This is wrong. Neurasthenia is a condition and not a disease—in men as well as women. Operation never cures insanity. He had seen 75 cases operated upon with no benefit except that associated with the general improved condition of the patient. He believes nervous disorders follow lacerations of the perineum more frequently than lacerations of the cervix. GEHRUNG believed the metrorrhagia, menorrhagia, dysmenorrhea, and amenorrhea may cause serious mental disorders. We should repair organs and not remove them, and should prevent excessive menstrual flow when there is any tendency to mental disorder. J. T. JOHNSON said if we would conserve diseased pelvic organs and permit them to perform their normal function we would hear less of neurasthenia and other nervous affections. Poor elimination and poor circulation are the cause of many nervous disorders charged to diseased pelvic organs. G. T. HARRISON said we should study each case separately and fully. He had never been able to get any assistance from a neurologist. Insanity is rarely due to diseased pelvic organs.

## SECOND SESSION.

**The Etiology, Pathology and Treatment of Puerperal Sepsis.**—HIRAM N. VINEBERG said: 1. Severe puerperal sepsis may be caused by a variety of pathogenic germs. The variety of germ found in the uterine discharge in a given case is no criterion of the severity of the case and forms no safe guide as to prognosis or as to the treatment to be adopted. 2. Bacteriologic examination of the blood is of little value, either from a prognostic or therapeutic standpoint. 3. The treatment of puerperal sepsis must be based chiefly upon the clinical history and physical signs of each individual case. 4. Wounds of infection in the perineum, vagina or cervix are to be treated on general surgical principles of irrigation and drainage. 5. Curetage is indicated when there are evidences of placental decidual residue in the uterus independent of the variety of bacteria that may be found in the uterine cavity. 6. In those rare cases in which adherent and sloughing placental tissue cannot be removed, either with the sharp curet or fingers, hysterectomy is indicated, providing the patient is not already moribund. 7. Hysterectomy is also indicated in septic endometritis, or infection of the placental site, so long as the infection is still limited to the uterus, and when the symptoms steadily grow worse in spite of uterine irrigations, with or without curettage and appropriate hygienic stimulating treatment. 8. In absence of the uterus the abdomen should be opened, and when feasible the purulent foci are to be drained and the uterus

preserved. If the uterus be studded with small abscesses, hysterectomy is indicated. 9. The abdominal is to be preferred to the vaginal route for hysterectomy. 10. If the infection passes from the uterus into one or other tube and sets up a violent grade of inflammation, the abdomen should be opened and the infected tube removed before a general peritonitis develops. 11. When the infection passes through the uterus and sets up a general peritonitis, a patient may occasionally be saved by a timely abdominal section and drainage. 12. In cases of parametric exudates the treatment should be of a conservative nature, and surgical intervention is indicated only when there are evidences of pus formation. 13. In obscure cases in which the pathologic lesion cannot be determined, and the symptoms are steadily growing worse, it may be advisable to open the abdomen to search for a hidden purulent focus, or for a circumscribed slough of the uterus. 14. The procedure proposed by Trendelenburg, and executed by him and others, of ligating the pelvic veins when they become infected and thrombotic, is worthy of further trial.

**Discussion.**—W. R. PRYOR stated that in his belief puerperal sepsis, especially severe cases, are always caused by the streptococcus. This germ varies greatly in its virulence. Notwithstanding the frequency of the streptococcus as the etiologic factor, it is found in the blood in only about 33% of puerperal cases. The curet should be employed rarely, if at all, in these cases, because a local injection may by this means be converted into a general infection. We should never do hysterectomy in puerperal septicemia, but it may be necessary in some instances when the infection is confined to the uterus. Experimental work done during the past six months showed that fluid and debris removed from the posterior culdesac in cases of puerperal sepsis almost always contained the streptococcus. Experiments made with iodoform gauze and with iodine during the same period convinced him of their great value in these septic cases. Rabbits injected with a lethal dose of streptococcus culture had their lives prolonged six times what it otherwise would have been by injecting an aqueous solution made by taking a saturated alcoholic solution of iodine and adding the same to water until a solution of 1-5,000 was made. He advocated the use of this drug locally and by injection in cases of puerperal sepsis. J. WHITRIDGE WILLIAMS thought bacterial examination of the blood of these patients is highly essential, even though at times it is negative. Blood examinations are less satisfactory, but they should be made. We have found that though the streptococcus may be found in the blood, the case is not necessarily fatal. The curet is harmful in streptococcus infection. He simply douches with salt solution. If it retains secundines and saprophytic germs are present he uses the finger to empty the uterus. The curet is indicated only after abortion. The field for operation in puerperal sepsis is limited to abscess in uterine wall, pyosalpinx, and very rarely a hysterectomy may be necessary. MATTHEW D. MANN said gonococcus infection after delivery occurs rarely. He reported a case in which the temperature ran from 107° F. to 108° F. for several days, finally going to 111° F. before the patient died. Bacteriologic examination repeatedly made showed no germ except the gonococcus. Iodine and iodoform gauze are valuable in streptococcus infection; also the silver salts given by inunction, and Credé's solution copiously given by injection are valuable in such cases. GILL WYLLIE said in our early experience with cases of puerperal sepsis they practically all died. Operation was instituted and many lives were saved. But now with improved methods of treatment, bacteriologic examination of the blood and the contents of the uterus, such operations as hysterectomy are rarely necessary. Our object should be to empty and thoroughly wash out the uterus several times if necessary. The patient being in the recumbent posture drainage from the uterus is deficient and a nidus for germ proliferation is formed. Empty with the finger if possible, otherwise with a small pair of forceps. E. P. DAVIS said we should empty pus when and wherever found. Bacteriologic examinations should be made to ascertain the form of infection to be dealt with. Hysterectomy is indicated only in those rare forms of adherent and infected placenta. Drainage with iodoform gauze loosely placed is indicated. Empty the uterus with the finger if it can be done, otherwise the very gentle use of a blunt curet in proper hands is practically without danger. He recalled two cases of puerperal sepsis caused by the colon bacillus, as proved by bacteriologic examination. McLEAN regarded the curet as dangerous. The uterus should be emptied, of course, but no injury should be done to the endometrium. He has been advocating iodine and iodoform gauze in these cases for 16 years. He saturates a cotton sponge with the comp. tr. of iodine and allows it to remain for a short time in the uterus. FRY said we should make a bacteriologic examination early, wash out the uterus and defer further treatment, unless very urgent, until the result of the bacteriologic examination is known. The curet is harmful and should not be used. Rubber gloves should always be worn by the medical attendant in these cases. ROBERT MURRAY said we should empty the uterus with finger if we can, with the curet if we have to. Thorough and repeated douching should be done to keep the uterine interior clean. H. J. BOLDT said bacteriologic examinations give us no indications whatever as to the line of treatment to pursue. He carries it out in all cases but has failed to achieve anything by it. HORACE WETHERILL said infection following abortion differs from that following

labor and requires a different treatment. The curet is indicated in these cases. For puerperal sepsis the alcoholic method of irrigation and rubber tubular drainage gives the best results. PRYOR said, in closing, that more women die now of puerperal sepsis than in the preantiseptic days.

**Repeated Cesarean Sections on the Same Patient.**—CHARLES M. GREEN stated that a second section had been done in eight instances in the Boston Lying-in Hospital, and in one instance a third cesarean section was done, both mother and child surviving. Hysterectomy should never be done in these cases unless some pathologic condition other than inability for spontaneous delivery be present. After a brief summary of the experiences of the Boston Lying-in Hospital with repeated cesarean sections, Green raises the question whether it is justifiable, in performing cesarean section for either an absolute or an elective indication, to remove normal organs or to resort to other procedures with a view to preventing subsequent pregnancy and the risk of a repeated section. The writer seeks to answer this question in the negative.

**Discussion.**—J. WHITRIDGE WILLIAMS agreed with view last expressed by the above writer except as to paupers, and with these he never does a hysterectomy in the first pregnancy, but ordinarily does in the second. E. P. DAVIS said a woman and her husband have a right to request that the woman be made sterile by hysterectomy at cesarean section; he has acceded to such a request and thinks it right. When the uterus is not removed an effort should be made to cause adhesions between it and the anterior abdominal wall, so that if a subsequent section be necessary the old scar may be entered and the operation be performed without entering the peritoneal cavity. I. S. STONE thought that induction of labor at, say the eighth month, should be considered rather than cesarean section at term, especially this in the country and remote from competent operators. FRY had in three instances refused to sterilize women by hysterectomy. Should sterilization be deemed wise resection of the tubes is preferable to hysterectomy.

**Renal Decapsulation for Puerperal Eclampsia.**—G. M. EDEBOHLS detailed a case in which convulsions were not relieved by delivery. Decapsulation of both kidneys was done 72 hours after the uterus had been emptied, with the result that convulsions ceased and the patient made a good recovery. Casts and albumin are not rapidly disappearing. His operation for eclampsia was the logical outcome of the numerous instances in which the writer has done renal decapsulation for chronic Bright's disease. From the results in the reported case and from those secured in chronic Bright's disease, which he has previously reported, the writer holds that a woman suffering from uremic convulsions of renal origin is entitled to the benefits of decapsulation whether pregnant, in labor, or in the puerperium.

**Discussion.**—J. T. HARRISON said it is the present belief that very few cases of eclampsia are of renal origin, the kidney changes are secondary and not primary. It therefore appeared to him that the operation had a very limited field of usefulness, but he believed it worthy of trial in appropriate cases. CRAGEN said that in 29 cases of eclampsia occurring at the Sloane Maternity Hospital there was but one death. He therefore doubted whether operation of any kind could show a lower mortality. G. M. EDEBOHLS, in closing, said Dr. Cragen's figures were not of value, because he did not give the number of cases of eclampsia of renal origin and only in these cases does he advise operation.

**The President's Address.**—In his address President JOSEPH E. JANVRIN paid a high tribute to the three members deceased since the last meeting, viz., Drs. JOHN BYRNE, T. G. THOMAS, and EDWARD W. JENKS. The main theme of his address was then dwelt upon, it being cancer of the uterus. A somewhat exhaustive review of the literature on the subject was given. Hysterectomy for malignant disease has become somewhat unpopular because too often done when the disease has progressed too far for hope of arrest. During the past 15 years, with selection of cases, the results are better. Cancer early is distinctly local and early operation gives the only hope of cure. Local irritation is probably a strong causative factor in producing cancer of the cervix. For this condition the entire uterus should be removed and a full inch of healthy vaginal wall below its junction with the cervix should be cut away. Whether the vaginal or abdominal route shall be chosen depends much upon the predilection of the operator. Care should be taken not to infect raw and bleeding surfaces of the wound with cancerous tissue. Many statistics were given concerning various methods of procedure and the results therefrom.

**Carcinoma of the Cervix Uteri.**—THADDEUS A. REAMY stated that spontaneous recovery from carcinoma does not occur. He detailed a series of cases in which undoubted recovery, lasting from 10 to 25 years, of two cases following removal of the diseased and adjacent tissues proves the curability of carcinoma of the cervix. It is principally local in origin, and if attacked in this stage can be cured. Women should be educated by the physician to report early any pelvic disorder from which they may be suffering, that appropriate measures may be instituted if malignant disease is found.

**Primary Carcinoma of the Vulva.**—REUBEN PETERSON reported in detail four cases, all operated upon, but recurrence and death occurred in three; the fourth was operated on but recently. It occurs mostly in the old. Some writers have

placed carcinoma of the vulva at 5% of the cases occurring in the genital apparatus, but the writer is of opinion that this percentage is much too high. Operative treatment must be early and radical if recurrence is to be prevented. In one of his cases enlarged inguinal glands removed at operation and subjected to repeated microscopic examination showed no malignant change, while in other cases the glands were found undergoing cancerous change. Pruritis was an early and persistent symptom in three of his cases. Pain was complained of in only one instance.

**Pseudohermaphroditism.**—J. RIDDLE GOFFE reported the case. The person was essentially a female. Photographs were shown illustrating the condition. At her request he removed the rudimentary penis, which was about three inches in circumference, preserved the skin thereof, made an artificial vagina, the lining of which was composed of the inverted skin of the penis. This was preferred to the other skin of the region on account of absence of hair follicles.

[To be continued.]

## AMERICAN ASSOCIATION OF GENITOURINARY SURGEONS.

FIRST SESSION.

**The Permeability of the Urethra for Certain Salts.**—E. C. BURNETT (St. Louis) first discussed the new light thrown upon the diagnosis and treatment by the discovery of the gonococcus and its lesions. He then cited experiments performed on dogs and rabbits with argyrol 1% and 5% and also silver nitrate 1-3,000 and 1-1,500. Examination of the urethras showed that in all the experiments the silver salt had not penetrated the epithelial layer.

**Discussion.**—JOHN VAN DER POEL (New York City) spoke of the infection of the prostate in chronic posterior urethritis. That the posterior urethra is affected often in the first week of the disease and that the follicular and catarrhal forms of prostatic infection are more amenable to treatment than the parenchymatous form.

**Specimen of Strangulated Testicle from Torsion of the Cord.**—ARTHUR C. CABOT (Boston) emphasized the necessity of early recognition of the condition and initial symptoms. He reported a case in a male of 26, vigorous, well developed, and with no venereal diseases. He was suddenly seized with paroxysmal pain in the hypogastric region. The next day the pain increased and was referred to the testicle. On the third day the testicle was swollen with an appearance of an epididymitis. On the fifth day the tissues were edematous and the scrotum adherent. There was great pain; the temperature was 99°. At operation, on opening the tunica vaginalis a small amount of bloody serum escaped. The cord was found rotated from within, downward and outward, for one complete turn. There was no adhesion of testicle to tumor.

**Discussion.**—RAMON GUIERAS (New York City) cited a case in which on operating for a varicocele he found the vas deferens running from the external and posterior side of the cord, across the anterior surface to the inner and posterior side, giving a complete torsion of the cord and yet no symptoms. JOHN VAN DER POEL (New York) cited a case in which there was an undescended right testicle until the patient was 2 years old. When 21 the man began to have attacks of pain along the right cord to the testicle. The cord allowed one and three-quarter turns before symptoms of torsion were elicited, while the left cord allowed one turn. The case was fully reported before the genitourinary section of the New York Academy of Medicine.

**Report of a Case of Complete Avulsion of the Scrotum, Skin of Penis and the Left Testicle.**—ALFRED C. WOOD (Philadelphia) stated that the cause of injury was the patient's shirt being caught in a belt and his being carried around the shafting. The scrotum was entirely absent, and the skin of the penis dissected down to the musculocutaneous junction; the left testicle was torn off. At operation the left cord was ligated at the external abdominal ring and a new scrotum made by lateral flaps taken from the inside of the groin and brought together in the middle line. The denuded surface of the penis was allowed first to granulate and then skin was grafted on by Rundau's method. The patient recovered and has full use of his genital organs.

**Discussion.**—RAMON GUIERAS (New York) cited a case of an Italian with complete sloughing of scrotum. Four skin flaps were used in making an artificial scrotum, two above being taken from the upper side of the pubes and two below from the inner sides of the groin at the junction of the scrotum. The flaps were sewed together somewhat like the cover of a baseball.

**The Conservative Treatment of Cases of Tuberculous Lesion of the Genitourinary Tract.**—GEORGE CHISMEN (Boston) stated that the profession was divided into two classes, those who believe a prompt surgical interference and those who rely upon general measures alone and that each have published statistics of results but that both are open to a great source of error, *i. e.*, from premature claims for cures. He advocated the expectant treatment with good hygiene and tonics, and said that local applications and treatment often

aggravated the symptoms, particularly that of frequent micturition. He reports six cases of his own and also one of Lyman Wilbur (Leland Stanford University) and one of Herbert Moffit (San Francisco). Three of his cases were apparently of traumatic origin; one followed grip and one a stricture. Frequent micturition was marked in three cases, in which the bladder or kidney or both were involved but absent in the cases where scrotal contents only were involved, so long as the urethra was not invaded by instruments or irritants. The speaker gave as his prognosis that the cases will be of long duration, slow and that there is a good chance of ultimate recovery under general hygienic treatment.

**Discussion.**—OTIS indorsed the hygienic treatment, and advocated surgical treatment only when necessary, and said that then it should be radical. THORNDYKE (Boston) spoke of the increasing facilities for early diagnosis and opportunity for early operation, because of its presence and yet showing no symptoms. He emphasized that when palliative measures are necessary one should not be deterred, even though it is known that all the diseased parts cannot be removed.

**A Case of Calculous Anuria.**—ARTHUR C. CABOT (Boston) reported the case of a sailor, aged 57, subject for the past 15 years to attacks of pain in the right lumbar region, extending down to the penis. The pain was accompanied by nausea, vomiting, and bloody urine, and with each attack a small calculus was passed. Two years ago he had a couple of attacks of pain in the left lumbar region, extending to the penis, and with anuria for the 24 hours previous to operation. At operation an exploratory incision was made in right kidney. The kidney was found to be enlarged, double in size and dotted with milary abscesses. No stone was found in the kidney or ureter. The wound was closed with drainage. During the first 24 hours after the operation the patient passed 900 cc. of urine; during the second 24 hours he passed 1,500 cc. On the fourth day the urine ceased coming through the bladder and the drainage through the wound increased; later, the bladder working, the drainage was decreased. On the second day there were two slight attacks of pain; on the fourteenth the bladder was washed and two small stones were found; on the twenty-fourth day one small stone was found. Later a cystoscopic examination of the ureters showed the left ureter plugged with pus, and pressure over and along the ureter expressed a considerable quantity of pus into the bladder. Cabot considers that the exploration of the right kidney restored it to function.

**Conservative Perineal Proctectomy: A Presentation of New Instruments and Technic.**—HUGH H. YOUNG (Baltimore) first spoke of the problems that early presented and reported briefly eight of his early cases. Case I: The patient already had a suprapubic opening for drainage. A tremendous intravesical outgrowth of the middle lobe was enucleated through the suprapubic opening. In Cases II, III, and IV the hypertrophy was confined to the lateral lobes of the prostate. These patients were operated on by Alexander's method with both suprapubic and perineal openings. Cases V, VI, VII, and VIII were characterized by considerable median enlargement. He used the suprapubic route and with the assistance of the finger in the rectum was enabled to enucleate without injury to the urethra. He advocated Bottini's operation in men of 65 years and over and in those in poor physical condition. His principal objection to the perineal route was the necessity of an accompanying suprapubic opening, thus causing considerable hemorrhage, greater duration of convalescence, and development occasionally of suprapubic hernia. Other objections were the depth of the perineal wound and the inaccessibility of the prostate. For traction on the prostate to bring it down into the external perineal wound he devised an instrument consisting of two fenestrated blades attached to shafts, one of which revolves around the other. On introduction into the intravesical limits of the prostate lobes the blades are separated and are ready for traction to bring the prostate well down into the wound. Before giving the details of his operation he spoke of the anatomic relations of the ejaculatory ducts to the prostate and of the necessity of saving these ducts in order to preserve the sexual power and functions. In his operative technic the essential features are a median skin incision in thin subjects and an inverted V in fat or heavy ones. The apex of the inverted V being over the bulb, with the two lateral arms each 5 cm. long, extend down to half way between the anus and ischial tuberosities. He divides the central tendon and also the rectourethral muscle, opens the membranous urethra, inserts his instrument, and by traction draws the prostate down into the superficial wound. In enucleation he makes two convergent lateral incisions on each side of the middle line for nearly the entire length of the posterior region of the prostate, thus leaving a bridge of tissue containing the ejaculatory ducts. He enucleates first the lateral and then the median lobes. After enucleation he uses drainage consisting of a catheter and an ordinary tube passed through the urethra into the bladder, and a continuous irrigation of normal salt solution is begun immediately and kept up for a week. He packs the two spaces left by the lateral lobes with gauze, which he commences to slowly remove after the second day. In the median incision he closes the posterior part of the wound, while in the  $\wedge$  incision he closes one-half and part of the other. On the ninth day a catheter is passed into the bladder and retained for several days, giving permanent drainage. He stated that in 12 cases operated upon all are living and well.

All can empty their bladders completely, the perineal fistula has closed except in recent cases, and the sexual power present, the spermatozoa being active and the lecithin bodies of prostatic secretion present.

## AMERICAN ASSOCIATION OF PATHOLOGISTS AND BACTERIOLOGISTS.

Third Annual Meeting, Held in Washington, May 12, 13 and 14, 1903.

[Specially reported for *American Medicine*.]

### FIRST SESSION.

First in order was the report of the Council and the election of officers. For the ensuing year the following officers were elected: President, Eugene Hodenpyl, of New York; vice-president, Simon Flexner, of Philadelphia; secretary, Harold C. Ernst, of Boston; treasurer, Herbert U. Williams, of Buffalo; member of the Council, Alfred S. Warthin, of Ann Arbor. The election of new members followed. The next meeting of the Association will be held in New York City the Friday and Saturday preceding Easter of 1904.

**The Agglutinative Reactions of the Group of Bacilli Found in Dysentery.**—W. H. PARK (New York) first demonstrated cultures showing the grouping of the several diverse strains of the dysentery bacillus by means of their reaction in mannite litmus agar. The object of the work was to determine in how far we may consider the agglutination test specific in its relation to the dysentery organisms. Control tests with normal sera have shown that a normal serum can give high agglutinative reaction, and further that normal sera vary among themselves in both agglutination and in bactericidal properties. The serum of patients suffering from diseases widely different from dysentery can give positive agglutination tests; this was found in several cases of typhoid, and in a case of staphylococcus abscess. Because of the fact that normal sera contain agglutinins for both groups of dysentery, it is evidently necessary to find a normal serum which contains none of the agglutinative substance. After some search Park has found that the serum of young goats contains no agglutinins, and by using these animals he has come to the conclusion that the agglutinins produced by immunizing an animal against a member of the Manila group are not identical with those produced by immunization against the Shiga group. The diagnostic value of the reaction is, however, brought into question by the discovery by Park of an organism which morphologically resembles colon, but which in its agglutination and bactericidal reactions seems to belong to the dysentery group. He has found this organism in four cases of chronic dysentery.

**The Reaction of Certain Water Organisms with Dysentery Immune Serum.**—D. H. BERGEY (Philadelphia). The diagnostic value of the agglutination test in suspected dysentery is rendered even more doubtful in this paper. He started with the idea that the summer diarrheas of children might have their source in polluted waters, and several suspicious cultures were isolated from samples of water submitted to the laboratory for analysis. The cultural characteristics of these organisms did not resemble dysentery, but the agglutination reactions of all of them were positive. Experiments with higher dilutions showed that agglutinins for the water organisms were present in the specific dysentery immune sera up to as high as 1:400. Normal sera showed also the presence of agglutinins. A rabbit immunized against a water organism gave a reaction of 1:3,000 for the organism used for the immunization; for the Shiga group of dysentery this serum gave positive results in 1:10; for the Manila group in dilutions of 1:500. Bergey further tested the specific immune sera by saturation with different cultures. His experiments have led him to the conclusion that the agglutination reaction cannot be relied upon in differentiating organisms of this group. Immunization with one bacillus increases the agglutinins for a whole group. Normal sera contain agglutinins for many of the organisms.

**The Presence of the Dysenteric and Allied Bacilli in the Normal Intestine.**—W. W. FORD (Baltimore) has been impressed for some time with the presence in the normal intestine of organisms which from the cultural standpoint resemble the dysentery bacillus. He describes at length the cultural characteristics of certain organisms which he has isolated, and discusses the literature of the so-called pseudodysenteric group of microorganisms.

**Discussion of these three papers upon the dysentery bacillus followed.** FLEXNER (Philadelphia) shows the value of the observations recorded in the first two papers in the question of the diagnostic value of the agglutination test. He considers the only positive proof of the presence of the dysentery bacillus to be the isolation and cultivation of the bacillus. He further discusses the grouping of the dysenteric organisms, and refers to the valuable work of Gay (Philadelphia), who has been able to demonstrate that the various members of the group are more independent in their relation to the Neisser-Wechsberg phenomenon than in their relation to the agglutination test. Gay has further found that there is a cross protection between the

groups, a point of great value in the matter of the serum therapy of the disease, although the quantities of the immune sera needed for protection are variable. Any given serum will protect against the infection with the bacteria of any other group than that used in the immunization of the animal from which this serum was taken, but it must be used in multiple doses. Flexner objects to the use of the term "pseudo" at all. He thinks that with improved methods the true dysentery organism will be isolated from some normal individuals, for it is evidently present in instances where the disease is not subsequently developed. EWING (New York) points to certain technical difficulties in the methods of applying the agglutination test.

The complete title of the paper by HARRY T. MARSHALL (Baltimore) is **studies in hemolysis**. (a) A comparison of the receptors of the erythrocytes of the man and the monkey. (b) Hemolytic properties of normal human serum against various bloods, and the behavior of human erythrocytes in the presence of the serum from various normal animals. (c) Hemolytic properties of human exudates and transudates. In the discussion upon Marshall's paper EWING (New York) says that he has been able to separate human blood from the blood of the lower monkeys by means of the biologic method, but has not been able to differentiate between the blood of man and the anthropoid apes.

**A Study of the Proteolytic Enzymes and of the Socalled Hemolysins of Some of the Common Saprophytic Bacteria.**—A. C. ABBOTT and N. GILDERSLEEVE (Philadelphia) state that certain degree of immunity against the enzymes has been produced which manifests itself in a specific neutralization of the enzyme action. Normal sera have also a certain neutralizing action. The work upon the hemolysins has led to the conclusion that the hemolysis in the filtrates of bacterial cultures is due to the action of the proteolytic enzyme upon the corpuscles. The hemolytic action of filtrates of pyocyanus cultures was thought by Jordan to be due to an accumulation of hydroxyl ions; Abbott and Gildersleeve have found that the simple neutralization of the filtrate will destroy both hemolytic and proteolytic action. The culture of the bacteria in a proteid medium contains a greater amount of the proteolytic enzyme; the cultivation in the presence of blood-corpuscles causes the reproduction of a greater amount of the hemolysins.

**Notes on the Agglutinin Reaction of the Pneumococcus with Certain Normal and Immune Sera.**—AUGUSTUS WADSWORTH (New York) discusses the literature upon this question and then describes a new technic which has given positive results in his hands. This consists in using a suspension of pneumococcus cultures in isotonic salt solution, which suspension is then concentrated by the use of the centrifuge. The conclusion of the study is that the use of concentrated pneumococcus cultures will give positive results which can be of value in practical work. Reactions heretofore unknown have been demonstrated in normal sera. Positive precipitin reactions have also been obtained.

**Embryonal Adenosarcoma in the Kidney, with Microscopic Demonstrations.**—GEORGE BLUMER (Albany) describes the microscopic appearance of the tumor, which was made up of a connective tissue, a glandular tissue, and the sarcomatous tissue, which was located almost entirely around the glandular structures. Blumer would classify the tumor as a periglandular adenosarcoma. The paper continues with a discussion of the position of these tumors and of the cases which have been described in the literature.

In the *discussion* which followed LECOUNT (Chicago) called attention to the fact that Jacobi some ten years before the work of Birch-Hirschfeld described the existence of such a tumor group, and described especially its clinical aspects. WARTHIN (Ann Arbor) described a somewhat analogous case of tumor of the bladder. OELMACHER (Gallipolis) discussed the theory of the origin of these tumors, and especially the theory advanced by Hertzog. LOEB (Montreal) called attention to the possible source of error in the discussion of the theory of the origin of such tumors, namely, that tissues under pathologic conditions may form very different structures than under normal conditions.

**On the Occurrence of Syncytium and Ectopic Ova, and on the Origin of Papillary Cysts in Certain Mammalian Ova.**—LEO LOEB (Montreal) has made a comparative study of the ova of 100 guineapigs, cut in serial sections, and of 100 ova which were not studied in serial section. In 12 instances out of these 200 ova he has found syncytial cells. The origin of these cells is the connective tissue surrounding the follicles; giant cells occur, which he thinks are formed from the cells of the theca interna. Papillary cysts may also arise. He has found ova in all stages occurring in the medullary canals, structures which are thought to arise from the Wolffian bodies; these ova usually undergo atrophy, but Loeb thinks that they may sometimes persist.

CHARLES A. BENTZ and HERBERT U. WILLIAMS (Buffalo) demonstrated a **new method for mounting museum specimens**, which seems to obviate some of the difficulties of the methods at present employed. The method consists in embedding the tissues in a medium made of agar-agar, salicylic acid, and acetate of potassium. They have not succeeded in obtaining a clear agar. They further demonstrate a holder for slides while making smear preparations.

**Case of Strongyloides Stercoralis Occurring in a**

**Native of Ohio.**—A. P. OHLMACHER (Gallipolis) described this interesting case. The patient was an epileptic idiot. He believes that the infection occurred in the closed wards of the hospital, although he has failed to find the parasite in the stools of any of the other patients.

[To be continued.]

## AMERICAN ORTHOPEDIC ASSOCIATION.

[Specially reported for *American Medicine*.]

### FIRST SESSION.

**The Mechanic vs. the Operative Treatment of Rha-chitic Deformities of the Lower Extremities.**—R. TUNSTALL TAYLOR (Baltimore) said that all rha-chitic deformities should be treated when the bones are soft and in the early stage, and held by some fixed dressing, with the child in the recumbent position. Constitutional treatment in conjunction with this is imperative. When this opportunity has been neglected and the bones become hardened osteotomy or osteoclasts must be done. He presented his newly-constructed osteoclast, which is like the one in common use, except that it works by a lever instead of a screw, thus permitting more perfect adjustment of the limb and being more rapid in its action.

**The Surgical Pathology of Genu Varum and Genu Valgum.**—WALLACE BLANCHARD (Chicago). The skiagraphic observation of genu varum usually shows three contributing curves in order of development: (1) An exaggeration of the normal outcurve of the lower part of the femur; (2) an outbend of the upper part of the tibia; (3) a distributed outbend of the tibial shaft, the most pronounced curve being in the upper part of the tibia. The least overcorrection, therefore, is necessary at the culminating point to assimilate and give straight and lengthened legs. In genu valgum the primary inbend is usually in the upper part of the tibia and a succeeding incurve becomes distributed through the tibial shaft. The condyles remain normal. The least overcorrection for the best results should be at the apex of the deformity in the tibia. Lorenz and Renier claim that epiphysiolysis corrects by attacking at the central deformity situated in the condyles. This operation is founded on a proved pathologic error, and several of Renier's illustrations show the opening of the outer knee articulations without indications of any separation of the epiphyses or fractures. Its results have been about the same as Lorenz's recently discarded operation of overstretching the external ham-string tendon.

**The Treatment of Paralytic Talipes by Tendon Transplantation, Supplemented by Other Operative Procedures.**—ROYAL WHITMAN (New York). The results of the operation of tendon transplantation as at present performed are unsatisfactory. The favorable effects of the operation are more often temporary than permanent, and are due in many cases to the correction of the preexisting deformity, to subsequent retention, and to the removal of the deforming force rather than to a permanent gain in muscular power. Many of the operations of this class are manifestly impracticable. Simple operations, whose issue may be predicted, in which both the positive and negative effects of transference of muscular power can be utilized, should be selected. The attachment of transplanted tendons to those of the paralyzed muscles should be replaced by direct implantation at a point of selection. Periosteal implantation is less effective than that to the bone itself. The effect of the transplantation should be assured, whenever possible, by secondary operation. Such are arthrodesis of the mediatarsal joint for the prevention of varus or valgus deformity and astragalectomy, in case of insecurity at the ankle-joint, particularly of the calcaneus type.

**Early Operative Treatment of Tuberculous Ostitis of the Knee.**—BERNARD BARTOW (Buffalo) said that in the early stages the disease is limited to the femoral epiphysis, or more often to the inner condylar region. The focal area is often found before it has invaded the joint by trephining the condyle above the attachment of the capsule. There is no middle course in use today between the protective treatment and excision of the knee. The latter is indicated when the disease has invaded the joint. Diseased tissue should be removed with the curet, the cavity treated with carbolic acid, iodine or zinc chloride, and the operative incision closed with suture. Severe flexor contraction can be relieved by open division within the tendon sheaths and preserving their continuity, and during the regeneration of the tendons intra-articular tension is removed. The knee should be fixed by plaster bandages when the incision heals. Locomotion may be permitted with the aid of crutches and a high shoe. The advantage of this early treatment is that invasion of the joint is often prevented, the duration of the disease shortened, and functional conditions conserved. While on its failure to arrest the disease an extra articular vent for escape of pus can be provided, and should excision finally be necessary its good results are not impaired by the foregoing procedure.

**Excision of the Knee for Bony Ankylosis: Report of a Case.**—A. J. STEELE (St. Louis) is of opinion that time has shown the profession that excision doesn't give the useful limb as expected, that it leaves a deformity from lack of firm bony structure. If the condition is a progressive pathologic destruction (usually tuberculous in origin) arthroectomy and arthrot-

omy are indicated. If the disease has spent itself and there remains deformity with ankylosis, then osteoclasts or osteotomy are the proper methods. The former is mainly applicable to true ankylosis, because of the great deformity and danger of lighting up the old condition. In the following case cuneiform osteotomy seemed applicable: The patient was a boy, aged 14, with the right knee flexed to an angle of 90°. There was a history of needle in the joint at seventh year, which caused synovitis at the time of accident. The attending physician opened the joint, and shortly after abscesses formed. The condition was neglected, the limb became flexed and finally ankylosed. At operation a V-shaped flap was turned up, the patella torn loose from the femur, and a wedge-shaped piece removed from femur. Two steel nails, three inches long, were driven upward and posteriorly through the head of the tibia into the femur. Dressings were applied, with an iron rod splint to prevent motion. The limb was placed perpendicularly for 36 hours on account of oozing. The nails were removed on the eleventh day and a plaster cast substituted for the wire splint. In the fifth week the boy was permitted to walk with crutches. In the eighth week a leather splint was applied and the patient now walks unaided with but slight halt.

**The Abuse of Flat-foot Supports.**—WISNER R. TOWNSEND (New York) states that a correct diagnosis of talipes plantus is necessary before correct treatment can be instituted. Some of the most frequent errors in diagnosis are confused with ostitis of the tarsus or ankle, metatarsalgia or neuritis, inflammatory rheumatic condition about inner side of foot, pain due to talipes cavus, and periostitis of the os calcis. Flat-foot can be differentiated from these conditions by careful inspection, use of the x-ray, by the presence of atrophy of calf muscles, and by reflex muscular spasm. Treatment: Because flat-foot exists doesn't always imply immediate necessity for application of a support. Extreme spasm, marked deformity, or inflammatory conditions may contraindicate its use, the support doing more harm than good under such conditions. If the patient discovers the deformity he may do irreparable damage by buying a readymade support at a department store, shoe store, or other shop, all of which should be prohibited from handling them. The kind of support depends on each individual case. They must fit the foot, be strong enough to correct the deformity and maintain its shape. While the support can overcome the deformity it in itself is inadequate to cure. Perfect reduction may be gained, yet by not exercising the muscles and cultivating normal movements the foot may be weakened rather than improved. Therefore it is obvious that intelligent treatment of this deformity can only be done by medical men, and the routine practice of patients treating themselves by readymade supports sold by those with no knowledge of the true anatomic or pathologic conditions should be discouraged.

[To be continued.]

## AMERICAN DERMATOLOGICAL ASSOCIATION.

[Specially reported for *American Medicine*.]

### FIRST SESSION.

**Sarcomatosis Cutis.**—G. W. WENDE (Buffalo). The patient was a colored woman, aged 38. She had no previous diseases except the diseases common to childhood. The disease, resulting from an injury, made its appearance two years before her death in the form of tubercles, resembling very much varicose veins, which disappeared for a year and then returned; these tubercles were markedly pigmented and varied in size from a millet seed to that of a pea. They were accompanied by violent and persistent pain. One year later, when the lesions were about the size of a bean, they began to break down, and the pain disappeared. The inguinal glands were not enlarged. These necrosed lesions suppurated and were followed by exuberant granulations and free discharges. The patient lost appetite and began to fail in health. Blood examination showed no leucocytosis. Eight months later the lesions were still confined to one leg; a few nodes existed which were necrotic, and were followed by exuberant excrescences and offensive discharge. The patient was prepared for amputation of the leg when the disease was also found in the back, and the operation was not done. The progress of the disease was gradual, not painful. The urine contained no albumin nor sugar. Ten days before death the patient developed a cough, but no lung lesion could be found. Upon microscopic examination, the skin lesions consisted of round-cell infiltration with scanty intracellular stroma. These formed nodules which were chiefly in the hypoderm. The cells were of variable sizes and were either oval or round. They were not connected with the lymphatics. There were small deposits of chromatin, but no infiltration into the epidermis; many leukocytes were found in the epiderm. In summing up the writer said that the cells were proliferating around the lymphatics; cells were not of mycotic condition; lymph-nodes were not enlarged; the disease was confined to middle age; spots recognized by palpation, and were of a reddish tint, and hence point to sarcomatosis cutis. Arsenic was administered with relief to the patient with disappearance of the nodules, which does not correspond to sarcoma. The etiology is obscure. Syphilis is excluded.

The disease should be classified, as Fuldt has suggested, among the granulomas rather than as a true neoplasm.

**Discussion.**—THOMAS stated that since there are so many types of sarcoma we must progress along the line of bacteriologic examination. There are sarcomatous tumors resembling leprosy, tuberculosis, and syphilis, hence we must progress along the line of bacteriologic observations and not put too much stress on clinical. He also stated that sarcoma of the surgeon differs from sarcoma of the dermatologist—the latter lasting a long time with slight evidence of malignancy. T. C. GILCHRIST said that he had never seen a case of true sarcoma cutis; this case is more of a granuloma. E. B. BRONSON cited a case in which the symptoms were similar to this; lesions began on nose were removed, later large dusky tumors appeared on the ears, then on the legs, then on the feet. In this case pain was intense. Microscopically, sarcomatous elements were found but they were associated with the nerves.

**President's Address.**—J. T. BOWEN (Boston) said one of the most important subjects we can consider is **methods of teaching dermatology.** The value of didactic lectures, clinical demonstrations, recitations, and teaching by bedside instruction are relative. There is a growing tendency to subordinate the didactic lecture and to devote most of the time to clinical exercises in small sections of students. An ideal course in dermatologic teaching would demand the control of the dermatologic department of hospitals and also a certain number of hospital beds, in order to keep typical cases for teaching. He urged the importance of having the students divided into small groups. The best results are obtained from section work, and success in teaching dermatology depends upon the number in the section. The training of the eye in this work is of the utmost importance; the accurate observation as to color, size and shape of the lesion must be emphasized. In order to acquire this the student must be brought in close proximity with the patient and afforded sufficient time for careful and accurate examination. For the beginner it is best not to use a large number of cases, but use few and typical cases; have the students examine carefully and discuss such cases; in so doing there will not be the confusion as if a large number of cases were shown. The advantage of this method is that the student is made to think for himself; his mind instead of passively receiving what is brought to it, is in constant activity. The student should be made to describe what he sees with accuracy, and then led to form proper deductions. Experience in Latin nomenclature is of first import; a previous college education is necessary; the third year in college of medical study is as early as advisable to begin the study of dermatology. The student should read at first the more common skin diseases; should be able to master the principles of symptomatology, then should be presented for study patients with common diseases, leading on to the more complex. Didactic lectures have materially altered during the last 25 years by the many textbooks which the student may have as his guide, and which formerly did not exist. The clinical lecture is the most common method of teaching dermatology in America, and it is unlikely that it will be wholly superseded. Its advantages are very great where material is small and assistants limited. The didactic lecture, clinical demonstrations, and recitations all have a place in the teaching of dermatology. The educational side of the hospital is of direct benefit to patients as well as to students and physicians.

**Recent Contributions to Our Knowledge of the Hysterical Neuroses of the Skin.**—A. VAN HARLINGEN. The so-called neurotic excoriations of older writers have been classed as erythema since that is the dominant appearance, and in many cases the process goes no further, or at most terminates in very superficial destruction of epidermis. Balzer reports a case in which urticaria, erythema, and pemphigoid bullas occurred in successive attacks; some of the lesions terminating in ulceration, later with patches of gangrene and finally in keloid scars. TONNELLER, in his thesis, divided the hysterical gangrenes of skin into a number of types: 1. Slight circumscribed pemphigoid eruption on an anesthetic skin, without pain, or with very slight accompanied pain; either progressive ulceration or rapidly healing ulcers. 2. (Slenbenranch's type.) Injury, with painful eruptions at the point of lesion, healing with keloid scars. 3. (Ehrli's type.) Same as No. 2, but eruption attacks distant parts. 4. (Bayet's type.) Injury, eruption not at the lesion but in its neighborhood, the lesion remains circumscribed. 5. (Blandin's type.) Unilateral development. 6. (Leloir's type.) Generalization with relapses. 7. (Kopp's type.) Unilateral, with pain in certain nerve areas. 8. (Veillon-Bayet type.) Symmetrical localization upon the hands. Most hysterical skin affections appear at least, at first, to be vasomotor in character. In one case a hard edema showed itself and when this lesion had disappeared pemphigoid blebs followed which developed into intractable ulcers. Although the type varies greatly in the different cases of hysterical gangrene, each case showed characteristics peculiar to itself, yet certain points common to all. The great majority of the cases occur in young females showing signs of hysteria, usually of a mild type. The affection frequently develops after some slight accident; a burn or some injury from a corrosive, a cut or a puncture. The first eruption commonly occurs at or in the immediate neighborhood of injury, with considerable sensory irritation which usually introduces subsequent outbreaks. Sometimes the prodromes

of gangrene are entirely absent, at other times the gangrene develops from urticaria or erythema, or frequently from pemphigoid blebs. When gangrene is established the separation of the eschars often leaves an intractable ulcer, terminating in a keloid scar. While the favorite seat of hysterical gangrene is upon the extremities, the face, mammary region, and other localities are sometimes involved, as the external aural cavity or the mucous membranes. The question of self-infliction is of great import in the study of these cases. Bettman says that, first, the motive of any self-injury remains unknown; simulation may be the result of compulsory action of an abnormal psyche. Such self-inflicted injuries belong to the same category as the compulsory habits of nervous subjects, as onychophagia, dermatothlasia, trichotillomania, etc.; second, self-injury may be inflicted upon a skin of diminished resistance. Analgesic areas may become the seat of gangrene, not only because the patient is more likely to attack such parts of the skin as are least sensitive, but also because these parts are under such trophic influence as to permit a more decided effect from any violence. Often there is difficulty in making a differential diagnosis between hysterical gangrene and that which occurs in syringomyelia. Sometimes both conditions are present in the same patient. Next in frequency to the reported cases of gangrene in hysterical cases have been those of hemorrhagic eruptions of various kinds. Some of these have been collected by Bert in his thesis. Very few cases of hysterical skin affections other than gangrene and hemorrhage have been reported in the last few years. Montfort and Miralie report the case of a woman accustomed to heavy work with the right arm, who had three separate attacks of pain in this arm and hand, with outbreaks of dry, scaly, eczematous eruption at the palmar base of the thumb and over the neighborhood of the hypothenar eminence. The patient had at various times showed distinct signs of hysteria. Rest and the application of a splint to the forearm, with suggestion, cured the condition in a short time.

**Recurrent Bullous Dermatitis in a Hysterical Subject.**—C. J. WHITE. A young woman, aged 23, American, has shown distinct hysteric symptoms for several years and gave a history of marked neurotic and tuberculous parentage. During the past three years she has been the subject of a left-sided, recurrent, grouped, bullous dermatitis, which has during each year attacked one part of the body and by repeated attacks has gradually advanced its position. Each attack has lasted about a week and then disappeared entirely, leaving no mark. The patient is well nourished and does not complain of any gastric disturbances.

**Discussion.**—E. B. BRONSON said that we ought not to bind ourselves to a fixed diagnosis in these cases. Many patients are susceptible to skin changes, due to slightest causes. Decubitus may bring about just such a condition. In many instances co-operation on the part of the patient may bring about hysterical changes and trophic changes. F. C. GILCHRIST said that when the practitioner did not know the cause he would call it neurotic. He cited a case in his own practice of a girl of 16 with a number of lesions on the forearm—keloidal growths, which encircled the wrist as a bracelet; one of these lesions was necrotic. Later she developed a necrotic lesion on the left hand near the metacarpophalangeal articulation, which sloughed and exposed the bone, apparently destroying the tendons. The girl was very hysterical and later developed worse mental symptoms. The patient was kept under close observation for a period of two years, in which time the keloidal growths disappeared and the necrotic scar healed entirely with perfect use of her finger. F. J. SHEPHERD said that when these patients were kept under strict observation bullous lesions did not recur. He said he was doubtful if there was spontaneous recurrence in any case. He cited instances in which patients inflicted the lesions upon themselves with cigaret burns or by hot water bottles placed against the skin. W. A. PUSEY believed that some lesions were of spontaneous origin—not all are produced by artificial irritants. M. F. ENGMAN stated that most cases of eruptions in hysterical patients are feigned and that hysterical persons have irritable vessels which dilate on the slightest trauma. He believed that the psychopathic feature played a considerable part in these cases. A. VAN HARLINGEN thought that the neurologist ought to be consulted in these cases, as they are more in contact with and have more to do with hysteria than the dermatologist. He thought that vasomotor disturbances were the cause of a great number of hysterical eruptions; some interference with the internal force of the patient and not arthropathic.

**Fragilitas Crinium.**—G. F. JACKSON reported two cases. I. Male, aged 35, a clerk, closely confined to the office, was somewhat nervous. He had his hair cut close, and it was noticed that it did not grow in regularly. Was scant on the top of the head and the scalp was bound down. There was a patch on right and left side of head which resembled ringworm, in which the hair was curled up close to the scalp and broken off. II. Man, aged 55, a lawyer, was in apparent good health, took no exercise and smoked considerable, spent most of his time in the office, and had paralysis agitans. He noticed that his hair was matted on the back of his head, two large patches in which the hair was broken off and curled up close to the scalp. Microscopically, no parasites could be detected. Jackson thought the last case might be trichorrhesis nodosa.

**Discussion.**—F. C. GILCHRIST told of a similar case in a lady,

in which there was quite a large spot in which the hair would only grow about one inch and then break off; the hair was of good thickness and luster, but with no amount of treatment would it grow in. With consent of the patient he pulled out of root all the hairs of the area, with the result that it only grew in about one-half inch longer. There was no dandruff nor evidence of parasitic disease. Since then her hair has grown but very little.

## AMERICAN MEDICAL ASSOCIATION.

Fifty-fourth Annual Meeting, Held at New Orleans, La.,  
May 5 to 8, 1903.

[Specially reported for *American Medicine*.]

### Section on Practice of Medicine.

#### FOURTH SESSION.

**The Mode of Transmission of Yellow Fever.**—JAMES CARROLL (U. S. A.) stated that the commission appointed in the United States Army began its work in 1897. They attempted to find a germ constantly occurring in yellow fever cases and answering to the description of that announced by Sanarelli, but failed. They then began work on the theory that the mosquito is the agent which conveys the germ. This theory was first announced by Finlay, in 1881. His theory of transmission, however, was one which had to be abandoned. A general explanation and description of the experimental work done in Cuba was dwelt upon with some detail. To prove the correctness or incorrectness of the theory that fomites is the source of contagion, the commission placed three men, nonimmunes, in a closed room, where they lived continuously day and night for 20 days, sleeping between sheets, on mattresses and pillows, and under bedclothes that had been recently used by yellow fever patients. In the room were placed feces from such patients, clothing which they had worn, and other articles which had been used by them. These had been handled daily by the inmates of the room. The whole of this was repeated with two other nonimmunes and on a subsequent occasion by two others, making seven in all, which had lived in the room for a period of 20 days. In no instance was yellow fever contracted. Weeks after these same individuals were subjected to the *Stegomyia* and four of the seven contracted the disease. The shortest period elapsing from the time the infected *Stegomyia* had bitten a victim and the appearance of the initial symptoms of the disease was 12 days, and the longest period 57 days. From this the writer doubts if any of Finlay's cases were the results of his own experiments, since the time of incubation of his cases was too short. After numerous experiments and observation, Carroll is firmly convinced that the mosquito is the sole cause of yellow fever, and that fomites is never responsible for this scourge.

**Discussion.**—STANFORD E. CHAILLÉ, the venerable dean of Tulane University, who has been in all the epidemics in New Orleans during the past 50 years, and who has given much time to the subject of yellow fever, has given up the theory long held that fomites carries the virus, and now believes that the mosquito is the sole agent. He holds that four facts are established: 1. Fresh blood taken from a victim of yellow fever during the first few days of the disease and injected hypodermically into a nonimmune will cause the disease. 2. The female mosquito (*Stegomyia*) can and does convey the poison, and 12 days is the shortest period, so far ascertained, elapsing before the disease arises. 3. Fomites failed to infect after prolonged exposure seven nonimmunes, and in a subsequent experiment eight nonimmunes escaped infection. 4. Working on the mosquito theory, all yellow fever cases are explainable and on this theory the disease has been excluded from Havana for the longest period within 140 years. The author then gave in detail the results of his investigation of certain epidemics, which were thought to have been certainly caused by fomites—his conclusion being that in each instance the mosquito could have been easily the cause. He then took up the various arguments advanced by those who hold the theory that fomites causes the disease and showed them untenable. He, however, approved of retaining in operation for the time being the quarantine regulations of the various boards of health in southern States and cities, since public sentiment, at least, favors such regulations, and health officers are the servants of the people. EDWARD SOUCHON spoke from the standpoint of a medical officer of the Louisiana State Board of Health. He stated that the board had carefully examined into the various epidemics which had occurred in the State, and as yet they are unable to agree with Reed, Carroll, and their associates, that fomites never causes yellow fever. And, furthermore, public sentiment favors the carrying out of the present quarantine regulations, and should an epidemic occur after such regulation had been abandoned, public censure and criticism would inevitably follow. FOMENTO held that while no doubt the mosquito causes yellow fever it has not been conclusively proved that fomites do not. He gave as an illustration a few wellknown cases in which the mosquito theory appeared wholly untenable and upheld the views announced by Souchon. C. W. STILES

stated that the disease must be caused by a bacterium, a flagellate or a sporozoon organism; the latter alone, taken in connection with the mosquito, fills all the requirements demanded to produce yellow fever. The life history of the other organisms failed to comply with these demands. Therefore from a biologic standpoint the mosquito as the carrier of some sporozoon must be looked upon as the causative agent. CARROLL, in conclusion, was surprised at the general unanimity with which the mosquito theory had been accepted, and he held that the burden of proof that any other agency can and does produce yellow fever rests upon those advocating such theory. At the present time wherever yellow fever is treated in the United States Army service, a mosquito bar is kept at all times over the patient; and in no other way does his general treatment differ from other fever patients.

[To be continued.]

### Section on Surgery and Anatomy.

#### THIRD SESSION.

**Multiple Osteomyelitis.**—JOHN T. BOTTOMLEY (Boston) reported a case of multiple osteomyelitis affecting the left humerus, the left tibia, and the right ulna. The interesting features were the fact that the disease occurred in an adult. Multiple osteomyelitis is extremely rare in adults, only one case being reported in literature so far as Bottomley has been able to find. Another interesting feature was that the infection was by the streptococcus, which is also quite rare and necessitates specially early operation and drainage of these cases.

**Osteomyelitis.**—EDWARD H. NICHOLS (Boston) gave the results of extended studies of the pathology of osteomyelitis. He finds that the disease usually begins in the marrow of long bones and is limited to the shaft. Softening of the compact bony tissue takes place, the pus burrowing outward beneath the periosteum, and if operation is not performed escapes through the soft parts. For repair of the damage new bone is formed from endosteum and periosteum. If operation is undertaken early the marrow cavity should not be cured, as is so commonly done, for this destroys the endosteum and retards repair. Early cases should be trephined at once, but in subacute cases it may be desirable to let the shell of involucrum throw out beneath the periosteum have some time to thicken before the sequestrums are removed. Three or four months may be necessary to accomplish this. In these cases the favorable time for operation may be determined by excision of a small section of periosteum and examination microscopically; needling may be of some aid; the x-ray is less helpful. In chronic cases the indication is to remove the dead sequestrum.

**Discussion.**—WILLARD (Philadelphia) finds that not only general practitioners but surgeons are often slow to make a diagnosis of acute osteomyelitis. In many of these cases the true cause of the trouble is overlooked and the patient is treated for rheumatism sometimes for months. It is always important to keep in mind the possibility of osteomyelitis when bone pain is situated in the region of joints. STEWART (Minneapolis) finds that an erroneous diagnosis of typhoid fever as well as of rheumatism is frequently made. He believes that not to remove the marrow, as suggested by Nichols, is to leave infective material and does not consider it a suitable treatment in such cases. He advocates the attempt to obtain healing under blood clot. MURPHY (Chicago) insists on early diagnosis and believes that the history is so clear in these cases that the cause of the trouble should never be overlooked. There is always acute pain located in the bone near its extremity, with elevation of temperature, usually preceded by a chill. There is no tenderness in early cases, except on long continued deep pressure. The pain begins near the epiphysis and high temperature continues so long as absorption of septic material continues, that is, until the escape of pus occurs by breaking through along a Haversian canal. If operation is performed within 48 hours of the onset of the trouble great destruction of bone is saved. GIBBONS (Scranton, Pa.) called attention to the fact that there is often pain on percussion when there is not on deep pressure in these cases. NICHOLS, in closing, expressed the belief that the diagnosis is by no means easy in these cases. It is frequently overlooked in children. In the early stage of the disease the destruction is limited to the marrow, not to the bone itself, and it is frequently unnecessary to remove the entire shaft, as is so often done in these cases. Apparent cures by healing under blood clot are frequently followed by recurrences.

**Treatment of Vascular Tumors by the Injection of Boiling Water.**—JOHN A. WYETH (New York) referred to the difficulties of the operative treatment of nevi, if extensive. Very many of these tumors cannot be successfully excised, although much depends upon the form of nevus, whether it be capillary, venous, or arterial. Some time ago Wyeth undertook to treat these tumors by the injection of melted paraffin, oil, and later boiling water. These liquids were injected into the main branches of vessels leading into the tumor. Several cases which had been successfully treated by the injections of boiling water were reported. In one case of a very large tumor covering the greater part of the posterior surface of the right side of the patient's back was successfully treated in this way. Under anesthesia the needle was inserted at 11 different points

and the hot water injected without any slough and with practically no scar resulting. This treatment may be used for circoid aneurysm; it is more difficult to successfully treat capillary nevi. Wyeth does not approve of the injection treatment of hemorroids, but if this method be employed in certain exceptional cases the use of boiling water is safest.

**Discussion.**—MAYO (Rochester, Minn.) had the opportunity of seeing two of Wyeth's patients who were treated by the boiling water injections, and considered the results in these cases most satisfactory. He has since treated a case of angioma of the face by the injection of half an ounce of boiling water into different parts of the tumor, with complete relief of the condition. LORD (Omaha) reported a case which he had treated in this way after trying the electric needle and Paquelin cautery without success. In order to avoid accidents from dislodgment of an embolus he believes that it is wise to make pressure with the finger in the region of the injection.

**Further Experience With the Vertical Overlapping Method for the Radical Cure of Umbilical Hernia.**—WILLIAM J. MAYO (Rochester, Minn.) called attention to the difficulties of successfully treating umbilical hernia in very obese patients with thin abdominal walls. Overlapping from side to side, which he first practised, is difficult in certain cases, because of the wide separation of the recti muscles in the region of the umbilicus. He first advised the overlapping method in 1898 and described it in the *Annals of Surgery* of that year. Since then the number of his cases has reached 35. There have been no relapses in the cases treated by vertical overlapping and only one relapse among the cases treated by overlapping from side to side. An elliptical transverse incision is made surrounding the hernia and exposing the fibrous margin of the ring. After freeing the ring and returning the abdominal contents, the lower margin of the ring is liberated for 1 inch laterally each side and is slid  $2\frac{1}{2}$  inches upward into a pocket between the aponeurosis and peritoneum. In this way, the weight-bearing structures are given a fixed place of attachment on sound tissues above the site of the umbilicus and traction is widely distributed. A brief report was given of the main features of interesting cases among the 35 operations which had been performed. The patients are kept in bed three or four weeks after operation and it is not necessary for them to wear any abdominal support.

**Discussion.**—OCHSNER (Chicago) called attention to the large mortality claimed for operations for umbilical hernia in textbooks and monographs on the subject. Recurrences are also considered numerous. The reason for the mortality in these cases is the extreme and unnecessary traumatism required for approximation and the straining on the abdominal muscles, which are drawn tightly together and interfere with respiration. MURPHY (Chicago) reported a case in which death followed shortly after operation from pulmonary edema. This resulted from incapacity for respiration, because of the tension on the abdominal muscles. Such tension is entirely avoided by Mayo's vertical overlapping method. Murphy considers the question of umbilical hernia perfectly satisfactorily settled by the introduction of this method.

**Evolution of the Mammalian Straight Gut with Special Reference to Peritoneal Changes Incident to Rotation.**—W. T. ECKLEY (Chicago) demonstrated an ingenious apparatus for teaching the difficult anatomy of the peritoneum by means of rubber tubing to represent the intestine and rubber dam for the peritoneum.

[To be continued.]

## Section on Obstetrics and Diseases of Women.

### SECOND SESSION.

**Infection of the Gallbladder and Biliary Duct Contents.**—E. W. RICKETTS (Cincinnati, Ohio) thinks that the nomenclature, that of gallstone, is incorrect. Infection may exist with or without stone. The gallbladder may be anastomosed to the stomach or duodenum. The simplest procedure is that of cholecystostomy, stitching the edges to the abdominal incision for free drainage. Contraction occurs after drainage. Three-fourths of the cases of gallstone occur in women. The typhoid and colon bacillus are the most common infections. The cystic duct may remain free from infection and perform its function. Colic is often due to obstruction of the duct or flexion of it. The patient may become septic. Residual bile may collect in the bladder; firm adhesions of the bladder may occur. The freeing of adhesions often effects a cure. An infected gallbladder with accompanying symptoms especially demands treatment. The question as to how much should be done when associated with stone in the common duct is an important question. Jaundice is a serious complication. Rupture of the gallbladder from vomiting may occur. Sudden escape of infected contents may produce speedy death. Incision should be made over the gallbladder and pressure exerted or force a lodged stone either upward or downward. If the stone cannot thus be dislodged the duodenum should be incised near the entrance of the duct and the stone pushed upward. If the duct contains a deposit of plugs, they should be washed out by the use of a catheter. Early diagnosis is not difficult; it is as easy as in appendicitis. Operation may be done under local anesthesia. Let it be well understood that cholecystitis is not

a harmless disease. The secretions of the liver are most abused in health and most neglected in disease.

**Discussion.**—DUNNING (Indianapolis) raised the most important question, as to how much should be done when cholecystitis is associated with stone in the common duct. In septic conditions, with much jaundice, he thinks it well to be content with drainage only; otherwise the mortality is high. He would also hesitate to add the dangers of opening the duodenum. He believes better results will be accomplished by incising the common duct, thus removing a stone and finally inserting a tube for drainage. He would advocate, in severe cases, two operations, the first one for drainage only, a later one for the removal of the stone. THEINHAUS (Milwaukee) approved of the transduodenal route when the stone is impacted in the duct near its entrance into the duodenum. He believes that the method advocated by McBurney in such cases is the only proper method. THOMPSON (Scranton, Pa.) cited a case in his experience in which, by the usual operation, 60 gallstones were removed. The patient did well for two months, when the temperature rose to 104°. Spontaneous reopening of the wound with discharge of bile and pus recurred at intervals. The case was finally cured by the operation of anastomosis of the gallbladder, with the duodenum by the use of a Murphy button. The cause of the prolongation of the condition he was unable to determine. HALDERMANN (Ohio) discussed the difficulty of determining early in some cases whether the condition was not one of malignancy. The pain is not pathognomonic. He has been much in doubt, particularly in conditions of atrophy of the gallbladder. He concludes that exploratory incision is justifiable. MARCY (Boston) considered that when and how to make the diagnosis is more important than operative detail. He believed it lamentable that the general practitioner so often fails to recognize and diagnose the condition. It so happened that he was the first to remove a stone from a common duct. He pleaded that the surgeon might have the cases earlier. DUDLEY (New York) stated that he makes it a practice of aspirating the contents of an infected gallbladder before opening it. Thus a more perfect diagnosis can be made with reference to infection. He injects the bladder with 1-500 formalin solution, reaspirating several times. He believes in serious cases in drainage of the bladder, after thoroughly washing with the formalin solution. RICKETTS closed by referring to the difference in opinion now as compared with that of eight or ten years ago. We are far ahead of that time. He believes that a stone never exists in the common duct without symptoms having long pre-existed, rendering possible the prevention of the formation of the stone. The necessity for proper drainage for the liver, the largest organ of the body, was emphasized. Delay in operation has caused more deaths than all experiments performed. He begged for the privilege of operating before the condition presented a handful of pus.

[To be continued.]

## Section on Diseases of Children.

### SECOND SESSION.

**The Pathology of the Summer Diarrheas of Children.**—G. W. BOOR (Evanston, Ill.) is of the opinion that the term "cholera infantum" is best applied to the fulminating cases of food poisoning. This class merges imperceptibly into the next class, that in which diarrhea is chiefly due to bacterial infection. Streptococcus infection appears to be an occasional cause of infantile diarrhea, such cases occurring usually as a part of a general septicemia. It is probable that a bacillus of the colon group, though of a distinct species from the common colon bacillus, is the specific cause of most summer diarrheas. This organism is better known as the bacillus of Shiga. Duval and Bassett had succeeded in isolating it from 42 cases of summer diarrhea in infants. This bacillus was found in almost pure culture in the mucous stools.

**Every Day Problems in Infant Feeding.**—HENRY ENOS TULEY (Louisville, Ky.) at the outset declared that it was so very exceptional for the mother's milk to disagree with the infant that weaning, for this cause, should only be done for the best of reasons. Milk, modified at the laboratory or at the home, now afforded a fair substitute for breast milk, but in some instances even this form of feeding would prove most troublesome to the physician. Eternal patience was the price of success.

**Infant Feeding.**—ALEXANDER McALLISTER (Camden, N. J.) pointed out that the laity were prone to judge of the value of an infant food by false standards, usually by whether or not the child lived and also by the amount of flesh it gained. These criteria, all physicians knew, to be notoriously misleading. The main point after all was not whether or not the milk was sterilized or pasteurized, but the individualization of infant feeding by appropriate modification of cow's milk.

**The Infant Digestive Disturbances.**—ALFRED C. COTTON (Chicago) read this paper. With regard to cholera infantum he expressed the opinion that this disorder was an intense form of acute gastroenteritis or a dyspeptic diarrhea, plus some unknown intoxication. It was well to bear in mind that a prolonged attack of summer diarrhea was prone to leave the infant with evidences of retarded development, so that these unfortunate children should have a hygiene especially adapted to them

and not merely to the average child of their age. He thought if only a small fraction of the energy expended upon artificial feeding were bestowed upon a study of the physiology of lactation it would be better for mankind.

**Suggestions for Reducing the Prevalence of Summer Diarrhea in Infants.**—J. ROSS SNYDER (Birmingham, Ala.) asserted that this disorder was preventable, and that if the minds of the laity and of some physicians could be disabused of the notion that this disease was chiefly dependent upon heat and humidity greater progress in prophylaxis would be made. It did not follow that bad cow's milk necessarily came from a bad dairy, for there were numerous ways in which the milk became contaminated after its delivery to the consumer. The tenement house poor furnished the hot-bed for summer diarrhea, and these people should not only be educated in the simple principles of proper infant care and feeding, but they should be supplied by milk of excellent quality, such as milk certified to by a medical commission.

**Observations on Breast Feeding from an Obstetrician's Point of View, with Report of Cases.**—EFFA V. DAVIS (Chicago) made, as her first point, that the newborn infant should be started out with its full birthright by refraining from ligating the umbilical cord and severing it from the mother until all pulsation had ceased. In the next place, the obstetrician should personally supervise the first application of the infant to the breast, beginning on the first day, and gradually reducing the interval of nursings in the course of three or four days from six to two hours. Engorgement of the breast could be largely avoided by the application on the second day of a properly fitted cotton-flannel breast binder. She had found that when the mother was much opposed to suckling her infant the coincident mental perturbation often altered the quality of the milk very materially. In the exceptional cases in which it really seemed as if the mother's milk did not agree with her infant it was her custom to stop the nursing for a short time and make use of some substitute food and note the result. When it was evident that the child did better when the nursing was stopped it was better in these exceptional cases to resort to artificial feeding than to allow the child to do indifferently, or even badly, while vainly attempting by a persistence in the breast feeding to accomplish the impossible.

**Aphthæ and Herpes Contracted by Children Drinking Milk from Cows Suffering from Foot-and-mouth Disease.**—E. F. BRUSH (Mount Vernon, N. Y.) presented a brief sketch of his efforts to obtain evidence of the recent occurrence in this country of the foot-and-mouth disease among cattle and its transmission to human beings. His conclusion was that this disease among cattle had been absent from this country for thirty years, but was now prevailing in Vermont, Massachusetts, and New Hampshire. It had been prevailing in England for the past sixty-four years and in Germany for about the same period. The disease was recognized as eminently contagious in cattle and herpes and aphthæ in the human race corresponded clinically with foot-and-mouth disease in the bovine; moreover, aphthæ sometimes appeared as an epidemic among children. He cited the occurrence of five cases in children of one family who got their milk from a herd of cattle afflicted with the foot-and-mouth disease. The milk lost its virulence the longer it stood after milking and boiling entirely destroyed the aphthous poison.

**Observations on Prolonged Withdrawal of All Food in the Management of Certain Cases of Intestinal Disorders.**—THOMAS D. PARKE (Birmingham, Ala.) said his object was to call attention to the fact that one could with impunity and with advantage deprive infants of all food except water for a period of five days or more. He contended that the character of the stools and the patient's condition should be the sole indications for a return to food.

**Discussion.**—H. M. McCLANAHAN (Omaha) said that the need for greater attention being given to the subject of lactation was evident from the fact that recently, after a considerable search through the literature, he had found only two articles giving this important subject special consideration. Another matter worthy of serious attention was the prevalent, though erroneous, notion that if a mother did not have enough milk to nurse her baby the infant should be weaned. This was a serious error and wholly ignored the great value of supplementary feeding. The question of the antitoxic influence of human breast milk, as recently referred to by Dr. William M. Welch, was also of great interest. CHARLES G. KERLEY (New York) said he had never found any woman, no matter what her station in life, who was not willing to nurse her child if she could. If she was in the higher walks of life and had been accustomed to having a good deal of liberty and recreation he found that if tied down to the inexorable two-hour intervals of nursing she began to chafe in the harness, and the quality of the milk deteriorated. For these persons he allowed the infant one bottle feeding each day, and this added liberty had proved most salutary. He did not know of any specific medication which would serve to increase the supply of maternal milk; it could only be successfully done by a proper daily hygiene, including in this a generous diet and proper exercise. Much of the dissatisfaction with infant feeding arose from the error, prevalent even among physicians, of trying to feed sick children just as if they were well. In many of these discouraging and troublesome cases great benefit would accrue from a resort to stomach washing, and it was no unusual thing for the

stomach-tube to cause the discharge of a large quantity of mucus. This treatment was of service even if there were no vomiting. The speaker said he looked upon condensed milk as a sick food, and wholly unfit for well children. In connection with this general discussion he desired to enter a strong plea that the section would take up the advocacy of State control of the production of pure milk, and the securing of pure food for those who could not afford to pay for it. So far he had seen eight or nine cases of Shiga diarrhea treated with the Shiga serum, and the results obtained had impressed him favorably. During the past two summers the annual mortality in New York City from diarrhea had been over 4,000, and yet this tremendous mortality was preventable largely by supplying pure milk, securing better hygienic conditions and suitably educating the ignorant. R. B. GILBERT (Louisville) spoke of the pressing need of securing more nursing mothers. He did not think the mother should be wearied by attempts at nursing during the first few hours after delivery; at this time the newborn infant only required a little warm sterile water. Emotional influences markedly affected the secretion from the mammary glands. He recalled a case in which after a violent fit of anger a mother nursed her infant, and within an hour the little one died in convulsions. The use of whisky, and especially tobacco, by the nursing mother greatly deteriorated her milk. Sexual intercourse also markedly influenced the secretion of breast milk, so much so that he believed a nursing infant should not be put to the breast for three or four hours after sexual excitement. AULD (Chicago) indorsed what had been said by Dr. Parke regarding the starvation of infants. He had often been called to cases in which infants of about a year old were in convulsions, and believing that milk was the cause of the convulsions in most of these instances he had stopped milk and put the children on adult food. This action was based on information obtained from veterinarians to the effect that adult dogs and cats could not digest milk at all and that adult rennet was inert. He declared that he had no faith in a child of over 1 year successfully digesting milk. P. T. BARCUS (Crawfordsville, Ind.) emphasized the need for the physician's attending to the minutest details of the treatment. He firmly believed that the infant should be put to its mother's breast within the first hour or two of life, but if the colostrum persisted it was necessary to draw the milk with a pump and not give the infant this colostrum. Ordinarily these little infants did not receive nearly enough water. THOMAS S. SOUTHWORTH (New York) was disposed to believe in the case reported by Dr. Tuley, in which breast feeding had been abandoned because of the disturbance caused by menstruation, that the nursing might have been continued if the breasts had been pumped out at the menstrual period and the infant given some artificial food during this time. Dr. Davis' admirable paper reminded him that a good deal of persistence was requisite to succeed in many instances in maintaining breast feeding. We should not be too easily discouraged in our attempts to restore to a normal standard breast milk which did not apparently agree with the infant.

[To be continued.]

## Section of Materia Medica, Pharmacy, and Therapeutics.

### FIFTH SESSION.

**Drugs Used in Nervous Diseases.**—GEO. F. BUTLER (Alma, Mich.) stated that nerve fatigue is not tire only, but nerve poison. He reviewed the drugs used in nerve affections and their action. The remedies acting directly on nervous systems are divided into two classes—stimulants and narcotics. Certain elements must undergo biochemic change before having action in the body. He then discussed the mineral sedatives. He concludes that nerve action means nerve waste, and therefore nervous exhaustion must be treated by restoratives and stimulants.

**The Mind as a Causative and Therapeutic Factor in Medicine.**—BITTLE C. KEISTER (Va.) thinks that consideration of the mental factor in medicine has become almost obsolete, and gave instances to show how far it has become overlooked. If more attention was paid to this great subject, less success would attend mental healing and all other charlatanry. He urged that some measure be taken to create chairs for the purpose of teaching this important subject in our colleges, and quoted several observers who reported cases of malignant disease developing from mental disorders, laying stress on the close relationship between mind and body. The surgeon, oculist, aurist, otologist, and general practitioner should make a closer study of the mental condition of their patients.

**Discussion.**—BALLARD spoke of the beliefs among the negro in hoodooism, and reported a case of convulsion brought on by the mental state, and the treatment he adopted. BUTLER considered mental therapy very valuable in certain conditions, especially hysteria. He spoke of the faith placed in physicians by their patients, relating several interesting instances. SOLIS COHEN thought most cases which can be benefited by suggestive treatment are cases of hysteria. He had long considered that Graves' disease was in a great measure due to "crystallized fear."

**The Composition of Some of the So-called New Synthetics.**—W. J. ROBINSON (New York) gave instances where

physicians prescribed remedies of the composition of which they were practically ignorant. The new combinations on the market are in many cases old remedies renamed. Facts show that most of these preparations are impure and dangerous. Some steps should be taken to prevent their sale and advertisement. It is high time that the physician stopped buying them. He proceeded to give analyses of different preparations which were old ones with new names, and spoke of the absurdly low cost of their preparation and the extremely high price of sale.

**Discussion.**—CHAMBERLAIN spoke of the impurity of the so-called new preparations and gave instances known to him when a physician had made an analysis of a preparation whose advertisement was conspicuous in a leading medical journal, and on finding it impure wrote to the journal. He stated that the advertisement still appeared in that journal.

**The United States Pharmacopoeia.**—CARL S. N. HALLBERG (Chicago) gave reasons why the United States Pharmacopoeia for 1900 had not appeared. The committee had lost valuable men since they were appointed which had delayed the work in many ways; there is marked limitation in number of pure drugs. Most of the impurities are only in a very small proportion. For this reason the standard can not be too high. It is not absolutely imperative to have strictly pure medicinal chemicals. Ethical medical laws do not permit the use of patent combinations or of combinations controlled by unlimited proprietary rights. No patent drugs will be admitted to the United States Pharmacopoeia of 1900 unless the patents expire before 1910. He then gave a list of those combinations which will be admitted, also those to be excluded. Biologic and pharmacologic tests not to be admitted to the United States Pharmacopoeia and physiologic doses will not be given. The great question is as to what serums will be admitted. He then gave instances of pharmacopoeial nomenclature, and reasons therefor.

**Discussion.**—ROBINSON considered the United States Pharmacopoeia superior to any in the world. Few physicians study or own a pharmacopoeia, a fact explained by its not containing many drugs which progressive physicians use constantly. He suggested that a supplement be made containing the drugs not admitted to the United States Pharmacopoeia. KELLY did not think that the supplement would be of any aid to the physician, because as we grow older we use fewer drugs. HILL said the metric system and dosage were the two "bugbears" of the United States Pharmacopoeia. He hoped to see the metric system made permanent, and discussed measures by which the practitioner might be induced to take it up. OSBORNE said the fault of the profession in not using the metric system was due to the colleges, and gave reasons. Students are very apt to be confused by the two systems. WEBER considered that laziness was in a great way responsible for the profession's using the old way of prescription writing. He said that in Germany after one year the metric system had been adopted everywhere. HALLBERG, in closing, said that the United States Pharmacopoeia was practically a revision of all the pharmacopoeias of the world. He did not think the supplement suggested in the discussion would be valuable. The committee was going to change the strength of many tinctures, which would be important.

**Dry Superheated Air in Therapeutics.**—C. E. SKINNER (New Haven) thought it necessary that the physiologic action of an agent should be known before the agent should be used. The general body temperature and pulse are rarely affected by the use of superheated air, but certain changes take place in the body after the heat treatment. The functional activity of all organs is augmented. Dr. Skinner gave results caused by the local and body application of heat and reviewed diseases and affections benefited by this treatment. He also reviewed the pathology of sprains, dislocations, contusions, etc., and their treatment by heat.

**Discussion.**—ROBINSON said that American physicians have been blamed for some time for their ignorance of certain drugs and treatment, this due to the fact that the quacks get results with drugs and remedies which the profession does not use. TOMPKINS wished to know if this treatment would spread infection in a case where the tissues were destroyed beyond redemption by contusion. SKINNER, in closing, said that in such cases the formation of pus was hastened but the abscess was localized and glands were not involved. He had never seen a case in which the infection was increased by this treatment.

[To be continued.]

#### Section on Pathology and Physiology.

##### FOURTH SESSION.

**The Morphology and Biology of the Parasite from a Case of Systemic Blastomycetic Dermatitis and General Infection.**—F. J. OTIS and NEWTON EVANS (Battle Creek, Mich.). The paper dealt on the scientific study of this parasite in the different tissues of the body. It invaded all the structures and spread by extension, and through the circulatory system it multiplied in the tissue by budding, and possibly by sporulation. By artificial culture it produced mycelia, and multiplied by pieces of mycelia and lateral conidia—a few instances by budding. The organism fulfilled all the requirements of the law of Koch—it being most pathogenic to the guinea pig. It is destroyed by the usual antiseptics of custo-

mary strength in these experiments in less than two minutes, with the exception of hydrochloric acid, 2%, in which it seems to grow more luxuriantly. The fumes from cedar oil inhibited the growth, and by long exposure is completely destroyed.

**Further Observations of Ankylostomiasis in the South.**—CLAUDE A. SMITH (Atlanta, Ga.). This condition was supposed to be caused only by drinking water containing the larvae of the ankylostoma, but according to observations seem to enter the body through the skin. This disease is found most commonly in children, sometimes in adults, more in white than colored people; it seems to inhabit the South, its range being from the Carolinas to Texas; always in the country, never in cities. Eggs of the parasites are found in the feces of patients who have had several attacks of groundage; they are not hatched in the intestines, but in feces outside the intestines, and in the soil they hatch in 24 hours. The doctor related several cases in which those who have walked barefoot were infected with this bacteria while those whose feet were protected by shoes never showed any symptoms of the disease; a positive diagnosis could only be made by searching for the eggs in the feces.

**Demonstration of New Physiologic Apparatus.**—WINFIELD T. HALL (Chicago). No paper was read, only a description of the manometer tambour and an improvement on the frogboard myograph. This consisted of a simple oak board covered over with a piece of cork to which is attached the myograph; from a thread to which a curved or bent needle is attached is hooked on the split tendon of Achilles of the frog and threaded to the myograph.

**The Working Capacity of a Muscle.**—(Read by Dr. Hall, of Chicago.) J. G. HOLMES (Chicago). When the conditions are physiologic a muscle may work continuously through several successive hours without absolute local fatigue. The amount of work which a muscle will accomplish when working under physiologic conditions far exceeds the amount which has usually been accomplished in ergographic work.

#### Section on Ophthalmology.

##### SECOND SESSION.

**The Physiology of the Sympathetic in Relation to the Eye.**—GEORGE E. DE SCHWEINITZ (Philadelphia) gave a brief review of the general anatomy and physiology of the sympathetic nerve; its distribution in the eye to the iris and ciliary body; to the eyelids and to Müller's muscle. He considered its relation to the lacrimal secretion; its influence on the movements of the iris, with special reference to the mydriatic tract of the pupil and also a consideration of the ciliary spinal center. He considered the nature of the ciliary ganglion, with special reference to its relation to the sympathetic system and of the effects on the eye of lesions of this ganglion; the relation of the sympathetic to the mechanism of accommodation; the relation to intraocular tension; the ocular phenomena which follow galvanism of the sympathetic in the neck. He referred at length to the experimental exophthalmos and enophthalmos and "ptosis sympathetica" and the ocular phenomena which follow injury to the sympathetic in the neck, section of the sympathetic cords or extirpation of the cervical ganglia; the effects of drugs and toxic agents. He said that although lacrimal secretion may be caused by excision of the sympathetic or removal of the ganglion, the sympathetic itself should not be considered the nerve of secretion for the lacrimal gland. He also spoke of the effects of drugs and toxic agents, and concluded with remarks on the relation to the eye deduced from operations on the sympathetic cord in the neck or its ganglia in glaucoma, epilepsy, and exophthalmic goiter.

**The Influence of Resection of the Superior Ganglion of the Cervical Sympathetic in Glaucoma.**—WM. H. WILDER (Chicago) reviewed the history of the operation and reported cases of sympathetomy in various forms of glaucoma and considered its immediate and ultimate effect on vision, tension of the eye, pupil, visual fields, etc. He considered also the accidents and complications as a result of the operation and referred to the experiences of various ophthalmologists and their impressions of its utility in glaucoma. He concluded that the operation is not one to be considered of unusual danger and it should show a trifling mortality; that it was not an operation to be condemned too hastily; that it should be given an early trial where it is applicable; that the simple glaucoma chronica is the one most suited and next the hemorrhagic form.

**Influence of Resection of the Cervical Sympathetic in Optic Nerve Atrophy, Hydrophthalmos, and Exophthalmic Goiter.**—JAMES MOORES BALL (St. Louis) detailed the history of sympathetomy for optic nerve atrophy, reporting his own cases with the method. Few cases of hydrophthalmos had been treated by operation on the cervical sympathetic and the method seemed valueless. He considered excision of the cervical sympathetic was worthy of trial in those cases of simple atrophy which resist measures less heroic. It was impossible as yet to say whether or not bilateral operation was advisable in unilateral atrophy. The value of the method in hydrophthalmos has not been demonstrated. In exophthalmic goiter excision of the ganglion is followed by a larger percentage of cures than is any other proceeding.

## CONGENITAL DISLOCATION OF THE HIP: REPORT OF A BLOODLESS REPOSITION, FOLLOWED BY DEATH, WITH AN ANALYSIS OF TWENTY-THREE CASES IN PROCESS OF TREATMENT.

BY

H. AUGUSTUS WILSON, A.M., M.D.,

of Philadelphia.

Clinical Professor of Orthopedic Surgery in the Jefferson Medical College.

AND

J. TORRANCE RUGH, A.B., M.D.,

of Philadelphia.

Demonstrator of Orthopedic Surgery in the Jefferson Medical College.

PATHOLOGIC REPORT BY

W. M. L. COPLIN, M.D.,

Professor of Pathology and Bacteriology in the Jefferson Medical College.

[Concluded from page 787.]

The only fatal result is here fully recorded.

On March 10, 1903, B. D., a girl, aged 7½, was first seen by Dr. Rugh, she having been sent by the family physician, Dr. I. A. Fries. The family history showed tuberculosis on the father's side, a brother having died of pulmonary tuberculosis, but no history of any similar deformities on either side of the family.

The patient was the oldest of three children, the second one, however, died in its fourth year from meningitis. Birth of the patient was normal. She had measles at three years of age. All three of the children had very large heads when born and the disproportion remained quite marked, giving the appearance of hydrocephalus. Patient never was a robust child nor a hearty eater, but seldom complained of illness. When nearing two years of age she began to walk and the family physician began to notice that she appeared much shorter when standing than when lying. A careful examination revealed to him a double congenital misplacement of both hips upward and backward on the dorsum ilii. He immediately sent her to the orthopedic department of a hospital in this city where she remained under treatment for nearly two years. The treatment consisted in extension for over a year and then the application of plaster-of-paris with the legs in the position of slight flexion and slight abduction. Radiographs taken at the time showed the heads of the femurs to be *opposite* to but not *in* the acetabula. Braces were later applied and worn for two years, but the hips remained misplaced and her gait was very much impaired. When she was examined on March 10, and later, she presented the following appearance: A rather delicate looking child of ordinary height and somewhat under weight. The calvarium was very broad, the face somewhat narrow, accentuating the rachitic tendency, and the veins of the forehead and neck were quite prominent. The skin was almost transparent and presented a very waxy appearance. The chest was spare but of normal size; the abdomen retracted; the extremities thin and the muscles weak. There was marked lordosis of the lumbar spine and the gait was very awkward and rolling. The knees presented a pronounced condition of genu recurvatum and knocked together in walking. The ligaments of the several joints of the lower extremities were very much relaxed, allowing considerable abnormal motion. The feet were in the position of valgus and the toes were markedly everted. The hips were very freely movable and on standing the femoral heads and trochanters stood out prominently. They could be drawn down to the acetabula but not *opposite*. Muscular control was good but the muscles were weak. The adductors were very much shortened as were also the flexors, and the thighs could not be abducted in the line of right-angled flexion beyond 45°. The radiograph showed fairly well-developed femoral heads and acetabula. There being no apparent counterindication present, bloodless reposition was advised and assented to by the parents after the dangers were outlined to them. The patient entered the Jefferson Hospital on March 17, and was prepared for operation in the manner usual at that institution, viz., regulation of the diet, bowels and secretions, with rest in bed for a period of not less than 24 hours. The examination of the heart and lungs was negative and the urine examination was as follows: Urine clear, straw color, acid reaction, faint trace of albumin, 1.5% urea, amorphous urates, squamous epithelial cells and a few leukocytes. The operations were performed the following day at 11 o'clock by the writers, assisted by Drs. Dolson and Taggart, and the anesthetic was administered by Dr. G. J. Schwartz, the official anesthetizer for the orthopedic department. The right hip was first attempted, the various steps of stretching and tearing the adductors and flexors being carefully followed out, and then external rotation and circumduction with hyperextension in the abducted position

was employed but reduction failed. A very significant thing occurred while tearing the adductors, but was considered at the time as not having any special significance. As soon as abduction was made in the tearing of the adductors the skin over these prominent muscles where massage was used began to tear, showing the low state of vitality present. This occurred on both sides, and wherever pressure was made by the hands, or means of reduction, a blue mark appeared.

After several more attempts in the same manner were made the yarn rope was attached to the ankle and traction made to stretch the capsule downward as well as to bring the head opposite the acetabulum. The hip was manipulated while this was being done and then reduction was again attempted but was not accomplished. While the hamstrings were being stretched something was heard to snap and it was thought to be the tendons of the semitendinosus or semimembranosus muscles, but this was evidently when the ischium was fractured, although it did not seem like a bone breaking. When traction was being made on the femur, a tearing sound was noted and was supposed to be the Y-ligament, but evidently the femoral neck was fractured instead, although it could not be recognized at the time. After 25 minutes work by both operators the head was thought to be placed upon the acetabulum, as the leg could not be straightened at the knee, and this was given by Lorenz as the sign of replacement.

The child's condition seemed good and it was decided to attempt the reduction of the left hip at once. No greater difficulties to reduction appeared in the left leg than were encountered in the similar stages with the right, but the skin likewise gave way over the adductor tendons. The strong resistance of the hamstring tendons induced the operators to cease further efforts after 15 minutes time when it was realized that reduction by the bloodless method was impossible without unduly prolonging the manipulations that were made. It was decided to place the legs in the best possible position for repair of the torn structures and subsequently to resort to the intermediary operation of cutting down upon the joint and stretching the capsule and removing such other obstacles as might be found. When the legs were in position for the plaster casts it was found that the left leg like the right gave the test condition of resistance to extension of the leg and led the operators to believe that the head on this side also rested on the acetabulum. The error in this respect was demonstrated at the postmortem. Both legs were then placed in the position of hyperabduction and hyperextension ("frog position") and plaster-of-paris applied by Drs. Dolson and Taggart.

The following notes are given by Dr. C. A. Dexter, the house surgeon:

The child was brought up from clinic at 12.30 o'clock. The pulse was rather weak and rapid, and atropin sulfate, .3 mg. ( $\frac{1}{30}$  grain) and strychnin sulfate 2 mg. ( $\frac{1}{30}$  grain) were given hypodermically and external heat applied, and the child reacted very well. On coming from under the influence of ether about two hours later appeared to be in fair general condition. Later in the afternoon complained of some thirst, but not so much as the average ether patient. Was a little restless, but not so much as the usual case of a reduction by the same method. Was not nauseated and did not vomit during the afternoon. About 9 o'clock p.m. vomited about two ounces of a dark brownish fluid and once or twice during the night after this. Had stimulation during the night. After 10 p.m. the child became delirious, the delirium being of a mild talkative character and continuing throughout the night. At 8 o'clock a.m. the temperature was down to 97° and external heat was applied. Pulse was somewhat rapid and weak, and coffee and whisky by enema, atropin and strychnia hypodermically were given. The child apparently had begun to react, the pulse getting stronger. Was now perfectly conscious and said that she was not in any pain.

At 9 a.m. Professor Wilson was telephoned for and arrived ten minutes later. Instruments were in readiness for saline infusion, but the child's condition became so rapidly worse that an opportunity to use them was not given.

At 9.35 a.m. her condition seemed somewhat improved.

At 9.40 a.m. there was a marked change; breathing suddenly became gasping and superficial; pulse absent at the wrist; stimulation was again used hypodermically, but the breathing quickly became worse, the heart-beats weaker, and with a few convulsive gasps the child died at 9.45 a.m.

TEMPERATURE CHART.

Date.	Hour.	Resp.	Pulse.	Temperature.
March 17.	4 p.m.	20	90	98.4°
" 18.	8 a.m.	20	80	97.0°
" 18.	1 p.m.	32	100	98.0° after operation.
" 18.	3 p.m.	32	112	101.0°
" 18.	6 p.m.	36	104	101.4°
" 19.	5 a.m.	38	132	96.4°
" 19.	9 a.m.	40	156	99.4°
" 19.	9.45 a.m., died.			

In the light afforded by the very careful postmortem examination by Dr. Coplin in the presence of the staff

of the orthopedic department, it may be noted that this was a case in which replacement could not have been secured without removing the ligamentum teres, and that there was no way of predetermining the existence of the obstacles to the bloodless reposition.

The main factor was the length and size of the ligamentum teres, which more than filled the acetabulum on each side, and therefore the sign which indicates reduction—that is, the slipping out of the head from the acetabulum as the leg is brought into an extended position—was absent. While this one factor, *i. e.*, the ligamentum teres, was sufficient to have prevented reduction, the very thick capsule was elongated and had a tendency to fold in between the head and the acetabulum again, preventing the clear sound that occurred in other cases when the head, it is believed, entered the acetabulum. On both sides the articulating surface of the head was found placed above the posterior rim of the acetabulum, in which position it was placed at the time of operation, and was, therefore, decidedly anterior to the position which it had formerly occupied on the dorsum of the ilium. Just when or how the three fractures occurred it is impossible to determine, for while something was felt by the operators which was unusual, it did not partake of the nature of breaking bone, but closely resembled tearing fibrous tissue, and was so considered at the time of operation. The tearing sound was communicated to the operator who was holding the pelvis as well as to the one who was manipulating the left leg. It was a diffused sound and its origin could not be located. Twice this occurred, but a third fracture which was found postmortem cannot be accounted for. The bone-ends in all three fractures were in close apposition, clearly indicating that if death had not ensued, repair would have taken place in favorable position. That no fractures occurred upon the left side is due to the fact that efforts at reduction ceased in about one-half the time spent upon the right leg in realization of the inexpediency of continued efforts. The torn skin over the adductor tendons was accepted as an indication of the low vitality of the patient, as this did not occur in any other case, although several had had ecchymotic spots of quite large size for varying periods of from one to two weeks.

As to the force used it can only be compared with other cases and may be stated as having been skilfully applied and was much less and for a shorter time than in some of the other cases, and especially so in contrast to the fourth patient upon whom Lorenz operated. The forcible manipulations appeared to be suitable to the conditions and there was no recognizable counterindications. The previous condition of the child gave no distinct evidence of her deficient vitality, and it would seem as though the methods employed at reduction were less responsible for the death than the anesthetic, although the entire procedure must be considered.

The pathologic conditions found in the lungs and kidneys, which gave decided indications of very recent origin, could be caused by ether anesthesia for 1½ hours. Pneumonia following ether is sufficiently common in cases in which the operative procedures are of a mild character, and whether acute nephritis is likewise a sequel of ether intoxication is still a disputed point with pathologists, but the evidence in this case is strongly affirmative.

While the condition of the patient did not indicate shock at the cessation of reduction manipulations it was felt that the patient should be most critically safeguarded in every respect. When Dr. Schwartz, the official anesthetizer of the department, was obliged to leave at the beginning of the application of the plaster cast, it was deemed expedient for Dr. Wilson to take his place while Drs. Dolson and Taggart applied the plaster bandages, with Dr. Rugh maintaining correct position of the legs. This disposition of the responsibilities is a satisfaction to all concerned, in that it is believed that everything was done to secure a favorable recovery in this case.

The full details of the postmortem by Dr. Coplin are here given as an essential feature, and their value is enhanced by the disinterested manner in which the report is made, hoping that the conditions, methods, and results will be of service in guiding others in cases of this kind.

#### PATHOLOGIC REPORT.

Autopsy protocol, case of B. D., female, 7 years, white. Drs. H. Augustus Wilson and J. T. Rugh, surgeons. Died March 19, 1903, at 9.45 a.m. Autopsy held March 19, 1903, at 1.45 p.m.

*Anatomic Diagnosis.*—Bilateral congenital dislocation of the hip. Perforate foramen ovale. Persistent thymus. Atheromatous arteritis of aorta and coronary trunks. Acute catarrhal tracheitis. Acute catarrhal bronchitis. Acute catarrhal pneumonia. General tuberculous lymphadenitis. Acute diffuse hemorrhagic nephritis. Latent or obsolescent rachitis.

*External Examination.*—The body is that of a fairly well-nourished female child. Rigor mortis is quite marked in the upper extremities and the calf muscles, but is slight in the muscles of the thigh. There is marked saggillation on the posterior aspect of the body, neck, head and arms. The thighs are flexed at right angles to the body in the axillary lines, and the legs at right angles to the thighs. The thighs and pelvis are encased in the plaster dressing commonly used after bloodless operation. This is removed in the usual manner, using every precaution to prevent any alteration in the relation of the enclosed parts. In spite of every care there was some movement of the right femur, and it was thought possible that it might have been misplaced, although subsequent findings did not support the view.

From the symphysis to the extreme margin of the right inner condyle of the femur is 24 cm.; on the left side the distance between corresponding points is 32 cm. The circumference of the right thigh, 8 cm. above the inner condyle, is 20 cm.; 22 cm. above the inner condyle it is 29 cm. The circumference of the left thigh, 8 cm. above the inner condyle, is 19 cm.; 22 cm. above the inner condyle is 28 cm. The following external marks are present upon the right inferior extremity: On the inner aspect of the ankle, posterior to the malleolus, are a number of ecchymotic spots, petechial in character, distributed over an area of 4 cm. in the axis of the limb, and 3 cm. transversely. From this point downward the superficial veins are conspicuous, but not palpable, and clearly not thrombosed. Five centimeters above the inner condyle is a pinkish, ecchymotic area 1.7 cm. in length in the axis of the limb, and 5.5 cm. circumferentially. From the lower third of the thigh upward, on the anterior surface, the skin shows pinkish-red mottling almost or quite to the junction of the skin covering the pelvis. This mottling is also present on the inner surface, but less marked posteriorly. Five centimeters from the symphysis, beginning 2 cm. below Poupart's ligament and extending downward, is an abrasion 2.8 cm. in length by 1 cm. in width; 5.5 cm. from the symphysis is a second abrasion nearly parallel with the first, 2.5 cm. in length and 1 cm. in width. At these points the epithelial layers of the skin are stripped and possibly also the connective tissue layers, although the subcutaneous tissues do not protrude or the skin retract; the eroded areas are covered by glazed lymph, through which the ecchymotic bases can be seen. The areas just described are in a larger field of discoloration, greenish-purple with darker purplish mottling, and extending from a point 2.5 cm. to the right of the symphysis to a distance of 15.5 cm. from the symphysis and becoming continuous with the irregular mottling referred to as present in the lower part of the thigh. The axis of this area corresponds to the course of the femoral artery and the area measures, transversely, 9.5 cm. It extends above Poupart's ligament 3 cm., and from the median line to the anterior superior spine. The skin of the perineum and the cutaneous structures of the vulva are possibly a little redder than normal, while the mucosa of the vulva is suffused with blood and purplish in color, the suffusion being most marked around the urethral orifice. The large area of discoloration already described on the right thigh is soft and almost fluctuating near its center and quite resistant, almost dense at the margin; at the base, near Poupart's ligament, it is quite dense.

Left extremity: Near the ankle are areas of discoloration, petechial hemorrhages and prominent veins essentially of the same kind as described on the opposite limb. On the inner aspect of the leg just within the margin of the tibia is an old ecchymotic patch 7 cm. below the upper end of the tibia. It is purplish with greenish-yellow margins, oval in outline and possesses a maximum diameter of 1.8 cm.; 5.5 cm. above the inner condyle is a pinkish-red area of discoloration, the long axis being transverse to the long axis of the limb, 6 cm. in length and 1.4 cm. in width. Just over the patella is a small ecchymotic 0.7 cm. in diameter. The anterior surface of the thigh shows the same pinkish mottling already described as present on the opposite limb. Four and seven-tenths centimeters to the left of the pubis is an irregular laceration of the epidermis and derma 3.7 cm. in length, 0.4 cm. in width, bridged here and there by fragments of the deeper layers of the skin and margined by smaller fissured lacerations 1 to 2 cm. in length. The long axis of this area is parallel to the axis of the trunk. It is situated near the base of a large purplish-green area, irregular in outline, beginning 3.2 cm. from the symphysis

and extending in the axis of the limb 9.5 cm., and in the axis of the trunk 9.5 cm. This area of discoloration extends 2 cm. above Poupart's ligament, at which point it is 4 cm. in length (this latter measurement made parallel with Poupart's ligament). The area is less tense than the corresponding area on the opposite side but similarly colored and with denser margins.

The lower part of the abdomen is flat, or nearly so, the costal margins prominent and the epigastrium slightly bulging. There is a suggestion of a rachitic rosary. The sternal ends of the clavicles are slightly enlarged and the sternoclavicular attachments very relaxed, almost permitting discoloration. The shoulder and wrist-joints, and to a lesser degree, the elbow, knee, and ankle-joints are relaxed; the amount of lateral movement at the wrist and shoulder-joints is strikingly in excess of the normal. The lower end of the radius and tibia (right and left) are apparently enlarged but not conspicuously so. We were not allowed to incise them; they may have been slightly rachitic.

The forehead is prominent, the calvarium large, suggesting the general contour of a slightly hydrocephalic head, the lips are purplish and dry, the pupils are dilated and the eyes slightly sunken.

The axillary, cervical and submaxillary lymph-nodes are notably enlarged; in the axilla nodes possessing diameters of 1.5 cm. can be felt. The anterior cervical nodes are smaller, but distinct chains can be palpated along the posterior borders of the sternocleidomastoid muscle. Under each mandibular angle is located a node approximately 1 cm. in diameter. As none of these areas was subjected to dissection the measurements given could be estimated only. The tonsils appear slightly enlarged. The oral mucosa is pale but without any discernible lesion.

*Internal Examination.*—The subcutaneous fat over the chest and abdomen, along the median incision, is scanty but normal in color and texture. The musculature of the chest and abdomen is normal in color and texture, but rather poorly developed.

The peritoneum is normal, the transverse colon considerably distended. There is purplish discoloration of the tissues of all the right half of the pelvis extending down behind the rectum, along the anterior sacral border into the broad ligament, slightly over the posterior part of the bladder and upward anteriorly 4 cm. above Poupart's ligament, corresponding to the already described area of discoloration on the external surface; laterally, on the right side, the purplish shading reaches a point just above the head of the colon. This irregular area of purplish mottling and suffusion is not palpable, although its echymotic character is fairly marked. There is slight echymosis in the neighborhood of the femoral ring of the left side.

The pleuras are dry, as is the pericardium. Both serosas are normal.

The thymus is exceptionally large, extending anteriorly below the middle of the heart, latterly into the mediastinum, and above to and partly occupying the suprasternal notch. It is an arrow-shaped organ, 9 cm. in length, 5 cm. in width, and 0.7 cm. in thickness. It extends along the trachea as a single body for 1.5 cm., then divides into two equal parts more or less cylindrical in outline and 2 cm. in length that are projected upward along the sides of the trachea. Weight, 20 grams.

Histologically, the organ shows no specially noteworthy abnormality. The secondary lobules are much larger than normal in a child of this age. The increased volume seems to depend upon persistence or hyperplasia of the lymphoid elements. The differentiation between periphery and cortex is ill-defined. The bodies of Hassall (concentric corpuscles) are unusually abundant. At a few points rhexis has occurred, and small areas of intercellular hemorrhage, not at any point large or abundant, are occasionally seen. Lipomatous substitution of the adenoid tissue is not at any point in progress. It might be well to note that in many cases persistence of the thymus has been found as a part of the morbid anatomy of rickets.

*Heart:* The cavities of the right side are distended and occupied by clots, which for the most part are white or the color of chicken fat, with superimposed purplish coagulums. The left side is empty. The valves and orifices of the right and left sides appear normal, except as noted below. The foramen ovale is obliquely patulous, the opening barely transmitting a grooved director. It is 0.3 cm. by 0.25 cm. in size. There is a small patch of atheroma on the ventricular aspect of the anterior leaflet of the mitral. The myocardium is pale, but fairly firm in texture. Weight, 85 grams.

Histologically, the myocardium shows no conspicuous abnormality. Occasional fibers are slightly granular; fat is absent. The smaller coronary branches are not altered.

The presence of even a small atheromatous plaque in the mitral leaflet in one so young indicates the existence of some noxious influence, possibly syphilis, or it may be rickets, as the relatively small heart and thin walled vessels would seem to refute any suggestion that the alteration here noted depended upon heightened vascular stress. The change described below as present in the aorta also supports either of the former views.

The aorta just above the aortic orifice is the seat of a diffuse yellowish infiltration that surrounds the coronary arteries, completely encircling the aorta and has thickened the aorta particularly in the neighborhood of the coronary orifices. The thickening of the aortic wall is at the expense of the lumen. The right coronary artery is surrounded by a distinct zone of such infiltration. Other macroscopic evidence of arterial disease was not found beyond the aorta.

Histologically, longitudinal and transverse sections of the infiltrated aorta show the usual changes of an atheromatous patch. The intima is intact and slightly thickened; the subintimal elastica fragmented at the margin of the area and not demonstrable near its center. The media is partly involved and between the altered media and intima is a necrotic accumulation containing cellular debris, fragments of elastica and granular detritus. Evidences of calcific change are wanting. Sections so oriented as to include the coronary exit show that the process extends but a short distance (1 mm. or 2 mm.) into that vessel. As yet the sectional area of the coronary orifice has not been altered.

*Left lung:* The superior lobe contains a number of small areas of atelectasis 5 mm. to 10 mm. in diameter, irregular in outline, evidently recent. In the base of the lower lobe anteriorly is a larger, partly collapsed area, not, however, airless, measuring 0.5 cm. by 1.5 cm. The subpleural tissue posteriorly is edematous and the seat of numerous petechial hemorrhages; similar hemorrhages are also present on the diaphragmatic surface and along the anterior margin of the organ. Centrally and toward the upper portion of the lower lobe is a purplish red area 2.5 cm. in length and 1 cm. in width that appears quite airless. Toward the base are numerous smaller areas possessing the same characters. Areas of solidification varying in size from 0.5 cm. to 1 cm. are also present in the upper lobe. Weight, 110 grams.

*Right lung:* This organ is, in a general way, the seat of changes essentially the same as those noted as present in the left. They are a little more marked posteriorly and less evident at the apex and along the anterior and diaphragmatic aspects. Weight, 125 grams.

The larger bronchi of both organs are the seat of edema and redness of the mucous membrane, and often contain a frothy red mucus.

There is a mucosanguinolent frothy fluid in the trachea. Histologically, the changes present in the air passages and lungs may be summed up as (1) catarrhal bronchitis, (2) bronchiolitis, (3) lobular pneumonia. None of these is very advanced although all the blocks examined show the changes. The mucosa of the trachea and bronchi, large and small, shows epithelial desquamation, serous and leukocytic infiltration of the submucosa of the large tubes and peribronchial tissues of the smaller. Here and there throughout the sections are lobules or parts of lobules inundated with mucus or overdistended by compensatory efforts. There is very little inter-vascular cellular infiltration.

Properly stained preparations show the presence of an organism possessing the morphology and tinctorial characters of the pneumococcus. The bacteria are not numerically conspicuous although widely distributed.

The peribronchial and mediastinal lymph-nodes, and especially those situated at the bifurcation of the trachea are enlarged and slightly matted together. The larger masses vary in size from 0.5 cm. to 1.5 cm. in diameter, are tense, evidently swollen and, on section, contain greyish dots 1 mm. to 2 mm. in diameter possessing the macroscopic characters of tubercles. The histology of these glands will be given below with other lymphadenoid groups.

The spleen is relatively firm, its pulp of normal density, possibly a little paler than normal. The adenoid groups are not perceptibly changed. Weight, 55 grams.<sup>1</sup>

The adrenals are normal in size and general appearance.

The left kidney has retained its fetal lobulation; it is rather hyperemic, soft and cloudy. The cortex is slightly swollen; the labyrinthine areas hyperemic; the malpighian bodies not more evident than usual. The capsule is easily detached; the stripped surface is red and edematous; the redness is rather punctate. The pelvis is normal. Weight, 60 grams.

The right kidney shows essentially the same changes as the left. Weight, 55 grams.

The ureters are normal. The right ureter can be traced downward through the area of hemorrhage; there is no evidence of pressure on it within this area; the mucosa is normal.

Histologically, the kidneys manifest no evidence of any old lesion, but show to a most marked degree the presence of alterations of recent origin. The labyrinthine areas are frequently the seat of irregular intertubular and intratubular hemorrhage. The hemorrhages are recent, the extravasated blood unaltered; tubules are frequently distended with blood-casts. The epithelium of the convoluted tubules is often granular and stains defectively; at no point has it desquamated. The malpighian tufts are frequently engorged, but in exceptional instances only is a tuft found in which free hemorrhage has occurred.

<sup>1</sup>For convenience in reference the histology of the organ is incorporated with the autopsy record. The technic has been practically the same for all. Selected blocks of tissue were fixed in Bensley's solution, washed, dehydrated, infiltrated with paraffin, sectioned and stained by approved laboratory methods. The findings in each instance are epitomized in this report.

<sup>1</sup>Unfortunately the pieces of spleen, adrenal, stomach, duodenum and pancreas were not set aside for histologic study or were mislaid. There is no reason to suppose that a histologic study of any of these organs would throw additional light on the cause of death; possibly it might have shown lesions corroborative of the general condition indicated by what was found in other structures.

Bladder: With the exception of the subserous suffusion, already mentioned as present under the peritoneal coat, the organ shows no gross lesions. Urethra normal, except at external orifice, as previously described.

The internal and external genitalia show no noteworthy abnormality not already recorded.

The esophagus, stomach and intestines show no important change. The agminated patches are inconspicuous, the solitary follicles prominent. The mucosa of the stomach and lower end of the esophagus show slight erosions thought to be evidences of postmortem digestion.

The pancreas is partly annular, extending about half way round the duodenum. It shows no gross lesion. Weight, 45 grams.

Liver: The biliary passages are patulous and normal. The gallbladder lightly distended by apparently normal bile. The superior surface of the right lobe of the liver shows several areas greyish-white in color, irregular in outline, 0.2 cm. to 0.5 cm. in diameter—apparently focal necroses. Posteriorly the organ is lightly congested. There is no special noteworthy lesion.

The mesenteric glands are notably increased in size. Some of the largest are ovoid, measuring 1.5 cm. by 2 cm.; they are fairly numerous at many points, but particularly so in the sigmoid area. They are equally enlarged, though less abundant in the ileocecal region. The enlarged nodules are often tense, the exterior mottled, showing areas of greyish or yellowish-white on a rather pinkish background. The investing peritoneum is smooth and transparent, and the nodes easily freed from the adjacent tissue. On section they are greyish, succulent, and contain minute whitish areas that suggest tubercles; at points there is a suggestion of caseation, but nowhere is this change striking.

The retroperitoneal enlargements are evident, but less abundant. On section these nodes show the same general characters as those in the mesentery.

Macroscopically, the axillary, cervical, submaxillary, mediastinal, peribronchial, mesenteric and retroperitoneal lymph-nodes show essentially the same features. The following histologic description is based on examination of the mesenteric, mediastinal and peribronchial systems.

Histologically, the lymph-nodes manifest those changes characteristic of a moderate degree of widely disseminated infection by the tubercle bacillus. Distinct caseation is scantily present in occasional nodes from all the systems examined; it seems apparent that the peribronchial and mediastinal groups are most involved; they are also the seat of mixed infection. Many nodes are not caseous, nor do they contain macroscopic nor microscopic tubercles, although some of them contain tubercle bacilli. In such nodes the peripheral and follicular sinuses are distended by uninuclear leukocytes and desquamating endothelial cells from the walls; the medullary cords are also closely packed. Occasionally in the peribronchial system fibrin can be demonstrated indicating an acute and active character in the process. In some of these glands pneumococci were identified.

Dissection of the thighs and pelvis: From the median incision two incisions are extended laterally to about the center of Poupart's ligament and then downward on the anterior surface of each thigh following, as nearly as possible, a line parallel with the axis of Scarpa's triangle and extending beyond the area of notable discoloration. Inoculations are taken from beneath the deep fascia and finally the arterial and venous trunks partly exposed. Water is forced through the abdominal aorta into each iliac artery until the vessels distend fully. The water oozes from the adjacent infiltrated tissues while the arterial trunks become tense. The veins are similarly tested and with like results. These tests satisfactorily establish that none of the large trunks, or important branches, is lacerated. That the vessels are patulous is also established by opening them at Hunter's canal and observing that the water flows through without obstruction; the thin-walled femoral and iliac veins can be seen to be free from any obstructing or mural thrombus.

The dissection is now extended exposing the muscles of the thigh and finally the hip-joints. The anterior crural nerves and their branches are macroscopically intact. There is considerable difficulty in identifying the various anatomic structure on account of the extensive hemorrhagic infiltration to which the superficial discoloration already described evidently is due. The condition on the right side will be described in detail, followed by an account of the left side.

In the cellular and fatty tissue beneath the deep fascia are loculi containing coagulated blood; these small irregular cavities vary in size, the largest scarcely exceeding 1.5 cm. in its maximum diameter. Evidently a number of these spaces may communicate either directly or indirectly. The total amount of blood extravasated cannot be estimated with any degree of accuracy, but is considerable. The distinct cavities containing blood are in the neighborhood of the femoral sheath and beneath the sartorius muscle. (Later a few small loculi were found behind the bone; they were not, however, of notable size.) The inner border of the sartorius and the anterior part of the adductor longus are suffused to a moderate degree. The muscles forming the floor of Scarpa's triangle (iliacus, psoas, pectineus, and, in part, the long and short adductors) are also suffused with blood. The tensor vaginæ femoris and gluteal

muscles contain but a few points of interstitial hemorrhage. The intense purplish black staining of the muscles renders it quite impossible to determine accurately just how much, if any, real laceration is present. There are valid objections to complete dissection of the limb, but a fairly exhaustive examination of the exposed muscles fails to disclose any extensive single or massive laceration, although what might be termed a fibrillar dissociation is present in nearly all the dissected muscles already mentioned. The solutions in the continuity of solid muscle bodies are oblique, mixed longitudinal and slightly oblique, but not directly transverse fissurings. The muscles are notably flaccid, probably as a result of post-mortem rigidity and coagulative changes in the extravasated blood.

If there be any laceration of branches of the internal iliac artery a fairly comprehensive examination of the areas in which they are distributed, reinforced by the hydrostatic test already described, fails to disclose it. The intrapelvic suffusion previously mentioned is found on incision to be in the cellular tissue immediately beneath the serosa only, and so far as can be determined, has reached the areas mentioned by infiltration from the neighborhood of the femoral canal.

The hip-joint: The head of the femur seems to be almost in place, but on closer examination, after incision of the capsular ligament, is found to be resting with the margin of the articular surface on the posterior-superior brim of the acetabulum. The head, apparently as a result of fibrous adhesions, cannot be

Right hip-joint. A, thickened capsular ligament. B, capsular ligament at point of maximum thickening. C, ligamentum teres occupying the greater part of the acetabulum; the notable elongation is shown by the relaxed ligament extending to the head of the femur. D, the leader from D is over the line of fracture in the neck of the femur; the point of separation does not show, as it is covered by periosteum. E, fracture of ischium; the periosteum has been divided, showing oblique line of separation. F, second fracture of the ischium; the periosteum is intact and the line of fracture indicated only by the slight darkening due to subperiosteal hemorrhage.

replaced within the joint, although no degree of force was used in the attempt. The capsular ligament and ligamentum teres are relaxed. A slight effort at straightening the limb is followed by the immediate displacement of the head of the femur upward and backward. The innominate bone just back of and above the acetabulum is smooth and seems a little more dense than elsewhere. Realizing that a careful study of the bone and joint at the necropsy would not be possible the ilium was divided just below the inferior curved line and also through the body and ramus of the pubes near the angle and the femur sectioned just below the trochanter. Recognizing the presence of fractures great care is necessary in removing the specimen and force must be avoided in order to prevent any further alteration in the architecture and relation of the structures to be examined. This specimen was removed to the laboratory and partly dissected by Dr. Aller G. Ellis, who submits the following detailed description:

The specimen as removed consists of those portions of the right innominate bone and upper extremity of the right femur that include all the structures entering into the formation of the right hip-joint. The capsular ligament has been incised along the anterior and superior margin of the acetabulum; it is much thicker posteriorly and externally than below and in front. The acetabulum is slightly flattened, measuring 2.75 cm. in the vertical and 2.25 cm. in the horizontal axis. The greatest depth of the cavity proper is 0.7 cm. The ligamentum teres is 5.5 cm. long, 0.4 cm. wide, and 0.2 cm. thick at its

middle, expanding at both ends. The acetabular insertion is expanded so that it occupies all of the anterior third of the cavity. In addition to this an extension 0.3 cm. thick spreads over about half of the remaining two-thirds of the floor of the acetabulum. The iliofemoral ligament is indistinguishable from the capsular, and the cotyloid and transverse ligaments cannot be exposed without undesirable mutilation of the specimen. The head of the femur is slightly flattened antero-posteriorly. There is a lentic-shaped area of flattening of the articular surface that corresponds to the point of attachment of the ligamentum teres. The ligamentum teres is inserted on the upper portion of an almost plane surface that measures 1.75 cm. by 1.5 cm. This flattened surface corresponds to a similar area on the posterior margin of the acetabulum, the latter area being formed partly of the bony wall of the acetabular cavity and partly by compressed ligamentous tissue.

There is an intracapsular fracture of the neck of the femur. The line of separation passes obliquely across the neck of the bone and at the upper border almost reaches the juxtaepiphyseal line of the head. At the lower border it is 1.5 cm. from that line. The periosteum for some distance on either side of the line of fracture has been separated from the bone by subperiosteal hemorrhage. There is a fracture of the ischium extending through the body of that bone in an almost horizontal plane. The highest point of the line of separation is external where it is approximately 0.5 cm. below the acetabular margin. Subperiosteal hemorrhage is present around this fracture. There is also a second fracture of the ischium passing transversely through the ascending ramus at a point 0.8 cm. above the lower boundary of the obturator foramen. No fragment in any of the fractures shows the slightest displacement; there is no perceptible separation and the slight periosteal hemorrhage is the most conspicuous feature present at the line of separation. The periosteum holds the fragments in accurate apposition.

The left side differs from the right in degree of reposition but in no essential anatomic character. The hemorrhagic infiltration is very much less, but the distribution in the thigh is practically the same as on the other side. There are a few loculi similar to those mentioned as present on the right and distributed along the course of the femoral sheath. The intermuscular and intramuscular suffusion is nothing like so marked as that seen on the opposite side. The head of the femur is scarcely more than raised on the brim of the acetabulum upon which the articular surface rests. The condition of the acetabulum, head of femur and ligaments seems the same as on the opposite side, and a repetition of the description does not seem necessary. There is no noteworthy difference between the periarticular structures on the two sides except that on the left fibrous adhesions are more conspicuous and the head of the bone seems more firmly anchored. This difference is probably due to less thorough dissolution of adhesions possibly originally equally firm on the two sides. No fractures are present on the left side. After section of the almost unresisting muscles it was found almost impossible to place the head of the femur in the acetabulum, although the capsular ligament is opened anteriorly and two fingers placed in the joint as aids to reposition. The resistance to restitution to position seems to be great thickening and dense fibrous adhesions posteriorly; as on the other side, the bulky ligamentum teres occupies the cavity of the acetabulum. No specimen from this side was preserved.

Permission to examine the central nervous system was not obtained.

**Bacteriology.**—Inoculations on agar and into bouillon were made from the areas of hemorrhagic infiltration and loculi of blood in the thighs, also from the pleuras, pericardium, blood of the heart, spleen, and liver, but no growths were observed. Tubercle bacilli, as already noted, are present in many of the lymph-nodes, and an organism believed to be the pneumococcus is present in the sections of the lung and peribronchial lymphatics. The last named organism not infrequently fails to develop in cultures made from tissues in which it can be demonstrated by staining methods.

## ACUTE LEUKEMIA.\*

BY

JOHN BENJAMIN NICHOLS, M.D.,  
of Washington, D. C.

Personal experience with two cases of acute leukemia within the past two years directed my attention to this subject and led to a study of the recorded cases and data bearing on it. It is the purpose of this paper to present especially the clinical characteristics of acute leukemia, based on these personal observations and studies of the published data.

Leukemia is a disease sharply distinguished by certain marked blood changes, lesions of the hematopoietic

organs, and various characteristic anatomic and clinical phenomena. But while leukemia in general is thus distinctly characterized, the disease manifests itself in two or three forms or varieties which are ordinarily markedly and sharply distinct from one another. The two main hematologic and anatomic types of leukemia are the myelemic and the lymphemic forms.

The myelemic variety is characterized by lesions in the bone marrow (supposedly the primary and fundamental lesions of the disease), usually associated with great hypertrophy of the spleen, by an enormous increase in the number of leukocytes in the blood, myelocytes appearing in large number and basophile leukocytes also becoming abundant, and by a decrease in the number of red blood-cells and the appearance of numerous nucleated and other abnormal red cells. The lymph glands are little or only secondarily involved. This form of leukemia is called myelemic or myelocytic in allusion to the myelocytes and the marrow involvement; it is also termed the myeloid, myelogenous, medullary, and splenomedullary form.

The lymphemic or lymphatic variety of leukemia is characterized by enlargement and involvement of the lymphoid glands and structures, often or usually with hypertrophy of the spleen, by an enormous increase of the lymphocytes in the blood, and decrease of the red cells. The bone marrow involvement is usually much less marked than the glandular changes; myelocytes, basophile leukocytes, and nucleated or otherwise abnormal red cells are absent or few in the blood. The term lymphemic (or lymphocytic) alludes to the primary involvement of the lymph glands and the increase of lymphocytes. In some of the cases the small lymphocytes are the predominating variety of leukocytes; in others the large lymphocytes greatly predominate; these might be termed the microlymphemic and macrolymphemic forms of leukemia, respectively.

The spleen may be and usually is enlarged in both forms of leukemia, so that splenic hypertrophy taken alone does not signify which type of leukemia is present; the blood findings and other factors must be considered in making the diagnosis. By virtue of its malpighian bodies the spleen is partly a lymphatic structure as well as a hemal gland; and in some cases of lymphatic leukemia the spleen is affected alone, the lymphatic glands elsewhere being little or not at all enlarged.

Cases of leukemia can also be quite sharply divided into acute and chronic. The acute cases are chiefly if not exclusively of the lymphatic variety, and the blood is mostly of the macrolymphemic type. While the distinctions between the acute and chronic forms are rather differences of degree than of kind, yet the clinical course and characteristics of acute leukemia are so well marked that this form of the disease presents a distinctive clinical picture, contrasting well with the more chronic cases. Acute leukemia has only within the last fifteen years achieved recognition as a special form of disease, and it is not yet in standard manuals of medicine given the systematic consideration which its distinctive character warrants. The recorded observations of the disease are now sufficiently numerous to enable its clinical features to be laid down with some system and completeness.

**History.**—The first case of acute leukemia recorded was that of Friedreich's, published in 1857. In 1889 Ebstein published a study of 16 cases of acute leukemia found on record up to that time, together with a case of his own. Ebstein's paper directed attention to this subject, and since that time numerous cases and studies of the disease have been published. Up to and including the year 1902 I have found upwards of 119 cases of acute leukemia reported.

**Frequency.**—An estimate of the relative frequency of acute and chronic leukemia in this country can be obtained by combining the following series of cases of leukemia reported by American observers:

\*A portion of a paper which was awarded honorable mention in an essay prize competition under the auspices of the Medical Society of the District of Columbia, 1902. Read before the Medical Society of the District of Columbia, January 28, 1903.

Observer.	Date.	Number of cases of leukemia observed.				Reference.
		Acute.	Subacute.	Chronic.	Total.	
Osler .....	To 1901.	3	.....	21	24	Practice of Medicine, 1911.
Cabot .....	To 1901.	5	5	44	54	Clinical Examination of Blood, 1901.
Taylor .....	To 1900.	2	.....	14	16	Contributions William Pepper Laboratory Clinical Medicine, 1900, 148.
Doek .....	To 1900.	1	.....	19	20	Phila. Medical Journal, 1900, v, 741.
Janeway.	1898.	1	1	5	7	Transactions Association American Physicians, 1898, xiii, 146.
Total....		12	6	103	121	

Some of the cases here given as subacute would probably by other observers have been classed as acute. Out of a total of 121 cases of leukemia 12 (or more) cases were acute; if these are representative statistics, as they doubtless are, it can be accepted that in this country at least one-tenth, and perhaps one-eighth, of all cases of leukemia are acute. Data are not at hand on which to base an estimate of the frequency of acute leukemia in Europe; in the city of Berlin Fraenkel has claimed that the acute cases exceed the chronic in frequency.

According to the last census of the United States, during the year 1900 there were 207 deaths from leukemia in those parts of the country in which vital statistics were kept, representing a population of 28,807,269, and out of a total number of deaths for the year in those districts of 512,669; this gives a general rate of 40.4 deaths from leukemia out of every 100,000 deaths from all causes, and 7.2 deaths per annum out of every 1,000,000 of population; or 1 death from leukemia out of every 2,477 deaths, and 1 death from it annually out of every 139,166 inhabitants.

The deathrate from leukemia in the District of Columbia, as shown by the Health Office statistics, is not far from the general rate for the entire country. During the 15 years 1888-1902 there were 27 deaths from leukemia in the District, an average of 1.8 deaths per year out of an annual average of 5,780 deaths from all causes and an average population of 261,633; this is equivalent to 31.14 deaths from leukemia out of every 100,000 deaths and 6.88 deaths annually for every 1,000,000 of population.

Reckoning one-tenth of all deaths from leukemia as due to the acute cases there would be an average for the entire country of about one death from acute leukemia out of every 25,000 deaths from all causes, an average of about 55 deaths from the disease each year in the whole United States, and about one case in the District of Columbia for every 5½ years.

*Occurrence in Animals.*—Like the other varieties of the disease acute leukemia may occur in animals, a typical case in a calf having been reported (Wolf').

*Age.*—While the greater number of cases of chronic leukemia occur during the middle decades of life acute leukemia affects by preference the first three decades. About three-fourths of all the cases of acute leukemia develop below the age of 30 years. The second decade of life, from 10 to 20 years, leads in the number of cases, though nearly as many cases occur from 20 to 30; a considerable proportion of the cases, perhaps one-fifth, develop under 10 years; numerous cases also occur from 30 to 40, but over 40 the cases are much less numerous. Acute leukemia has been reported at as late as 59, 60, and 71 years (though in the latter case there is some question as to the diagnosis). In the youngest case reported an infant was born with symptoms of the disease and died of it 19 days after birth. As at no time is susceptibility to the disease greater than during the early years acute leukemia, even though rare, must be included among the diseases of childhood.

*Sex.*—As in the chronic forms of the disease males are much more liable to acute leukemia than are females. The males affected outnumber the females two or three to one.

*Duration.*—On account of its frequent gradual and insidious development it is difficult to fix a definite time of beginning in many cases of acute leukemia, and consequently to determine the duration of the disease with exactness. The time from the beginning of symptoms sufficiently marked to attract attention or require treatment can be more definitely estimated. The duration of the active period of the disease ranges from a few days to several weeks, ordinarily from three to six weeks. The briefest case recorded was alleged to have lasted only three and a half days, and in several cases the duration has been under ten days; in some of these instances there was probably an unobserved preliminary period of development of the lesions, or a premature termination was caused by some such accident as cerebral hemorrhage. On the other hand, some observers have considered cases lasting as long as three or four months acute. Some authorities fix an arbitrary time limit, six to nine weeks, as the dividing line between acute and chronic cases, those whose duration falls within the limit being classed as acute, those exceeding it as chronic. No such arbitrary time limit can be fixed on any rational or satisfactory basis; the distinction between acute and chronic cases of leukemia rests rationally and naturally on the characteristic virulence and rapid progress of the morbid conditions in the former. While intermediate cases difficult to classify may occur, or while what one classes as subacute another will regard as acute, a differentiation between cases of acute and chronic leukemia can be made entirely without reference to any fixed time limit as readily as, for instance, between acute and subacute rheumatism.

*Course.*—Acute leukemia usually begins to develop gradually and with prodromal phenomena, though sometimes it starts in abruptly. The advent of the active period of the disease is declared by various initial symptoms too prominent to escape notice; after which it pursues a steady and progressive course to a fatal termination.

*Prodromes.*—The disease often begins with prodromal symptoms, malaise, weakness, indisposition, lassitude, etc., which develop insidiously and gradually, and continue for a few days or even two or three weeks before the active period sets in. In some cases, however, the onset of active symptoms is abrupt and sudden, without being preceded by prodromal phenomena. The leukemic changes may attain considerable development without their presence being suspected, and be well advanced before symptoms appear to call attention to their existence.

*Onset.*—The initial symptoms ushering in the active stage of acute leukemia which first attract special attention to the case, and for which medical advice may be first sought, vary in different cases. The commonest initial symptom is hemorrhage in some locality, most frequently into the subcutaneous tissues or from the nose or mouth, less frequently from other situations, as the stomach or urinary organs; many of the reported cases have, at the outset, been diagnosed purpura hæmorrhagica. Another frequent introductory condition is the stomatitis or pharyngitis that is so conspicuous a feature of this disease. A smaller number of patients first come under treatment for headache, pains in the face, side, or limbs, chills, fever, asthenia, anorexia, tonsillar enlargement, edema of the face, and occasionally for symptoms simulating articular rheumatism.

*General Conditions.*—Fever in most cases is a regular and well-marked feature of the disease, though in some of the cases it has been absent; it is usually irregular in type, at times intermittent, ranges from moderate to high (up to 104° or over), and may be present through the greater part of the course of the disease. Chills are

not usual, except sometimes at the beginning. Perspiration is apt to be abundant, and the skin is often bathed in copious sweat. A disagreeable foul odor often emanates from the body, derived from the oral lesions or the perspiration. The skin is very pale and anemic. Asthenia is marked, beginning early or in the prodromal period as a general lassitude, and gradually increasing to profound weakness. Emaciation is marked and progressive, and may reach an extreme degree toward the end. The extreme prostration of the patient gives the impression of being due to profound toxemia. While the progress of the disease is almost always continuous and uninterrupted, in two or three cases a temporary remission of symptoms has occurred.

**Circulatory System.**—As acute leukemia is primarily a disease of the hematopoietic organs and blood, the most marked and characteristic features of the disease are manifested in these structures. Of the two morphologic types of leukemia, myelomic and lymphatic, acute leukemia is almost always, if not always, of the lymphatic type. Only a few of the acute cases are recorded as of the medullary type, and in these the conditions present are mostly reported incompletely and unsatisfactorily, either prior to or without the use of recent hematologic methods, so that a satisfactory judgment as to whether the myelomic form of leukemia can run a typical acute course can not yet be formed. According to Askanazy, the very rare cases of purely medullary leukemia (without splenic or glandular involvement) are mostly acute, but the precise relationship of myelomic and acute leukemia is yet to be worked out.

Acute leukemia is, then, preeminently, if not exclusively, of lymphatic type; and of the two forms of this type, associated with a predominance of small or of large lymphocytes respectively, it is preeminently of the latter or macrolymphemic form.

**Lymph Glands.**—In accordance with its lymphatic type, the lymphatic glands and other lymphoid structures undergo marked and widespread enlargement in the great majority of cases of acute leukemia, due to the excessive lymphocytic hyperplasia. Occasionally glandular enlargement is absent, or very slight, or confined to a single gland (as the thymus), or a group of glands; the spleen, however, is enlarged in such instances. The enlargement may be unevenly distributed, one group of glands being affected while others are not, and different glands being enlarged unequally. The glandular hypertrophy begins early in the disease, but increase in size does not progress throughout the entire course; after reaching a certain size (which may be early) no further enlargement occurs. The size attained by the glands varies greatly; it is usually moderate, but may be extreme. The enlargement is usually less than that common in pseudoleukemia and other conditions. At times the glandular enlargement subsides under the influence of intercurrent infections or hemorrhage.

Enlargement of the superficial lymph glands, submaxillary, cervical, axillary, and inguinal, so that they can be seen or at least felt, usually occurs and is a conspicuous and characteristic feature of the disease; usually the submaxillary or cervical glands reach a greater size than the other superficial glands, and are often more enlarged on one side than on the other. At times the superficial glands are not enlarged materially, while autopsy may show hypertrophy of the internal glands. The bronchial, mediastinal, mesenteric, portal, and other deep-seated lymph glands share in the general hyperplasia. The thymus is often enlarged in young subjects or persistent in older ones; the enlargement may be so great as to be evident on physical examination during life. The lymphoid structures of the alimentary tract usually participate in the hyperplasia, causing the marked involvement of this tract in acute leukemia. The tonsils are usually enlarged, causing obstruction to deglutition; hyperplasia of the lymphoid tissue in the mucous membrane of the mouth and pharynx may pro-

duce the characteristic stomatitis and pharyngitis of the disease. Enlargement and ulceration of the lymphoid follicles of the stomach, and especially of the intestine, occur in many of the cases.

**Spleen.**—The spleen enlarges in the great majority of the cases along with the glands. At times it is enlarged, perhaps to an extreme degree, when the lymph glands are affected little or not at all. The hypertrophy may be slight; exceptionally it may be enormous, and the organ may exhibit precisely the same excessive size and hardness characteristic of the lienomedullary form of leukemia. The splenic hypertrophy often develops rapidly under direct observation in the earlier period of the disease, the progress of the enlargement being observable from day to day. The organ does not ordinarily continue to enlarge throughout the course of the malady, but after reaching a certain development its size remains constant. Sometimes toward the end or under the influence of sepsis or hemorrhage the hypertrophied spleen undergoes decrease of size.

**Marrow.**—Tenderness of the bones is present in many cases of acute leukemia, and it is believed that in all cases there is more or less morphologic alteration of the bone marrow. The marrow lesions in all ordinary cases of acute leukemia are, however, comparatively slight, much less marked than in the true medullary forms of leukemia. If acute myelomic leukemia occurs, primary marrow lesions with less glandular involvement would be expected in such cases.

From the foregoing it will be seen that, so far as the hematopoietic organs are concerned, acute leukemia occurs in two types: a glandular type, much the most frequent, in which the glands are predominantly enlarged, with or without splenic hypertrophy; and a splenic type, in which the spleen is hypertrophied (often to an extreme degree) with the glands but slightly or not at all involved.

One case of acute lymphemic leukemia has been reported in which it was alleged that no enlargement or macroscopic changes of the lymph glands, spleen, or marrow were present (A. Dennig<sup>2</sup>). Another case of acute leukemia has been recently reported presenting typical lymphemia with extensive lymphoid alteration of the bone marrow, but with the lymph glands and spleen practically unaffected (Dorothy Reed<sup>3</sup>).

**Blood.**—The changes exhibited by the blood are highly characteristic, and in most cases the diagnosis of acute leukemia can be made from the blood findings alone.

The *red corpuscles* steadily, continuously, and rapidly decrease in number from the beginning to the end. The hemoglobin also diminishes parallel with the number of red cells. This rapid progressive anemia, running along with the progressive emaciation and asthenia, is highly characteristic of acute leukemia. The number of red cells often goes below 2,500,000, and sometimes below 1,000,000 per cubic millimeter. In marked contrast to the conditions present in myelomic leukemia, nucleated, poikilocytic, and polychromatophilic red cells are usually (though not always) absent or very scarce in acute leukemia.

The *leukocytes* in the circulating blood are greatly increased in number in acute leukemia. Sometimes their number is as great as ordinarily occurs in the chronic forms of the disease, that is, up to or exceeding 500,000 per cubic millimeter. As a rule, however, their number is much lower than in the chronic cases, in many instances not going over 100,000 or even 50,000. A few cases have been observed before the leukocytes had begun to increase in the blood—the so-called "pre-leukemic stage"—the number of leukocytes being found normal. While it is rare that cases are detected thus early, before the increase has begun, the patients often come under observation while the leukocytes are still increasing in number, and the rapid increase can be followed from day to day. The leukocytes may not con-

tinue to increase in number throughout the entire course, but after attaining a certain figure may remain stationary.

The varieties and proportions of the leukocytes in the blood in acute leukemia are very characteristic. An overwhelming majority of the leukocytes are lymphocytes, large and small, amounting usually to over 90% or 95% or even 99% of the total number of leukocytes. Polymorphonuclears and eosinophiles are very scarce; they may be not only relatively diminished but their absolute number per cubic millimeter is often reduced far below normal. Myelocytes and basophile leukocytes are usually absent, but are present occasionally. The leukocytic changes in the blood in this form of leukemia therefore ordinarily consist of a vast increase of lymphocytes without any increase or even with a decrease of all other forms of leukocytes—a lymphocythemia.

Much interest and importance attach to the relative proportions of the two kinds of lymphocytes, large and small. In the great majority of cases the large lymphocytes greatly outnumber the small in acute leukemia, while preponderance of the small lymphocytes is the rule in the chronic cases of lymphatic leukemia. Exceptions occur, microlymphemia being occasionally manifested in acute leukemia and macrolymphemia in chronic lymphatic leukemia, but as a general rule a great predominance of large lymphocytes is strongly diagnostic of acute leukemia and prognostic of a severe and rapid course to a fatal termination. If acute medullary leukemia occurs the myelomic blood picture of that form of the disease should be presented.

When, as frequently happens, infections develop as complications in acute leukemia the same remarkable retrogression of the hematologic phenomena takes place as in chronic leukemia; that is, the number of leukocytes in the circulating blood usually undergoes great diminution, even to or below normal figures; the relative proportions of leukocytes may or may not continue without change, either the lymphocytes remaining upward of 90% or 95% or an increase of polymorphonuclears taking place.

*Leukocytic Deposits.*—In acute as in chronic leukemia the accumulation of leukocytes in microscopic or macroscopic aggregations or nodules at numerous points in various organs, especially the liver, spleen, and kidney, is a marked feature of the disease.

*Heart.*—The heart sustains no organic change in acute leukemia, aside possibly from some myocardial softening and dilation at times in connection with the toxemia. The heart action is frequent and weak. Murmurs are sometimes present of hemic or anemic character.

*Arteries.*—In the published cases of leukemia little is said about the condition of the arteries. In my case reported below there was marked general arteriosclerosis of the diffuse, noncalcareous, toxic type. My attention being thus directed to this feature I took pains to examine the arteries in two cases of chronic leukemia since observed and in both found distinct arteriosclerosis. Whether this is common in leukemia cannot now be stated, but it is a point worthy of observation, as the arterial lesions may play a prominent part in the causation of the hemorrhages so characteristic of this disease.

*Hemorrhages* are among the most frequent, most characteristic, and most conspicuous features of acute leukemia. They probably occur in at least 90% (if not 100%) of all cases. No period in the active stage of the disease, from the beginning to the end, is exempt. Repeatedly have cases of acute leukemia when they first came under observation been diagnosed as purpura hæmorrhagica, a diagnosis which only blood examination or the progress of the case cleared up. The hemorrhages are usually multiple and repeated and occur in widely separated situations. The amount of blood actually lost varies from slight quantities to amounts sufficient to destroy life. The loss of blood in itself is not usually sufficient to endanger life, though it must

necessarily contribute to the prostration and anemia; occasionally death results directly from the loss of blood, while in other instances death follows extravasation of blood into a vital part, as in cerebral hemorrhage. While hemorrhage is a conspicuous feature of chronic forms of leukemia, in the acute cases the tendency is intensified into a profound hemorrhagic diathesis. The causes of this marked tendency are not well known; the severe anemia is one favoring factor, arteriosclerosis may be another, while in the alimentary canal the ulcerations may open into bloodvessels; but that some other factors must be influential is shown by the fact that hemorrhage may be one of the earliest manifestations of the disease before the conditions mentioned have developed to any great extent.

Much the most frequent seats of hemorrhage are the skin and the nose. Bleeding may occur in these situations from first to last. In the skin it takes the form of purpuric extravasations into the subcutaneous tissues; the purpuric areas vary in size from minute points to large patches; they are usually multiple, often very numerous, and scattered over widely separated parts of the surface. Epistaxis is also very frequent, sometimes introduces the active period of the disease, and may be repeated, profuse, and dangerous.

Bleeding from the mouth is frequent, especially in association with stomatitis. Hemorrhage from the intestine is rather common, from the stomach less frequent, sometimes originating from intestinal or gastric ulcers, sometimes not. Hematuria and hemoptysis occur occasionally. Retinal hemorrhages would probably be found in nearly all cases if looked for. Cerebral hemorrhage has occurred in a number of cases, causing hemiplegia, coma, and death; in one case it took place as early as the fourth day of active symptoms. Visceral and subserous hemorrhages and infarctions are often noted at autopsy. Aural hemorrhage may be one cause of the deafness that sometimes develops. Slight wounds may be followed by severe or fatal hemorrhage, as has occurred from splenic puncture and extraction of teeth; profuse hemorrhage has even followed a needle prick of the skin. Wounds do not always, however, bleed excessively.

Uterine hemorrhages are not common. It is a remarkable fact that so far as the few observations recorded show, labor occurring in a woman affected with acute or chronic leukemia is attended with less bleeding than in normal parturitions, some of the labors being practically bloodless.

*Alimentary System.*—In acute leukemia the alimentary tract suffers in intensity and prominence to a degree closely approaching that of the circulatory system, chiefly through the involvement of the lymphoid structures abounding in this region. Scarcely any of the organs or portions of the alimentary tract are exempt.

*Mouth.*—Stomatitis occurs in most of the cases, only a small proportion escaping. It is of the severest character, and usually causes much more pain and distress than any other feature of the disease. From the uniformity of its occurrence, its severity and painfulness, stomatitis must be ranked as one of the most prominent and characteristic clinical features of acute leukemia, almost or quite corresponding in importance to the gland and blood changes and the hemorrhages. Often it is the earliest or one of the earliest features of the disease; it may attain a high degree of development early in the case, or it may gradually progress and reach its maximum later or toward the end. The morbid condition is chiefly due to excessive proliferation of the abundant lymphoid tissue in the mucous membrane lining the gums and oral cavity, resulting in inflammatory or ulcerative conditions. The stomatitis occurs in two forms, ulcerative and pseudoscorbutic.

The ulcerative or gangrenous type has occurred in only a small proportion of cases of acute leukemia. It consists in the development of an ulcer or localized necro-

sis of tissue progressing to slough-separation and ulceration at some circumscribed area or areas in the oral cavity from the tonsils to the lips. Occasionally a pseudomembrane forms over the ulcer. The portions of the gums and oral surfaces not directly involved in the necrotic process may be entirely free from any morbid involvement.

Much the commonest and most characteristic form of stomatitis or gingivitis occurring in acute leukemia is the pseudoscorbutic type, in which the oral lesions closely resemble those of scurvy. It begins with swelling, softening, and tenderness of the gums, gradually increasing until the gums are excessively swollen, soft, edematous, and spongy, and sometimes ulcerated. Serum and blood ooze abundantly from the gums, or free hemorrhage may take place. The teeth become loose, and even fall out. The lips may become greatly swollen, dry, fissured, and incrustated with sordes. Edema of the neighboring structures, as the side of the face, is frequent. The ulcerated and edematous tissues are very apt to become affected with infectious inflammations. A foul odor is given off from the mouth. The parts are very sensitive, painful, and tender. In its maximum development the stomatitis is the source of extreme discomfort and distress to the patient. On account of the swelling and pain, swallowing and movement of the mouth are greatly interfered with, and the mouth can be opened only a narrow space. The difficulty in taking food thus caused contributes materially to the malnutrition and asthenia of the patient.

*Tonsils.*—The tonsils, participating in the general lymphatic involvement, are frequently enlarged. The enlargement may be so great as to occlude the fauces and cause pain and difficulty in swallowing. Severe tonsillitis analogous to the gingivitis may develop, and at times the tonsils undergo marked necrosis and ulceration; pseudomembranes may form on the tonsillar ulcers. The faucial tonsils suffer most, the lingual and pharyngeal tonsils less frequently and usually less severely.

*Pharynx.*—The pharynx often presents lymphoid hyperplasias and inflammations similar to those of the tonsils and gums. Enlargement of the adenoid structures of the nasopharynx may be sufficient to obstruct respiration.

*Stomach.*—The stomach is not usually affected severely in acute leukemia. Its functional power is good, and food is well digested without distress or indigestion. The appetite may be poor or lacking, though in some cases it is remarkably good. At times the stomach presents hyperplasia of its lymphoid structures, ulcerations and hemorrhages.

*Intestine.*—The intestine very frequently exhibits enlargement of the lymphoid follicles, which may go on to ulceration. The mucous membrane presents large numbers of minute nodules or ulcers thickly scattered over long stretches of the bowel. The functional activity of the intestine is often not disturbed to a degree commensurate with the organic changes. Diarrhea may occur, but constipation is frequent. Intestinal hemorrhage is not infrequent, and may occur even in the absence of ulceration. Gangrenous colitis has been observed.

On the supposition that acute leukemia is infectious certain authors have suggested that the ulcers in the mouth, stomach, or intestine are the portals by which the infection enters the system. The suggestion has special weight in the case of the mouth and tonsils, on account of the severe local lesions there and the fact that the submaxillary and cervical glands are usually more enlarged than other groups of glands. The ulcers in the mouth and intestine are, however, apparently secondary to lymphoid hyperplasia, so that the leukemic process is in existence before the ulcers appear; in view of this and the fact that specific microorganisms have not been demonstrated in leukemia, the ulcers apparently do not afford entrance to primary pathogenic germs. They do,

however, often serve as points of entrance for secondary infections.

The *liver* is usually slightly or moderately enlarged to a degree evident on physical examination. This is due to aggregations of lymphocytes that are deposited in the liver substance throughout the organ, chiefly in the portal and interlobular regions.

The *respiratory system* in general suffers little in acute leukemia. Epistaxis is exceedingly frequent, often profuse, and has even proved fatal. Lymphoid proliferation and catarrhal inflammation may occur in the nasal fossas. Adenoid overgrowth in the nasopharynx may interfere with or completely obstruct respiration through the nose. Edema of the glottis, produced by extension from the neighboring tonsillar or pharyngeal inflammation, has occurred in a few instances, necessitating tracheotomy at least once. The lungs are ordinarily little affected, aside from occasional secondary conditions, as bronchial catarrh. Cough, usually slight, is not infrequently present. Hemoptysis and pulmonary infarction occur occasionally. Dyspnea, manifested by frequent respiration, is common, due probably to anemia and toxemia.

*Skin.*—Purpuric hemorrhages into the subcutaneous tissues are among the commonest and most characteristic features of the disease, and may appear from the very first to the very last. They may be small or large, few or many, and may appear in widely separated parts of the surface. Perspiration is usually very free. Edema of one or both sides of the face or of the cervical region is frequently observed, consequent upon the severe oral inflammation. Edema of the legs has been observed in two or three instances. Leukemic nodules and tumors of or under the skin, similar to those occasionally appearing in chronic leukemia, have been noted rarely.

*Urinary Organs.*—The kidneys usually present areas of characteristic leukemic infiltration, a diffuse and crowded accumulation of lymphocytes between the uriniferous tubules. Hematuria occasionally occurs. The excretory powers of the kidney are but little or not at all diminished.

The *urine* possesses the same characteristics prominent in chronic leukemia. The quantity is often increased, sometimes to more than double the normal amount. Uric acid and allied substances, derived from the breaking down of the excessive number of leukocytes, are greatly increased. Slight albuminuria may occur, but not constantly; at times peculiar proteids derived from the leukocytic nucleins appear.

The *genital organs* are rarely involved. Leukemic priapism has been observed in one case, a boy of 10. The tendency to hemorrhage does not seem to affect the uterus greatly, even postpartum bleeding being remarkably slight.

*Nervous System.*—The nervous phenomena in acute leukemia are chiefly functional, due apparently to toxemia; but in some cases severe conditions result from hemorrhage or leukemic infiltration into the nervous structures.

Headache, which may be intense, is not infrequent in the early period of the disease. In a few instances pain in the left side, in the splenic region, has been an early symptom; early pain in the right side has also been noted. Pains in the limbs, sometimes with swelling of the joints, a condition simulating articular rheumatism, ushered in a few of the cases. Sensitiveness of the bones on percussion is frequent. The enlarged glands are generally not painful or tender, but may be sensitive. The lesions of the mouth and throat may cause great pain and distress.

With the progress of the case the general pains—in the head, side, limbs, etc.—usually subside, and the patients often are markedly somnolent. Vertigo is frequent, and delirium of a quiet character is sometimes observed.

Cerebral hemorrhage is not infrequent, and is fol-

lowed by hemiplegia, coma, and death. Localized paralyzes, as of the facial nerve, have been observed in a few cases, due probably to hemorrhage or leukemic infiltration into the nerve.

*Eye.*—Retinal hemorrhages are very frequent. Leukocytic infiltration may take place in the ocular and orbital tissues, sometimes producing amaurosis. In one case the orbital leukemic infiltration was so massive as to cause marked exophthalmos.

*Ear.*—The development of deafness has been a notable feature in a number of cases (as in mine), probably due to hemorrhage or leukocytic infiltration into the aural structures or the auditory nerve. The anatomic relation between the facial and auditory nerves perhaps indicates some association between the deafness and the facial paralysis sometimes present.

*Complications.*—Acute leukemia presents conditions unusually favorable for the development of secondary infections, local and general, and complications of this character appear in a large proportion of cases. The ulcers in the mouth, throat, stomach, and intestines afford ready means of entrance for pathogenic bacteria, the lowered general condition lessens the power of resistance against bacterial growth, and the inflamed tissues in the mouth and elsewhere present favorable soil for their development.

The principal bacteria causing these secondary infections are the ordinary pyogenic organisms, staphylococci, streptococci, colon bacilli, and others. The particular form and site of the infection vary; cellulitis or abscess in the tissues about the mouth and face, alveolar abscess, suppurative tonsillitis, suppuration of cervical glands, are among the commoner complications; septicemia, endocarditis, empyema, abscesses in the lungs and other organs, phlebitis, or venous thrombosis (observed once in femoral vein, once in portal vein with ascites), etc., also occur.

These secondary infectious complications affect the clinical picture not only by superimposing their own characteristics on those of the disease, but still more by profoundly modifying the leukemic process itself. An infection complicating either acute or chronic leukemia produces marked and characteristic changes in the blood and hematopoietic organs. Under the influence of a complicating infection in acute as in chronic leukemia the leukocytes in the blood almost always greatly decrease in number, sometimes down to or even far below normal; very exceptionally the number does not decrease and even increases. Under these circumstances the differential proportions of the different kinds of leukocytes often remain unchanged; that is, the same vast preponderance of lymphocytes may continue after the incidence of an infection even when the number of leukocytes is much lowered thereby. In other cases the relative number of lymphocytes becomes lower while the polymorphonuclears are greatly increased by the infection, thus restoring the differential count to something like normal.

Not infrequently a complicating infection causes a marked subsidence and decrease in size of the enlarged glands and spleen, even to their normal volume, and with this a general improvement and amelioration of the leukemic symptoms may occur, but only temporarily. Infections, therefore, antagonize the leukemic process.

*Termination.*—All the cases heretofore reported have invariably progressed to a fatal termination. No authentic case of recovery or of transformation of the acute into a chronic form has yet been recorded. The commonest immediate cause of death is exhaustion, collapse, or toxemia; a minor proportion of patients die from cerebral hemorrhage or from the direct effects of excessive hemorrhage.

*Diagnosis.*—The characteristics of acute leukemia are so marked that difficulty in diagnosis should rarely be encountered if the case is properly investigated. The enlargement of the lymph glands and spleen, the charac-

teristic blood findings, the hemorrhages, stomatitis, febrile course, and leukemic infiltrations are conclusive. The blood conditions alone—increase of leukocytes, great preponderance of lymphocytes (especially if large)—is fairly pathognomonic. The cases often have been and are apt to be mistaken for purpura hemorrhagica or scurvy, and doubtless cases of acute leukemia have passed for such without the error ever having been discovered; but the glandular and splenic enlargement and above all the blood examination should clear up the diagnosis. Pseudoleukemia is distinguished by the blood examination. The febrile course sometimes suggests typhoid fever; but the clinical features of the two diseases are otherwise so distinct that with any degree of care confusion should hardly be possible.

General sepsis at times assumes such a form that it may closely simulate acute leukemia. It may present irregular fever, prostration, asthenia, glandular and splenic enlargement, and an increase of leukocytes as great as occurs in some cases of acute leukemia. Sepsis does not often manifest a hemorrhagic tendency, and would very exceptionally be associated with severe stomatitis. The crucial point of distinction lies in the differential count of the leukocytes; in acute leukemia nearly all the leukocytes are lymphocytes, in sepsis they are nearly all polymorphonuclears. In some of the cases reported as acute leukemia, in which differential counts are not recorded, the diagnosis as against some form of sepsis is not beyond doubt on account of the lack of complete blood examinations. It should be remembered also that sepsis is apt to complicate acute leukemia, so that even if infection is demonstrated by bacteriologic methods leukemia is not necessarily excluded.

It may occasionally happen that the blood finding may be misleading. At a stage of the disease so early that the leukocytes in the blood have not yet commenced to increase—the “preleukemic stage”—blood examination is negative; this rarely happens, but has occurred and caused confusion in diagnosis. In cases of this kind that are otherwise suspicious, examination of the blood at intervals will, if the case is acute leukemia, show the development at some time of the characteristic blood changes. Also, when under the influence of a secondary complicating infection the leukocytes have subsided to a normal number, or to a number within the range of an ordinary septic leukocytosis, difficulty in diagnosis may arise; in these circumstances a differential count showing great predominance of lymphocytes still points to acute leukemia, although lack of this characteristic predominance does not prove the absence of leukemia. In the latter case hematologic verification of the diagnosis becomes impossible; but even then, the other clinical and anatomic features of typical cases are so characteristic that, in the presence of an infection to account for a negative blood finding, a diagnosis of acute leukemia might be justified.

The *prognosis*, according to uniform experience with the disease, is hopeless, and death within a few weeks is inevitable.

*Treatment.*—No therapeutic measures hitherto employed seem capable of retarding or antagonizing the disease process. Arsenic in large doses, perhaps with quinin or iron, may be tried as a sort of forlorn hope. The antagonistic and favorable effects exhibited by infectious complications suggest the trial of a line of treatment similar to that of sarcoma with streptococcus toxins.

Symptomatic treatment is practically all from which results may be expected. The last days of the patient should be made as comfortable as possible, by nursing and treatment. Occasional sponging may be agreeable when fever is high or perspiration abundant; but it is not worth while to disturb the patient by systematic cold bathing for the fever. Nothing is gained by restricting the diet; the patient should be allowed whatever

his appetite may crave or he can swallow, solid or liquid, so long as the stomach is not disturbed. Strength may be sustained by liberal feeding, stimulants, and tonics. Constipation or diarrhea, excessive perspiration, tendency to bedsores, pain, etc., demand appropriate treatment. The distressing condition of the mouth and throat should be alleviated as much as possible by cleansing, antiseptic, deodorizing, astringent, or sedative lotions and applications. The usual measures for control of hemorrhage from the nose, mouth, intestine, or elsewhere should be employed. It should be remembered that even a trifling operation like opening an abscess, pulling a tooth, splenic puncture, or even pricking the skin may provoke serious or fatal hemorrhage. Complications like erysipelas, cellulitis, abscesses, edema, etc., call for the usual treatment.

*Relation of Acute to Chronic Leukemia.*—There are no physiologic or anatomic features presented by acute leukemia that do not occur (even though rarely) in chronic leukemia. Fever, cachexia, hemorrhages, etc., are of frequent occurrence in chronic leukemia; stomatitis and pharyngitis, while rare, have been observed in chronic cases. Conversely, there are few or no features of chronic leukemia that may not at some time appear in acute cases. The one highly though not invariably distinctive morphologic feature of acute leukemia, the excess of large lymphocytes, is probably not so much due to any essential difference in the morbid process as to its intensity or rapidity causing the appearance of leukocytes at an earlier or different stage of development.

The distinction between acute and chronic leukemia is therefore one of degree rather than of kind, and rests upon the clinical picture, the overwhelming intensity and virulence of the symptoms, the rapidity of the course. The phenomena that in chronic cases extend over three or four years are in acute cases compressed into as many weeks. The intensity of the morbid process is such that conditions that are rare in the chronic forms, such as stomatitis, are brought out with great frequency and prominence in the acute cases. It is entirely by the character and malignancy of the clinical features that acute leukemia is distinguished from the chronic forms. No arbitrary time limit can be satisfactorily fixed as a dividing line between acute, subacute, and chronic leukemia; and while intermediate cases difficult to classify may occur, just as with other diseases, in the great majority of instances the acute and chronic cases can be easily distinguished and recognized. A case running a mild course, terminating prematurely within a month or two of its onset through some such untimely accident as cerebral hemorrhage, could not be regarded as acute; and, on the contrary, it is probable that a chronic case of long standing could take on a sudden access or exacerbation of virulence and then run a really acute course.

It has been suggested that cases of leukemia can not be considered really proved acute unless blood examination at or before the beginning of the course showed the previous blood condition to have been normal, and that there was no previous latent or unsuspected leukemic condition out of which the acute case developed. Cases rarely come under observation early enough or under such circumstances that the condition of the blood prior to the leukemic changes has been determined; yet in a few instances early blood examinations have shown previously normal conditions, so that the possibility of leukemia running its entire course within a few weeks is fairly demonstrated.

The relation of pseudoleukemia to acute leukemia is a very interesting subject, but presents no features differing from its relation to lymphatic leukemia in general.

*Etiology.*—Acute leukemia presents strongly the appearances of an infectious disease, and has by many been regarded as of infectious character. As the acute and chronic forms of leukemia are morphologically iden-

tical and differ only in the intensity and rapidity of development, the two forms are obviously of like etiology. The results of a study of the etiology of leukemia will be presented in a subsequent article, in which the causation of acute leukemia will be considered in connection with the disease in general. Suffice it to say that for neither acute nor chronic leukemia has a causative parasite been demonstrated, nor has any direct proof of infectiousness, transmissibility, or contagiousness been obtained.

**CASE I.**—The first patient with acute leukemia seen by me was under the charge of Dr. J. R. Bromwell, of this city,<sup>4</sup> who reported it to the Washington Obstetrical and Gynecological Society April 4, 1902. This was a case of the splenic type, the spleen being enormously enlarged, but no glandular involvement in the absence of an autopsy being apparent. It was in a boy of 14 and ran a typical course, the active period of the disease lasting three weeks. Stomatitis was severe and death was caused by cerebral hemorrhage. The leukocytes reached 529,000 per cubic millimeter (1 white to 7.6 red cells); 85% of them were large lymphocytes, 10% small lymphocytes.

**CASE II.**—The patient, P., white, born in Virginia, was a waiter by occupation, and nearly 22 years old at the time of his last illness. His various places of residence were Virginia, the District of Columbia, West Virginia, and (the winter of 1901-02) Chicago. He was taken with his final illness in West Virginia. His father was living and in sound health. His mother had died of acute tuberculosis after five months' illness. His grandparents lived to old age. After the diseases of childhood the patient had no severe illness up to his final attack. He had occasional slight ailments and was rather subject to headache. He had gonorrhoea in the latter part of December, 1901, and was vaccinated about the middle of March, 1902. Before the beginning of his illness he weighed 150 pounds.

At the end of the first week in April, 1902, the inguinal glands began to enlarge, followed by the glands in other regions in succession. The end of the third week in April the patient "caught a cold." He became progressively weaker, gradually lost weight, but his appetite continued good. He had no hemorrhages. On account of his increasing illness he was compelled to quit work May 1. On May 5, 1902, the patient applied to Dr. J. J. Richardson for treatment for obstruction to breathing and difficulty and pain on swallowing. Dr. Richardson found marked and general hypertrophy of the tonsillar ring, the lingual and faucial tonsils and the pharyngeal lymphoid structures being much enlarged.

An examination of the blood May 8, 1902, showed red corpuscles 4,042,000 to the cubic millimeter; hemoglobin 80%; leukocytes 67,800 per cubic millimeter, all of which excepting a small proportion were large lymphocytes. A diagnosis of acute lymphatic leukemia was made, and death within a few weeks was prognosticated, although at this time the general physical condition, aside from the blood findings, would not indicate so serious a prognosis.

The difficulty in swallowing greatly improved under Dr. Richardson's treatment and on May 11 the patient was transferred to my charge. His condition was as follows: He was white, of blond type, and of markedly good muscular development; the beard was scanty and deficient. He was weak, pale, anemic, and moderately emaciated, having lost twenty pounds within three or four weeks. He perspired freely and a strong disagreeable fetid odor emanated from him, probably chiefly from the mouth and nose. He was at the time running an irregular fever temperature.

The inguinal, axillary, and cervical lymphatic glands were enlarged on both sides. The enlargement of the inguinal and axillary glands was moderate in degree, the largest not being over two or three centimeters long; the glands were not fused together, the separate glands could be distinguished individually; the enlargements were plainly visible. The cervical and submaxillary glands were very much enlarged and massed together in packets that formed conspicuous swellings at the angles of the jaw; the group of glands on the right side was much more enlarged than that on the left.

The adenoid structures of the nasopharynx were much hypertrophied, completely closing the nasal passages. The nasal mucosa was in a catarrhal condition, with a thin serous discharge. Respiration was "sniffly" and the voice nasal. The lungs were normal. The gums were swollen and spongy. The patient could open his mouth but a short distance, but could swallow moderately well. Appetite and digestion were good, and his bowels had been acting fairly. His liver was enlarged, extending from the costal border up to about two centimeters below the nipple.

The heart action was frequent, but the organ manifested no other abnormality. The radial arteries were markedly sclerosed, feeling cordy and rolling under the fingers, but not calcified. The vascular tension was very low, the pulse being soft and very easily compressible; on compressing the radial artery a recurrent pulse from the ulnar was very distinctly palpable. Examination of the blood May 11 showed: Red corpuscles, 3,686,000; hemoglobin, 73%; corpuscular hemoglobin ratio, 1; leukocytes, 134,800 per cubic millimeter; proportion of white to red cells, 1 to 25; differential count of leukocytes:

	Percent.	Number per cubic millimeter.	Normal number per cubic millimeter.
Small lymphocytes.....	7	9,486	1,900
Large lymphocytes.....	91.3	123,072	450
Polymorphonuclears.....	1.5	2,022	5,500
Eosinophiles.....	.....	.....	150
Myelocytes.....	.2	270	.....
	100	134,800	8,000

No basophile leukocytes and only two or three abnormal red cells (one or two polychromatophiles, one doubtful megaloblast) were seen.

The spleen was enlarged, extending to, but not below, the border of the ribs. The patient suffered no pain and felt fairly comfortable. He was rather drowsy. His pupils were moderately dilated. Hearing was normal.

Examination of urine May 11 gave the following result: Amount in 24 hours, 1,025 cc.; amber, nearly clear, moderately acid; specific gravity, 1.027.73; total solids, 7.605 grams in 100 cc., 78.951 grams in 24 hours; albumin and nuclealbumin absent; sugar absent; indican normal; urea, 4.65%, 47.66 grams in 24 hours; uric acid, .1174%, 1.20 grams in 24 hours; ratio of uric acid to urea, 1 to 40; phosphoric acid ( $P_2O_5$ ) .217%, 2.22 grams in 24 hours; chlorids ( $NaCl$ ), .4%, 4.10 grams in 24 hours; microscopically showed numerous mucous threads and a moderate number of squamous epithelium cells.

From this time on the disease ran a rapid course until death occurred, 18 days later. The patient's weakness and emaciation progressed steadily, until at the end the emaciation was extreme. He continually perspired freely. Fever continued, of an irregular remittent type, occasionally reaching 104° or over, and attaining a maximum of 105° the evening before death. The fever ranged rather higher after the advent of cellulitis of the face, though the increased temperature was probably only partially (or even little) due to the complicating infection. During the last week of life ecchymoses appeared on the ankles and thighs.

No further change in the size of the inguinal, axillary, cervical, or submaxillary glands took place, and no enlargement of any other superficial glands (except a slightly enlarged gland in the right mammary region) was detected. When the fever became high, tenderness of the inguinal glands was complained of. No tenderness over the bones was noted. No further material change in the size of the spleen was observed. The nasopharyngeal obstruction diminished from about May 20, so that the patient was able to breathe through the nose. With this improvement the foul odor diminished.

On May 14 cellulitis began to develop in the right alveolar region from a decaying fragment of a tooth. This fragment was removed, the bleeding following being insignificant. The cellulitis continued and increased, the right side of the face becoming generally swollen and edematous, though not very painful. The swelling later subsided, leaving an indurated area in the cheek, which did not soften or suppurate. The inflamed region was not lanced. This complicating infection was followed by the characteristic reduction of the number of leukocytes in the blood, and also perhaps caused a higher range of fever.

The most troublesome local feature of the case was the condition of the gums and mouth. The gums became more and more swollen and spongy, and the teeth became loose; the lips were dry, fissured, and incrustated with scordes. The patient could open his mouth only slightly, though for the most of the time he was able to swallow fairly well. In the last few days the mouth was in a most distressing condition, much like that of scurvy; the gums were exceedingly swollen, bloody serum constantly oozed from them in large amount, the teeth became so loose as to drop out, the lips were swollen, fissured, and sore; he could scarcely open his mouth, and swallowing became difficult and finally impossible.

His appetite remained good, and he ate both solid and liquid food with relish. Digestion was good, and there was no gastric disturbance except once or twice, due to the medicines used. At first there was some tendency to constipation, but later the action of the bowels was satisfactory. The stools were light brown to a very light yellow, sometimes well formed, sometimes soft and watery. Microscopic examination of a specimen of feces May 23 showed finely divided food detritus, some fragments of vegetable tissue, and numerous crystals of ammoniomagnesium phosphate. During the last four days (May 25-29) there was diarrhea, with from five to ten passages daily, of large yellow liquid stools (some containing milk curds), becoming pale and watery. There was no blood in the stools at any time. The abdomen was distended and tympanitic the last day; previously it was flat and undistended.

The condition of the heart continued without material change, except that its contractions became weaker and more frequent; its rate ranged mostly from 110 to 140, varying with the temperature. There were no murmurs at any time. The respirations mostly ranged from 18 to 24. All the accessible peripheral arteries showed marked sclerosis. As the emaciation progressed various arteries, radial, brachial, femoral, popliteal, could be picked up and rolled between the fingers;

all had a cordy feeling, but were not calcified. The temporal arteries were tortuous, but of small caliber, and their pulsation was distinctly visible. Arterial tension was very low throughout.

In the blood the hemoglobin and red corpuscles decreased steadily; the number of leukocytes was lowered from the earlier figures, apparently the effect of the complicating alveolar and buccal cellulitis, but the high proportion of large lymphocytes was maintained. The hemoglobin and red corpuscles decreased in corresponding degree, a corpuscular hemoglobin ratio of approximately 1 being maintained.

Blood examination May 17 showed: Hemoglobin, 53%; red corpuscles, 2,960,000; one doubtful normoblast was the only abnormal red cell observed; leukocytes, 29,600; differential count of leukocytes:

	Percent.	Number per cubic millimeter.
Small lymphocytes.....	3.5	1,036
Large lymphocytes.....	94.5	27,972
Transitional.....	1.1	325
Polymorphonuclears.....	.6	178
Eosinophiles.....	.3	89
	100	29,600

Blood examination May 23: Hemoglobin, 45%; red corpuscles, 2,232,000; leukocytes, 22,150. In the blood examinations May 17 and 23 bleeding from the needle punctures was free and prolonged.

Aside from the exceedingly sore mouth and occasional slight tenderness in the inguinal glands the patient suffered no pain, and in general was comparatively comfortable. There was some headache at times, perhaps due to the salicylate administered. He had vertigo when he got up at stool. He was drowsy and slept much during the daytime, but was rather restless at night. When awakened his mind was clear. He was very optimistic as to the outcome of his illness.

Hardness of hearing developed during the course of the disease, and increased progressively, until at the last he was very deaf and it required considerable elevation of voice to make him hear.

His pupils at times were dilated, at times normal. The findings of an ophthalmoscopic examination made May 27 by Drs. James Stuart and O. A. M. McKimmie were as follow: Both discs were clear and distinct, the retinas pale and anemic. The arteries were small, pale, and somewhat tortuous in both, but especially so in the left eye. The veins were full and tortuous, and large in comparison with the arteries. Two arterial hemorrhages were seen in the right eye; one dark irregular one, the size of the disc, being up and out, away from the disc, 2½ diameters of same; the other, one-fourth in size, was down and out 1½ diameters of the disc. One small venous hemorrhage was seen in the left eye, being down and out from the disc 4 diameters of the same.

Slight hematuria was observed once, on the day before death occurred.

*Treatment.*—Fowler's solution was given, but interrupted by temporary gastric disturbance. Iron was given for a time; also potassium iodid, in view of the arteriosclerosis. No perceptible effect was produced by these drugs. Full diet was allowed, and stimulants given. Sodium salicylate was administered at times as an antipyretic. The mouth and nose were treated with cleansing and sedative applications. Ice was applied to the swollen submaxillary region. The facial cellulitis was treated with iodine, ice, and poultices.

The steady and rapid progress of the disease was unaffected by treatment, and the patient died of exhaustion May 29, 1902. The total duration of the disease was about seven weeks, during the last four weeks of which the patient was confined to bed.

*Autopsy* (two hours after death).—Body extremely emaciated and anemic. There were a few small subcutaneous ecchymoses about the trunk and arms, and numerous small and large ecchymoses on the anterior aspect of the ankles. Bloody serum was oozing from the mouth. The superficial arteries were sclerotic. The cervical, axillary, and inguinal glands were enlarged, also a small gland near the right breast.

The bone marrow of the ribs was dry, scanty, and very pale. The mesenteric, portal, retroperitoneal, and bronchial glands generally were much enlarged; they were dark or mottled in color, and fairly firm. No structures having the appearance of hemolymph glands were distinguished.

The pericardium contained a somewhat increased amount of serum. The heart was pale, firm, rather small. The thoracic aorta showed patches of slight atheroma.

The spleen was enlarged to about three times its normal size, measuring 20 by 12 by 7 cm., and weighing 600 grams. It was dark-colored, congested, fairly firm, and had five or six small white lymphomatous nodules on its surface.

The mucous membrane of the small intestine showed a few small scattered ecchymoses. The mucous lining of the colon was studded with large numbers of minute pin-head sized nodules (enlarged solitary glands), ecchymotic, some with a minute erosion in the center.

The liver was dark, firm, congested, and enlarged, extending from the costal margin to the nipple.

The kidneys were enlarged and showed punctate subcapsular hemorrhages. Their substance was pale, with areas still paler. The bladder was distended with clear, pale, nonbloody urine.

The lungs showed hypostatic congestion. The right lung contained a large infarction.

**Microscopic Examination.**—The inguinal, mesenteric, and retroperitoneal lymph glands exhibited general lymphocytic hyperplasia, largely obscuring the structural elements of the glands.

Sections of a much enlarged bronchial gland showed throughout the lymphoid area a peculiar arrangement of short straight slightly wedge-shaped narrow striae, running in all directions, often in radiating groups; these striae consisted of clear spaces alternating with narrow cords of lymphoid tissue. Scattered about the gland were a number of small necrotic tubercles. In places, especially in the larger tuberculous nodules, there were abundant deposits of pigment granules.

The spleen contained deposits of iron-containing pigment granules, especially in the capsule and trabeculae. The Malpighian lymphoid bodies were indistinct in many places, and some of them contained a homogeneous hyaline eosinophile substance in their interior. The splenic pulp was infiltrated with leukocytes, chiefly mononuclear cells, with a few red corpuscles. The intercellular reticulum in the pulp was well marked. The macroscopic lymphomas consisted of aggregations of mononuclear cells.

The cellular elements of the marrow of the rib consisted chiefly of nongranular mononuclear cells, with red cells absent or very scarce.

The liver showed scattered throughout its substance large numbers of typical leukemic nodules of microscopic size, composed of aggregated mononuclear cells and located chiefly in the portal and interlobular regions. Homogeneous hyaline material was present in the largest of these lymphomatous nodules. The capillaries also contained large numbers of leukocytes. The liver cells were degenerated and their nuclei in general stained poorly. Particles of iron-containing pigment were scattered plentifully through the liver substance.

The colon showed hyperplastic enlargement of the solitary follicles. The heart-muscle and lungs were normal. The kidney showed extensive and diffuse areas of dense infiltration of lymphocytes between the uriniferous tubules, also in the capsule. The epithelium of the tubules was degenerated and desquamated.

The lymphocytes or mononuclear cells observed in the organs—lymph glands, spleen, liver, kidney—were mostly of medium size; the chromatin of their nuclei, instead of being distributed evenly through the nuclei, was mostly broken up into irregular granules, but mitotic figures were not observed.

**Bacteriologic Examination.**—In sections of liver, rib marrow, and inguinal gland were seen a very few cocci occurring singly (excepting one cluster seen in the liver). Smears from the spleen and a mesenteric gland showed a few scattered bacilli of medium size, moderately thick, and staining evenly (possibly colon bacilli), and a few doubtful single coccus forms.

Of agar and blood-serum tubes inoculated at autopsy from the heart blood, liver, and spleen, and grown both aerobically and anaerobically, some tubes from the blood and liver yielded pure cultures of a coccus, while those from the spleen and others from the blood and liver remained sterile. This coccus, probably the same as that seen in the organs, grew in the original tubes, both aerobically and anaerobically, in minute round white colonies a millimeter in diameter; it was barely viable on culture media, as no further growths could be obtained on transplanting from the original to second or third tubes. The cocci stained from the cultures occurred singly and in pairs, a few in tetrads and small clusters, and decolorized by Gram's method.

Tubes inoculated by having portions of an inguinal gland rubbed over the surface of the culture media yielded luxuriant growths composed of bacilli of two kinds, for convenience termed "Bacillus I" and "Bacillus II."

Bacillus I in the original tubes formed growths covering nearly the entire surface of the media. It was a motile thick bacillus with rounded ends, forming oval spores and occurring singly, in pairs, and in chains. It stained readily and did not decolorize by Gram's method. On account of the presence of the nonstaining spore in the middle of the cell the stained bacilli often had an oval form with a clear central space and only the ends colored. The bacillus grew readily on culture media, most rapidly at 37°. On agar slants it formed a broad, whitish, dry growth with marked marginal serrations. In agar stabs numerous fine lateral filaments grew out along the stab. Gelatin was rapidly liquefied. In bouillon a thick white surface pellicle formed, later settling to the bottom. On potato it formed a thick, moist, shining white growth. It coagulated and decolorized litmus milk. It formed indol.

Its pathogenicity was tested by inoculation of a white rat, two rabbits, and three white mice, with practically negative results as to the production of leukemic or any other morbid conditions. The rat, twice inoculated intraperitoneally, remained perfectly well and rapidly increased in weight, but a month after inoculation died suddenly, apparently of heat-stroke; the spleen was somewhat enlarged, there was old peri-

tonitis in its vicinity; on the surface of the liver were three small white cysts; microscopic examination of the spleen and liver was negative; Bacillus I was obtained in pure culture from the spleen. A rabbit, which received two intravenous injections of cultures of Bacillus I and was observed for a period of 6½ months, showed no material morbid results; for a few weeks it did not thrive, and showed indurated nodules in the ears at the sites of the injections; later it gained weight and appeared perfectly well; blood examinations at intervals showed no increase of leukocytes. Another rabbit, inoculated intraperitoneally, became ill, lost weight, developed leukocytosis, and died after nine days; but its symptoms were probably due to an injury sustained by the animal. Three mice were inoculated with the bacilli obtained from the spleen of the rat; one died a few hours after an intraperitoneal injection; the other two, observed for five months, showed no effects from subcutaneous injection.

Bacillus II grew in a single small separate colony in one of the tubes inoculated from the inguinal gland. It was motile, rather smaller and narrower than Bacillus I, did not grow in chains, and formed spores, which in stained specimens gave the appearance of a clear central space. It was not decolorized by Gram's method. On agar slants it formed a moist white growth, narrower than that of Bacillus I. Agar stabs gave a nodular, not arborescent, growth. It liquefied gelatin, did not produce indol, in bouillon formed a white pellicle which later settled to the bottom, decolorized but did not coagulate litmus milk, and on potato formed a widespread dry, white, wrinkled growth. A rabbit inoculated intravenously with the bacillus showed no leukemic developments; it continued well, gained weight, and the blood examined at intervals showed no increase of leukocytes; it died after six months from the effects of an abortion, and autopsy showed no enlargement of spleen or lymph glands. After intraperitoneal inoculation with the bacillus a guinea pig remained apparently normal and well for six months, when it died suddenly; its leukocytes 4½ months after inoculation numbered 23,130 (ratio to reds 1:248), and at death numbered 23,100. Autopsy showed atrophy and ecchymoses of stomach wall, but no enlargement of liver, spleen, or lymph glands.

In brief, in this patient a coccus differing from the ordinary known cocci was present in the blood and organs. The mesenteric glands contained bacilli, perhaps identical with one of those grown from the inguinal gland, perhaps colon bacilli. An inguinal gland yielded growths of two spore-forming bacilli, neither of which appeared to have any pathogenic properties, and one (or both) of which was probably due to accidental contamination.

**Animal Experiments.**—Besides the animals inoculated with the bacteria isolated, four other animals were inoculated with material obtained at the autopsy. A rabbit was given an intraperitoneal injection of blood from the patient's heart; the following day the animal was listless, but recovered, and, under observation for seven months, continued normal and well, and gained greatly in weight; its blood, examined from time to time, showed no increase of leukocytes.

A guinea pig was inoculated intraperitoneally with the heart blood. It gained in weight for a time and then lost weight, down to about the original figure; but aside from this malnutrition it presented no abnormal conditions until about 3½ months after inoculation, when it was suddenly seized with a convulsive attack and died in a few hours. At the time of death blood examination showed 6,460,000 red cells, 25,300 leukocytes; seven weeks previously the leukocytes had numbered 16,750. There were a few minute black spots in the stomach wall, perhaps old hemorrhages or healed ulcers; no enlargement of glands, liver, or spleen, or other morbid condition was observed.

A white rat was inoculated subcutaneously with the patient's heart blood. It continued perfectly well, gained greatly in weight, and when killed, over 4½ months after inoculation, exhibited no material abnormal conditions, and no increase of leukocytes.

A second rabbit was inoculated intraperitoneally with portions of the inguinal glands of the patient, but died of shock a few hours later.

The animal inoculations, therefore, do not appear to have produced leukemic or any other material morbid developments.

I here record my indebtedness to Drs. J. J. Richardson, James Stuart, and O. A. M. McKimmie; also to Dr. T. A. Clayton for seeing the patient in consultation, to Dr. D. W. Prentiss for assistance at the autopsy, and to Mrs. Louise Tayler Jones for assistance in the laboratory work.

This case was highly typical and illustrative of acute leukemia. It exhibited very characteristically the irregular febrile course, the extreme emaciation and weakness, the general glandular and splenic enlargement, the steady decrease of red blood cells and absence of qualitative changes in the red cells, the enormous increase of lymphocytes (especially the large ones) and decrease of other varieties of leukocytes, the tonsillar

enlargement, the enlargement of the liver, the leukocytic deposits in the liver, spleen, and kidneys, the enlargement of the solitary follicles of the intestine, and the rapid progress typical of this disease. Hemorrhage was not so pronounced a feature as it often is, but the pseudoscorbutic stomatitis was of the most severe character. The marked arteriosclerosis and the development of deafness were features of special interest. The development of a complicating cellulitis and its effect in causing a decrease of the leukocytes were also highly characteristic.

## RETROCECAL APPENDICITIS WITH RETROPERITONEAL PELVIC ABSCESS.\*

BY

A. ERNEST GALLANT, M.D.,

of New York City.

Professor of Gynecology, New York School of Clinical Medicine, etc

According to Virchow<sup>1</sup> paratyphlitis should be regarded as a retroperitoneal phlegmon, which has usually originated from inflammation and perforation of a vermiform appendix that is situated extraperitoneally behind the cecum.

From the records of 1,400 autopsies at the Boston City Hospital, Monks and Blake<sup>2</sup> found the direction of the appendix recorded in 572 instances, divided according to the points of the compass as follow: Down and in, 179; down, 79; in, 62; up, 52; up and in, 39; up and out, 29; out, 9; down and out, 5; in pelvis, unclassified, 14; with 104, or 18.2%, behind the cecum.

Howard Kelly<sup>3</sup> enumerates 14 varieties of pelvic abscess, and states that it is rarely met in the cellular tissue of the pelvis.

In a communication on "Walled Off Appendiceal Abscess," J. B. Deaver<sup>4</sup> describes (1) the postcolic or postcelic abscess, lying between the layers of the mesocolon, as the most common; (2) those beneath the parietal peritoneum, walled off by the cecum, intestines, omentum and lymph, frequently communicating with and including the pelvis; (3) when the pus collection is wholly confined to the pelvis and shut off from the general peritoneal cavity, with the appendix located in the pelvis; (4) circumscribed pus located near the median line and to the inner side of the cecum, walled off by the agglutinated viscera; (5) free pus in the general peritoneal cavity.

Rotter<sup>5</sup> claims that the most frequent location of abscess in perityphlitis is in the pelvis (41 of 132 of his own cases), and admits that it is difficult to tell whether pus found in the pelvis is of appendicular or tubal origin.

It is only after a long and careful search of the literature on appendicitis, that failing to find any record of the particular variety of abscess to be described, I have ventured to bring to your attention the following three cases:

CASE I.—Retrocecal gangrenous appendicitis, with retroperitoneal pelvic abscess.

E. L., a girl of 13 years and 4 months, on January 7, 1900, fell, striking upon the abdomen. While in school she vomited three times and complained of feeling sick. She stayed at home next day, taking citrate of magnesia, which resulted in bile-colored stools. She did not complain of pain. She attended school daily until January 18, when she complained of pain in the right iliac fossa. She was put in bed, and it was noticed that the sheet became wet with an egg-like substance, apparently coming from the rectum. Pain and discharge increased during the night, and on January 19 Dr. James K. Latham was called and made a diagnosis of appendicitis, and the same afternoon I concurred with this diagnosis. Palpation

defined a circumscribed mass in contact with the anterior abdominal wall, extending obliquely from the umbilicus downward and outward toward the right iliac fossa and apparently into the true pelvis, tympanitic on percussion. There was a mucopurulent discharge from the vagina and the stools contained considerable mucus.

Operation was performed January 19 at 4 p.m. A McBurney incision was made. As the index finger wormed its way between the cecum and the lateral wall it opened a cavity from which more than a pint of very foul-smelling pus escaped. On exploring the pelvis we were surprised to find the whole pelvis free from any evidence of peritonitis; the uterus and adnexa were in a healthy condition, the culdesac was nonadherent, its peritoneal covering perfectly smooth. A finger introduced into the vagina came in contact with the finger in the abscess introduced from above, and it was made clear that the abscess was located in the cellular tissue between the rectum and the posterior vaginal wall (see cut). An opening was made through the vagina and a large rubber tube placed in the cavity, which was washed out with hydrogen dioxide, and the upper portion of the abdominal wound packed with sterile gauze for drainage.

CASE II.—Postcecal appendicitis, with postperitoneal pelvic abscess.

E. W., a girl of 10, on April 29, 1900, was not feeling well. She vomited and was feverish. The next day she complained of pain in the abdomen; on the third day the pain was localized below the umbilicus; on the fourth day she was seen by Dr. Latham, who recognized the appendicular origin of the trouble. His diagnosis was confirmed by me.

Operation was performed at 8.30 p.m. The abdomen was quite uniformly tender, rather tense, most severe pain in the right iliac fossa; a distinct, well-defined mass was found lying

Relations of retroperitoneal pelvic abscess, AB; rectum, R; Douglas's culdesac, D; uterus, U; vagina, V; bladder, B.

obliquely along Poupart's ligament, and dripping into the pelvis. This proved to be the caput coli, which had been lifted upward toward the anterior abdominal wall, surrounded by masses of exudate, especially to the outer side. The index finger was wormed between the caput coli and the false pelvis, and entered a large abscess which occupied the greater part of the pelvic cavity. Other than the above named exudate confined to the region of the cecum there were no adhesions, though a considerable amount of seropurulent fluid escaped as soon as the peritoneum was opened. Working by gaslight we were unable to locate the appendix, and deemed it safer to pack with gauze, after washing out with hydrogen dioxide. Two days later the gauze was removed and the gangrenous appendix too friable to be sutured was ligated and removed. It had been originally behind the caput coli. On account of the tender age of the child, no attempt was made to drain through the vagina. Four days later, while examining the cavity, an enterolith was found and removed. On May 30 a small sinus was still open. The temperature rose to 102.2°, pulse 120, but she promptly responded to one dose of quinin daily, given seven hours before the apex of the temperature-curve of the previous paroxysm.

CASE III.—Locomotor ataxia, retrocecal appendicitis, retroperitoneal pelvic gumma.

E. L., a man of 40, in whom an initial lesion occurred in 1888. He had syphilitic ophthalmia early in 1896, first recognized while under the care of Dr. J. E. Weeks. In September, 1896, he came to me complaining of difficult micturition, impotence, lightning pains, band sensation indicative of locomotor ataxia. This diagnosis was confirmed some months later by Dr. M. A. Starr, and the antiluetic treatment continued, with ataxic symptoms in *statu quo* up to October 6, 1900, when he came to my office complaining of pain in the abdomen and

\*Read before the Surgical Section, New York Academy of Medicine, December 8, 1902.

irregularity of the bowels for the past 10 days. He had always feared appendicitis, and would admit of no other symptoms. Examination showed a large, tympanitic mass, bulging upward toward the umbilicus and downward toward the true pelvis. Through the rectum a mass could be felt, lessening its caliber, and on bimanual palpation was apparently continuous with that above the pelvic brim.

Operation was performed the same evening; a McBurney incision was made; colon was found displaced upward against the anterior abdominal wall; there were no adhesions of the intestines. As the finger was lifting up the caput coli, it broke into a sac containing 10 or 12 ounces of a clear, yellow-tinted fluid, in which floated a considerable number of white flocculi, such as we see in tuberculous or gummatous collections. There was no perceptible odor. The cavity was located behind the pelvic peritoneum, having burrowed its way between that membrane and the rectum. The appendix was not found. Sterile gauze strips were inserted in the opening, under the caput coli, and in the wound. On the third day the abdomen was considerably distended, the bowels had not moved, and owing to his unusually bad appearance, Dr. Morris was asked to see him the next morning. Under massage and laxatives the bowels moved freely during the night, and when seen the next morning his condition was looked upon as favorable, Dr. Morris saying that reaction was about to take place. On removing the gauze it was noted that there was no evidence of any reparative action in the wound, which presented a very unusual, pale, cadaveric appearance. During the following week the patient was unable to retain any nourishment, either by the stomach or bowel, nor could the latter be controlled, so that the potassium iodid administered during the few days previous failed to have any effect, and he died from exhaustion on the tenth day after operation. From the clearness of the fluid in the pelvis, the absence of odor, the presence of flocculi, and the indisputable history of syphilitic ataxia, the nonhealing of the wound, and the absence of any adhesions in the abdominal and pelvic cavities, we feel justified in charging his death to lues.

It has been my fortune to have operated on quite a number of patients in whom the appendix was found lying behind the cecum, with an accumulation of pus and exudate around and under the caput coli, but in only the above mentioned instances have the abscesses been located in the pelvis behind the peritoneum. This variety of appendicular disease (retrocecal) has been characterized by the usual acute onset, with nausea, vomiting, malaise, general abdominal pain, which later becomes localized in the right iliac fossa (in Case II most severe on the left side), unequal abdominal rigidity, constipation, and moderate elevation of the temperature and pulse. After the bowels have been freely evacuated the man may go about his business, or the child attend school, not feeling ill enough to go to bed until the increasing size of the abscess with increasing fever and exacerbations of pain forces them to go to bed and to secure professional aid. At this late date it is not a difficult matter to recognize the tumefaction in the right iliac fossa, but one must not be misled by the fact that on percussion a tympanitic note can be elicited; and on examination per vaginam or rectum, the pelvic abscess, when present, can be easily made out. Further, the temperature may reach 102° to 103° F., with a pulse-rate of from 100 to 130, and the drawn, septic appearance of the face will remove any doubt as to the necessity of operation without further delay. Cases I and II were evidently due to colon bacilli, as evidenced by the characteristic odor.

**Decrease in Cuban Deathrate.**—A recent communication to the State Department by Mr. Squires, United States Minister to Cuba, states that since January 1, 1899, the beginning of the American occupation of the island, there has been a continued decrease in the deathrate and that the rate 21.19 per 1,000 for the year just ended is the lowest in the history of the island between 1870 and the present time. The highest deathrate was 91.03 per 1,000; this occurred in 1898, the year of the Spanish war, when the reconcentration camps were in operation and many people starved. The lowest rate under Spanish rule was 29.30 per 1,000 in 1885 and the average rate for the 30 years ending 1900 was 41.95 per 1,000. It is believed that if the present good sanitary conditions prevail the low rate will be maintained.

## FRACTURE OF THE ISCHIO-PUBIC RAMUS AND RUPTURE OF THE BLADDER: RECOVERY AFTER OPERATION.<sup>1</sup>

BY

LINDSAY PETERS, M.D.,  
of Columbia, S. C.

In a series of 90 cases of fracture of the pelvis with rupture of the bladder collected from the literature by Mitchell,<sup>2</sup> in 1898, a mortality of 83.3% was found. If it were possible also to take into consideration unreported cases, the actual mortality would undoubtedly prove to be even greater. On account of the rarity of the injury, therefore, together with the high mortality attending it, the following case is of interest:

The patient was a negro laborer of 16, single. His family history was negative. For several years he had had a urethral discharge, burning micturition, and at times difficulty in voiding urine.

His injury occurred in this manner: While standing between a freight car and a grain elevator an engine came up unawares and moved the car, rolling him between the car and the elevator.

I first saw the patient about half an hour after he was hurt. He was lying on his back in a shed at the oil mills in which he was employed. The examination made at that time revealed no evidence of very serious injury. The mental condition was good and there was apparently not very great suffering. Quite extensive, though superficial, abrasions of the skin were seen over the outer side of the right hip, and pressure or movement of the right lower extremity caused severe pain in the region of the right hip and throughout the pelvis and lower abdomen. The pulse was 88 per minute and of good quality. In order to investigate as to possible injury of the urinary organs, I requested the patient to void his urine, but on attempting to do so he found it impossible to expel even a drop. He was then taken to his home, where I saw him half an hour later; he then seemed comparatively comfortable, but was still unable to pass any urine. The history of gonorrhoea and dysuria gave grounds for suspicion of stricture of the urethra as a possible cause for the difficulty in emptying the bladder. I left instructions to make every effort to get a specimen of urine, using cold water over the loins and region of the bladder. The attempts at micturition were all of no avail until I returned to see the patient again eight hours after the injury, whereupon a sterilized rubber catheter was passed into the bladder without meeting any obstruction and two ounces of bloody urine were drawn off. The abdomen now, besides being very tender, was slightly distended and tympanitic. The temperature was 99° F. and the pulse had risen from 88 to 104 per minute. The diagnosis of rupture of the bladder was thus made, and I advised immediate operation, to which consent was given. The patient was taken to the Taylor-Lane Hospital, arriving there at 10.30 p.m., November 24, 1902.

**Operation.**—After thoroughly cleansing the abdomen, the operation was begun at 11 p.m. (10½ hours after injury), under chloroform anesthesia, Drs. Coward, Guerry, and Owens assisting.

A median incision about 8 cm. long was made just above the symphysis pubis. Having cut through the aponeuroses between the recti muscles, the peritoneum immediately came into view, the subperitoneal fat being very scanty. The peritoneum was of a dark, port-wine color, intensely congested and thickened. On snipping the peritoneum a considerable quantity of bloodstained fluid escaped, which was taken to be urine, although no odor was detected. The finger was then introduced through the incision, and the underlying intestines were found to be tightly matted together by fresh adhesions. On passing the finger deeply into the pelvis for exploration a fracture of the right ischiopubic ramus was detected, the posterior fragment of the bone being somewhat depressed and presenting a sharp, jagged edge.

Bloodstained fluid continued to escape throughout the examination. A sterilized rubber catheter was now passed into the bladder per urethram, and sterilized normal salt solution allowed to flow into it from a fountain syringe. The fluid injected into the bladder flowed out of the abdominal wound, and after a long search the rent in the bladder through which the fluid escaped was found deep down behind the symphysis pubis, in the anterior wall of the bladder, just above the vesical neck. The opening was just large enough to admit the index finger, and being so remote from the abdominal wound, its closure was a problem fraught with difficulties, which were increased by poor illumination (two kerosene lamps furnishing the light) and the frequent obscuring of the cavity by fluid welling up from the bladder. Under the guidance of touch the sides of the rent were caught with forceps and dragged upward, but the friable tissues tore away and the opening had to be sought for again with the aid of the injection of salt solution

<sup>1</sup> Read before the Columbia, S. C., Medical Society, February 2, 1903.

<sup>2</sup> Mitchell, Johns Hopkins Hospital Bulletin, Vol. ix, p. 5.

into the bladder. After locating the tear the second time, its upper angle was caught with artery forceps and, having dried out the cavity, the injured portion of the bladder was displaced backward (as it could not be drawn upward) in order to gain the best exposure possible. In the first attempt to suture the opening under the guidance of touch a curved needle was broken off and could not be found again. I finally succeeded in bringing the edges of the tear together by a continuous suture of fine silk. To test the closure, salt solution was again injected into the bladder, and it was seen that the bladder wound still allowed the escape of fluid, but much less freely than formerly. It being found impossible to make an accurate closure of the bladder wound owing to its inaccessibility, the cavity was dried out finally and filled with an abundant gauze drain passing from the lower angle of the abdominal wound down to the rent in the bladder. The upper half of the abdominal wound was closed with silk wormgut sutures, an abundant gauze dressing put on, and the abdominal bandage applied. A rubber catheter was introduced just beyond the posterior urethral orifice and retained in place for drainage by means of adhesive strips carried up the sides of the penis. The patient was on the operating table about two hours in all. After being put to bed his pulse was 88 per minute.

He was attended throughout convalescence by Dr. J. H. McIntosh, and the following notes are taken from the charts and records kept under his direction: Immediately following operation the patient passed a fairly comfortable night, but there was a gradual rise in pulse, temperature, and respiration, reaching 100, 100°, and 48, respectively, by 9 a.m. the following morning, when the wound was dressed. The dressings were saturated with slightly bloody urine and only one ounce of urine had drained through the catheter. The abdomen was considerably distended, tympanitic, and somewhat tender. During the day the distention became more marked and the respirations more rapid *pari passu*. By 1 p.m. the distention caused considerable discomfort, and the respirations reached 54 per minute. Calomel was administered by mouth, and at 7 p.m. a rectal enema, of water one quart and alum one ounce, was given. This was followed by a large, formed bowel movement with a great deal of flatus, which afforded great relief, and the respirations fell soon afterward to 32 per minute, and by the following morning to 24 per minute. Some distention still remaining, however, the enema was repeated, and was expelled with a great quantity of gas. The tympanites then rapidly disappeared and the respirations fell to 22 per minute.

There were no other complications of the convalescence, except that on the fifth day the patient pulled the catheter out of the urethra, and this was followed by a transient rise of temperature to 102° on the next day and increased leakage of urine from the abdominal wound. A few days later, however, small quantities of urine were voided through the urethra, and from now on the amount of urine escaping from the abdominal wound gradually diminished, while that passed from the urethra increased.

The abdominal dressings were changed as often as required by the leakage of urine (once to three times daily for the first two months). The iodoform gauze drain was pulled out and cut off a little at a time from day to day, beginning about the seventh day, until it was entirely removed; thereafter a fresh drain was loosely placed in the wound down to the bladder daily.

The patient was discharged from the hospital in robust health on the seventy-sixth day after entrance. There then remained only a pinpoint sinus in the scar of the abdominal wound, from which a few drops of urine occasionally escaped. I have learned from Dr. McIntosh that the sinus has closed entirely and that there has been no leakage from the bladder since two weeks after discharge from the hospital. The fractured pubic ramus gave no trouble other than a little lameness for the first few days after the patient began to walk.

I have been unable to find in the *Index Medicus* of the *Journal of the American Medical Association* or in the indices of other medical journals any other cases of fracture of the pelvis with rupture of the bladder reported since Mitchell's publication.

## ANOMALIES OF RESPIRATION IN HIGH ALTITUDES.

BY

W. A. BRIGGS, M.D.,

of Sacramento, Cal.

During the month of August, 1902, which I spent in mountain-climbing in and about Glen Alpine at altitudes ranging between 6,500 and 10,000 feet, I made some observations regarding respiration in high altitudes that to me were new and interesting, and in one instance even startling. Whether the cases I am about to report are exceptional, or even pathologic, my observations are not numerous enough to determine. I

observed in general what, on reflection, one would naturally expect, that on account of the greatly diminished atmospheric pressure nasal obstruction develops in high altitudes from slighter causes than at sea-level, and that, even in the absence of nasal obstruction, sighing respiration is of extremely frequent occurrence.

CASE I was that of myself. It was observed very imperfectly because of the fact that the characteristic phenomena fully developed during sleep only. Lying down on the mountain-side after a morning climb I would often drop into a doze, and then in a few moments awake with precordial distress and labored breathing. In a moment this distress would cease and the breathing become superficial, when I would again doze off, to awake again with dyspnea, and so on indefinitely. When awake I breathed regularly, except for the occasional sigh, of which I have already spoken. On exertion even at an altitude of 10,000 feet I was not unduly dyspneic.

CASE II.—Mrs. —, who had a slight "cold," complained severely of nasal obstruction, particularly when recumbent, and of frequent sighing. During sleep the respiratory cycle consisted of 6 or 8 equal respirations, followed by a deep sigh and a prolonged interval of 4 or 5 seconds.

CASE III.—Mrs. —, who was in perfect health and free from unusual dyspnea on exertion, has had for 30 years, and still has, double second cardiac sound, invariable and entirely unaccompanied by symptoms. During sleep the respiratory cycle consisted of two increasing, one maximal and two diminishing respiratory movements occupying 12 seconds, and followed by apnea of 8 seconds. The maximal inspiration was accompanied by jerking of the arms, seemingly due to overflow of the respiratory impulse. The heart's action was normal at all times. During waking hours respiration was also normal, with the exception of the sighing previously spoken of, but which in this case was not more marked than in others. Gradually this respiration-cycle became less marked, but it was distinct and invariably present during sleep for two weeks from its first discovery and until the patient returned to sea-level, when it disappeared at once.

The cause, at least the exciting cause, of these anomalies of respiration would seem to be dependent on high altitude, whether, in the extreme types, engrafted on some pathologic condition, I am in doubt. The genetic chain would seem to me as follows: diminished supply of oxygen under diminished pressure; oxygen hunger; increased activity of the respiratory apparatus; exhaustion of the respiratory muscles and the respiratory center; irregular respiratory impulse. In some cases obstruction of the air passages, due to diminished atmospheric pressure, and dilation of the right heart, due to increased resistance in the pulmonary circulation, may be contributory.

## A RAPID METHOD FOR HARDENING AND EMBEDDING TISSUES.<sup>1</sup>

BY

B. MEADE BOLTON, M.D.,

of St. Louis, Mo.,

AND

D. L. HARRIS, M.D.,

of St. Louis, Mo.

A simple method for hardening and embedding tissues for microscopic examination which we have recently devised has given such satisfactory results that we feel justified in recommending it, particularly in those cases in which an early diagnosis is desired; for since the necessity for preliminary hardening and dehydration is done away with, the time is much shorter than that usually required for the purpose. Notwithstanding its simplicity and the short time required, the sections obtained by this method are not inferior, so far as we can determine, to those obtainable by the slower and more complicated methods now in common use.

The method consists essentially in placing the fresh tissues in a hot 2% solution of agar-agar, to which 10% of formalin has been added. The temperature of this fluid should be kept at about 70° C. After remaining in the solution for from one to several hours the tissues are

<sup>1</sup> From the Laboratory of Pathology of the Marion Sims-Beaumont College of Medicine, St. Louis, Mo., Medical Department of the St. Louis University.

removed and attached to blocks with a 5% solution of agar-agar containing 10% of formalin. The heat and the formalin harden and fix the tissues at the same time that the agar-agar impregnates it. After fixing the tissues to blocks these are placed in 95% alcohol and allowed to remain from two to four hours, and the tissues are then ready to be cut into sections, which can then be stained, cleared and mounted on slides in the usual way employed for celloidin sections.

We have found that fresh material placed in the melted agar-agar for one hour and then transferred to alcohol for two hours was readily cut at 14 $\mu$ . The liver and the kidney of a rabbit were cut at this thickness even after an impregnation of only one-half hour followed by one hour in the alcohol, though the sections obtained by shortening the process to this extent, it is true, were fragile and resembled somewhat those obtained by making sections from frozen tissues.

The 2% agar-agar solution should be filtered to avoid the granular detritus which is otherwise found in the sections. The 5% agar-agar can be cleared by sedimentation in a steam sterilizer, where it is allowed to cool slowly. The agar-agar solutions may be made up in bulk and preserved in air-tight vessels to prevent evaporation. The formalin is added at the time of the original preparation in the proportion of one part of formalin to nine of the agar-agar solution.

As is evident from the description, the process consists in substituting an agar-agar solution containing formalin for celloidin. The advantage over the celloidin method being that the aqueous solution of agar-agar at once penetrates the tissue, making preliminary dehydration unnecessary.

2. The New United States Pharmacopoeia. JOSEPH P. REMINGTON.
3. Case of Funnel Pelvis with Cesarean Section. CHARLES B. REED.
4. Theories of the Transmission of Hereditary Syphilis. ALFRED SCHALEK.
5. The Treatment of Leprosy. A. H. OHMANN-DUMESNIL.
6. Anatomic and Physiologic Correspondences of Child and Adult. W. T. ECKLEY.

**1.—Mixed Infections in Pulmonary Tuberculosis.**—Practitioners who differentiate conditions among their tuberculous patients with a view to selecting appropriate remedies and nutrition are still in the minority. P. Paquin illustrates his paper with 13 colored cuts showing different forms of complicating bacterial invasion requiring different treatment. He also shows the various kinds of debris found. A consideration of the lymphatic system in the lungs demonstrates how important nebular intrapulmonary medication is in all cases in which the lymphatics must be reached. The circulatory system explains the success of internal and hypodermic medication. It is not good practice to apply 40 or 80 pounds of pressure to tuberculous throats, thus causing hyperemia, nor to seriously inflamed bronchi, and sometimes there is danger of rupturing the air cells. Nebulæ will not penetrate consolidated areas, which, while not receiving blood freely do absorb its essentials from neighboring sources. Proper nourishment and air are the first indications. Special complications demand special measures of relief. The juice of 4 to 6 pounds of steak daily between meals acts as nourishment and medicine both. [H.M.]

**2.—The New Pharmacopoeia.**—J. P. Remington gives an outline of the organization of the committee and their present method of working by correspondence, of the assistance afforded by the "Digests of Criticism," which are compilations of criticism and suggestion from pharmaceutical journals throughout the world. The idea of an international pharmacopoeia has proved impracticable, but all civilized nations should agree on a uniform strength for "potent remedies."

The new pharmacopoeia will not please every one, but will be abreast of the times. [H.M.]

**3.—Funnel Pelvis.**—C. B. Reed reports a case successfully operated on, and reviews the subject generally. Prognosis in general is not favorable, but the result depends on the degree and variety of contraction and especially on the operation. [H.M.]

**4.—Transmission of Hereditary Syphilis.**—A. Schalek concludes from a study of the evidence that the father's sperm-cell may contain the syphilitic virus and convey it to the child without participation of the mother; the maternal generative cell may contain the virus and result directly in a diseased fetus; the placental circulation permits the passage of the infectious matter either way. Several or all of these factors may combine, and the more of them are present the less probable the escape of the child; the probabilities of transmission through the mother are greater because of more ways of possible influence. [H.M.]

### Medical Record.

May 16, 1903. [Vol. 63, No. 20.]

1. Uremia and Its Treatment. W. H. THOMSON.
2. A Study of the Rectum, with Reference to the Causative Factors of Obstruction (with Demonstrations). LOUIS J. HIRSCHMAN.
3. Is the Gallbladder as Useless as It is Dangerous? WOODS HUTCHINSON.
4. Ocular Symptomatology in Diagnosis. HENRY B. HOLLEN.

**1.—Uremia and Its Treatment.**—W. H. Thomson reports a fatal case of suppression of urine, without any uremic symptoms, due probably to calculus, and concludes that the poisons generated must have been different from those of uremia. In the latter disease the poison acts like suprarenal extract, as a vasoconstrictor. He considers aconite the ideal vasodilator, and ascribes the arteriocardillary sclerosis of long standing kidney disease to high tension. The resulting obliteration further increases tension. When obliteration is widespread we cannot expect much from vasodilators, and in senile heart aconite must be given with discrimination. In puerperal eclampsia the speediest dilator is venesection, and next large doses of veratrum viride. He does not incline to the view that eclampsia is caused by deficient thyroid secretion, since similar conditions occur in acute alcoholism in men. Degeneration of visceral cells is not due to a special toxin, but to the arterial ischemia. There are some cases of deficient urea elimination in which Thomson would not prescribe aconite. Many of these are dependent on gastrointestinal, not organic kidney disease. In scarlatinal nephritis he gives calomel daily till the tongue desquamates. The danger signal here is not the appearance of albumin, but deficient quantity of urine and low specific gravity. In threatening suppression a normal saline rectal douche of two gallons, at 115° F., is most certain in its results. Uremic convulsions may be the first announcement of chronic Bright's disease, the sudden change being due to invasion of the kidneys by bacteria. Mercurial cathartics and urotropin with sodium benzoate .65 gm. (10 grains) each, should be given. Patients with cirrhosis should not eat heartily after midday. The best remedy for autoinfection is outdoor life. Increasing the arterial supply of the kidney by operation seems rational

treatment. Change from liquid to solid diet acts well in some cases of dropsy. [H.M.]

**2.—A Study of the Rectum: Obstipation.**—L. J. Hirschman insists that too little is known about the rectum, its diseases, and the reflex symptoms which they may cause. Numerous diseases, referred symptomatically to the genital tract, the digestive tract, and other remote parts of the body, are due largely to a pathologic condition in the rectum. Sciatic pain, incontinence or retention of urine, herpes, and nasal symptoms may arise from lesions in this situation. Obstipation is some mechanical obstruction preventing or limiting the normal fecal discharge. It may be an enlarged prostate, retroverted uterus or prolapsed ovary, etc., but it is most commonly due to enlargement and hypertrophy of one or more of the rectal valves. A thorough rectal examination with the proper instruments should be insisted upon in any case of suspected rectal trouble. The technic of rectal examination is given. Obstipation may be responsible for symptoms of intestinal indigestion, gaseous disturbances, palpitation, sciatica, acne, furunculosis, and other spinal affections and numerous reflex disturbances. The enlarged and hypertrophied rectal valve should be operated upon when it is the cause of obstipation, as it frequently is. Having exposed the valve with the speculum make a V-shaped cut with scissors from its free border to the base, then grasp and crush the free-cut edges with the author's valvotribe. Pack the rectum with iodoform gauze, with a rubber tube in the center, and keep the patient in bed for from three to seven days. [A.B.C.]

**3.—The Gallbladder Useless and Dangerous.**—Wood Hutchinson deals at some length upon the comparative anatomy of the gallbladder and gives a summary of his findings and conclusions from the viewpoint of the internist. They are as follows: The gallbladder is a nearly functionless organ, inadequate in size to act as a reservoir of any value for the bile, inadequate in muscular power and in mechanical position to exercise any important effect upon the pressure of the bile flow, entirely absent in many species without interfering with the processes of digestion or the vital functions in any way, capable of removal from a species in which it is normally present without noticeable injury, and chiefly notable as a settling basin for the formation of gallstones, a suitable harbor for the multiplication of pathogenic bacteria, or for the assumption of pathogenic properties by nonpathogenic forms. In short, it seems a source of danger at least double any possible usefulness which it may possess. He believes the bile itself is not so necessary to digestion as has been supposed by physiologists, and that it is for the most part an excretion. [A.B.C.]

**4.—Ocular Symptomatology in Diagnosis.**—H. B. Hollen thinks disregard of the eye as unpardonable as failure to feel the pulse, as ocular disturbances are often the first manifestation of important lesions. He deplors unfamiliarity with the ophthalmoscope. He points out the value of ophthalmoscopic findings, and of attention to subjective ocular symptoms, as well as to conditions noted in unaided inspection of the eye and its appendages. [H.M.]

6. Astigmatism Cured by Corneal Trauma. PERCY FRIDENBERG.

1, 2, 3.—See *American Medicine*, Vol. V, No. 19.

**4.—Pulsating Emyema Necessitatis.**—A detailed account of a case seen over 22 years ago is given by J. P. Henry. Meager notes were then published in a volume of society transactions not accessible to the general reader. The patient was a woman of 30. On the left side of her chest were three strongly pulsating tumors; one in the mammary region the size of half a large orange; a second, much smaller and of conical shape, in the left anterolateral region, *i. e.*, in the eighth intercostal space

in a line with the anterior axillary border, and a third, the largest of the three, in the left posteroinferior region, its longest diameter, about four inches, corresponding with that of the vertebral column. The large anterior tumor contained air and fluid. The patient was operated on and was known to be alive and well one year thereafter. The subsequent history is unknown. Henry adds references of 15 additional cases of pulsating pleurisy to the 68 tabulated by J. C. Wilson in 1893. [C.A.O.]

**5.—A case of epidural abscess of otitic origin** is reported by J. Guttman. The patient, a girl of 15, was taken with influenza, and this was followed by an acute purulent inflammation of the middle-ear. Later cerebral complications became evident, and upon opening the antrum a stream of pus came out. A fistula was found leading from the antrum downward and backward to an epidural abscess. About two ounces of pus were removed, it was under high pressure and was pulsating. The dura was covered with a thick, villous, fatty, grayish-colored granulation tissue, which was removed with a sharp spoon. The wound was packed and recovery followed. [C.A.O.]

**6.—Astigmatism Cured by Corneal Trauma.**—The case reported by P. Fridenberg is that of a physician who was struck in the eye with a piece of wood. The detailed ophthalmologic conditions before and after the injury are stated. He considers the mechanism of the cure to be exactly that which produces astigmatism after cataract extraction, *viz.*, the flattening of the corneal curve from scar contraction. As the corneal section is usually upward or downward the vertical meridian is affected, becomes flattened, requires a convex cylinder, axis horizontal, to increase its refraction; we have astigmatism against the rule. This decreases within the first month or two after operation, by which time an irreducible minimum is found, the amount of which depends upon the extent, position, and manner of healing of the corneal section. In the case reported there was no actual section, merely a superficial—although extensive—incision of the cornea. The astigmatism was correspondingly slight and by a most peculiar chance just sufficient to neutralize a preexisting inequality of curvature. [C.A.O.]

1. Fracture at the Base of the Skull: Neurologic and Medicolegal Considerations. PEARCE BAILEY.
2. Notes on Blood-pressure in Man. S. S. GOLDWATER.
3. Some Recent Advances in Medical Therapeutics. THOMAS E. SATERTHWAITHE.

**1.—Fracture at the Base of the Skull: Neurologic and Medicolegal Aspects.**—Pearce Bailey reports 68 cases of fracture at the base, which, with those of Heer, Van Nes, and Phelps, comprise an aggregate of 494. The mortality in this series was 57%. According to statistics given 62% of the deaths occurred during the first 24 hours, and 95% during the first five days. Alcoholism profoundly affects the immediate and ultimate prognosis. The writer has been able to follow 15 of the 29 cases which recovered in his series of 68; and from these he believes the probability of mental impairment following fracture at the base of the skull is very small indeed. From certain figures given he estimates that at least 150 persons are discharged annually in New York City as cured of fracture at the base. The exceedingly small number of patients appearing at the asylums with the above history further strengthens his conclusions based upon his own cases. He says it would seem, therefore, that fracture at the base is an entirely unimportant cause of mental states which make commitment necessary or which render the patients incapable of earning their livelihoods. From this condition it is not proposed to generalize too freely. Fractures at the base can hardly be compared to those of the vault with the direct involvement of the cortex in the latter. But it seems justifiable to apply such conclusions as we have arrived at in regard to the ultimate results of fracture at the base to the ultimate results from simple concussions of the brain. [A.B.C.]

4. Gastric Carcinoma Associated with Hyperchlorhydria and with Attacks of Stupor. NORMAN B. GWYN.
5. Foreign Bodies in the Bladder. SWITHIN CHANDLER.

1.—**Tumors of the Breast.**—Jonathan Hutchinson, Jr., first briefly refers to Paget's eczema, which, in certain cases, is a precursor of malignant tumor. The supposed parasites in Paget's eczema are only the results of epithelial degeneration. As regards treatment, supposing the nipple is affected, excision of the breast is the safest procedure, since experience with all kinds of caustics and local applications has been disappointing. If it is necessary to excise the nipple and surrounding skin, obviously the patient is better without the breast, which can be of no use and which may become cancerous. Of the cysts in the breast 80% are retention cysts; they are of especial interest because of the frequency with which they are mistaken for carcinoma; their contents are almost invariably of a milky nature and a majority of the cases are cured by a single tapping. Before excising a breast, the surgeon should first cut into the substance of any suspected cancer, to make sure of the diagnosis. The knife that has entered the tumor should be at once laid aside, the edges of the incision clamped together with volsella forceps, then there can be no real risk of infecting the surrounding tissue with cancer cells. There is no evidence that carcinoma especially selects the breasts that are the seat of multiple cysts, and, unless the patient is very anxious about her condition, it is best to leave them alone. Cystic sarcomas are too frequently diagnosed as abscesses. He has done 100 complete removals of the breast in the London Hospital for Malignant Disease, with a mortality of 4%. In making a diagnosis of carcinoma of the breast, cachexia is the least reliable sign; the most important sign apart from the stony hardness of the tumor is the adherence to the skin in the early stages, and this should be most carefully looked for. Retraction of the nipple is not a very constant feature, and, therefore, not a safe one to rely upon in making a diagnosis. The glands just under the pectoral muscle and against the side of the chest are those earliest involved. In order to obtain primary union wherever possible, do not carry the incision through the middle of the axilla, but upon the pectoralis major. Avoid drainage-tubes. Never tie the arm to the chest, but always bandage with the arm away from the side. This is to avoid subsequent stiffness. Dissect out the glands that are adherent to the axillary vein, do not cut the vein. Always clean out the axilla. With regard to the value of oophorectomy in the treatment of cancer, the evidence is that in a few cases it retards the growth, and that is about the best that can be said for it. There is no safe "time limit" of cure. The more experience one has with recurrences, the more one is encouraged to operate. Even when the deposits recur in what would apparently seem a most hopeless form with multiple nodules scattered round about the scar, one occasionally gets a cure from persisting excisions. [F.C.H.]

2.—**Femoral Thrombosis in Acute Croupous Pneumonia.**—D. M. Miller reviews the literature of femoral thrombosis in acute croupous pneumonia and details the history of a case, which is the first he has seen in a hospital experience of 18 years. A possible explanation of the infrequency of thrombosis in pneumonia is the short duration of that disease. Much evidence has been accumulated to show that the thromboses of the acute infectious diseases as well as other thromboses are due to bacteria or their toxins; in the case herein reported cultures taken from a branch of the internal saphenous vein near the ankle on the third day remained sterile. [F.C.H.]

3.—**Tetanus.**—G. W. Norris details a study of 57 cases of tetanus from the records of the Pennsylvania Hospital, Philadelphia. The patients were admitted to the hospital between January, 1874, and 1903. Curiously there was an absence of tetanus cases between the years 1886 and 1893, for which there hardly appears any explanation. Of the 57 patients 48 died, rendering a general mortality of 84.2%. This includes all

varieties of cases under different modes of therapeutics. Death, while more common in the first four days after the onset of symptoms, occurred with almost equal frequency up to the eleventh day, which is contradictory to Yandell's statement, that if a patient lives five days there is good hope for recovery. The belief that the longer the period of incubation the better would be the chance of recovery has not been corroborated by this series of cases. Of 13 cases, with a urinary specific gravity above 1,026, 77% died. The first symptoms of the disease were usually pain and stiffness in the back of the neck. Fever was present in all cases. In 11 patients death occurred during convulsions, in 12 instances from asthenia without convulsions; 7 of the patients were treated by the Bacelli method, with a mortality of 85%; hence in this series it has proved valueless. He concludes as follow: Tetanus toxin is found mainly in the nervous tissues; that once united with these antitoxin is powerless in its action on already affected cells; that antitoxin is harmless but deteriorates rapidly, therefore it should be procured freshly and administered in continuous and large doses with the hope of immunizing the intact nerve cells; that all cases of wounds in which there is a possibility of tetanic infection should receive prophylactic injections of antitoxin; local treatment is of great importance, hence the infected area should be excised. When this is impossible extensive disinfection, preferably with carbolic acid, should be carried out; furthermore, that as Behring has shown, antitoxin is of benefit locally as well as systemically; every effort should be made to maintain the nutrition of the patient, for Castronuovo has demonstrated that antitoxin is of no value in tetanic animals which have been starved. [F.C.H.]

4.—**Gastric Carcinoma.**—N. B. Gwyn details a case of gastric carcinoma associated with hyperchlorhydria and with attacks of stupor. The origin of the stupor was obscure. Death eventually occurred, and a partial autopsy was obtained; 5 cm. from the pylorus, in the anterior wall of the stomach, there was a mass the size of a goose egg. The tissue removed showed the tumor to be a typical adenocarcinoma. [F.C.H.]

5.—**Foreign Bodies in the Bladder.**—S. Chandler details the history of two cases. One was a man of 58, who inserted a combination glass penholder in the urethra in order to practice masturbation; the penholder slipped into the bladder, and necessitated an anesthetic for its removal. The other was the case of a girl of 18, who at one time suffered from cystitis, and was taught how to catheterize herself. By placing the glass catheter part way into the meatus she managed to practice masturbation. The portion of the instrument in the urethra on one occasion was broken and slipped into the bladder, giving rise to a cystitis. She concealed the true cause of the condition for seven months, when she sought medical attention. The uterus was thought to be the cause of the uncontrollable cystitis. Upon exploring the bladder, however, the broken catheter was found. [F.C.H.]

## CLINICAL MEDICINE

DAVID RIESMAN

A. O. J. KELLY

## REVIEW OF LITERATURE

**The Clinical Value of Urinary Signs in Hepatic Insufficiency.**—L. Ingelrans and M. Dehon<sup>1</sup> contribute the results of a research into the value of certain urinary signs commonly considered to be of value as indicating hepatic insufficiency. The following were investigated: Alimentary glycosuria, hypoazoturia, hyperammoniuria, urobilinuria, and indicanuria. Sixteen patients having various hepatic lesions and three healthy persons formed the basis of the investigations. The principal conclusions reached are: (1) Alimentary glycosuria is frequently absent in diseases of the liver, even when the parenchyma of the organ is markedly altered. Its absence then simply proves that the glycogenic function of the liver is still retained; (2) hypoazoturia is nearly constant when the liver is anatomicly altered; (3) while it is possible that hypoazoturia and fluctuations in the azoturic ratio may not be sufficient grounds on which to affirm hepatic insufficiency, these two signs are of great value in calling the attention of the clin-

<sup>1</sup> Arch. de Med. Exper. et d'Anat. Path., March, 1903.

icjan to the state of the liver; (4) indicanuria is a sign of secondary importance; (5) urobilinuria appears to be a sign of cholemia and not of hepatic insufficiency; (6) the signs of hepatic insufficiency are not constantly united in any one patient. The functions of the liver are readily dissociated, and one may be at fault while the others remain in good condition. [A.G.E.]

**Infantile Scurvy.**—H. S. Beadles<sup>1</sup> reports the case of a child 22 months old. The patient was anemic, with quickened pulse and respiration, furred tongue, and a history of constipation. The gums were swollen, spongy, and purple in color. There was beading of the ribs, enlargement of the ends of the radius, ulna, tibia, and fibula, and the anterior fontanel was open. The left thigh was more than twice the size of the right, tender to the touch, and the skin tight and brawny. The left shoulder was swollen and the muscles were flabby. Syphilis was excluded. The child had been nursed until 10 months of age, since which time it had been fed on a predigested food. This food was stopped, and the child was given plain, unboiled cow's milk, slightly diluted with barley water. Raw meat juice, beef tea, yolk of egg, juice of one orange daily, some green vegetables boiled until soft and passed through a sieve and mixed with cream, were all given. Dialyzed iron, citric acid, and glycerin were administered. The child at once began to improve, and within three weeks had recovered. The author is of the opinion that the case was one of undoubted infantile scurvy. [A.B.C.]

**True Hermaphroditism.**—Garré<sup>2</sup> operated on an individual 20 years of age who was anxious to know the sex he belonged to. He had been raised as a boy, but of late had developed characteristics belonging to both sexes. His breasts were large, and he had a regular menstrual flow; his sexual thoughts connected themselves with the female sex, and were associated with a white mucoid discharge. Externally, also, he presented characteristics of both sexes. At the operation an apparently useless tube and ovary were removed, as well as portions of what seemed to be testicle and epididymis. Microscopic examination confirmed this diagnosis. According to Garré, this is the first case where in the living subject both ovarian and testicular structure, the latter in an aspermatogenic state, were positively recognized. [E.L.]

**The Medical Treatment of Tuberculous Peritonitis in Children.**—L. Guthrie<sup>3</sup> says that in discussing this subject he is hampered by the prevalent notion that surgeons alone are able to cure this disease. His own experience leads him to think that the prognosis in uncomplicated cases of tuberculous peritonitis in children is by no means so grave as we are taught to believe and that the triumphs of surgery in curing this disease have been overrated. Of 41 patients treated at the Paddington Green Children's Hospital, 14 underwent laparotomy and 7 died, while of the remaining 27 treated medically only 4 died. Guthrie states that medicinal treatment is almost entirely symptomatic, the chief symptoms calling for treatment being pain and abdominal tenderness, flatulency and indigestion, diarrhea or constipation, vomiting and ascites. In most of the medical cases cited mercury was given, either by inunction or internally. In acute cases it is inadvisable to remove ascitic fluid unless it produces great distention and distress. In more chronic cases it should be withdrawn. In these cases there is no mystery in the results of simple laparotomy, that procedure being useful only because it lets out fluid. In dry cases, also supposed to be cured by operation, the patients would recover equally well if let alone. Surgical interference is necessary in cases of obstruction, suppuration, and perforation. Caseous mesenteric lymph-nodes should be removed. It will be observed in all of these cases something more is necessary than merely opening the abdomen and looking inside. [A.G.E.]

**Myogen, a New Albumen Preparation.**—Myogen is a purely animal albumen, prepared from the blood-serum of freshly killed cattle, in such a manner that the molecule of albumen cannot change in the least. R. O. Neumann<sup>4</sup> has investigated its properties and reports as follows: Both the

powder and the cakes are well assimilated, the organism being able to absorb as large quantities of it as of meat; it has, however, not quite the same nutritional value as fresh meat. The cakes are probably preferable to the powder, as they are of more agreeable taste, and are more concentrated, containing 20% of albumen, 50% carbohydrate, 10% fat. [E.L.]

**Experimental and Clinical Investigations with Saline Infusions.**—W. Ercklentz<sup>1</sup> gives a detailed review of the literature on the use of saline infusions in acute anemia, intoxications, and infections. The value of the infusion in the two latter classes is due to the production of a profuse diuresis. A 0.6% solution is not the harmless agent it was formerly believed to be, as bad results have been produced by its use, both experimentally and clinically. Investigations have shown that a 0.9% to 0.92% solution is more desirable. The author gives the results of original investigations as to the value of saline infusions in cases of poisoning by various drugs. His experiments in animals show that it is possible, through increased diuresis, to wash out the poison to a considerable extent. A poison such as cantharides, however, which exerts a deleterious action on the kidneys, will diminish urinary excretion, and thus counteract the saline infusion. Likewise with a poison such as strychnin, which acts so quickly and energetically on the vital centers, the infusion will come too late. The possibility of washing out the poison also depends, to great extent, on the strength or weakness of the combination which exists between it and the bodily tissues. The author has found saline infusions to be of value also in cases of infection, in uremic conditions, and in severe anemias of apparently toxic origin. [B.K.]

**Potassium Permanganate in Erysipelas.**—E. T. Martynowski<sup>2</sup> has used potassium permanganate in numerous cases of erysipelas and is gratified with the results. The drug was employed in solutions simply prepared by adding enough water to obtain a deep violet color. A linen cloth folded three times and wetted with the solution was applied to the diseased area. It is not advisable to soak the linen in the fluid, but rather to keep the compress wet by pouring the lotion upon it. This method promptly alleviates pain and promotes recovery, beside having the advantages of cheapness and simplicity. The author has also tried the serum method in erysipelas, but without success. Nevertheless he is convinced that serotherapy will be the ultimate outcome of our efforts. [L.J.]

**Boric Acid in Medicine.**—G. Merkel<sup>3</sup> prescribed boric acid in the form of a watery solution to 11 different patients suffering respectively from hepatic cirrhosis and chronic nephritis. They were given 30 grains (2 grams) daily for periods varying from two to eight days. In all of the cases the urine was increased to double the previous quantity; seven patients, however, complained of symptoms of gastrointestinal disturbance, such as colic, gastric pain, and diarrhea. Now inasmuch as the amount of boric acid taken in the course of the day, when meats preserved with it are used, must exceed the amount used as a drug, it goes to show that it certainly is not the harmless agent that some people are claiming it is. [E.L.]

**Snake Venoms: Their Physiologic Action and Antidote.**—G. Lamb<sup>4</sup> finds the poisonous properties are due to various albuminous substances, each venom containing two or more differing from those secreted by a different variety. Cobra venom acts directly on the central nervous system, causing complete paralysis, the heart beating 20 or 30 minutes after respiration has ceased. It has marked distinctive action on the red cells and diminishes the coagulability of the blood. Local poisoning is marked, a deep-black slough forming. He has never seen paralysis from daboia poison. Convulsions set in almost immediately. If the dose has been large, the whole of the blood is found clotted solid. Apparent action on the central nervous system is due to carbonic acid poisoning. Death is from cardiac depression. In chronic cases coagulability is diminished, the red cells are broken up, the capillary walls are injured, becoming more permeable, and exudation occurs, hemorrhages and edemas being common. The tissues around the wound die, forming a nidus for bacteria, and death usually

results from secondary infection. In the bungarus or Krait family the venom causes thrombosis similar to that in daboia poisoning. In rapid cases there are paralytic symptoms like those from cobra venom. Calmette's serum is of no avail in daboia poisoning. In cobra poisoning it should be injected in a vein, 40 cc. (1½ oz.) being necessary in some cases, repeated later should symptoms come on. A ligature should be applied about the bite, and nothing else be done locally. Daboia and Krait poisoning must be treated on general principles. [H.M.]

**Bacteriologic Diagnosis of Typhoid Fever.**—C. Hayashikawa<sup>1</sup> concludes that the bacteriologic diagnosis of typhoid fever is of great importance in those cases resembling typhoid in which the clinical history cannot be differentiated from typhoid. The presence at one time of the Gruber-Widal reaction has not much value, as this reaction may appear off and on for a long time after an attack of typhoid. It is absolutely necessary to repeat the examination at intervals of three to five days. It is scarcely possible to establish a certain diagnosis by the Gruber-Widal reaction alone in a short time. The bacteriologic examination of the stools was positive in 60%; of the urine, 18.1%; of both, 65%. This is explained by the fact that in typhoid fever in Prague the ulcers of the intestines are insignificant. Examination of the roseola in 12 cases was positive in 7 cases. Puncture of the spleen was positive 17 times out of 18. For the early and positive diagnosis of typhoid fever puncture of the spleen is indispensable, at the same time harmless. In many cases the typhoid bacilli become discharged in bulk in the stools, diminishing during the next day to a very small amount. [J.H.W.K.]

**Treatment of Pneumonia.**—J. B. Herrick<sup>2</sup> emphasizes the following points: (1) Do not shut off fresh air from the patient; (2) do not feed according to any fixed rule; (3) give water with a free hand; (4) morphin will give good results in cases of protracted insomnia or obstinate pain; (5) fever should be controlled by hydrotherapy; (6) local applications are seldom indicated; (7) bleeding is not out of date in selected cases; (8) few pneumonics need alcohol; (9) the only rational treatment is the expectant and symptomatic. Do not follow a "treatment" for pneumonia. It will lead to useless or overdrugging of many patients. [A.G.E.]

**Exercise in the Treatment of Pulmonary Tuberculosis.**—Penzoldt<sup>3</sup> makes the statement that most cases of pulmonary tuberculosis exercise much more than they should, especially when in sanatoriums for treatment. He urges many points, which make it seem that in most of the cases, even the very earliest ones, too much rest is better than too much exercise. Patients with a rectal temperature of 100.4° F. or over he places at absolute rest, giving them as much fresh air at the same time as possible. If the temperature is lower than this he permits careful walks of from ¼ to ½ hour duration, but urges the taking of the temperature by rectum immediately upon its conclusion to note the effect of the walk. If it rises abnormally he cuts the walk down or off; if otherwise, he cautiously increases it. [E.L.]

MARTIN B. TINKER

A. B. CRAIG

C. A. ORR

### REVIEW OF LITERATURE

**Simple Method of Operating for Hemorrhoids.**—A. B. Mitchell<sup>4</sup> has followed a simple method of operating for hemorrhoids for some years which he deems worthy of report. The sphincter is dilated and the hemorrhoids brought into view as usual. The pile is then clamped in a long, narrow-bladed forceps (Kocher's artery forceps answer well). The pile is then cut away with the forceps still in position, and a continuous catgut suture is carried through the hemorrhoidal stump, the number of turns being taken depending on the length of the stump. The forceps is now removed and the suture drawn tight and tied, thus preventing any hemorrhage and practically closing the wound to infection. Each pile is treated in the

same way. The advantages of this method are its rapid accomplishment, little loss of blood, the hemostatic action of the suture after forceps are removed, no danger of subsequent hemorrhage, and the fact that the bowels may move in the regular time and way after operation. [A.B.C.]

**The Surgical Treatment of Marked Ascites.**—F. Lejars<sup>1</sup> reviews at length the results of surgery in cases of ascites, stating that while the conclusions of the advocates of omentopexy are, in his opinion, too optimistic, this is only one of the surgical procedures that may be employed in these cases. He endeavors to prove that surgery, in a relatively large number of ascitic affections, is capable of producing a cure which other therapeutic means cannot bring about. In other conditions, impossible to cure, it is still the best means of relieving the patient and of prolonging his life. In cases of doubtful diagnosis early operation is indicated. Lejars' experience with omentopexy is limited to three cases, two of which were too late in the course of the disease to judge of the value of the operation, while in the other only temporary relief was given. He holds that a marked cirrhotic ascites is an indication for laparotomy, and to give positive results it must be done early. [A.G.E.]

**Teratoma of the Sacral Region.**—J. Preindlsberger<sup>2</sup> reports two cases. The tumors were congenital in both, but came under observation in the first month in one case, and not until the nineteenth year in the other. In the infant's case the teratoma was about twice as large as the child's head, and was attached to the buttocks by a broad pedicle. In the second case the tumor was the size of an orange, and was situated between the coccyx and the anus. Both tumors were cystic. The cysts were lined with squamous, cuboidal or columnar epithelium, in one or several layers, the cells in some places being ciliated. The cystic fluid in the second case contained cholesterol crystals. The solid parts of the tumors were made up of fatty and connective tissue, and also contained blood and lymph-vessels, medullated nerve-fibers, neuroglia, ganglion cells, smooth muscle-fibers, and tubular and acinous glandular tissue. The tumor in the second case also contained rests of cartilaginous and bony tissue, in one place amounting even to a rudimentary rib and costal cartilage, surrounded by striped muscle-fibers. [B.K.]

**Fibrous Stricture of the Rectum Following Dysentery.**—R. J. Blackham<sup>3</sup> reports that a medical man who had resided five years continuously in India was first attacked by dysentery in 1898. This was followed by other attacks in the two following years. None of the attacks was severe, and all yielded to ordinary treatment. For five years prior to the diagnosis of stricture the patient suffered from grave irregularity of the bowels, constipation alternating with diarrhea, some "ribboning" of the stools, all of which had been attributed to hemorrhoids. Purgation and enemas became necessary in order to effect a passage. Digital examination revealed a narrowing of the gut 1½ inches from the anus. The stricture contained a central aperture, which barely admitted the tip of the forefinger. The patient returned to England, where, under surgical care, the stricture was forcibly dilated under an anesthetic and a passage of bougies resorted to. He is now convalescent, but the author is of the opinion that bougies will have to be used for several months. The stricture is believed to have been induced entirely by the attacks of dysentery. [A.B.C.]

**Splenic Infections, With Reports of Cases of Splenotomy and Splenectomy.**—A. L. Stavely<sup>4</sup> says the pathologic conditions of the spleen which interest surgeons are tumors, splenic anemia, leukemia, tuberculosis, syphilis, amyloid disease, enlargements connected with cirrhosis of the liver, congestive hypertrophies, wandering spleen, malarial hypertrophy, infections (pyogenic), and infarcts. These are considered seriatim. Two cases are reported. The first occurred in a woman of 33, the diagnosis being splenic abscess with perforation of the kidney and discharge of pus by the urethra. A lumbar opening on the left side revealed an abscess from which a pint of pus was obtained. The second case was that of a

<sup>4</sup> Washington Medical Annals, March, 1903.

woman of 32, who had an abdominal tumor reaching into the pelvis, the diagnosis of hypertrophied septic malarial spleen being made. Splenectomy was performed, the degenerated spleen being found within an abscess sac. Operation and later examination of the removed organ showed the true condition to be a complex one, consisting of displacement of the spleen, malarial hypertrophy, hemorrhage, suppurative perisplenitis, infective splenitis, thrombosis of the splenic vessels and infarction. The spleen weighed 944 gm. (31 ounces). The patient recovered. [A.G.E.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### EDITORIAL COMMENT

**The Sex-determining Factors.**—In an address recently delivered before a scientific society in Budapest, v. Lenhossék<sup>1</sup> enunciates some interesting theories regarding the factors that determine sex. He maintains that the development of male or female individuals is solely and exclusively dependent upon the presence in the ovary of two sorts of eggs, male and female. Therefore sex is a gift from the mother; while in the inheritance of other qualities father and mother share, inasmuch as the same number of chromosomes from the paternal and the maternal organism exist in the fertilized ovum. A distinction is thus drawn between the inheritance of sex on the one hand and that of the remaining qualities on the other. The spermatozoon merely serves to inaugurate the development of the ovum, and is the carrier of the transmissible parental qualities. The arguments are supported by illustrations from zoology and by observations on human twins. As regards the latter point, it is known that bival twins may be of different sex, while unioval twins are always of the same sex. If v. Lenhossék's contentions are substantiated, it follows, as he himself indicates, that the human embryo is, from the very earliest day, sexually differentiated. He rejects Schenk's theory as to the voluntary determination of sex in man. Students of this subject should not overlook the very suggestive study of Kolipinski, published in the *Medical News* of November 22, 1902.

### REVIEW OF LITERATURE

**Colpeurynter in Incarceration of Reflexed Gravid Uterus.**—W. Albert<sup>2</sup> claims that the physician often fails to cure or uses wrong measures because of error in diagnosis; but diagnosis is not difficult when two points are sufficiently considered: (1) The cessation of the menses; (2) the immediate catheterization of the bladder in obscure conditions of the female pelvis. In incarceration of the reflexed gravid uterus, naturally the first measure is manual reposition with or without an anesthetic, as the case requires. A breaking up of adhesions by the finger may be necessary, and this in many cases may prevent abortion. When manual reposition, however, can not be effected, or signs of difficulty occur, before resorting to surgical measures the colpeurynter should be tried. Albert has used it for five years in such conditions, and reports five cases. The method is simple, but should always be preceded by emptying the bladder and bowel. The rubber balloon of moderate size is introduced between the uterus and the pelvic floor and filled with from 200 cm. to 300 cm. of sterilized water. If this does not suffice to replace the uterus, after one-half or one hour, repeat with increased amount of water, 600 cm. being about the limit, until reposition takes place. In the cases reported these measures were employed at an early stage of pregnancy, varying from the second to the fourth month, with restoration of the uterus to its normal position and the continuance of pregnancy. [w.k.]

**A New Pessary for Inoperable Genital Prolapse.**—Menge<sup>3</sup> refers to the existing pessaries, points out their defects,

and claims that they all fail to meet the requirements necessary in cases of inoperable prolapse of uterus and vagina. What is necessary is a ring which can be introduced into the vagina without any injury to the distended tissues, and yet be of sufficient size effectually to support the uterus and vagina in normal position, and be prevented by a peculiar mechanism from placing itself on edge, and which can be readily introduced and removed. Such an instrument Menge has attempted to construct. The new feature in this instrument, which he calls a club pessary, is that the ring and the club are fastened together by a bayonet clasp by means of which both parts are easily separated and reunited so that they can be introduced separately into the vagina and afterward they can readily be fastened together in their proper position. Thus one has gained the possibility of introducing a large ring edgewise through the introitus, and then above this in the wider part of the vaginal canal, the club stem is attached to it and a permanent transverse position assured. One advantage of this form is that, because of the round, thick end of the club, there is no fear of pressure necrosis of the vaginal wall; and secondly, through the increased size of the cone the sidewise pressure is entirely controlled. [w.k.]

**A Case of Interstitial Pregnancy.**—Max v. Holst<sup>1</sup> reports a case of interstitial pregnancy occurring in a woman who had had six previous normal pregnancies and deliveries. In the fifth month of the seventh pregnancy, while out walking, she was overcome with faintness and was sent to the hospital. The symptoms indicated internal hemorrhage, but as there was no temperature the patient was given eight days to recover strength. The abdomen was then opened showing a mass of old clotted blood from a part of the fundus uteri. The removal of this exposed a fetus lying in the abdominal cavity. On the left part of the fundus and adjacent uterine wall there was a small enlargement the size of a hen's egg extending to the point of tubal origin. In the posterior wall of this was an extended laceration within which was a swimming mass of blood and the placenta to which the navel cord was attached. The fetus and all its attachments being removed, the walls of the interstitial cavity were drawn together with deepseated, strong silk sutures, and the edges of the wound were united with fine silk sutures; this was followed by a careful toilet of the peritoneum with closure of the abdominal cavity. The patient made an ideal convalescence. A year later the woman returned to the hospital, being seven months pregnant and suffering from distressing pain in the region between the navel and symphysis. After a few days' observation a small exploratory abdominal incision was made, and the cause of the pain was found to be omental adhesions, which were broken up and the abdomen closed. At term the patient, after a normal labor, was spontaneously delivered of a female child weighing 3,250 grams. [w.k.]

### TREATMENT

SOLOMON SOLIS COHEN

H. C. WOOD, JR. L. F. APPLEMAN

### EDITORIAL COMMENT

**Epinephrin (Suprarenalin) Powder in the Asthmatic Paroxysm.**—The editor of this department has on several occasions called attention to the value of adrenal preparations in the treatment of that variety of asthma associated with lowered vasomotor tone. The great difficulty has been in the administration of the drug. Taken into the stomach it often fails; it must be absorbed from the tongue or given hypodermically to get the best results. The latter method is obviously to be avoided if possible. Adrenal extract or desiccated adrenal substance in powder or tablet may be held in the mouth for a time, but usually the sufferer grows impatient and swallows the drug. A few drops of adrenalin chlorid solution may be placed on or under the tongue, but this has proved an uncertain method; for just what reason it is difficult to say, unless it is because the patient swallows the solution with his saliva.

<sup>1</sup> *Blolog. Centralb.*, April 15, 1903.

<sup>2</sup> *Münchener medicinische Wochenschrift*, March 24, 1903.

<sup>3</sup> *Zentralblatt für Gynäkologie*, April 11, 1903.

<sup>1</sup> *Münchener med. Woch.*, March 10, 1903.

Often adrenalin chlorid is effective if applied to a clean nasal mucous membrane—and this apart from its local effect, which is also helpful. Recently Abel's epinephrin has been placed on the market under the name "Suprarenalin." It is marketed both as a nonhygroscopic powder and as a solution. In the latter form it seems to have about the same powers and applicabilities as the adrenalin chlorid solution. It is the powder, however, which is so admirably adapted for internal use. Placed on the tongue it is quickly absorbed and effective. The pulse is felt to become more full and more tense in less than 60 seconds after  $\frac{1}{8}$  grain is placed on the tongue of a normal adult. One-half grain was taken by the writer of this, with transient ill-effects—throbbing of the temporal arteries, sensation of constriction of the head, sensation of weight upon the chest, and slight tendency to nausea. Similar effects were observed by a physician who permitted the same dose to be given to him in the same way. Exact measurements of blood-pressure were not taken. Powders containing  $\frac{1}{12}$  grain of epinephrin in sugar of milk were made up and given to a patient suffering with vasomotorial asthma. Immediate relief to a paroxysm having been brought about by application of suprarenalin solution to the nose, the powders were taken at first every hour, then every second hour, then every third hour, with the apparent effect of preventing a return of dyspnea. A suitable form for administration would appear to be tablet triturates containing, say, .003 gram and .006 gram ( $\frac{1}{20}$  grain and  $\frac{1}{10}$  grain) each of epinephrin, with the least quantity of sugar of milk needed to give minimum bulk. These would probably dissolve readily and be even more convenient for lingual and buccal administration than powders or solution. In a number of other conditions associated with lowered vasomotor tone—among them hay-fever, as was first pointed out by the editor of this department in July, 1898—adrenal therapy is indicated and usually effective. A series of clinical experiments, with measurement of blood-pressure, in these conditions has been instituted and will be reported in due time.

#### REVIEW OF LITERATURE

**Therapeutic Use of Glycerophosphates.**—Street<sup>1</sup> says that glycerophosphate of sodium after prolonged administration causes improvement in the appetite and assimilative function, greater activity in the nitrogenous exchange and a reduction in phosphatic waste. Small doses cause a disappearance of nervous phenomena, such as neurasthenia and insomnia; larger amounts may occasion wakefulness. The glycerophosphates are indicated in all cases of nervous impairment due to overwork or excesses of any kind. They are especially useful in those neurasthenic conditions characterized by vertigo, occipital headache and inability for mental effort. In premature senility, in cases of hysteria and in various forms of neuralgia they have been useful. Magnin asserts that in diabetes he has seen the sugar diminish under their employment. They are counterindicated in albuminuria, in diseases characterized by excessive organic oxidation, and especially in any nervous state characterized by acute excitability. [H.C.W.]

**Unilateral Restriction of Thoracic Movement to Produce Reexpansion After Pleurisy.**—Tissier (Pneumotherapy, Cohen's System of Physiologic Therapeutics, Vol. x) points out that the respiratory insufficiency of one lung after a unilateral attack of pneumonia, bronchopneumonia or pleurisy results not so much from permanent structural alterations as from muscular insufficiency. The muscles, immobilized during the active stage of the disease, tend to undergo atrophy in the same way as the muscles of a limb after fracture or an attack of arthritis. When recovery ensues, the patient fails to use the side or member affected to its full capacity. Reeducation is necessary to restore to the affected muscles their previous power, and for this purpose the best form of gymnastics is one that compels the side or member to resume its function. This

result can be obtained by restricting the movements of the member on the healthy side, and in the case of the lung a similar plan may be pursued. The healthy lung not being allowed to perform its function as before, the deficiency is made good by the diseased lung; at first with pain, but later with greater and greater ease. In cases of unilateral lesions, such as diminution of the respiratory capacity, pleural adhesions, muscular atrophy following pleurisy, which are so common, the following procedure was advised by Schreiber in 1858: During inspiration the patient applies the corresponding hand flat to the healthy side, while he raises the arm of the diseased side and places the hand upon the head. The expansion of the healthy side is thus interfered with, while that of the affected side is facilitated. In cases of unilateral pulmonary lesions Schreiber likewise makes use of a restrictive appliance designed to compress exclusively the healthy side. It consists of two metallic plates suitably lined, one applied in front and one behind, united by a semicircular band of steel. By means of a screw attached to this band the patient approximates the two plates at will, and thus regulates the degree of compression of the thorax. This apparatus should be worn almost continuously.

**Puerperal Sepsis Treated with Antistreptococcic Serum.**—W. T. Schwabland<sup>1</sup> reports excellent results from the use of antistreptococcic serum in a case of puerperal sepsis. The serum was begun the fifth day and a total of 150 cc. used, 30 cc. every 24 hours. After the use of the serum the temperature fell, the pulse-rate diminished, and the mental condition improved. Schwabland states that the serum demonstrated its specific action in this case as markedly as does diphtheria antitoxin in cases of diphtheria. [A.G.E.]

**Fluoroform in Pertussis.**—Stepp<sup>2</sup> reports in detail 14 cases of whoopingcough treated with fluoroform. The ages of his patients ranged from 1 month to 7 years. The duration of the disease from the beginning of his treatment varied from 11 to 28 days. In all of his cases the administration of fluoroform was followed almost immediately by a lessening of symptoms. Hence the author believes this preparation has a specific influence upon whoopingcough. The exact mode of its action is not known. Fluoroform is tasteless, odorless, and not poisonous. Two of the author's patients, aged 2 and 3 months respectively, took in a period of three and one-half to four weeks 1,400 to 1,600 cc. of fluoroform with no ill effects. The dose is 1 to 2 teaspoonfuls hourly. [W.E.R.]

**Thiocol in Tuberculosis.**—L. Friedmann<sup>3</sup> considers thiocol preferable to all creasote and guaiacol preparations. It is odorless and easily soluble in water. Clinical observation and experimentation upon the lower animals proved thiocol to have a specific influence upon tuberculosis. All the author's cases treated with this preparation showed amelioration of symptoms. Friedmann also used thiocol in tuberculous affections of the pleura, the trachea, etc. Because of its antiseptic action thiocol may also be used in other bacterial diseases of the air passages. [W.E.R.]

**Preparation of Patient for Anesthesia.**—Cardie<sup>4</sup> advises that the patient remain in bed two or three days before an operation in order to produce both physical and mental relaxation. The diet should be light, and abundant fluid ingested. The free use of water before etherization very distinctly lessens after-nausea. This it does by aiding the elimination of the ether and diluting such portions of it as are eliminated by the stomach. The purgation usually preceding anesthetization draws off a considerable amount of water from the system, tending to increase the sickness. A glass of water should be drunk immediately before taking the ether. Cardie highly recommends the administration of morphin and atropin before anesthetization. The atropin, if used in sufficient quantity, .6 to .9 mg. ( $\frac{1}{100}$  to  $\frac{1}{75}$  gr.), reduces the irritability of the vagus, preventing the inhibitory heart arrest seen sometimes, especially with chloroform; it also acts as a stimulant to the heart and the vasomotor centers and respiration. The morphin lessens the fear of the operation, prevents any excitement which the full dose of atropin might cause, and allows a decidedly smaller

<sup>1</sup> Iowa Medical Journal, April, 1903.

<sup>2</sup> Prager medicinische Wochenschrift, March 12, 14, 20, April 2, 1903.

<sup>3</sup> Prager medicinische Wochenschrift, April 9, 1903.

<sup>4</sup> Treatment, 1903, vii, p. 7.

quantity of the anesthetic to be used. Alcohol is sometimes of advantage before the operation to quiet a nervous patient, while strychnin and cocain are both serviceable on account of their stimulant influence. [H.C.W.]

**FORMULAS, ORIGINAL AND SELECTED.**

Lewis<sup>1</sup> recommends the following prescription for a sedative in neurasthenia:

Potassium bromid . . . . .	15 grams (4 drams)
Tincture of ferric chlorid . . . . .	12 cc. (3 drams)
Glycerin . . . . .	8 cc. (2 drams)
Water sufficient to make . . . . .	125 cc. (4 ounces)

A ½-teaspoonful three times a day.

Under its influence there is a decrease of the neurasthenic pains and, better, more restful sleep. [H.C.W.]

From *Merck's Archives* we take the following formula for removing rust from surgical instruments:

Potassium cyanid . . . . .	16 parts
Chalk, levigated . . . . .	30 parts
Soap, shaved . . . . .	15 parts
Water . . . . .	sufficient

Dissolve the soap in sufficient water to make, with the chalk, a thick paste, in which incorporate the cyanid. With this paste rub the blades well until the rust disappears and a polished surface is attained. The operation is rendered more rapid if the blades or other objects be soaked in kerosene over night and the surface rust scraped off with anything that will not scratch the blades. The deadly nature of the scouring paste must, of course, always be borne in mind, and the proper precautions always taken to protect the hands. [H.C.W.]

**THE PUBLIC SERVICE**

**Changes in the Medical Corps of the U. S. Army for the week ended May 16, 1903:**

ASHBURN, JAMES K., contract surgeon, is granted leave for one month from about May 1.

HARTNETT, First Lieutenant EUGENE H., assistant surgeon, orders are so amended as to direct him, upon his relief from duty at Fort Columbus, to proceed to Key West Barracks for duty, to relieve First Lieutenant Charles N. Barney, assistant surgeon, who will proceed to Fort Schuyler for duty.

REAGLES, JAMES, contract surgeon, is relieved from duty at Fort Snelling and will proceed to Fort Keogh for duty.

WALL, FRANCIS M., contract surgeon, is relieved from duty at Fort Thomas, and will proceed to Columbus Barracks for duty, to relieve Contract Surgeon Harper Peddicord, who will proceed to Vancouver Barracks and report to the commanding general, department of the Columbia, for assignment to duty in Alaska.

WILCOX, Lieutenant-Colonel TIMOTHY E., deputy surgeon-general, chief surgeon, department of the Columbia, will proceed to such posts of that department in Alaska as may be necessary on business pertaining to the sanitary and medical inspection thereof.

LIPPINCOTT, Colonel HENRY, assistant surgeon-general, is granted leave for one month, to commence about June 1, with permission to apply for an extension of two months and fifteen days.

ROBERTS, D. M., contract surgeon, is granted leave for one month, to take effect May 15, with permission to apply for an extension of two months.

PETTYJOHN, JOS., contract surgeon, is relieved from duty in the department of the Columbia, and will proceed to his home, Augusta, Ga., for annulment of contract.

**Changes in the Medical Corps of the U. S. Navy for the week ended May 16, 1903:**

SMITH, R. K., passed assistant surgeon, resignation accepted to take effect May 19, 1903—May 11.

DYKES, J. R., acting assistant surgeon, U. S. N., appointed assistant surgeon, April 18, 1903—May 11.

**Changes in the Public Health and Marine-Hospital Service for the week ended May 14, 1903:**

GADDINGS, H. D., assistant surgeon-general, to proceed to Elkins, Va., for special temporary duty—May 11, 1903.

CARMICHAEL, D. A., surgeon, granted leave of absence for seventeen days from May 19—May 9, 1903.

KALLOCH, P. C., surgeon, to assume temporary command of the service at Portland, Maine, during absence, on leave, of Surgeon S. D. Brooks—May 14, 1903.

BROOKS, S. D., surgeon, granted leave of absence for three days from May 19—May 14, 1903.

OAKLEY, J. H., passed assistant surgeon, granted leave of absence for three days—May 8, 1903.

GRUBBS, S. B., passed assistant surgeon, granted leave of absence for one month—May 13, 1903. To rejoin station at Gulf quarantine at expiration of leave of absence—May 13, 1903.

DECKER, C. E., assistant surgeon, granted extension of leave of absence, on account of sickness, for fourteen days from April 10—May 5, 1903.

RICHARDSON, T. F., assistant surgeon, granted leave of absence for three days from May 8, 1903, under provisions of paragraph 191 of the regulations. To proceed to Gulf quarantine station for special temporary duty—May 13, 1903.

GLOVER, M. W., assistant surgeon, to proceed to Newbern, N. C., for special temporary duty—May 12, 1903.

DUKE, B. F., acting assistant surgeon, granted leave of absence for four days from May 18—May 9, 1903.

GOLDSBOROUGH, B. W., acting assistant surgeon, granted leave of absence for five days—May 11, 1903.

GREGORY, G. A., acting assistant surgeon, granted leave of absence for four days from May 18—May 11, 1903.

KENNARD, K. S., acting assistant surgeon, granted leave of absence for twenty-one days from April 25—May 8, 1903.

STEVENSON, J. W., acting assistant surgeon, granted leave of absence for seven days from May 11, 1903, under provisions of paragraph 191 of the regulations.

ROEHRIG, A. M., pharmacist, granted leave of absence for five days from May 12, 1903, under provisions of paragraph 191 of the regulations.

VOL. V, No. 22.

MAY 30, 1903.

\$5.00 YEARLY.

**The Sick as Commercial Imports.**—All are familiar with the old yarn of the enterprising western town which was so new and so healthy that it had to purchase from a neighboring State the one necessary article to start the new cemetery in a businesslike way. When a new and enterprising national profession imports famous foreign surgeons it has happened that there was a scarcity of clinical material for the operator and his entertaining hospital. Borrowing patients from a more fortunate and rival hospital in the same city provokes a smile in the students of quizzical medical sociology. But the pleasure is more pronounced when it is told that not even in a whole large city was an appropriate case of the special disease to be found. Not to lose the opportunity the aid of a neighboring city was sought. Trained nurses, attending physicians, a special private car, *tout ce que vous voulez*, were fervently offered for the loan of a single patient. One does not understand why the air, water, or other conditions necessary for the production of the desired disease are present in one city and not in the other only a short hundred miles away. It was, indeed, a pity that operators were more in evidence than patients.

"Tell them the joyous Time will not be staid,  
Unless they doe him by the forelock take."

**Fresh Milk.**—It has not been sufficiently well recognized that one of the most important problems of the milk supply of a large city is the avoidance of too old and of soured milk because of the time required between the country milking and the feeding of the distant city babies. With the advent of the summer the Chicago Health Department reports an increase of 33½% in the number of deaths, under five, of children—138 week before last, 184 the next. This is charged to milk of poor quality, due chiefly to the fact that farmers and poor city families often have no ice, and that the milk may be from thirty-six to sixty hours old when given to the child. Under such circumstances there must be a rise in the infant mortality. With the trolley lines now running into every part of the neighboring country the abuse of long kept milk should be instantly abated. There is no reason why cold and pure milk should not be delivered at the doorstep within a few hours after the milking. This is one of the great possible blessings of the development of the trolley system. Let our health boards at once set about its utilization.

**The Life-cost of Accidents.**—It is strange how negligent we are as a profession, and especially as a nation, of the loss of life and the cost of accidents. It is calculated that more disability is caused by them than by consumption, pneumonia, and cardiac diseases combined. Compare this fact with the space taken up in medical and other literature by the consideration of accidents. Has there been a single paper read in the last two national medical conventions on accidents? And yet is it not certain that careful attention to the prevention of accidents would result in as much saving of life and expense to the community as the same amount given to the three diseases named? Statisticians reckon that 10,000,000 accidents occur in the United States each year, killing 60,000 persons. This number, says Dr. D. J. McMahon, of New York City, is greater than that of all the casualties of the 17 years' Napoleonic wars. In all, 68,000 working people are annually disabled for life in our country, 55,000 for more than three months, and 400,000 incapacitated for less than three months.

**Bad Personal Characteristics and Official Positions.**—In his presidential address Dr. Keen speaks wisely of qualities other than medical which make it advisable or necessary to exclude aspirants for professorships, hospital positions, etc. Among these he puts a "quarrelsome disposition," "other personal disqualification," "drunkenness," "libertinage," etc. We wish the matter could have been treated more in detail. It is indeed worthy of an entire lecture by one so well fitted as Professor Keen is to describe the abuse with merited indignation and discrimination. He might have spent considerable time upon the fact that when the man with quarrelsome disposition, the libertine, the drinker, etc., does manage to get the coveted position, there is no critic that criticises, except in vague general terms, no censor that is really incensed, and all are friends of the great succeder. Time might also be spared to plead against the common custom of making such appointments often depend upon what Mr. Dooley calls "infloence," political intrigue and cunning, whereby the most capable and the most modest, the least "otherwise disqualified," are certain to be beaten by the "pusher" and "hustler." Then there are so many types of "personal disqualification," so many other

characteristics which may be as bad as drunkenness and libertinage. For instance, the man with a fad, who sees everything medical from his hobby-horse, or through the blue goggles of his specialty. There is the man ruined by his avarice, who does not know or pretends that he does not know that his tricks of charging and getting excessive and unjust fees make him the despised of colleague and public; from this habit may also arise all the arts of the secret advertiser, the cunning seeker after office, etc., in order really to get new patients. One man in a western city is famous for writing thousands of letters to all and sundry upon every possible suggestion, medical or nonmedical; another in an eastern city advocates every popular reform, and as carefully ignores every unpopular one, although this may be a thousand times more needed. There are also the unadulterated egotist who is always on the lookout for getting his name and fame before others' eyes, the religious hypocrite, the "soured man," the LL.D. hunter or parader, the antivivisectionist, the plagiarist, the stealer of other men's ideas and selfish utilizer of their ambitions, the gormandizer of a score of hospital positions, the surgeon with a fury for operating—the list could be made much longer!

**The Antivivisectionist as a Self-describer.**—If one will take any number of a typical antivivisectionist journal, *e. g.*, *Dawn*, Vol. 4, No. 10, just sent us, he must marvel at the expert way in which these good-bad people describe themselves in their supposed descriptions of us. For instance:

It is not sympathy that the world stands so sorely in need of; it is understanding—understanding which savors of a just interpretation of motives, etc.

Now, nine-tenths of these people do not understand, do not try to understand, our motives, but are all the time lashing themselves into a fury by their emotions or their "sympathy," in order to drown the need and duty of understanding.

Again, on the same page of *Dawn*:

Keep thee far from a false matter, etc.

And yet every issue of every antivivisectionist journal is filled with "false matters." *Dawn* especially, and surely this number is so filled, setting forth the following theses:

1. That vivisection is immeasurably cruel.
2. That its methods are those of cowardice, treachery and deceit.
3. That it is a menace to human life; in one word, murderous.
4. That it is a deliberate corrupter of children and youth.
5. That through the strong and influential institutions where it flourishes, backed by an aggregate of enormous wealth, it would escape question and molestation by blunting and depraving the public conscience.
6. That it is a threat to personal liberty, as shown in the steady multiplication of "serums," to be by-and-by successively forced upon the people by compulsory "health" laws of corrupted legislation.
7. That it is a travesty upon real science, in its empty achievements and in its preposterous promises of favors to come, two of the latest being the procuring of bodily immortality and the restoring of the dead to life.

Now, of course, vivisection is "cruel" in the sense

*Dawn* implies, but there is no such vivisection among scientists today, and—

1. There is plenty of such vivisection among the meat-eating antivivisectionists.
2. The methods of the antis are those of cowardice, treachery and deceit.
3. Antivivisection is a menace to human life; in one word, murderous.
4. It is a deliberate corrupter of children and youth.
5. That through the strong, etc., etc., it is blunting and depraving the public conscience.
6. That it is a threat to personal liberty, etc., etc.
7. That it is a travesty, etc., etc.

Lastly, the motto of *Dawn* is, "Unless what you accomplish is useful, your glory is your folly."

If this motto could be understood by the foolish!

But the anti does not fail to relieve the tedium of tragedy by occasional mirth-provoking paragraphs. As for instance:

Meanwhile the antimicrobe physician goes his rounds fulfilling his mistaken mission, administering his poisons to the healthy and unhealthy alike, to will and to do, not of his own wit and pleasure, but the will of the most exacting professional tyranny, tolerated by a mercenary and unthinking age, to depart from whose behests would mean to him professional ostracism. Mr. Lincoln's apothegm begins to assert its force. The schoolmaster is abroad. Brave men resent their intellectual slavery. Lorenz, Elmer Lee and a gathering host have thrown off the yoke of bondage with remarkable relief and unqualified success. Osteopathy has erected its colleges and despatched (*sic*) its beneficent missionaries.

Lorenz and Elmer Lee! Science and soapsuds!

**Pneumonia 125% more fatal than tuberculosis**—such is the statement of the Bulletin of the Chicago Health Department. In view of this amazing fact it is justifiable to say that although having no such an eye-catching name as the "Great White Plague," pneumonia deserves far more attention of profession and public than it gets. It is desirable to collate the statistics of the whole country and not those only of one or more cities. But there can be no doubt that pneumonia is in our country a more fatal disease than tuberculosis, and none about the advisability of giving the greatest attention to the greatest enemy. Probably the chief reason for the increase of the pneumonia mortality is the general neglect of popular teaching as to the infectiousness of the disease. Over-attention to the contagiousness of one or more affections is likely to produce under-attention to that of another even more dangerous. Somehow the people will not care for the fact in the case of pneumonia, and a general crusade for popular education is most urgent.

**Cleanse and Sterilize the Filters.**—It seems sufficiently difficult to get people to buy and use good filters, and those who do so are likely to think that they have no further duty to keep them clean. It has been demonstrated that filters finally permit the bacteria to fill the pores and even multiply on the inside, so that under these circumstances they do not protect against the infections of water-borne diseases. Boards of health should be authorized to conduct the examination and laboratory tests of domestic filters. Railway companies, public and office buildings, etc., especially need looking

after by some official of the local health board with power to demand and execute protection against this method of propagating disease. Where this is not done all conscientious private consumers, corporations, schools, etc., will see to it that their filters are periodically cleansed and sterilized.

**Mendicants are criminals**, nine-tenths of them with criminal records, is the report of those who have investigated these wretches who are allowed to parade their simulated miseries upon our streets. Those who are in fact legless or armless have lost those undesired and useless organs as tramps in stealing rides on railroad trains, etc., and even the few really blind of the many that pretend to be so, were made so purposely, or are glad they are so. New York City is ridding herself of these impostors by the simple expedient of showing up their frauds. In the slang of these worthies, "New York is jimmied." By taking the good arms out of splints or the sound legs out of casts, exposing the sham blind, and the malingering paralytic, punishing the frauds, etc., the streets are cleared of them. Other cities are yet to learn the lesson. "Chi Slim" made a large income, some \$50.00 a week for years, in an hour or two a day, in New York, playing the paralytic. "British" was almost as successful. "P. P." is the name given by the fraternity to the plaster-of-paris bandage men. The "sap" men are the crutch and cripple frauds. The "cane men" are those who go no farther than canes. The "human crab," the "human dog," the "human alligator," are other types. The "crust-thrower" is the fellow who slyly drops a moldy crust of bread before the passer-by, and then seizes it as if with hunger. The "duckets" or "dockets" are those who parade signs, verses, etc., on placards. When "Florida Shine," "Boston Charlie," "Toronto Peg," "The Crane," "Dutch Harris," "St. Louis Joe," or "Chi Slim" gets arrested, his companions of "the trust" contribute and hire a lawyer for him, or secure means for his escape. •

**The sober second thought as to child labor** was emphasized by several at the recent Atlanta Conference. The sentimentalist is of excellent service, provided he or she are not allowed to make the laws before the physician, the statistician, and political economist have had time to give reason and justice to the measures of relief proposed. The Mayor of Macon, Ga., who is also president of a manufacturing company, says that manufacturers are not in favor of child labor, and that work in the mills has been "a godsend" to both children and parents, and that the mills have restricted instead of increasing the total amount of child labor. He contends that the necessity is deep-rooted in our social system, and before it can be stopped there must be real preventives in the form of checking unrestricted marriages, poverty from inheritance and misfortune, from death of parents, etc. "We are in Georgia suffering more from idleness than we are from ignorance." An excellent statistician, Mr. Hoffman, of the Prudential Life Insurance Company, says that unwarranted conclusions are being drawn and hasty proposals made

in the matter of legislation because of the lack of a broad basis of evidence and careful statistics. It is quite probable that our public schools are as great producers of ill-health as the mills. It was found that in Cleveland 25% of the girls and 18% of the boys had to withdraw from the high school mostly because of bad health, and that in other places as high as from 36% to 48% of the children were affected with bad eyes, headache, sleeplessness, etc. It is plain that legislation must be founded upon a better basis of investigation and a more cautious gathering of facts than has so far been shown. The evil is evident, but, as usual, the method of cure is by no means so certain.

**A Noisy or Noiseless Fourth of July.**—Good parents and really patriotic citizens have long dreaded the annual epidemic of deaths, accidents, tetanus, increased illness, etc., which has invariably followed a noisy Fourth-of-July. The more noise the more death and injury; but the less patriotism, is a pretty safe rule. Regret must therefore be expressed for the public declaration of the mayor of an eastern city that he believes in a fire-cracker Fourth. Perhaps that is a better plan than to publicly condemn the toy cannon, etc., and privately condone all offenses against the unexecuted law. The toy-pistol boy is often the criminal in the making. The "Chicago idea" is said to be to celebrate noiselessly by means of good literature, speeches, etc., but Minneapolis tries to abolish the noise-making, and replace it by innocent games and athletic sports. These methods are surely more hygienic, and will cheat the doctors out of their yearly crop of emergency cases and accidents, but from the anti we will scarcely get credit for such worthy or unworthy motives.

**A Great Scientist on Mortality Statistics and Smallpox.**—Spencer and Wallace and many other great men have convinced themselves, and have attempted to bring the world to their view, that vaccination is far worse than useless, and that other causes have been those ridding the world of the horrible and death-dealing smallpox. But even they and all other anti-vaccinationists are convinced that smallpox is loathsome instead of lovely, and that it brings death and suffering. It remained for another great scientist, Dr. Thomas Mulligan, according to the newspaper reports, an eclectic practitioner, to take the sole remaining step in the logic of the anti. At the convention of the Connecticut Eclectic Medical Association on May 12, Dr. Mulligan is said to have contended that "smallpox is a good thing to have in a community. It crowds out other diseases, and lowers the deathrate. It is therefore something to wish for rather than to fear." When smallpox does prevail, he said, there are fewer deaths from it than from any other disease, and in years when it rages violently there are fewer deaths from all causes than in years when there is no smallpox. Dr. Mulligan condemned the use of vaccine virus and antitoxin because, he said, "their use prepared the victim for either another disease or an early grave." If Thomas has not been vaccinated he should surely be allowed to put his theory in practice. We suspect he can show good scars.

**Governmental Responsibility for Military Sins Against the Public Health.**—The interdependence of military and social life is again illustrated by an incident that has occurred in England. The much criticised War Office is again brought up standing by the fact that there has been a narrow escape from an outbreak of typhoid fever in London and thirty or more industrial centers from the sale and distribution of army blankets from the fever hospitals in South Africa. The danger has only been averted by the energy and vigilance of the sanitary authorities. It is said that experts have discovered the army blankets warehoused were blood stained and infected with typhoid bacilli. These blankets were sold in South Africa by the authority of the War Office after the close of hostilities, and there was carelessness in neglecting to classify the superfluous army stores, disinfect all the goods and destroy those used in the fever hospitals.

**The Smoke Nuisance.**—It was said at the time of the anthracite strike that its worst result would be to perpetuate the black-smoke nuisance, as the public would get so used to this that all attempts to stop it would be futile. The energetic Dr. Lederle, of New York, does not agree to this let-alone policy and is bringing to court all offenders of the law against black smoke. Other cities, however, are unconcerned about this destroyer of health, pure air, and sunshine. It is hoped that Dr. Lederle's example may incite other health officers to a most desirable emulation.

**Pneumonia Epidemic.**—The *Chicago Tribune* states that Surgeon Banks, of the Marine-Hospital Service, has reported to the central office in Washington that Chicago is suffering from an epidemic of pneumonia. He quotes the figures of the city health department to show that the deaths from that disease in the last two months are 22% of the entire mortality. From all causes in the last two months there have been 5,341 deaths in the city, and 1,186 of these have been caused by pneumonia. The disease has reached almost epidemic proportions. In this report it is related that as many as four deaths have occurred in one family, and that six friends who attended the funeral of a victim of the disease were fatally attacked.

**The Cigar Stump and the Street Boy.**—A source of infection not hitherto emphasized, but which deserves attention in connection with the street boys of every city, has been the subject recently of investigations in the University of Padua. These investigations, says a note in the *Boletín Mensual de la Lliga contra la Tuberculosis en Cuba*, have proved, "as might have been expected, that the stumps of cigars smoked by consumptives may transmit tuberculosis. The experiments described by L. Peresico establish the fact that the ends of cigars are virulent two weeks after having been smoked by a consumptive, if kept dry: but they lose their power of infection in ten days if kept in a damp place." This must be because the germs are transferred to the water, not because they are destroyed.—[*Charities.*]

**Rush Medical College** is rapidly approaching the standard which it has set as to requirements for admission, namely, such requirements as will ensure the possession of a bachelor's degree by every graduate of the college. Another step is taken in advance this year, and the requirements beginning with the summer quarter, 1903, will be increased so as to demand 12 majors (14 years of ordinary college work) in addition to a four years' high school course, one-half of which must be in specified branches specially preparing one for the study of medicine, and which must include one year of college chemistry in addition to a year of high school chemistry, and a thorough course in elementary biology; in lieu of these 12 majors, however, nine will be accepted if the work is done at the University of Chicago in the branches specially recommended as a premedical course. In June, 1904, another advance will be made, and in June, 1905, the completion of the Junior College course at the University of Chicago, or an equivalent thereof, will be demanded, and the preliminary work must have covered a year of college chemistry (inorganic), one major of organic chemistry, one major of college physics, a thorough course in biology, and a reading knowledge of French and German.

## AMERICAN NEWS AND NOTES.

### GENERAL.

**Dead from Cholera.**—News from Manila is to the effect that Mabini, the former Minister of Foreign Affairs of the Filipino Government and a member of Aguinaldo's Cabinet, is dead from cholera.

**Manila Clean City.**—Governor Taft's executive secretary lately arrived in San Francisco, and he is quoted with the following remark relative to the sanitary condition of Manila: "Manila is now the cleanest city of its size in the world, with less crime than any city of which I know."

**Plague Stamped Out at Peru.**—Mr. Calderon, the Peruvian Minister, has received a cablegram from his government stating that no cases of bubonic plague have appeared in Peru since the seventh instant, when four cases were found in Callao. Callao has been isolated since the first appearance of the plague, and the government has opened the port of Ancon, 21 miles to the north, for the exportation and importation of merchandise, so that trade may proceed as usual with other countries.

**Fevers on the Isthmus.**—General Hains, a member of the Isthmian Canal Commission, who has just returned from the isthmus, says that fever is prevalent there, and that it is quite dangerous to white men. He says it is either yellow fever or such a malignant type of malarial fever as to be as bad as yellow fever. The condition can be improved, but it would require control by the government of sanitary measures. He thinks it would take about a year to place the canal region in proper sanitary condition.

**To Study Tropical Fevers.**—Professor George E. Beyer, of the department of biology and natural history at Tulane University, has gone to Vera Cruz, Mexico, where, with other members of the Fever Commission appointed by the United States Marine-Hospital Service, Professor Beyer will this summer make investigations similar to those conducted last year, when Professor Beyer and Dr. Pothier, under direction of Dr. Parker, of the Marine-Hospital Service, investigated the connection between the mosquito *Stegomyia fasciata* and yellow fever.

**Adulterated Food Imports.**—Careful investigations made by United States Government chemists has shown that Germany is sending to the United States every year immense quantities of foodstuffs into which harmful preservatives have been introduced. Other countries are probably sending foodstuffs to which the same objection could be made, but so far it appears that Germany is the chief offender. A measure which was put through Congress at the closing hours of the session authorizes the Secretary of the Treasury to refuse entry of foodstuffs which the Secretary of Agriculture finds to be adulterated so as to be injurious to health. This amends the previous law which authorized the exclusion of adulterated foods, but which required our officers to prove that they were harmful. The new law relieves them of this

**Length of Life Increasing.**—The *Indiana Medical Journal* is authority for the following: Medical men are discussing a lecture by Professor Pflüger, of the University of Bonn, on longevity, in which he asserts that the average length of human life is steadily increasing. He maintains that one-third of all the deaths registered in Munich are due to heart disease, brought on by the immoderate use of beer, and that tobacco also claims a large percentage of the victims. Among 40 centenarians who have come under his notice there was only one smoker, while nearly all professed to a moderate use of alcohol. What Professor Pflüger most seriously warns people against is the thought and fear of death. The mind must be occupied, he says, in order to secure longevity. Hard-working men who retire rarely live much longer.

**The Flight of Mosquitos.**—Captain S. P. James, who has lately written a book on malaria and mosquitos, had for many years made a study of anopheles in India. He states that the usual distance of flight of anopheles rarely exceeds half a mile, and at this distance from the focus of infection a person is practically safe from malaria. He found that altitude had no particular influence unless beyond 4,000 feet. He said: "Complete protection from malaria and black water fever may be ensured by any individual who is willing to take the trouble to pay scrupulous attention to the use of a good mosquito curtain at night, and to protect himself adequately from being bitten by mosquitos during the evening hours. If these simple precautions are taken it is quite unnecessary to use quinin as a prophylactic. No other precautions than these have been used by any of us during our tours through some of the most malarious parts of India, and none of us have experienced a day's fever during this time. By the use of the same precautions also, and without taking any quinin, Dr. Stephens previously passed two years in the most malarious parts of Africa without a single attack of malaria."

## EASTERN STATES.

**Diphtheria at Newport.**—It is said that diphtheria has appeared among the naval apprentices on the vessel "Constellation" and on the monitor "Amphitrite," where many boys are on board. The disease appeared among the apprentices some two weeks ago and camps were established upon the line. It gained ground and 740 boys were transferred from the barracks to the above named vessels where it was thought they would be safe. The precaution was not successful.

**Coroner's Office Abolished.**—The *Sanitary Bulletin* says the "coroner's inquest" is a thing of the past in New Hampshire and the office of "medical referee" has been created to take the place of the coroner's office. The law provides for the appointment of 16 physicians for the State, to investigate suspected criminal causes of death. It is not infrequent that such investigations require skilled professional knowledge, and it would seem remarkable that a law which places such investigations in the hands of a layman should have remained so long on the public statutes. The medical referee plan which has been in operation for some years in other States is far superior to the old coroner system.

## NEW YORK.

**Treatment of Rabies.**—It appears as an outgrowth of the late injustice which patients have been subjected to in the treatment of rabies by certain persons connected with the New York Health Department that President Ernest Lederle has caused a room to be set aside in the main building in the Health Department which is to be fitted up and utilized exclusively for the treatment of all such patients applying to the department for treatment.

**Use of Soft Coal.**—An exchange says that Dr. Lederle, the Commissioner of Health, is determined that the users of soft coal in defiance of the sanitary code throughout the city shall be made to desist, or shall be punished. The commissioner has again ordered out the health department patrol tug to skirt the shores of the North and East rivers to search for ordinance violators. Wherever a factory chimney belched out the dense black puffs which indicate bituminous furnace fuel or at least a 30% bituminous fuel alloy, the tug put for shore and arrested the engine-room chief of the offending manufactory.

**To Restrict Consumptive Camps.**—Governor Odell has signed the bill prohibiting the establishment of any hospital or camp for consumptives in any town in the State without the formal consent of the supervisor of the county and the town board of such town. He has filed his reasons for signing such bill, which appear, however, not altogether satisfactory to the medical profession in Greater New York, who consider that great hardship is inflicted upon the tuberculous poor of the city on account of this veto. They assert that it will be practically impossible to gain the consent required from the numerous officials before such hospital or camp can be erected.

**Birthrate in New York.**—Statistics compiled by the Board of Health show that the population of New York is increasing at a remarkably rapid rate. The births reported in Manhattan borough alone during the first four months of the present year were 2,000 in excess of those reported in the same period last year. The cosmopolitan population and the large proportion of foreigners in the city may account for the high birthrate. The health department now holds any physician accountable who neglects to report a birth. There has been a falling off in the percentage of deaths. The city has also gained enormously by foreign immigration. The Board of Health has estimated that the population of the city has grown from 3,437,202 at the time of the last federal census in 1900 to 3,732,930 at present.

## PHILADELPHIA, PENNSYLVANIA, ETC.

**Recognition of Homeopaths.**—The committee on charities and corrections from the council has approved an ordinance authorizing the Director of Public Health and Charities to establish five wards in the Philadelphia Hospital under the care of homeopathic physicians. There will be a surgical ward for men, another for women, a medical ward for men, another for women, and a medical and surgical ward for children.

**State Board of Health of Pennsylvania.**—The fifty-fourth meeting of the State Board of Health was held May 23, in Philadelphia. Among the matters considered was a resolution calling for a conference with reference to bubonic plague in California. The present smallpox situation was discussed. Benjamin Lee, the secretary, reported that during March and April there were 1,416 cases of smallpox, and 61 deaths therefrom in this State. Included in this number are: Philadelphia, 219 cases and 20 deaths; Pittsburg, 153 cases, 15 deaths; West Fairfield township, Crawford county, 137 cases; St. Mary's, Elk county, 100 cases; Tyler, Clearfield county, 55 cases; South Fork, Cambria county, 50 cases, and fourteen other towns or townships throughout the State in which there were from 20 to 50 cases in each.

**Cerebrospinal Meningitis at League Island Navy Yard.**—In spite of the energetic efforts of the officials at League Island Navy Yard to stamp out the few cases of cerebrospinal meningitis aboard the receiving ship "Minneapolis" it turns out that additional cases have appeared, and this time on the monitor "Puritan." The vessel has been used as an auxiliary receiving ship during the crowded condition at the navy yard and nearly 400 were quartered aboard her. Two landsmen were found afflicted with the disease and sent to the naval hospital.

**Dean of Hahnemann Medical College Resigns.**—Dr. Dudley, for seven years dean of Hahnemann Medical College, has resigned that office. He says he has not been sustained in his administration, particularly with reference to reforms in the school and changes in the curriculum, and complains that as a result the school has deteriorated. The average for many years until within the past eight years has been 65 to 70 matriculates. Last year only 52 entered and this year there were but 43. He retains the professorship of hygiene and the institutes of medicine.

**Smallpox.**—The number of cases of smallpox reported in Philadelphia indicate that the disease is on the increase. This is unusual for the season of the year. During the week ended May 16, 30 new cases were reported. The previous week there were 26 cases, and the week before 16. This situation of affairs is not confined wholly to Philadelphia. From Connecticut comes the complaint that smallpox exists in a number of towns in the State, notwithstanding vigorous efforts are being made to stamp it out. Chicago likewise complains of more cases of smallpox than the city has shown for some time. The \$50,000 recently appropriated by the Legislature of Pennsylvania to be used by the State Board of Health for combating this disease should be promptly utilized in stamping out the disease by vaccination and otherwise.

## WESTERN STATES.

**To Electrocute "Bugs."**—It is stated that an employe of the Minneapolis Water Works Department has devised a plan to kill typhoid and other germs which may be present in the water by the application of electricity. The system, which provides for the aeration of the water and the electrocution of the germs by a strong current from a dynamo, has been tested. It is stated that a bacteriologist reported the plan successful from the fact that 70% of the germs were destroyed. It appears that the remaining 30% might occasionally cause disease.

**Application of Electricity to Remove Foreign Body.**—It is reported that an apprentice at the navy yard at Vallejo, Cal., who was severely injured recently by a piece of steel flying from a tool and imbedding itself in his face had the foreign substance removed by an electrician, who had arranged an electromagnet of his own design for the purpose. The magnet, which was capable of lifting 500 pounds, was held directly over the orifice and the current turned on. In an instant the piece of metal flew from the wound and attached itself to the magnet.

**Great Quarantine of Cattle.**—From Denver, Colo., comes the news that what will be the most extensive quarantine of cattle in the West for many years will be in effect within a few days as the result of the general prevalence of the mange. Governor Peabody will issue his proclamation today. Other States and Territories to the number of six or eight will come under the same rule before the end of the week. Cattle from the Mexican border to Canada will come under these regulations and practically all of the territory from the Rockies to the Missouri river will be affected.

**New Law With Reference to Drugs and Druggists.**—The law recently passed by the Legislature of Illinois and signed by the Governor, and which is to become operative July 1, provides in part as follows: It shall not be lawful for any druggist or any person to retail or sell or give away any cocaine hydrochlorate, or any salts of, or any compound of cocaine, or any preparation containing cocaine, or any salts of or any compound thereof, except on the written prescription of a physician or dentist, licensed under the laws of the State, which prescription shall only be filled once, and must have written plainly on it the name and address of the patient. Provided, that the provisions of this section shall not apply to sales at wholesale by any manufacturer or wholesale dealer, who shall sell to the retail druggists, or other person so sold, as original packages only, when such manufacturer or wholesale dealer shall have affixed to each box, bottle, or package containing such cocaine hydrochlorate, or salts or compounds of cocaine, or preparations containing cocaine, a label specifically setting forth the proportion of cocaine contained therein. Any druggist or other person who shall retail or sell any cocaine hydrochlorate, or salts or compounds of cocaine, or any preparation containing cocaine, or salts or compounds thereof, in violation of this act, and any druggist or other person who shall prescribe any cocaine hydrochlorate, or salts or compounds thereof, to any person addicted to the habitual use of cocaine, or any preparation or compound thereof, in any form, shall, for the first offense, be fined not less than \$50, nor more than \$200, and for each subsequent offense not less than \$200, nor more than \$1,000, and if the person so offending shall have a license as a physician, dentist, or pharmacist, such license shall be revoked.

## FOREIGN NEWS AND NOTES

## GENERAL.

**Blaming the Piano.**—A Berlin physician of renown, believing that excessive practice at the piano is responsible in a measure for the alarming spread of nervous diseases, has instituted a campaign against beginning the musical education of children at the early age now customary both in this country and in Europe. In his opinion no girl should be permitted to enter upon the study of music before the age of 16, and even then the hours of drumming upon the keyboard should be restricted to two a day. Of 1,000 girls who undertook piano practice before the age of 12, 600 later became afflicted with some form of nervous disease, but of 1,000 whose musical education was neglected, only 100 ever suffered in this manner.

## CONTINENTAL EUROPE.

**Comparison of Sexes in Italy.**—Official figures of a recent Italian census show that in Italy there are 16,155,130 males against 16,320,123 females. Until within recent years Italy was the sole country in Europe in which the males exceeded the females and this reversal of sex predomination in that country is attributed to excessive migration on the part of the males. The census of those having ability to read and write was 31.2% in 1872. In 1877 a law requiring compulsory education was put into effect, yet the recent census shows only 48.5% of the Italians are able to read and write. Complaint is being made by the newspapers of that country that the enactment requiring compulsory education is not being enforced.

## OBITUARIES.

**Thomas G. Morton**, one of the foremost physicians of Philadelphia, died May 20, at Cape May, after an illness of two days, aged 68. He was graduated from the medical department of the University of Pennsylvania in 1856, and shortly afterward became an interne in the Pennsylvania Hospital. Later he was appointed attending surgeon to that institution. During the Civil war he won a national reputation as a hospital manager. He organized various military hospitals, and some of the systems perfected by him at that time are still in vogue in well-regulated hospitals throughout the world. He was one of the founders of the Polyclinic Hospital, and he also founded the Orthopedic Hospital, and up to the time of his death he held a position on the consulting staff of this hospital. He was surgeon at the Satterlee Hospital and consulting surgeon at the United States Army Hospital at Chestnut Hill, beside holding positions in many other hospitals, including the Philadelphia Hospital for the Insane; St. Joseph's Hospital, the Wills Eye Hospital, the Jewish Hospital, Howard Hospital, the Woman's Hospital, and the Pennsylvania Institution for the Deaf and Dumb. His many services to the State on various boards and commissions included the erection of a State Hospital for the Insane for the Southern district of Pennsylvania, as chairman of the committee on plans and buildings of the commission appointed to carry out this work in 1876. In 1880 he was chosen president of the Pennsylvania Society for the Restriction of Vivisection, and the same year vice-president of the Society to Protect Children from Cruelty. In 1883 he was appointed a commissioner of the State Public Charities, and in 1886 he was made chairman of the State Committee on Lunacy. In 1886 he introduced at the Pennsylvania Hospital a bed elevator, and in 1874 a ward dressing-carriage, for which he received a medal at the Centennial Exhibition. He belonged to many societies and organizations, among them being the College of Physicians of Philadelphia, the Philadelphia Academy of Natural Sciences, the American Medical Association, American Surgical Association, Philadelphia County Medical Society, the Philadelphia Board of Education, and the Philadelphia Academy of Surgery, of which he was president. He was a frequent contributor to the *American Journal of the Medical Sciences*, beside publishing many standard works, including "The Transfusion of Blood and Its Practical Application," and jointly with Dr. William Hunt, "The Surgery of the Pennsylvania Hospital." Among his most recent works is a history of that institution.

**John P. Bryson**, in St. Louis, Mo., May 5, aged 57. He was graduated from the Humboldt Medical College, St. Louis, in 1868. He was professor of genitourinary surgery in the medical department of Washington University.

**John B. Burdett**, at Jersey City, N. J., May 21, aged 70. He was graduated from the New York College of Physicians and Surgeons in 1856, and had practised in Jersey City since 1855.

**Israel Pattison**, at Oelwein, Iowa, April 26, aged 62. He was graduated from the University of Buffalo in 1867, and was for many years a surgeon of the Great Western Railway.

**Andrew J. Sauer**, of Baltimore, Md., May 20, aged 30. He was graduated from the Baltimore Medical College in 1894.

**J. W. Kirkpatrick**, of Wyoming, Iowa, May 13. He was graduated from the Rush Medical College, Chicago, in 1888.

**H. D. Shrader**, of Washington, D. C., May 21, aged 52.

## SOCIETY REPORTS

## SIXTH TRIENNIAL CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

Held in Washington, May 12, 13 and 14, 1903.

## ASSOCIATION OF AMERICAN PHYSICIANS.

[Specially reported for *American Medicine*.]

**Address of the President.**—The president, JAMES STEWART (Montreal), acknowledged the great honor conferred upon him in making him president of the Association of American Physicians, and said that the Association was one whose work had made it known and respected wherever modern medicine was taught, and that he appreciated most highly the compliment paid, not only himself, but his colleagues across the line; he felt that it was a matter for which all should be deeply grateful that the Canadians had been received into the Association from the beginning in such a generous manner. The existence of the Association, which was one of clinicians, pathologists, bacteriologists, and chemists, was an index of the advancing character and increasing precision of the work. He said that it was apparent, in contrasting the work performed by the Association since its inception in 1886 with that of the last few years, that there had been a considerable change in the character of the papers read; that the proportion of more or less purely scientific papers had steadily increased in numbers and value; that the papers of the more or less purely clinical type had been from the first of a high order and that they continued to be of the same high character. He considered the program of the meeting an index of the very valuable and laborious work that would be recounted during the session. Stewart said, quoting the words of a recent writer, "The new century begins its history from a vastly higher standpoint all round than its predecessor did. Our chief hope for the future lies in the desire, which has become so much more acute within the last few years, to get away from the bondage of theories and hypotheses and to be able to question and cross-question facts till their meaning becomes plain. The true students of medicine are now everywhere struggling to get at the heart of the disturbing influence which breaks up the harmony of health and life." The part that many members of the Association were taking in the solving of these problems that had so long resisted investigation was very gratifying, and the very recent splendid contribution to practical medicine made by one of the members would stand forever to the glory of American medicine. He spoke highly of the way in which hospitals and research laboratories had been endowed in the United States and Canada, and considered it a harbinger of a time that would come when the recurring waves of charlatanism would cease. He said that the names of Johns Hopkins, Rockefeller, Morgan, Vanderbilt, Strathcona, and others would live to be blessed for ages. In closing, STEWART paid a tribute to the members who had passed away during the last year, all of whom he said were men of high promise who had left behind them much evidence of excellent and abiding work. These men were Wyatt Johnson, who died of septic poisoning acquired in the postmortem room of the Montreal General Hospital; Frederick A. Packard, who died of typhoid fever; and Major Walter Reed, whose death was caused by appendicitis and whose fame rested mainly upon the researches conducted on the yellow fever commission of the United States Army.

**Bathycardia (Low Heart).**—E. G. JANEWAY (New York) proposed this term to signify a low position of the heart due to anatomic conditions; not to disease. The patients all have long flat chests, and there was generally difficulty in placing the apex of the heart, the tendency being to place it too high rather than too low. It was liable to be mistaken for other conditions of the heart and often led to the supposition of an abnormal state of the lung.

**Discussion.**—OSLER (Baltimore) said a very interesting condition might be the descent of the heart in conditions of great hypertrophy, especially hypertrophy of the right heart, which caused bulging in the right parasternal area. The condition was sometimes mistaken for aneurysm. WILLIAMS (Boston) asked if there was any record of the position of the tube and the distance from the patient when the radiograph was taken and said that it made considerable difference whether the tube were near or far away. It was of importance that there should be attached to the radiograph a memorandum indicating the position of the tube as only in this way could the radiographs of different cases be compared. McPIEDRAN (Toronto) asked if Professor Osler referred to hypertrophy with dilation. He had had a few days ago a death due to mitrostenosis, without dilation but with extreme hypertrophy. There existed on the thorax no sign of any derangement. In closing, JANEWAY said that the radiographs had been taken by Dr. Caldwell and he had no memorandum of the exact distance at which they were taken; they were rather to show the position of the heart than anything else.

**Posttyphoid Sepsis.**—FRANCIS DELAFIELD (New York) said that the different fevers following typhoid, which might be due to the typhoid bacillus or to other infections, must be

distinguished from the true relapses of typhoid fever, and a number of charts were exhibited explaining the diagnostic points. He considered the question of the moderate rise of temperature occurring a short time after the end of typhoid fever and lasting but a few hours, and the posttyphoid fevers lasting for weeks. In order to bring these fevers to an end the author considered it necessary to get the patients out of bed and give them solid food; some improved on being given solid food alone, but it was usually necessary to get them out of bed as well.

**Discussion.**—KOPLIK (New York) thought it common to see the temperature run as illustrated in the charts. Where the child had been sick with typhoid fever for several weeks and the temperature had fallen to normal, he immediately gave the patient food in spite of the low temperature which might exist. He did not believe it proper to starve these cases, for it had been his experience that the temperature would disappear when the patient was gotten out of bed and given proper food. The condition was due to lack of nutrition or to some reinfection aside from that of typhoid fever. PEABODY (Boston) agreed with Delafield and Koplik, and thought the best solid food to begin with in these cases was hard boiled egg, boiled until a touch would reduce it to a fine powder. This he considered easier to digest than the soft boiled egg, because the work of coagulation had already been done. ROBINSON (New York) thought there were a certain number of cases in which this plan would not be a good one, and that if food were given the temperature would not drop. He thought the use of mild purgatives would do much to lessen the number of these unexplained cases of rise in temperature.

[To be continued.]

## AMERICAN GYNECOLOGICAL SOCIETY.

[Specially reported for *American Medicine*.]

SECOND SESSION (CONTINUED).

**Discussion** on papers of THADDEUS A. REAMY and REUBEN PETERSON (of May 13). P. A. HARRIS reported a case of cancer of the cervix operated on seven years ago and the patient is still well, but most patients die within two years. He had operated on one case of cancer of the vulva in a woman of 70, but recurrence caused her death 2½ years later. C. P. NOBLE said cancer of the cervix is worse than cancer of the uterine body. He recalled two cases operated on 15 and 13 years ago that are now well. The vast majority have recurrence. Hysterectomy cures about 10%. The curet and zinc chlorid are efficient agents for removing the diseased tissue. He has operated on four cases of cancer of the vulva. Three of the patients are dead, one appears well 1½ years after the operation. J. W. BOVÉE had seen no case of cancer of the vulva sufficiently early for operation. The early cases of cancer of the uterus demand more extensive operation than late ones, which are merely palliative. The cautery is a valuable instrument in these cases. I. S. STONE reported a case of cancer of the cervix which was cured by operation. The cautery cures a few of these cases and should be used. In sloughing cases zinc chlorid should be used before operation. The electric angiostribe is a good thing but does not scar all the raw surfaces. MATTHEW D. MANN said some of the most hopeless cases of cervical cancer turn out the best, and vice versa. He did a high cervical amputation eight years ago for cancer of the cervix and the patient is still well. He has had three cases of cancer of the vulva. One case after curetment of the diseased part improved for a time under Röntgen ray treatment, but recurrence caused her death. The Röntgen rays should be tried in these cases, some are benefited. REAMY closed the discussion of his paper by calling attention to the fact that it dealt with cancer of the cervix only, which is claimed by some to be incurable. A few permanent cures established the fact that the disease is originally local. PETERSON closed the discussion of his paper by stating that not always in cancer of the vulva are the lymphatics involved. He believes that here, as elsewhere in the body, we have two forms of cancer: (1) Diseased area is small, soft, and after operation recurs early; (2) diseased area usually large, and there is often no recurrence after operation.

**Should the Uterus be Removed When Operating Through the Abdomen or Vagina in Cases of Double Pyosalpinx.**—Several papers were contributed on this subject. P. A. HARRIS said: When suppuration has become well established in both tubes, their excision is the only operation which can be relied upon to effect a cure. By excision is meant the removal of the lumen of the tube to the uterine mucosa. Less radical operations, as hemisection and disinfection of the ampullas and larger portions of the tube, probing and washing of the tube and amputation of distal portions of pus tubes are incomplete operations, and are proportionately unsuccessful in that they leave behind a diseased sinus, which not only continues to exist, but is productive of discomforts and other ill consequences to a greater or less degree. In bilateral excision of double pyosalpinx sufficient ovarian stroma may be left to influence and continue menstruation in at least 95% of any large class of cases operated upon. The ovaries frequently participate in suppuration which they derive from pus tubes. But in them suppuration is more easily terminated, and excision is not advised, excepting for extensive abscess of the ovary

at the time tubes are excised, or a belief or knowledge that the suppuration in the ovary is tuberculous in character. Simple excision of double pyosalpinx affords the maximum degree of relief, with a minimum of mutilation, and interference with the functions of the pelvic organs. The complaints arising from the existence of endometritis often cease after simple excision of double pyosalpinx. If the symptoms of endometritis continue and greatly harass the patient, the uterus may be removed by vaginal section. The price of removal of the uterus in every case of double pyosalpinx may be partly estimated by the following results: 1. Loss of menstruation in every instance. 2. Partial or complete extinction of the sexual quality in a large proportion of the cases, together with incomplete physical capacity for sexual participation. 3. Injury to the nervous system of the patient, arising from her knowledge and appreciation that she has been prematurely and possibly unnecessarily deprived of these and other qualities which render her physically and to a certain extent morally inferior to other women. ANDREW F. CURRIER had prepared a paper which in effect said: If this is proposed as a matter of routine the writer would reply emphatically, No. If it is proposed as an expedient, when the uterus itself is diseased, extensively diseased, the writer would say, Yes. It may also be removed if it has been greatly injured in the extrication of the appendages, or if it should seem to be required as a means of controlling troublesome hemorrhage. To remove the uterus in a young woman may possibly produce unfavorable mental effect as a consequence, near or remote. To remove the uterus from one near, at or past the menopause may add an element of risk to the operation. To remove the uterus may weaken the pelvic roof, and may introduce an element of danger from enterocele. To remove the uterus unnecessarily is bad morally, for it tends to establish the impression of the unimportance of the organ and that it may be unhesitatingly extirpated by any one who has the requisite skill. To remove the uterus on the ground that it may possibly be the seat of malignant disease in the future is assuming more than clinical history teaches in the great majority of cases, and is, moreover, a reproach to surgery, making it destructive instead of conservative. I. S. STONE said no organ should be removed unless absolutely necessary. In a large majority of cases the pus found in diseased adnexa is sterile, therefore the chief element of danger from sepsis is eliminated, and the uterus is not the seat of dangerous microbial infection. An exception to the above rule may be found in puerperal infections. When purulent adnexa are removed the uterine cornua should be excised and the uterus permanently sealed, and thus made a barrier against further, and also to permit effective treatment of that organ should it later become necessary. Hysterectomy requires additional time, causes further traumatism, and necessitates changes in the anatomic relations of vagina, bladder, etc. If necessary to drain the pelvis by way of the vagina, the usual route through the culdesac posterior to the uterus answers every purpose. Many women object to panhysterectomy, and the question of its effect upon the mental status is still *sub judice*. MATTHEW D. MANN said that almost the sole cause of pus tubes is gonorrhoea, though there may be a mixed infection. The gonococcus infects the surface of mucous membrane and spreads by continuity of structure as no other germ does; hence preceding infection of the tubes there is uterine infection. This may cause serious trouble, and since the organ is now useless, especially if the ovaries are removed, it should be removed. If left the uterus may become the seat of cancerous disease, but this is, of course, rare. In acute infection removing the uterus secures the best means of drainage. The result by the vaginal route, when the uterus is always removed, warrants its removal in operating by the abdominal route. The woman's sexual life is unaffected by the removal of the uterus, hence nothing need be feared from that source. The additional time taken for its removal is more than counterbalanced by the securing of good drainage. HENRY C. COE (read by abstract) said the uterus is by no means always diseased in these cases, and when so it can be successfully treated by curetment. Should one or both ovaries be healthy and left undisturbed the retained uterus will permit menstruation and prevent the disturbances attendant upon an early climacteric. The chances of pregnancy are too remote for consideration. In most cases ample drainage can be secured without removing the uterus. Hysterectomy does add to the immediate and subsequent risks of the operation, recent favorable statistics notwithstanding. Atrophy of the vagina in young married women is an objection to hysterectomy, and may lead to marital unhappiness. Much depends on the condition of the uterus at the time of operation. If the organ is thoroughly softened and diseased, the seat of fibroid changes, or extensive laceration, no question remains as to the propriety of its removal. The wishes of the patient must be considered. Many women prefer to take the risk of a second laparotomy or vaginal hysterectomy rather than have everything removed at the first operation. C. P. NOBLE (Philadelphia) gave a summary of his personal experience with operations in cases of double pyosalpinx. Removal of the ovaries produces no effect on the sexual desire. He has never seen a vaginal hernia result from removal of the uterus. Some advantage results to young nulliparas from leaving the uterus and ovaries, in other cases they should be removed. He has operated on 58 cases of pyosalpinx with abscess of one or both ovaries, and has had 1 death. He

almost uniformly removes the uterus. In 6 cases similar to the above, but with intraperitoneal suppuration, he has had 4 deaths. In these no hysterectomy was done.

**Discussion.**—GORDON favored the removal of the uterus in these cases. It is an infected organ and liable to be the seat of leukorrheal discharge and a focus of congestion and pain. BACHE EMMET asserted that the uterus does not remain long infected even when the disease passes on to the tubes, hence it is unnecessary to remove it unless it is the seat of disease. It affords support to the pelvic viscera and should not be wantonly sacrificed. J. W. BOVÉE said much depends on the condition of the uterus at the time of operation. He does not remove the uterus unless there is some special indication for it. THADDEUS A. REAMY advised against removal of the uterus unless there was some pathologic condition specially indicating it. DUDLEY favored removal of the uterus if the pyosalpinx is septic—often the pus is sterile. The social condition of the patient, her wishes and a number of other things must be taken into consideration before hysterectomy is advised. The uterus assists materially in the diaphragmatic action of the pelvic floor, and in maintaining the pelvic organs in correct position, hence it should not be unnecessarily removed.

[To be continued.]

## AMERICAN ASSOCIATION OF GENITOURINARY SURGEONS.

[Specially reported for *American Medicine*.]

SECOND SESSION.

**Acute Vesiculitis with Special Reference to Treatment.**—J. P. TUTTLE (New York City) described the anatomic location of the seminal vesicles, and stated that the symptoms were more often rectal than of the genitourinary system. He condemned Valentine's apparatus for irrigation of the urethra, considering it dangerous from its causing distention of the ducts, thus carrying infection up to the vesicles. The diagnosis can only be made positive through rectal examination. Pain is referred to the perineum and rectum, and with vesiculitis is associated with epididymitis. There is tenderness along the vas deferens. In a few cases he uses counterirritation with either silver nitrate saturated solution or electrocautery over the congested area and on the anterior wall of the rectum. Very commonly he uses cold irrigations of the rectum (temp. 55° F. prolonged); occasionally hot irrigations (temp. 110° to 115° F.). He closed his paper with a warning against too hot or too cold irrigation, and also against the use of the ordinary rectal irrigators.

**A Further Report of the Author's Method of Exposing and Draining the Seminal Vesicles.**—EUGENE FULLER (New York City). For the technic of the operation see "A Preliminary Report" in the *Journal of the American Medical Association*, May 4, 1903. He reported a second series of 12 cases, 9 of which were operated upon for the relief of chronic vesiculitis, 3 for draining vesicular abscesses. There were no deaths, but in one case an extensive perforation of the rectal flap occurred. In these cases sexual power which had been lost was recovered in from five to six months after the operation.

**Discussion.**—HUGH H. YOUNG (Baltimore) considers chronic prostatitis more difficult to cure than chronic vesiculitis. If the chronic prostatitis is relieved, he considers that the vesicular condition rights itself. GEORGE K. SWINBURNE (New York City) cited a case in which the symptoms of vesiculitis suggested prostatic disease, but the prostate was found to be normal. GEORGE R. KEYES, JR. (New York City) advocated draining the vesicles through the rectum, as causing no increase of infection and being of much simpler operation.

**A Vesical Calculus of Unusual Dimensions.**—ABNER POST (Boston) reported the case of a male, aged 66, who had symptoms pointing to vesical calculus; namely, frequent urination, sudden stop of flow of urine, pain, discomfort, and difficulty in standing. These symptoms dated back 14 years, when the patient had had a urethral hemorrhage. Examination showed dulness over the pubes, inability to enter a catheter into the bladder properly, urine foul. This last was relieved by urotropin. A suprapubic incision was made and the bladder exposed, and with difficulty the calculus was removed. The wound was closed and dressed, and there was continuous irrigation of the bladder. The patient died five days later. The calculus measured three-quarter inches in its largest circumference, and weighed 660 grains.

**Some Suggestions in the Management of Prostatitis About to Enter Catheter Life.**—GEORGE K. SWINBURNE (New York City). This paper will appear in a future issue of *American Medicine*.

**Cancer of the Prostate.**—ROBERT H. GREENE (New York City) states that statistics in regard to cancer of the prostate are very meager. This is probably due to the fact that cancer of the prostate is so small as to render careful pathologic examination of the gland necessary in order to discover the cancer. He estimated that cancer is present in 5% to 10% of cases of enlarged prostate, and quoted two cases reported by Brooks and Greene in which cancer was found in 58 examinations of enlarged prostate. He considers the residual urine bears no relation whatever to prostatic cancer. Pain is referred to the perineum, rectum, and also to the sciatic nerve. The youngest case reported was in a man aged 49; average age is 68. For the secondary

enlargement of the lymphatics he refers to 71 autopsies of cancer of the prostate, in 85% of which the glands were infected, 30% inguinal, and a still larger percent postmesenteric and the glands along the iliac vessels—5% axillary glands. He reported a case in which the patient had a burning in the perineum, a small amount of residual urine, and slight enlargement of the prostate. Prostatectomy was performed. The right lobe was found to be cancerous, and the left lobe of the organ was simply hypertrophic.

**Medicolegal Studies in Cases of Alleged Syphilis.**—ABNER POST (Boston). At the request of the author, because of legal complications, this paper was not abstracted.

THIRD SESSION.

**Demonstration of Author's Ureterocystoscope.**—J. TILDEN BROWN (New York City) states that in the use of his instrument the patient is placed in a dorsal position, with the lower end of the table elevated; legs supported on a lateral leg rest, and the instrument and irrigating apparatus at one side. The instrument consists of an obturator acting also as a catheter for the preliminary bladder irrigation; telescope, on the under side of which were two tubes, through which the ureter catheters passed. The lamp was an open one. With this instrument he was enabled to irrigate the bladder, cystoscope it, and also to catheterize the ureter separately. The proximal ends of the catheter were covered, so that no contaminating material could enter them during the manipulation, and the urine so drawn off could be examined bacteriologically without having been contaminated.

**Use of the Cystoscope in the Study of Prostatic Hypertrophy.**—HUGH H. YOUNG (Baltimore) states that in the ordinary cystoscope the field of vision is at right angles to the shaft of the instrument, the focusing distance being about 2.5 cm. In its use on the prostatic orifice the tissues are so close as to give great magnification and contract the field of vision to about 60°; therefore, in order to use the entire orifice—namely, 360°—it requires six different views of 60° each. He had devised an instrument to look backward, but because of the imperfections due to poor instrument makers it was not as yet entirely satisfactory. The object of his paper was to show how to make ordinary cystoscopy useful in examining the prostatic orifice. He exhibited two series of charts, the first series showing the different shapes assumed by the prostatic orifice from pressure either lateral, anterior, posterior, or their combinations. The enlargement of the middle lobe particularly gave a Y-shaped appearance to the orifice, thus giving two lateral passages into the bladder, making accurate cystoscopy difficult. The second series showed the appearance of the different segments within the limits of the field of the cystoscope. One of the chief faults of the cystoscopic examination of the prostatic orifice was the inability of the operator to determine the character of the enlargement, thus enabling him to make a more complete removal without a possibility of leaving any behind.

**Report of a Case of Filariasis.**—J. TILDEN BROWN. This case was previously reported before the Pathological Society of New York and published.

**Some Observations on the Surgical Treatment of Chronic Bright's Disease.**—RAMON GUIERAS (New York City) had read a preliminary report before the Association in 1902. The theory of the operation was that the circulation in the kidney is increased by anastomosis formed with the surrounding or enfolded tissues. In the general summary of these cases and those collected from literature the results shown were good. A fair percentage were cured and a large percentage were improved.

**Discussion.**—EDEBOHLS (New York City) stated that he had not reached any definite conclusion in regard to the operation, recognizing that some time must elapse before definite results. He mentioned the indefinite value of animal experimentation. He cited a postmortem on a case of his operated on four months previously. Serial sections were made and showed enormously enlarged vessels entering the new-formed kidney capsule from the surrounding fatty capsule. Those cases which had survived the operation showed improvement, with a uniform result of a steady increase in the elimination of urea. Subjectively all the cases were reported as feeling much better. In his operation he simply decapsulates the kidney and returns it to its fatty bed, where it is firmly supported. He considers that the operation will have to go through certain amount of evolution before finding its definite place.

**Rupture of the Kidney.**—F. S. WATSON (Boston) reported 5 cases of his own and the results of examination of 660 cases gathered from literature. The causes of rupture were varying, muscular action causing 10%. He was struck by the slight force necessary for rupture to take place. Blows over the front of the abdomen with the patient on his back was one of the causes of rupture. The kidney was never ruptured on one side with an accompanying injury to an organ on the opposite side. Intraperitoneal symptoms were usually due to rupture of the peritoneum. Tumor formation occurred in 143 cases. Hemorrhage was the frequent cause of death. In all the cases there was a striking absence of injury to the omentum or the intestine. **Indications for operation:** (1) Marked and persistent hemorrhage; (2) presence of a rapidly increasing tumor or area of dulness in the loin; (3) development of a tumor in the loin 10 days or more after the injury; (4) immediate operation when

there are signs of free fluid in the abdominal cavity; peritonitis or other peritoneal injuries. *Treatment:* Expectant, incision, and tamponing, nephrotomy, and finally nephrectomy. In nephrectomy the fatalities were greatest—21%.

**Some Observations on the Effect of Catheter Drainage on the Functions of the Kidney and Pyelonephritis.**—ARTHUR P. CABOT (Boston) considers that the back pressure on the kidney by enlarged prostate or other causes is relieved by constant and thorough drainage of the bladder by a retained catheter. This gave a relief of tension and freedom to the glomeruli and tubules of the kidney. As a result there was a considerable increase in the amount of daily urine and a proportionate increase in the elimination of solids. The catheter drainage should be continued until urine is normal. *Method of removal:* 1. All urine through the catheter is stopped for short intervals, the intervals being gradually increased. 2. The withdrawal of the catheter for gradually increasing intervals. He does not consider that the catheter treatment should supersede other operative procedures on the prostate.

*Discussion.*—EUGENE FULLER (New York City) spoke of the element of bacterial nephritis occurring through back pressure of infected urine and it is relieved by this method.

## AMERICAN ASSOCIATION OF PATHOLOGISTS AND BACTERIOLOGISTS.

Third Annual Meeting, Held in Washington, May 12, 13 and 14, 1903.

[Specially reported for *American Medicine.*]

### SECOND SESSION.

This session attracted a larger attendance than any of the sessions, because of the general interest in the question of the discovery by Dr. Councilman of the cause of smallpox. The session was devoted entirely to the papers upon variola.

**A Bacteriologic Investigation of Vaccine Virus.**—W. T. HOWARD, JR., and W. H. WEIR (Cleveland) gave the results of a series of studies upon the vaccine virus offered in the open market by several firms. Extensive tables classifying the results are exhibited, and the literature discussed. The work is confirmatory of the work done by many others in this country and abroad. The new facts of interest are limited to the finding of actinomyces in several of the preparations, which were discussed in a separate paper.

**The present status of the question of vaccine virus** was well summed up in the discussion by Dr. ROSENAU: Vaccine virus often contains germs of a more or less suspicious nature and in greater or less quantities. But we do find pure vaccine virus, and the matter is perfectly analogous to that of another bovine product, milk. It has been demonstrated that pure milk can be obtained with the proper care, and such is the case with the commercial preparation of vaccine virus. It is merely a question of cleanliness.

**A Study of Actinomyces Obtained from Vaccine Virus.**—W. T. HOWARD, JR. (Cleveland) described the cultural characteristics of the organisms which he has isolated.

*Discussion.*—BERGEY (Philadelphia) touched upon the weak point in this paper—the means employed in the diagnosis of actinomyces, since the pathogenicity of the organisms isolated and studied by Howard had not yet been determined.

**Streptococci in Variola: (a) Relation of Streptococci to Variola.**—R. G. PERKINS and G. O. PAY (Cleveland) described the results of a routine examination of 40 autopsies of variola cases, 38 cases showing the presence of streptococci in the skin lesions; in many of the cases streptococci were found in the heart's blood. The time of the blood invasion seems to be independent of the course of the disease. Streptococci are present in all severe cases of variola, but have nothing to do with the etiology of the disease. (b) **Identity of the streptococci in variola.** The conclusion from these studies was that various streptococci occur in variola. The point of entry is probably the bronchial mucous membrane. (c) **Serum treatment in variola.** Perkins and Pay have studied the effect of treatment with specific streptococcus serum. The results were negative, as one might expect if the streptococcus of the particular case did not happen to be the one used in the immunization of the animal from which the specific serum was taken.

**The Agglutination Properties of the Blood-serum in Variola and Varioloid for Red and White Blood Cells.**—W. T. HOWARD, JR. (Cleveland) has studied the effect of serum taken from variola patients upon the red and white blood cells from vaccinated and nonvaccinated patients, and from patients suffering from variola. The conclusions reached are: 1. The blood-serum of variola patients causes agglutination of the red and white cells of vaccinated and nonvaccinated individuals, and of rabbit's corpuscles, but does not agglutinate those of the ox. 2. This serum has no hemolytic effect.

**Observations on the Bacteriolytic Complement-content of the Blood-serum in Variola.**—R. L. THOMPSON (Boston) [read by W. R. BRINCKERHOFF] has used a modification of the method used by Longcope—the reactivation of the amboceptor found in the heated serum of animals by the complement of the human serum, which method permits of using

much smaller quantities of the human serum. Thompson concludes from his studies that there is a diminution of the bacteriolytic complement in the early stages of the disease, followed by a rapid return to the normal complement-content, except in cases of severe infection, where this return to the normal condition is not seen.

**A Study of the Bactericidal Properties of the Blood-serum in Variola and in Varioloid.**—R. G. PERKINS and G. O. PAY (Cleveland) by the use of Longcope's method, have reached the conclusion that there is a loss of complement in the early stages; later stages show less loss of complement, especially in infectious involvements. Wasting suppurations cause a loss of complement.

In the *discussion* of this paper HEKTOEN called attention to the fact that normal serum contains no complement for the streptococcus; we therefore cannot speak of a loss of complement as explaining the infection with streptococcus. Further in regard to Longcope's method, we must remember that very small amounts of normal serum suffice to kill very large numbers of the typhoid bacillus, and that we must bear in mind the phenomenon described by Neisser and Wechsberg.

**A Study of the Etiology and Pathology of Variola.**—R. G. PERKINS and G. O. PAY (Cleveland). This comprises inoculation and cultural experiments which have been entirely negative. No new contribution to the pathology is reported.

In the *discussion* EWING (New York) asked if Perkins has seen any specific lesions of the female genital tract. COUNCILMAN reported that they have found the same lesions in severe cases in the mucous membranes as in the skin; in one case lesions were found in the ovary, and in one case in the stomach. He referred further to the enormous streptococcus infection which occurs in all severe cases. PERKINS replied to Ewing that they have noted no lesions of the genital nor of the gastrointestinal tracts.

**Studies on the Infectiousness of the Late Stages of the Skin Lesions of Variola.**—W. R. BRINCKERHOFF (Boston) discussed the length of time that may ensue before the death of the contagium in the crusts of the late stages, and describes the results of culture experiments. By using fresh rabbit serum Brinckerhoff has found a method in which the contagium can be demonstrated; the rabbit serum causes the death of the greater number of the saprophytic organisms which occur in the crusts. The presence of the contagium was determined by inoculation into the cornea of the rabbit. A disc 88 days old gave positive results. The contagium could not be passed from one tube to another. Passage through a Berkefeld filter removes the contagium. Out of 12 corneas seven showed positive results. The conclusions were that the contagium is present in the crusts, and can remain alive for a long period; by appropriate treatment the specific contagium can be separated from the bacteria present in the crust, and can be made to grow under artificial conditions.

**Studies on Variola in the Ape.**—G. B. MAGRATH and W. R. BRINCKERHOFF (Boston) have made an important contribution to our knowledge. After a discussion of the literature and a description of the methods used, they describe the results in six inoculation experiments. Two monkeys developed local lesions only; one developed a local lesion, followed later by a general exanthema. The lesions contained the specific organism. Another monkey developed a primary lesion, with secondary papules in the vicinity. They conclude that monkeys are susceptible; the disease in monkeys is typical, and is accompanied by a disturbance of the leukocytic equilibrium. The lesions are essentially comparable with those of man, and contain both forms of the variola organism.

**The Fat of Pneumonic Exudates: Microscopic Demonstrations.**—H. A. CHRISTIAN (Boston). In the early stages of pneumonic exudation a substance giving certain reactions may be constantly found within the polynuclear leukocytes; in the later stages these cells contain a substance, also of fatty nature, which, however, gives a different reaction. The exact nature of these substances could not be determined.

**Intracellular Enzymes and Antienzymes.**—PHEBUS A. LEVENE and L. B. STOOKEY (New York) dealt with the presence of antienzymes in the tissues of the body. The conclusion is that such antibodies are present. Immunization experiments were reported, with positive results, but the paper was too long for the allotted time, and was not finished.

**The Etiologic Factor in Variola, with Lantern Slides.**—W. T. COUNCILMAN (Boston). It is impossible to report here this paper, since it consisted almost entirely of a demonstration of an excellent series of photomicrographs of the organism which Councilman has already described in preliminary publications. Of the most interest to the profession at large is the report of the discussion, and of the manner in which the paper was received. WELCH (Baltimore) says that he feels that Councilman has found the real thing. This opinion he bases upon his knowledge of Councilman's work and from the paper just read and from the photographs shown. We have here a definite structure and are not dealing with degeneration products. The discovery of the intranuclear forms of the parasite forms a very decided contribution to our knowledge. There are still many gaps to be filled, but Welch feels that America must be congratulated upon the work of Councilman. BERGEY (Philadelphia) reports that he has made a study of variola and has convinced himself of the correctness of Councilman's discovery. He was not able to see certain transition forms which have been

now brought out by Councilman between the stages of the parasite. HOWARD (Cleveland), since reading a preliminary communication sent to him by Councilman, has been able to find certain of the stages. EWING (New York) confesses that he has been working upon the opposite idea, but yet inclines to the idea that Councilman has found the specific organism. However, he would like to have certain facts explained before accepting the discovery entirely. He refers to the fact that these bodies have been seen by other observers, except the intranuclear forms, which is the most important advance in our knowledge, and yet these observers have differently interpreted the bodies. He is not yet ready to abandon the theory of degeneration products, and will await a satisfactory explanation of the disappearance of the nuclear contents.

[To be continued.]

## AMERICAN ORTHOPEDIC ASSOCIATION.

[Specially reported for *American Medicine*.]

### SECOND SESSION.

**Hip Disease Considered with Special Reference to the Combined Treatment.**—R. TUNSTALL TAYLOR (Baltimore) is of opinion that the diagnosis of this disease should be made by aid of the skiagraph and the tuberculin method relegated to history, because other conditions, such as syphilis, leprosy, etc., are known to give a positive reaction also. Anti-syphilitic treatment is dangerous, as serious results often happen from the delay in trying the test. The combined method should be employed in the treatment of the disease when it fails to respond to mechanical treatment, though never in the acute stages. The operation consists in making an anterior incision, erosion of the diseased area, disinfecting with formalin solution and suturing, leaving only a small wick drain extending to the bone and withdrawing it on the third day. Carbolic acid as a disinfectant is dangerous, producing death in some instances. The combined method was tried on the following groups: (1) Favorable cases in good condition; (2) cases in which suppuration was inevitable; (3) septic cases with discharging sinuses, and resulted (1) in good motion; (2) no shortening; (3) shortening duration of the disease. Dr. Taylor illustrated with patients and skiagraphs. The value of the x-ray in hip-joint disease cannot be overestimated, as it clears up all questions of diagnosis and should be employed throughout the course of treatment to determine the proper time to allow functional use and to anticipate any complications or relapse.

**Discussion.**—SIR WM. HINGSTON (Montreal) spoke in glowing terms of the paper and asked the advantage of the anterior incision over the posterior one commonly employed. He said Lorenz was not on trial, but his method of treating congenital hip dislocations; time alone would work out the best method. STARR (Toronto) laid claim to originating the carbolic acid treatment and said ill results following its use were due to following it with alcohol, which dissolved the coagulate of albumin formed by carbolic. He also favors early incision and complete suturing. MCKENZIE (Toronto) recommends that hospitals use tents (out door) during the pleasant months and believes the atrophy following hip disease is the result of traumatic lesion, not long mechanical treatment. TAYLOR, in closing, said that the anterior incision avoids damaging the muscles. He had had evil results following his use of carbolic acid, though no alcohol was used in conjunction with it.

**The Correction of Deformity at the Hip, the Result of Disease: A Study of Best Methods and Best Positions.**—V. P. GIBNEY (New York). Question, "Does the disturbance of the reparative process by forcible correction under an anesthetic cause a recurrence of the disease?" and reported the following cases: Case I.—Girl, aged 9, had been treated for considerable time and thought cured. She began to walk badly and symptoms returned. Forcible correction was performed and a plaster cast applied, the patient being kept in bed on account of a slight rise in temperature. A suspicion of fluid justified aspiration of the joint, with negative result. Night cries became intense and operation was performed, a permanent cure resulting. Incision was made above the trochanter, diseased portion removed with curet and wound closed with suture. Case II.—Boy of 15 asked for treatment to overcome a deformity of hip. The deformity was corrected and a plaster cast applied. The deformity returned and was overcome by osteotomy and the application of plaster cast. The boy developed measles during the course of the treatment and was removed from hospital. After recovering from the measles the hip was as bad as ever. Forcible correction was again applied. Later two sinuses appeared, but closed, leaving the hip still deformed. Gaunt's subtrochanteric osteotomy was then performed, but the condition was not finally cured till a cuneiform osteotomy was done. This case illustrates that no evils result from treatment and that forcible correction bears no relation to tuberculous meningitis. Gibney would recommend the subcutaneous method, since it is a "bloodless" one.

**Discussion.**—A. J. STEELE (St. Louis) reported congenital dislocation of the hip in a patient 8 years old. Lorenz advised forcible reduction. He divided the adductors and followed Lorenz's advice, and repeated the operation with good results, till a few weeks later the patient died of spinal meningitis (tuberculous). He doesn't advocate forcible reduction. JOHN

RIDLON (Chicago) reported five cases in three patients, all chronic. In four he cut the adductors and flexors and reduced; in one he cut the adductors and flexors and couldn't reduce; therefore he did an osteotomy close to the acetabulum, divided and broke the bone. Results: All the patients lived, the deformity was corrected, and good motion obtained.

**Some Points in the Treatment of Hip-joint Disease.**—GEO. B. PACKARD (Denver) states that there are many methods of treating this disease, most of which are successful; the acute symptoms of pain and spasm leave and the condition improves. In any method of treatment three points should be borne in mind: (a) How long should the treatment be continued? The following case will serve to answer the question. Girl, aged 14, suffered from double hip disease, with marked muscular atrophy. Both limbs were brought into position with no displacement of heads of femurs nor suppuration resulting. Flexion of the right femur occurred and crutches were used for five years, the weight being borne by the left limb. Bony ankylosis formed at the right hip, while the left limb, though in use, atrophied. (b) Massage, after the subsidence of the acute symptoms is often the means of preventing a recurrence of the disease and improving the atrophied condition. (c) Constitutional treatment for this disease has been neglected. Fresh air and abundance of sunshine is as necessary here as in tuberculosis elsewhere. The diet should consist largely of meats, fats, eggs, and milk, with an egg and glass of milk between meals and the anemia combated with iron, arsenic, etc. Neglect of this general treatment is often the cause for poor results.

**Resistance of Tissues as a Factor in the Manual Reduction of Congenital Hip Dislocations.**—E. H. BRADFORD (Boston) states that the practical use of this method of reduction is limited by the surgeon's power and the strength of the resisting tissues. Variations in the surgeon's strength may be disregarded; but the resistance is of great importance and the danger of using great force on strongly resisting tissues is fully realized in irreducible hip cases. To extend the usefulness of the method of reduction by manipulation it is necessary to determine as exactly as possible the relative importance of the resisting tissues and whether or not the resistance may be overcome by other means than stretching. 1. The Lorenz method is applicable in most cases in children under 6 years of age. 2. In irreducible cases in older children it may be necessary to incise the capsule and divide the tendons of the *adductor magnus* and the hamstring group at a distance from the hip. Why doesn't the Lorenz method and cutting of the capsule reduce the luxation? Because of the long fiddle-bow tendon of the adductor magnus. Experiments on the cadaver and on patients have proved that it is impossible to dislocate the hip by traction unless this tendon is severed. Lawer Bartlett, of Boston, seeing the method of traction Lorenz employed, has constructed an apparatus which will even dislocate the hip without dividing the adductor magnus tendon. It consists of a frame for each limb ending at the trochanters in a double cylinder, which has a handlike cup to fit shape of hip, and on outer side a handle to act as the fulcrum. This is grasped and, the feet having been fastened to frame, the frame is abducted. The fulcrum being at the trochanter, the head is forced down. If necessary a wrench can be applied to the handle, thus permitting more force to be applied.

[To be continued.]

## AMERICAN DERMATOLOGICAL ASSOCIATION.

[Specially reported for *American Medicine*.]

### FIRST SESSION (CONTINUED).

**An Unusual Case of Tuberculosis Cutis (?).**—T. C. GILCHRIST reported this case in a negro girl of 16, whose mother is living and well; father died of malaria. She is the youngest of 10 children, all of whom are living and well. She had prominence of eyeballs, and was treated at a dispensary in which probes were used in her eyes. Soon after lesions were noticed at the inner canthus. One year later the same were noticed at the side of the nose. Later she had sore throat and huskiness of voice. Upon throat examination the uvula was found destroyed; a scar in right tonsil, also in left larynx with dull, red, irregular nodules, covered with scabs which bled easily; two small pustules on the upper lip. There were no other eruptions. The submaxillary glands were enlarged and looked tuberculous. Upon microscopic examination, nodules with apparent organized bodies were seen resembling blastomycetes. Most of them were situated in giant cells, but some were not. Tubercle bacilli could not be found in the tissue. The enlarged glands of the neck were removed, and large numbers of similar bodies were found in them, and the majority of them had undergone definite calcareous degeneration. A guinea pig was inoculated intraperitoneally with this gland tissue, and it died in four weeks. Small nodules were found in the liver; these nodules contained large numbers of similar bodies to those found in the gland and skin lesion of the patient. The bodies were present in necrotic areas in the liver, and there were many commencing pathologic areas present in which no bodies could be found. No tubercle bacilli were present in the guinea pig. This experiment showed definitely that these bodies were

not inanimate objects, otherwise there would not have been found necrotic areas and much multiplication of these bodies. The death of the animal was apparently due to the presence and growth of these bodies. Further extended experiments with glands which were excised later from the patient did not produce definite results. Pathogenic lesions were produced in a dog and a guineapig. Bodies similar to those found in the patient were found in the cervical glands of the dog, which was killed four weeks later. A mold was grown in another case and in a potato a pathogenic streptothrix was obtained. Nothing could be grown on any medium. Five years from the time the patient first came under observation, scrapings from the nose of the patient were injected into a guineapig which on examination, four weeks later, showed tubercle bacilli.

**Discussion.**—M. B. HARTZELL said Gilchrist failed to prove this a case of tuberculosis; he did not demonstrate that a new infection could not cause the condition five years later. H. W. STELWAGON stated that making successive experiments and finding negative results and then at five years finding tubercle bacilli, does not prove that the organism was the primary cause.

**Note on a Method of Early Diagnosis in a Case of Leprosy.**—F. J. SHEPHERD detailed the case of a Chinaman, who had been in America two years and was admitted to Montreal General Hospital with a skin affection of an erythematous type. Redness and thickening of the skin on arms and forearms were marked, which was more noticeable in warm weather; in areas, size of a 25-cent piece to those of a 50-cent piece, similar patches were to be seen on the face. These were not painful, but itched greatly. Some of the areas were anesthetic, and all were covered with branny-like scales of a brown color. In the neck both external jugulars were much enlarged and the cervical glands were also much enlarged. The hands were perfectly normal. Both ulnar nerves were very much thickened. Leprosy was suspected, and the city authorities were anxious for positive diagnosis in order that the patient, if suffering from leprosy, might be sent home, as the Canadian Pacific Railway had offered free transportation. One of the ulnar nerves was cut down upon, a portion of the nerve was removed, and upon examination was proved to contain numbers of the bacilli of leprosy. Thus the diagnosis was positively established.

**Discussion.**—P. A. MORROW thought that in this case the symptoms were sufficient, and the bacteriologic examination was not necessary to make the diagnosis. He said the nasal secretions should be examined. The nose is the primary seat of lesions of leprosy. In a very large percentage of cases of leprosy the disease is identified by finding leper bacilli in nasal secretions. He said that physicians in charge of leper colonies in countries where leprosy abounds say that leprosy and catarrh go hand in hand. It has been shown that the posterior auricular nerve is the first nerve involved, and this is an aid in the diagnosis.

**Officers for 1903-1904.**—President, Joseph Zeisler, M.D., of Chicago; vice-president, M. B. Hartzell, M.D., of Philadelphia; secretary and treasurer, C. J. White, M.D., of Boston. Next place of meeting, Niagara Falls.

**The Use of the Röntgen Rays in Dermatology.**—H. W. STELWAGON said there is much difference of opinion as to apparatus; there is room for improvement over what we already have. Some dermatologists prefer the static; he preferred to use the storage battery and found advantage in the large coil and a six-inch spark. Low vacuum should be used, as it is safer, and better results are obtained from it. For the protection of the physician's hand, mittens lined with lead foil give good service. He obtained the best results from the use of x-ray in lupus vulgaris and epithelioma. He does not believe it should be used in all skin diseases, and especially when there is inflammation. The Flinsen light is of more value in lesions of the mucous membrane. In administering the treatment one should begin with a minimum dose and give short exposure. Some persons are more susceptible than others, hence it is difficult to determine the amount of flame we are giving each individual, as we do not know what the acting element of the flame is.

W. A. PUSEY's paper dealt most with the rational basis and indications for x-ray. There are found changes in the tissue and in bacteria on which the x-ray is used. All observers agree that in normal skin subjected to x-ray there is a hyperplasia of the epidermis followed by an increase in the pigment and proliferation of cells without mycosis. Later there is disintegration of cells. There are similar changes in the appendages of the skin. Atrophy of nails, hair, and glands. Upon the blood-vessels there are inflammatory changes; the cells of the intima are swollen. In diseased tissue there are changes similar to normal tissue. Tissue taken from nodules of cutaneous carcinomas showed disintegration—the nuclei are broken down and scattered; later the areas of carcinomatous tissue were filled with connective tissue. The bloodvessels showed marked endarteritis. There is degeneration and absorption of the diseased cells without effect on the healthy stroma. The Röntgen ray has a distinct effect on bacteria; when used on acne and syphilis they clear up and disappear; this may not be due to x-ray *per se*, but diseased cells are destroyed, phagocytosis is increased, and the healthy cells are better able to resist. The indications for the Röntgen rays are: (1) To remove hairs, especially in syphilis and tinea tonsurans; (2) in exfoliation of

nail substance; (3) to cause atrophy of sweat-glands; (4) to decrease the activity of the sweat-glands, especially valuable in acne roseacea; (5) for its destructive effect on bacteria in the tissue, the most brilliant results being obtained in lupus; (6) for stimulation of metabolism of skin, a very valuable adjunct in eczema, psoriasis, and lupus erythematosus; (7) for destroying tissues of low resistance, as in epithelioma; (8) to relieve pain and itching, especially of value in eczema and pruritus.

**Discussion.**—DUHRING said that he had used the Röntgen ray for a number of years and was convinced that it is of great value in many diseases. He has found the low vacuum to give the best results and does not have the inflammatory results on the surrounding tissue. To obtain results one must persist in its use, making applications every other or every third day. JAMES C. WHITE recommended the temperate use of the Röntgen ray as a therapeutic agent. It must be used with extreme caution, and especially where inflammation exists and in syphilis and psoriasis. He said he had seen serious results follow in the careless, injudicious use of the x-ray. He thought other remedies ought to be used along with the x-ray in tuberculous skin diseases and in carcinoma. WILLIAMS (Boston) said we have for the treatment of skin diseases a remedy of great value in the x-ray, if used with the greatest care. He said he had used it on 150 cases of superficial newgrowths, which had responded to its use. The disadvantages are the long time in treatment and the necessity for many exposures. He said he determined the amount of flame he used in each case by means of the fluorometer, thus avoiding any untoward effects. F. J. SHEPHERD said that he treated most x-ray burns by cutting out the burn and doing skin grafting. He believed the best results were obtained by using the low vacuum with short exposures and daily treatment. He thought that carcinoma of mucous membrane ought to be left alone by the dermatologist and properly treated by the surgeon.

[To be continued.]

## THE AMERICAN OTOLOGICAL SOCIETY.

[Specially reported for *American Medicine*.]

FIRST SESSION.

**A Case of Mastoiditis with the Picture of Osteomyelitis, Extension to the Occipital Bone and Abscess Under the Deep Muscles of the Neck.**—H. KNAPP (New York) had performed two operations, both very extensive in that they required the removal of all the cellular structure about the mastoid process and backward to the occipital bone, but without interfering with the tympanic structures; a complete recovery with preservation of good hearing resulted.

**Discussion.**—GRUENING advocated commencing the operation in such cases at the tip of the mastoid instead of first opening the antrum in the usual way. He believed that in that way we would frequently find that the pathologic process had progressed to the tip of the mastoid and left the antrum and that the dangers of reinfecting the antrum would be diminished. DENCH advocated always cleaning out or removing the tip of the mastoid with every case, even though the disease appeared to be limited to the antrum. BACON also believed in the routine opening of the mastoid tip, but CROCKET, while in favor of opening the tip first, so as to prevent infection of the healthy antrum, did not believe it would be necessary as a rule to remove the tip, and thought that less deformity would follow the operation if found possible to leave the bony tip in place.

**Abscess of the Cerebellum, with Specimen: Report of a Case of Abscess of Temporo-sphenoidal Lobe; Operation and Recovery.**—EMIL GRUENING (New York) presented the clinical histories of two very interesting cases. In the first an abscess in the cerebellum was diagnosed, and from the history of a chronic suppurative otitis media on the left side and the clinical features most prominent in the case it was concluded that the abscess must be situated in the left lobe. An operation was performed on that side of the head, but the child died some days later and the autopsy disclosed an abscess in the right lobe of the cerebellum, the side opposite to that on which the ear trouble had existed. The second case was an interesting one of cerebral abscess with no very definite symptoms other than the history of otitis media, subnormal temperature and slow pulse. An operation was performed with very satisfactory results.

**Discussion.**—DENCH said that one point that should be emphasized in these cases of cerebellar abscess was the fact that they often give rise to so few symptoms. He cited a case in which he thought he had done a very complete and careful mastoid operation. The patient did well for several days and then suddenly he noticed a foul odor about the dressings. The next day the temperature jumped to 104°, and the patient died before removal to the hospital could be accomplished. Autopsy revealed an abscess of the cerebellum, and yet this patient had no symptoms pointing in that direction, except possibly a little mental dulness for a few hours before death. RICHARDS cited a somewhat similar case, and added that in his experience a foul odor about the wound or dressings demanded a careful investigation. TANSLEY said that in abscesses of the brain he had usually noticed one symptom as fairly constant, that the patient turns the eyes to the side opposite that on which the brain

lesion is situated, and has difficulty in looking the other way. RANDALL (Philadelphia) said that he had frequently noticed this nystagmus, but that in several cases he had seen the eyes turned toward the affected side.

**Report of a Case of Acute Otitis Media with Sinus Thrombosis; Mastoidectomy, Excision of Internal Jugular Vein; Serous Meningitis, Exploratory Craniotomy; Death; Autopsy.**—E. B. DENCH (New York) stated that in spite of the extensive operation this patient did very well up to a few hours before death, which seemed to result from the rupture of a large vein at the base of the cerebellum. One interesting feature of the case was that during the operation the fourth ventricle was opened and yet the patient survived what has heretofore been considered a necessarily fatal accident for more than a week, and then the cause of death was in no way connected with the opening of the ventricle.

**The Clinical Value of the Encephaloscope.**—FREDERICK WHITING (New York) exhibited a series of these instruments varying only in size, which are in effect simply enlarged forms of the urethral speculum. He described his method of using them and the conditions under which they were of service. By introducing them into the wound and using proper illumination one can examine an abscess cavity in the brain and study the pathologic conditions not only of the pus sac and its side walls, but the entire drainage route. Its greatest value seemed to be as an aid to the postoperative dressings of such operations.

**Discussion.**—MCKERNON and DENCH testified to the usefulness of this new instrument, as they had seen it employed by Whiting and had used it a few times themselves.

[To be continued.]

## AMERICAN OPHTHALMOLOGICAL SOCIETY.

[Specially reported for *American Medicine*.]

### FIRST SESSION.

SAMUEL D. RISLEY (Philadelphia) presented a memorial to the late W. F. NORRIS (Philadelphia).

CHAS. H. WILLIAMS presented the report for the Committee on Standards and Methods of Examination, recommending a series of test-type cards, both for distant and near vision testing. The report of the committee was accepted and a resolution adopted appropriating sufficient money to prepare such cards so that they might be furnished to members of the society at the mere cost of printing.

**Tuberculosis of the Conjunctiva.**—EDW. JACKSON (Denver) stated that the patient, a girl 10 years of age, with a history of previous good health, had a sudden attack of fever associated with vomiting and swelling of the left cheek and eyelids. The first oculist who saw her made the diagnosis of syphilis, but in spite of treatment she continued to lose weight, and the swelling of the face increased and involved the glands about the angle of the jaw. On the conjunctival surface of the lids there were masses of granules, somewhat resembling trachoma, and in the retrolarsal fold considerable fatty necrosed tissue. The granules when examined closely bore a striking resemblance to miliary tubercles, and microscopic examination of the necrotic tissue showed typical tubercle bacilli. Under the general treatment for tuberculosis and the local use of a wash of trikresol, 1-1,500, the patient made a rapid recovery.

**Discussion.**—KNAPP (New York) said that he had a fresh case of tuberculosis of the conjunctiva under observation and that he had seen other cases which had all the principal symptoms but in which he was not able to demonstrate positively the bacilli. In view of the difficulty of catching these organisms, however, he thought that should not necessarily determine us against the diagnosis. BURNETT (Washington) remarked that he had seen quite a number of cases of tuberculosis of the conjunctiva, particularly among colored children. His treatment had been thorough curetment of the ulcer, followed by the application of formalin 1-60.

**Localized Tuberculosis of the Eye.**—J. A. SPALDING (Portland, Me.) reported: Case I.—A. B., a healthy boy of 8 years, with family history free from tuberculosis, fell from an express wagon, hitting his head and elbow, but escaping without any serious injury. Six weeks later he was seized with an intense chill, headache, pain in the left temple, and vomiting, followed by a rise of temperature to 101°. For about a week he had a subnormal temperature every morning and a rise to 102° every afternoon and complained of constant pain in the left temple. He became apathetic and his head was drawn noticeably backward. His physicians could not agree upon a diagnosis. Ten days after the first chill his parents noticed a yellowish reflex from the left pupil, redness of the eyeball, and loss of sight when the right eye was covered. After a few days all of his local and general symptoms decreased in intensity, but a week later there was a recurrence of all the symptoms except the orbital pain, and two weeks later the patient was brought to Dr. Spalding. Enucleation was advised, under the idea that the yellowish mass might be a glioma and the general symptoms due to purulent meningitis. The result of the operation, however, was a surprise, in that every symptom ceased as if by magic and for more than four years the patient has had no trouble. Microscopic examination of the eyeball showed that

it had been entirely destroyed by tuberculosis. Case II.—A delicate boy of 7, who had suffered an attack of ophthalmia in infancy, which terminated in the loss of sight in the left eye. The blind eye became painful and congested, and the right eye showing symptoms of sympathetic irritation it was considered necessary to enucleate. Following the operation the boy's general health begun at once to improve. Microscopic examination of the eye disclosed a tuberculous tumor springing from the choroid.

**Report of a Case of Acute Glaucoma Incited by the Use of Euphthalmic for Diagnostic Purposes.**—W. H. RING (New Haven) related a case in which, as indicated in the title, a few drops of euphthalmic, employed for the purpose of dilating the pupil to permit better ophthalmoscopic examination of the eye, was followed some hours later by an attack of acute glaucoma.

**Discussion.**—KNAPP (New York) said that he had seen three cases of acute glaucoma following the use of euphthalmic, but they all occurred while the patient was still in his office, and all subsided promptly after the application of eserine. He still employs it, believing it to be the most manageable mydriatic we have for such examinations, but he always detains such patients in his office for a half hour or so to watch them. POOLEY reported a similar case occurring in an eye where there had been no suspicion of increased tension, but on the other hand a marked myosis, and said that he did not see how we could accomplish much by detaining such patients a half hour, as the trouble usually appears after a much longer period. PYLE (Philadelphia) reported the details of a case in which homatropin was used and glaucoma came on after 72 hours, requiring posterior sclerotomy in addition to the local use of eserine and massage to secure relief.

**Concerning the Possible Etiologic Factors in Tobacco Amblyopia Revealed by an Analysis of the Urine of Cases of this Character.**—GEO. E. DE SCHWEINITZ (Philadelphia) had the assistance of an expert physiologic chemist to examine the secretions in a series of cases of tobacco amblyopia, and reports in detail the results of these careful examinations. It is impossible to abstract such reports fairly, and the paper should be read in full.

**Diseases of the Eye in the White and Negro Races.**—H. D. BRUNS (New Orleans) has carefully reviewed the case histories of 17,311 eye cases seen in the hospital during the years from 1893 to 1901. He finds certain characteristic differences as to the frequency of the same disease in the white and negro races. Blepharitis marginalis and hordeolum are found less frequently in the blacks than in the whites, while chalazion is much more common in the blacks. The negro is almost entirely immune to trachoma and diseases and injuries of the lacrimal apparatus are extremely rare. Phlyctenular disease of the conjunctiva is very common, while purulent conjunctivitis was unexpectedly rare considering their opportunities for infection. Diseases of the cornea are quite frequent and apt to be more destructive in the negro race and affections of the iris and choroid are likewise more common than with the whites. Anomalies of the muscles are almost unknown and refraction errors not frequently encountered.

**Discussion.**—KOLLOCK said that his experience was exactly in line with that of Bruns. He had seen considerable tobacco amblyopia among colored women who did not use alcohol. He had found that in treating the negro no matter for what condition it was usually necessary to give mercury because of the great prevalence of syphilis. HOWE said that several years ago he had examined the lids and conjunctiva in microscopic sections and had not been able to demonstrate any anatomic or histologic differences between the white and negro races.

[To be continued.]

## AMERICAN MEDICAL ASSOCIATION.

Fifty-fourth Annual Meeting, Held at New Orleans, La., May 5 to 8, 1903.

[Specially reported for *American Medicine*.]

### Section on Practice of Medicine.

#### FOURTH SESSION (CONTINUED).

**Sources and Manner of Plague Infection.**—W. J. CALVERT gave a historic sketch with reference of the great pandemics of plague which have occurred from time to time throughout the world, laying some stress on the fact that we are now in the presence of a somewhat mild pandemic. These pandemics have universally spread from a central epidemic, and have followed the various lines of commerce until becoming fairly general. Plague is essentially a disease of the lower animals. *Bacillus pestis* was described and its peculiarities given. Germs of the disease are conveyed for the most part by clothing, rats, cotton goods, mice, flies, fleas, and convalescent patients, in whose mouths it may be found for many days. In adults about 60% of the buboes are inguinal, 25% axillary, and the rest cervical. Among children cervical buboes preponderate. It is most probable that infection is received through some superficial wounds either in the alimentary tract, the respira-

tory apparatus, or through the skin. Where the disease abounds the vast majority of the cases occur among the poor, where dark, poorly ventilated houses are inhabited, and where the entire hygienic environment is conducive to ill-health.

**Prophylaxis of Plague.**—J. J. KINYOUN asserted that early diagnosis of plague is very important, but is often difficult to make, especially in the beginning of an epidemic. Many of the first cases die unnoticed and among many Oriental peoples are often unattended by a physician. Plague may assume such a variety of forms that it can be mistaken for anthrax, tonsillitis, mumps, diphtheria, erysipelas, pneumonia, acute pleurisy, malignant pericarditis, endocarditis, peritonitis, appendicitis, acute nephritis, meningitis, acute rheumatic fever, typhoid, typhus relapsing, and malarial fevers, acute dysentery, miliary tubercle, septicemia, pyemia, and syphilis; hence the difficulty of early diagnosis. Many mild cases are doubtless overlooked at the beginning of an epidemic, though the ambulant type is not so frequent as is commonly supposed. Filth, dampness, and general unhygienic conditions are the predisposing factors. But for the Chinese Exclusion Act, the United States would doubtless long ago have suffered from plague, but as it is the act does not wholly exclude this disease. Difficulties arise from the fact that plague frequently occurs in isolated localities where no facilities for examination exist. Bacteriologic investigation is necessary for correct diagnosis. The measures to be inaugurated in case plague is suspected come under the following headings: Isolation pending a diagnosis; segregation under medical supervision of contacts and suspects; disinfection of premises; sanitary measures in the immediate vicinity; destruction of all vermin, and their laboratory examination; and general measures against dissemination of the disease. In maritime commerce, where plague is suspected, health officers should look to the personnel of vessels, cargo, the vessel itself, the maritime quarantine, etc. Bombay received its present epidemic supposedly from a vessel. It is fortunate that our vessels in the Pacific do not actually touch at Oriental ports, otherwise all vessels would be infected. Sanitary authorities should have wider authority and not be held strictly to the letter of the law.

**Discussion.**—F. G. NOVY stated that Yersin and not Kitasato discovered *Bacillus pestis*. It should be remembered that plague is a disease of the lower animals, and it enters the system by way of a wound. The vitality of the germ is not so great as some seem to suppose; it is easily killed. It escapes from the body by way of pus from buboes, urine, saliva, etc. Vaccination against plague is used to some extent and gives immunity for several months. Yersin's serum when given promptly, copiously and properly gives perfect results. He detailed the history of a laboratory student infected with plague of the pneumonic type, whose life he saved by subcutaneous and intravenous injections of large quantities of Yersin's serum. E. RIXFORD (San Francisco), when called upon, stated that he had been with the conservative element in his city and State in the recent threatened epidemic in San Francisco. His people are not proud of their record, but they feared quarantine and its effects and naturally wished to avoid them. They believed that the national and State governments were fully competent to take care of the condition. Had the world three years ago known as much about plague as it now does all the serious difficulties in the Western cities would have been avoided.

#### FIFTH SESSION.

#### Sources and Manner of Infection of Typhoid Fever.

WILLIAM H. WELCH said the primary cause of typhoid fever is of course *Bacillus typhosus*, and this germ must gain access to the alimentary canal. The disease cannot be produced by hypodermic injection of the bacilli, and there is no clinical proof that germs taken by the air into the respiratory organs ever produce enteric fever. Practically they are eliminated only in the urine and feces, their occurrence in the sputum being too rare for serious consideration. Some 15% to 20% of cases will show the bacilli in the urine, and they remain there during convalescence and for some time after. Dosage at the relative number of bacilli necessary to cause infection is important, and must depend much upon the age and condition of the patient. Individual predisposition is both acquired and hereditary. The main source of infection is the *patient*. Could we properly treat the urine and fecal discharges of patients the disease would soon die out. Direct contagion occurs rather more frequent than is commonly supposed, but even then is rare. Tracing the source of an infection is often difficult, and from the nature of the case proof is often wanting. Drinking water is the main immediate source of the infection; yet this fact was long opposed by Pettencoffer and his school of hygienists. Water may become contaminated from contaminated surroundings, such as soil. The present conditions in this country which permit and favor a contaminated water-supply, and the questions involved in their correct solution, constitute the most urgent problem for our hygienists today. Sand filtration probably promises the most hopeful means of solution. Contaminated soil may lead to infection of the patient in a number of ways, such as through the drinking water, vegetables, flies, swallowed dust, and the various food articles. Milk by becoming contaminated after leaving the cow is a very fruitful source of infection. It should be remembered, however, that the *patient* is the ultimate source of the disease.

**Prophylaxis of Typhoid Fever.**—J. S. FULTON stated that among the American soldiers in the Cuban war one-half of all the cases of typhoid fever were unrecognized as such. Our medical colleges without exception need to teach more completely the recognition of typhoid fever. Dogmatic should give way to rational instruction; didactic should give way to bedside teaching. Confusion between malaria and typhoid is far too common, and often a case is diagnosed as the former when in fact it is the latter. A careful examination of blood from many subjects thought to have malaria in Maryland during the past four years found only 5% of cases to be malarial. There appears to be a widespread delusion that malaria is a considerable cause of mortality, when the fact is that many so-called malarial cases are in reality typhoid. The commonly accepted view that typhoid fever is for the most part a disease of large cities is erroneous. Statistics quoted by the writer go to show that typhoid cases occur in almost inverse ratio to the population. Rural mortality and morbidity are nearly three times that of the largest cities, as found from the census reports; while prophylaxis can be made to a large extent effective as applied to large cities, it cannot, by its widest conceivable extension, have a marked effect on the total typhoid mortality of the country; for municipal prophylaxis is concerned only with the least part, and not in immediate relation with this least part of the general morbidity from typhoid fever. The largest prime factor in the dissemination of typhoid occurs in the rural districts, where human excrement admits of distribution by wind, water, animals and insects. Special hygiene should consist essentially in defense against excremental contamination, including the general care of water and food, screening of privies, destruction of flies and other insects, and their exclusion from dwellings, etc. Typhoid fever cases should be isolated, and all the belongings of the sick, the hands of the attendants, and the excreta, so soon as passed, should be disinfected. The need of a rapid, simple and cheap method of disinfecting the feces of typhoid patients is urgently needed.

**Discussion.**—J. H. MUSSER said that early diagnosis can now generally be made by culture, blood-serum, etc., and there is little excuse for early failures. The conscience of physicians, to say nothing of the public, is not awakened to the dangers of typhoid fever and its prophylaxis. Wells near privy vaults and milk are common sources of epidemics. Communities, and most of all city authorities need to be educated to the urgent demand for prophylaxis against typhoid fever. He believed that it would pay each practitioner to have a trained assistant, skilled in laboratory work, to assist him by laboratory examinations and otherwise, when fewer mistakes would be made in diagnosis. If this cannot be done, then government control of all excreta, and of all sources of contagion from the patient should be had, while the practitioner should assume only the medical care of the patient. Urotropin is a valuable remedy, and should be given all convalescent cases of typhoid to disinfect the urine and prevent cystitis. All excreta should, of course, be thoroughly disinfected. DELANCEY ROCHESTER gave the history of an epidemic which occurred in Buffalo. The immediate source of the contagion was found to be milk, and on tracing this further it was found that the ultimate source was from the hands of a workman engaged in distributing the milk and in whose family typhoid fever existed. He stated that for disinfecting the stools of typhoid patients chlorinated lime is the best agent. KRAUSS condemned lay inspection as incompetent. The use of screens for doors and windows should be made compulsory to prevent infection from flies and other insects. He believed with Fulton that many mild cases of typhoid are charged to malarial infection. FRANK WARNER stated that cities should have water purified by sand filtration, and that physicians instead of engineers should have general superintendence of the water-supply. The engineer's duty should be to get the water to the people, and there his responsibility should end. He knows nothing about the purity or impurity of water. J. N. HURTY holds that prophylaxis should be accomplished by the proper care and disposition of all human excreta, from whatsoever source. Since flies come from the excreta of horses, all dejecta from this source should be carefully cared for. H. M. SEWELL stated that individual susceptibility should be taken into consideration. The "mountain" fever of Colorado is now called typhoid when severe, and he thinks the milder cases are probably due to the maladministration of the various organic forces of the body, resulting in a general lowered vitality. Such patients are easily infected with typhoid or other pathogenic germs. E. K. ROBINS holds strongly to the view advocated by Happel that there exists in the South a continued fever which is neither malarial nor typhoid, and which resembles neither except in duration. He has seen 90 cases within the past year the average duration of which in each case was two weeks. JAMES TYSON insisted on the general advocacy of boiling all drinking water. The poor perpetuate the disease by not complying with this essential. Filtration should, of course, be demanded, but it will not completely and continuously remove the obnoxious germs. J. J. WALSH held that civic duty alone should be sufficient to prevent typhoid fever. For every case of enteric fever which occurs some one is criminally responsible. W. SHROPSHIRE held that while the boiling of water materially reduces the danger it is not sufficient to prevent epidemics, which can easily arise from vegetables, flies, dust, etc.

[To be continued.]

## Section on Surgery and Anatomy.

## THIRD SESSION (CONTINUED).

**The Value of Enterostomy in Selected Cases of Peritonitis.**—FRED. B. LUND (Boston) reported three cases of intestinal obstruction occurring after operations for appendicitis with general peritonitis. The obstruction was relieved by forming a temporary artificial anus and the opening in the intestine was later readily closed by a secondary operation. Lund made a strong plea for the use of enterostomy in many of these cases of obstruction, which are due largely to distention with gas from paralysis of the intestine. The obstruction is relieved at once if the intestine is given a chance to empty itself. In these cases a more extended operation would mean the death of the patient in many cases.

**Discussion.**—TINKER (Baltimore) said the method of treatment suggested by Dr. Lund and used so successfully in his cases has also been employed for a number of years by Finney in the treatment of such cases in the Johns Hopkins Hospital. By bringing the intestine only up to the abdominal wall, not drawing a loop out, a secondary operation for closure of the enterostomy opening as was employed by Lund has not been found necessary. FOLLIS employed this method in treating typhoid perforation, bringing the perforation up and suturing it into the wound before this method of treatment was reported by Escher of Triest. The method is also valuable in the treatment of cases in which there is soiling of only a part of the peritoneal cavity. To attempt to relieve obstruction in these cases by any other method would frequently mean infecting the entire peritoneum. PORTER (Ft. Wayne, Ind.) believes that very many cases of general peritonitis die because of distention and tympanites. A number of these cases can be saved by making enterostomy early. Porter has not found it necessary to do a secondary operation for the closure of the opening. In his cases the intestinal opening has closed spontaneously. THOMAS (Spokane, Wash.) has employed this method in a number of cases of general peritonitis with fatal results in all. The indiscriminate use of an operation of this kind without first removing the main cause of the trouble he considers entirely illogical. BULLITT (Louisville, Ky.) thought that Thomas had misunderstood Lund's position. In such cases the usual method of treating the causes of peritoneal inflammation are always first employed. Then, if distention with resulting obstruction occurs later, this operation may be employed successfully in many cases in which the condition is so desperate that more extended operation would result fatally. LUND, in closing, stated that he did not advise this method for indiscriminate use, but he believed that it would turn the scale for a favorable result in some desperate cases.

**Cholecystectomy versus Cholecystorrhaphy and Cholecystostomy.**—F. D. SMYTHE (Memphis, Tenn.). The safety of the life of the patient demands removal of the gallbladder in malignancy and gangrene. It is important where the cystic duct is obliterated, though not demanded as life-saving measure. When operating for stones, if the gallbladder presents macroscopic evidence of disease, infection, thickening, etc., it is decidedly safer to do cholecystectomy. Gallbladders that are the seat of inflammation, cholecystitis, hydrops, with an appearance of fair health, on closer examination show infection, should be treated by removal. Other operations on the gallbladder often prove only palliative, the risk is as great as the radical treatment, which avoids relapse. Cholecystostomy and cholecystorrhaphy are not curative except in a small percentage of cases; secondary operations are frequently demanded for closure of fistula, re-formation of stones, hydrops, with its attendant pain and empyema. Where the patient's condition is extreme, incision with gauze drainage or cholecystostomy is justifiable occasionally as an alternative; rarely, if ever, the operation of election. The gallbladder is not an essential organ, and when the seat of disease requiring surgical aid extirpation should be the rule.

**Dangers Attendant on Attempt at Gaining the Period of Interval in Operation for Appendicitis.**—RICHARD H. GIBBONS (Scranton, Pa.). Division into subacute and acute varieties is all that is in appendicitis necessary for practical purposes. Further division or subdivision serves merely to confuse the diagnostician. An obscure or doubtful diagnosis serves to delay the operation until the opportune moment has passed. By palpation we can determine whether or not the appendix is involved by subacute inflammation. This is the refinement of McBurney's test as given to us by Edebohls, each of which has its own value as applied to the acute or subacute varieties of the inflammatory involvement. On the recognition of the relative value of these tests and their application, and prompt action taken from the knowledge gained therefrom, will depend the relative danger of early as compared with late operation. The dangers increase as we allow time to flit away in the vain hope that lost opportunity may come back to us, which is quite unlikely. No amount of medical treatment or dietary adjustment can ever make amends for such reckless determination. Early surgical intervention should be the shibboleth of every honest medical man.

**Discussion.**—NILES (Salt Lake City). Whichever way we choose in selecting the time for operation, we occasionally fall into error. Niles advocates early operation as safest in most cases, however. OCHSNER (Chicago) has been frequently misunderstood in his views upon the treatment of appendicitis. So

long as the infection remains within the appendix, the appendix should be removed if the diagnosis can be made. There is a time when the infection is outside the appendix after perforation has occurred, and in these cases Ochsner finds that the treatment which he has so frequently advocated (giving absolutely nothing by mouth, neither food, liquids, nor medicine, washing the stomach and using rectal feeding) will save 97% of the cases. In all cases the appendix should be removed whether before perforation has occurred or in the cases in which his treatment has been employed, after the acute symptoms have subsided. MAYO (Rochester, Minn.): All reputable surgeons agree that practically all cases of appendicitis should be operated upon within the first 48 hours if possible. After perforation has occurred, the condition is like that of a patient some time after a snake-bite when the poison has become disseminated through the entire system. When infectious material has escaped into the abdomen and general infection has followed, it is impossible to remove the septic material by operation. In these cases the treatment suggested by Ochsner should be employed, and it will reduce the mortality from the 12% or 15% which follows if all cases are operated upon to 2% or 3%.

## FOURTH SESSION.

**Sunshine and Fresh Air vs. Röntgen Rays and Finsen Rays in the Treatment of Tuberculosis of Bones and Joints.**—DEFOREST WILLARD (Philadelphia). The inhibitory action of light upon the growth of tubercle bacilli was demonstrated in the laboratory some years ago. While the bacilli are not directly exposed to the light when patients are treated, by being sent into the open air and sunshine very marked improvement frequently follows when such treatment is employed. Willard strongly advocates the treatment of tuberculosis of the bones and joints as well as of the soft parts by sending the patient out of doors in the sunshine, protecting their eyes from the sunlight if necessary by the use of green glasses, having them live in tents, and feeding large quantities of milk and eggs. The sanitarium treatment of disease of the hard as well as of the soft tissues will give correspondingly good results and tent life in the pine woods is especially favorable. The bactericidal action of light seems to be almost entirely in the blue violet and ultra-violet rays. In the laboratory electric light has a more powerful effect on the growth of bacteria than has sunlight, but this is not true in practice. The disadvantages of the Finsen light treatment are that a very large staff of nurses are necessary to carry it out, only a small area can be exposed, the treatment must be continued for a long time, and the cost of running a 4-lamp lens is not less than \$3,000 a year. The x-ray has also considerable germicidal power. The hard tube has greater power than soft tubes. It is very important to protect the skin in these cases. Further experience is needed to determine the best system for placing the tube, the length of exposure, and the extent of area to be exposed. All these methods are still in an experimental stage. The mechanical and other established methods of treatment should not be neglected. These newer methods promise to be of some aid and everything which will help us in the battle with disease should be employed. At least five years' experience in the use of these methods is necessary before we can say definitely what is their real value.

[To be continued.]

## Section on Obstetrics and Diseases of Women.

## SECOND SESSION (CONTINUED).

**The Better Methods for the Repair of the Perineal Structures.**—H. O. MARCY (Boston) said there is no general acceptance of any well settled method. The repair of an organ implies an accurate knowledge of the anatomy and function of the parts. The union of the transversi interdigitating with the levator ani muscle is the more common part to suffer injury. The repair of an injured organ should include its restoration so far as possible to its original normal condition. (Here followed by the author quite an exhaustive study of the anatomy of the pelvic floor, the function of the component parts and the conditions resulting from injury of these parts.) In considering the restoration of these structures attention was confined to methods found especially valuable in the author's experience. In his earlier experience he found that in resecting the posterior vaginal wall the line of division was not the mucous membrane from the underlying structures, but the attenuated posterior vaginal muscle. The separation is not difficult. Thus it is easy to differentiate the levator loop and to bring it with the ends of the separated transversus perinei into easy inspection. A further dissection upon either side of the sphincter ani makes the wound of sufficient size for easy manipulation. For holding the parts in coaptation he devised a lateral support by means of disjointed pins, which held the parts after the manner of ordinary safety-pins. Later he obtained tendon sutures from the tail of a kangaroo, which proved reliable, since when he has used only chromicized tendon sutures. The first step in the operation is to dilate the sphincter. The index and middle fingers of the left hand are introduced into the rectum and retained there. The septum is thus made tense. After a buttonhole incision in the posterior vaginal wall a special knife resects this wall, injuring neither vagina nor rectum.

Separation is often made much with the fingers. The posterior third or more of the vagina is thus separated from its attachments quite to the crest of the rectocele. This flap is held forward by an assistant. The deep sutures are carried through the transversi and levator ani muscles by a large curved needle, the eye being near the point. When drawn upon moderately these stitches coaptate the widely separated structures upon the median line and in fixation. The remaining tissues are united by a light continuous running suture. This stitch the author of the paper calls the parallel suture since the needle is inserted parallel to the long axis of the wound. In complete laceration there must be reconstruction of both rectum and vagina by separately reuniting them by continuous suture, care being taken not to penetrate the bowel or vagina. The operation is completed as in the incomplete laceration, except that the retracted fibers of the sphincter ani muscle must be freed and sutured. By free dissection and the use of buried absorbable sutures, the parts are entirely restored to their former normal anatomic condition and physiologic function. In complete laceration a large rectal tube should be inserted. The results of this operation have been remarkably good in the hands of the author of the paper.

**Discussion.**—GOELET (New York) doubted if deep through-and-through sutures would succeed in all hands, because, unless carefully tied, constriction would result. He considers it important to avoid handling the parts excessively by having a stream playing upon the field of operation. DUNSMAN (Missouri) believed that failure often results because of a faulty method of introducing the sutures. They should be introduced at the outlet of the vagina and should make their exit at the outlet. The desire should be to narrow and lengthen the vagina, and this is promoted by the use of two layers of sutures. HAYDEN (Indiana), while he did perineorrhaphy according to books, met failure for 15 years; he has used a flap method, catgut sutures, by which the muscles and then the mucous membrane are coapted. CARSTENS (Detroit) believes that by the usual method nothing is accomplished further than the puckering of the tissues like a purse. He uses from two to five layers of sutures, 30 to 40 stitches. It is ideal surgery to use buried sutures. DUDLEY (New York) by diagram explained the method and emphasized the necessity of properly coaptating the parts of the transversi perinei and the levator ani muscles. GRAHAM (Indianapolis) illustrated a method of perineorrhaphy used by her with uniform success for several years.

**The Repair of Cystocele by Utilization of the Anatomic Attachments of the Anterior Vaginal Wall.**—E. REYNOLDS (Boston) said cystocele should be treated as other hernias. Success in the repair of cystocele rests on an adequate conception of the anatomy of the anterior vaginal wall. The wall is firmly attached at its lower end to the pubes and at its lateral edges and upper lateral corners to the pubococcygeal and allied transverse muscles. These are only reinforced by the support of the posterior wall below. During labor the entire vagina is distended. The supports of the posterior wall are distended and often lacerated, but the supports of the anterior wall are subjected to little strain during the passage of the head. After labor the anterior wall is distended, but its edges are held firmly in place. When cystocele supervenes a portion or all of the anterior wall remains distended and useless, while its attachments are usually intact. Cystocele is a hernia of the bladder through the foramen formed by the attachments of the anterior vaginal wall. It is to be treated by excision of the hernial sac—the anterior vaginal wall—after separating it from the bladder, and suture of the raw edges of the firm tissues directly to each other. The exact shape of the excised portion is less important than the fact of its excision. The form of the excision should be adapted to the case. In descent of the cervix the vaginal wall is freed high upon either side, the excision being horse-shoe in shape. He has had excellent results in his work.

[To be continued.]

Section on Diseases of Children.

THIRD SESSION.

**Infant Feeding: Its Relation to the Diarrheal Diseases of Infancy.**—JAMES G. MASTIN (Chicago) said that the young infant was capable of digesting starch and sugar in proportion to the secretory capacity of the pancreas, and that starches, sugars, and fats in excess tended to exhaust the secretory powers of the digestive glands. Early and repeated examinations of the milk were demanded in order that a proper mode of living might be inaugurated. The digestion of the newborn infant having been once impaired it was a difficult task to restore the normal balance. When the breast milk was deficient one or two supplemental feedings with artificial food were required, and cow's milk, so modified as to secure the same proportions of proteids and sugar as in breast milk, afforded the best substitute food. The very great value of breast feeding could be inferred from Holt's statement, that out of 1,943 cases of death from infantile diarrhea only 3% of the cases had been nursed exclusively at the breast.

**Discussion.**—GEORGE W. ACKER (Washington, D. C.) said he could recall many mothers who refused to nurse their offspring and who had avowed their determination to do this even before the birth of the child. In some cases he had known the

wearing of corsets to be responsible for a deficient supply of breast milk. According to Holt, only about one American woman in ten was able to nurse her infant up to the third month, yet the milk of a mother, even if poor, was better than modified or laboratory milk. JOHN C. COOK (Chicago) said that although children often appeared to become seriously ill from a single indiscretion in diet it would usually be found that this illness was only the culmination of a long period of improper feeding, by which the child's powers of resistance had been lowered. SOUTHWORTH said that while no doubt some forms of diarrhea were due to the Shiga bacillus, he believed a very large proportion of the more acute intestinal disorders were not connected with this bacillus. In some cases of Shiga bacillus diarrhea that he had observed the stools had not been very frequent nor had they contained much undigested food and the autopsies showed varying degrees of enterocolitis. TULEY said that in the case criticised by Dr. Southworth he had endeavored to preserve maternal nursing, but the nervous excitability of the mother had caused a cessation of the lacteal secretion. It should be remembered that a child was not able to digest as strong a formula of modified milk in hot as in cold weather. A new idea had been given him by an old and efficient negro monthly nurse, *i. e.*, that by feeding the newborn infant only on water for the first three days and then putting the infant to the breast the child was not only good-natured and did not lose weight, but by avoiding the early and fruitless tugging at the nipples the mother was saved from the misery of sore nipples. A. C. COTTON declared that every time one took away from the baby even a mouthful of breast milk an injury was done the little one. He said that he had previously reported about 50 cases of disturbed lactation resulting from excessive coitus. DAVIS said that, according to her experience, the application of the infant to the breast within a few hours after delivery was not a tiresome process to the mother but a physiologic one and this procedure caused the milk to come in more gradually. It was true that the little one could go a considerable time without food, yet Holt had reported inanition fever from this cause. In some of the cases reported she had taken pains to exclude coitus as a disturbing factor.

**Case of Probable Gummata of the Liver in a Child of Six.**—M. OSTHEIMER (Philadelphia) reported this case, which had been studied with great care.

**Discussion.**—R. B. GILBERT (Louisville) reported two illustrative cases. C. F. WAHRER (Fort Madison, Iowa) reported a case of obscure syphilitic disease, with heart manifestations, which had puzzled him a long time until he had finally discovered that syphilis was the underlying factor, and then everything had cleared up promptly.

**Influenza in Children.**—WILLIAM CARVER WILLIAMS (Chicago) took the position that influenza was a much more serious disease in children than was generally supposed. The statistics of the Chicago Board of Health were quoted to show that not infrequently in cases in which the clinical diagnosis was diphtheria the bacteriological culture showed only the presence of the Pfeiffer bacillus of influenza. The chronic form of influenza received too little attention. The author's conclusions were: (1) Children of any age are susceptible to influenza; (2) repeated relapses and grave sequels are frequently observed in cases in which the initial seizure was mild, and (3) the clinical diagnosis should always be supported by microscopic examination, as such an examination was often of great value in connection with future developments.

**Discussion.**—CHARLES G. KERLEY (New York) referred to the fact that he had had this year ten cases in which it had been necessary to perform paracentesis of the membrana tympani. A symptom which was usually marked in influenza was extreme prostration. He was disposed to think that some of the cases reported as typhoid fever in children were really examples of the grip. P. J. BARCUS (Crawfordsville, Ind.) commented upon the fact that when scarlet fever and influenza were prevailing at the same time the type of the former was apt to be mild. H. M. McCLANAHAN (Omaha) said that he had noticed that in these cases of grip hydrotherapy for the control of the fever was not so well borne as in other diseases. He met with more cases of ear disease associated with grip than as a complication of scarlet fever. He favored the use of quinin in doses of 6 to 12 grains given by rectal suppository. JOHN C. COOK (Chicago) said he had known two infants born of women who were ill with the grip die suddenly within 48 hours after their birth. He had also recently seen a number of cases of cerebral disorder apparently due to the grip. In several cases of the grip that he had seen at the beginning of the last epidemic there was present an eruption closely resembling that of scarlet fever. The differential diagnosis from that disease was made by the absence of the sore throat, the rapid pulse and the high temperature of scarlet fever and the presence of the symptoms of the grip. HANNA (Tennessee) also reported a case in which the eruption had been scarlatiniform. WILLIAMS, in closing, spoke of a series of cases in which the eruption had closely simulated that of scarlatina, but was not associated with the other symptoms of that disease.

FOURTH SESSION.

**Capillary Bronchitis.**—PHILIP F. BARBOUR (Louisville) said that the great danger of capillary bronchitis was that the lungs would be "drowned in their own secretion." The congestion, spasm and dryness present in the first stage consti-

tuted the chief indications for treatment. The second stage was characterized by increased secretion. The excessive amount of mucin in the tissues of the child made the secretion of mucus in the bronchial tubes relatively greater than in the adult. During the coughing or vomiting spells the head of the little patient should be placed lower than the body in order to get the aid of gravity. Emetics were useful, but should be employed with much judgment so as not to cause undue exhaustion. They should not be resorted to oftener than two or three times in the 24 hours. He had found strychnin useful because of its power to improve the muscular tone and so favor expectoration. It should be given freely, or nearly up to the point of producing the physiologic effect. The chief danger in this disease was from the plugging up of the bronchioles with the secretion, and the consequent atelectasis. No remedy was superior to atropin or belladonna for this purpose. Aconite tended to equalize the circulation and withdraw blood from the congested area; it also tended to prevent the extension of the inflammation along the mucous membrane. Its depressing action on the heart could be obviated by the coincident administration of digitalis.

[To be continued.]

### Section on Sanitary Science and Hygiene.

#### SECOND SESSION.

#### Drainage, Sewerage and Water-supply of New Orleans.

—GEORGE G. EARL (New Orleans). An exhibition of a map of New Orleans and vicinity preceded the paper, with a history of the formation of the soil of New Orleans from alluvial deposits. He stated that 80 miles to the west of the city, 40 miles to the east of the city, and 80 miles to the south of Lake Pontchartrain was built up by the Mississippi river in this manner. Exhibition of map of New Orleans, showing streets. New Orleans is composed of 900 miles of streets, 600 miles of which were open and 400 of which were in resident districts. Thirty-one square miles of the city are well settled. The Mississippi river is often at gulf level. Description of Lake Pontchartrain, with a description of the canals or "bayous" leading to it. Position and origin of Metairie Ridge, one of the highest points in the city, stating that it was formed by alluvial deposits from a former "bayou." Twenty-three square miles south of Metairie Ridge is the district especially to be considered in a drainage system. Only eight square miles of this district has natural drainage, and nine square miles are below gulf level. The section with natural drainage is eight feet above the mean gulf level and ten feet above high-water level. The annual rainfall in New Orleans is 60 inches. On March 14, 1903, there was a record fall of eight inches in six hours. A description of the present method of disposing of sewage in the city was given, with the imperfections of it. Only a few hotels, the charity hospital, and a few office buildings have a sewerage system. These are private mains. The New Orleans water-supply is from cisterns, from artesian wells, and from the Mississippi river. The unfiltered water of the Mississippi river has been little used for drinking purposes owing to the large amount of suspended matter in it. An unsuccessful attempt was made in 1892 to filter this water on a large scale. Exhibition of a map showing the drainage system of New Orleans. There are four sets of systems corresponding to the four principal canals. That portion of the city along the river is the highest portion, and so drainage is toward the swamps. The smaller gutters of the system lead to medium-sized canals at right angles to the main drainage canals. The main canals lead to pumping stations where the water is raised to a higher level. The drainage canals of New Orleans are three times the size of those in Chicago on account of the excessive rainfall in this section. The present system is only a temporary system, as later the city will drain into Lake Borgne instead of into the swamps. A description of the means of accomplishing this are given. The drainage system will be distinct and separate from the sewerage system. There are objections to making the drainage system the outlet for sewage. In New Orleans there is no gravity which is necessary for a sewerage system and there is no natural water-supply. The necessary amount of water to carry off the sewage of the city is 100 gallons per capita per day. Exhibition of map showing the proposed sewerage system. The Mississippi river is the natural outlet for sewage and this is proposed. Exhibition of map showing the points at the lower end of the city at which sewage will be discharged and eddies in the river to be avoided. A concentration of the flow is essential. At the beginning of each lateral sewer there will be a large flushing tank to be refilled when empty and these will take the place of the natural supply. The average rate of flow through the sewers will be 2 to 3 feet per second. One-third of the soil moisture, which is very great in New Orleans, will be carried off by the sewers by leakage through the joints. At one time it was thought possible to obtain a natural supply of water from the rivers north of Lake Pontchartrain, but just the building of a canal would cost \$4,500,000, and the level would have to be 200 feet higher at the source than at the outlet in order to overcome the friction. A description of the proposed plant for purification of the Mississippi river water was given. It will cover 78 acres in the upper portion of the city

and it can supply sufficient water for a city of 1,000,000 inhabitants or its output will be 40,000,000 gallons per day. Mississippi river water at New Orleans contains  $2\frac{1}{2}$  tons of solid matter to 1,000,000 gallons. A description of the plan for the distribution of the water after purification. There will be a large reservoir wherein the unpurified river water will be contained. This reservoir can supply the city for 12 hours. The water will be allowed to settle in the reservoir and 35% of the solid matter can be gotten rid of thus. The addition of aluminum sulfate, 4 grains to the gallon, will form a coagulum which will purify the water after the coagulum is settled, but the water will be run through three sand filters. Only 3% of the filtered water required to wash the filter. The system outlined never failed to satisfy all requirements for a potable water. The successful operation of such a system depends upon the simplest form, and he is positive that this plant will operate successfully.

*Discussion.*—SWARTS (Providence, R. I.) asked why the pumping stations in the drainage system were so far from the river. EARL replied that he found that they gave the best distribution. J. S. FULTON (Baltimore) wished to know if simple sedimentation of the water would not take the place of alum coagulum. EARL replied that it is impossible to get rid of the milky suspended matter by simple sedimentation. S. G. EGBERT (Philadelphia) said that there was no criticism of the paper and he was glad to hear that New Orleans was taking such measures to improve the sanitary condition of the city.

[To be continued.]

### Section on Nervous and Mental Diseases.

#### SECOND SESSION.

*Ambulatory Automatism.*—HUGH T. PATRICK (Chicago) reported three interesting cases together with a brief review of the literature and a discussion of the nature of the trouble. He compared the etiologic relationship between epilepsy, hysteria, mental failure and degeneracy, and related cases illustrative of the different varieties of the affection. He expressed the opinion that the vast majority of cases that really deserve the name of ambulatory automatism, in which the patients traveled long distances covering a considerable period of time, and during which they performed many ordinarily complex acts, should be declared hysterical or at any rate implanted on hysterical basis.

*Discussion.*—H. G. BRAINARD (Los Angeles, Cal.) reported two cases of ambulatory automatism which had come under his observation. ALBERT E. STERNE (Indianapolis) stated that this trouble usually appeared about the time of adolescence. He mentioned one such case in which the condition was associated with profound hysteria. In another case coming under his observation, it was unquestionably associated with epilepsy, and the hysterical element was entirely wanting. WILLIAM J. HERDMAN (Ann Arbor) said that unquestionably a fundamental relationship existed between the mental phenomena attending epilepsy and hysteria, and those of hypnotism and what is known as double personality. They could all be looked upon as species of the same generic condition. The more we learned of normal psychology, the better would we be able to understand these various phases of a fundamental condition. LANGDON said the discussion proved that these cases of ambulatory automatism were not so rare as the literature on the subject led one to expect. He detailed two cases coming under his own observation. C. C. HERSMANN (Pittsburg) said he had seen a few cases in young, hysterical girls. F. SAVARY PEARCE (Philadelphia) emphasized the importance of trauma as the possible exciting cause in some of these cases. D. I. WOLFSTEIN (Cincinnati) said that in dealing with this class of cases the possibility of simulation should always be borne in mind. It was often very convenient to forget things and disappear suddenly. PATRICK, in closing, said he did not agree with Herdman that epilepsy and hysteria and hypnotism had the same fundamental basis. He thought they were very distinct from one another. The absence of hysterical stigmas did not prove that the case was not one of hysteria. In one of his cases of ambulatory automatism which was unquestionably hysterical there was only one exceedingly slight stigma, which consisted of an area of anesthesia about one ear. There were no ocular symptoms.

*Penetrating Wound of Both Cerebral Hemispheres, with Recovery.*—W. S. LINDSAY (Topeka, Kan.) gave this case, which was that of a young man who attempted suicide by shooting himself in the head with a 32-caliber ball. The bullet entered half an inch above and anterior to the meatus of the right ear, and passed entirely through the skull, penetrating both cerebral hemispheres. He made an uneventful recovery, and no sequels developed. Since the receipt of his injury the young man took up the study of telegraphy and had become quite an expert operator.

*Relation of Epilepsy to Chronic Gastrointestinal Diseases.*—G. W. McCASKEY (Fort Wayne, Ind.) stated that the real pathology of epilepsy was at present entirely unknown. There was probably some inherited organic defect in the nervous system, the precise nature of which could not be determined by our present means of research. The resulting instability rendered the individual liable to symptomatic phenomena

known as epilepsy. These phenomena were excited by causes which would not be operative with a healthy nervous system, and when so excited would tend to recur. Chronic gastrointestinal diseases by toxic and reflex influences excited, perpetuated, and exaggerated these phenomena. Their proper treatment was very important, but their obstinacy in yielding to treatment indicated that they were possibly in part the result of the nervous instability.

[To be continued.]

## Section of Laryngology and Otolology.

### FOURTH SESSION.

Secretary J. F. BARNHILL read a proposal from the Academy of Ophthalmology, Otolology and Laryngology in regard to holding a congress of prominent specialists of eye, ear, nose, and throat, to meet every five years.

**How Far Should the Specialist in Rhinology and Otolology Presume to Treat the Systemic Condition?**—C. M. COBB (Boston, Mass.) contended chiefly that the specialist should treat with certain limitations the systemic condition when the systemic condition is responsible for the local disturbance in the ear, nose, or throat. GEO. F. COTT (Buffalo, N. Y.) reported three cases. First, prolonged intubation, caused by stenosis following diphtheria, occurring in a girl aged 6 years. Tracheotomy was performed alternating with intubation for six months beside three operations for stricture, with final recovery. Second, esophageal obstruction, due to an upper alveolar plate. This was located by x-ray opposite the sternal notch. Third, partial extirpation of larynx.

**Early Manifestations of Laryngeal Tuberculosis: Their Recognition and Treatment.**—H. H. BRIGGS (Asheville, N. C.) dealt with the relation of tuberculous laryngitis to tuberculous diathesis, and its resistance to ordinary topical treatment. Stress was laid upon the characteristic yellowish-gray color of parts in diagnosis. Prophylaxis should be secured for laryngeal lesions in cases of pulmonary tuberculosis (secondary cases). This includes removal of all abnormalities in the nose or throat.

**The Immediate Relief of Hysterical Manifestations in the Larynx by Suggestion.**—H. M. LOEB (St. Louis) reported several cases illustrating his plan. Suggestion is all that is done, except a general treatment for the hysterical state is employed. The suggestion should be systematized to be successful.

**Discussion.**—BARNHILL (Fall River, Mass.) asked that the paper of Loeb be considered in a serious light. He had himself seen good results follow similar methods. HOMER DUPUY (New Orleans) reported a case illustrating systematic suggestion. Treatment of hysterical aphonia relieved by suggestion and manipulations in vault of pharynx, where the patient was told trouble resided. There was a relapse after four months and the patient would not submit to repetition of treatment. LOEB (St. Louis) said that suggestions must not be too definite, and this was probably the fault with Dupuy's case.

**Some Recent Experiences with Chronic Suppurations of the Ear.**—PHILIP HAMMOND (Boston, Mass.) reported three cases: 1. Occurring in a girl who had chronic suppurative middle-ear disease for three years. A rapid cure followed ossiculotomy. 2. Case of purulent meningitis complicated by pneumonia. The patient, a man, died. 3. Was that of a boy who had pain in the right ear, with suppuration for three years. The dura was exposed over a considerable area and the operator found it in last operation dark and covered with granulation. The patient died unconscious the morning following operation. Hammond thought caries of ossicles or temporal bone more common than usually supposed.

**Discussion.**—HOMER DUPUY (New Orleans, La.) thought Case II of Dr. Hammond's demonstrated clearly the fact that secondary septic infections could result without serious involvement, as in this case the suppurative process was limited to the middle ear. BARNHILL (Fall River, Mass.) asked that a note of warning be sounded concerning the dangers of middle-ear suppuration. The attention of the general profession should be called to the vital danger of this condition. The danger is that little pain or other objective symptoms are displayed.

### FIFTH SESSION.

The chairman appointed the following gentlemen a committee to bring about the general meeting of all societies devoted to ophthalmology, otology, and laryngology: Snow (Syracuse, N. Y.), Baker (Bay City, Mich.), and Loeb (St. Louis). John F. Barnhill (Indianapolis, Ind.) was elected chairman of the section for the following year. Otto T. Freer (Chicago, Ill.) was elected secretary, and the retiring chairman, Dr. Richards, was elected delegate of the section to the House of Delegates by unanimous vote. The retiring chairman will in future be a delegate to the House of Delegates according to unanimous agreement of the members of this section.

**Distribution of bloodvessels in the labyrinth of the ear** was demonstrated by GEORGE E. SHAMBAUGH (Chicago), with exhibition of some most excellent preparations and drawings, beside a fine lot of lantern slides, metal casts, of the middle-ear. Dr. Shambaugh was tendered a unanimous

vote of thanks by the section for his most excellent original work in this line.

**Perisinus Abscess of Lateral Sinus, with Metastasis in Liver and Sternoclavicular Arthritis.**—GORDON KING (New Orleans) reported this case, which occurred in a boy 14 years old who had had a suppurating ear since childhood. There was a discharge of thick fetid pus from the left ear, but there was no evidence of mastoid involvement. There was a development of hepatic pain, which subsided with copious evacuation of pus from bowels. Exploration of mastoid showed extradural abscess in contact with sinus wall, but no sinus thrombosis. There was also a metastatic abscess of the sternoclavicular articulation. The patient recovered completely. The case is given as an illustration of the fact that secondary metastatic infection may result from middle-ear suppurations without sinus thrombosis. Dr. King suggests that the germ-bearing leukocytes burrowed their way through the thin walls of the sinus, thus giving rise by their presence in the blood-current to the metastatic processes.

**Report of a Case of Cerebellum Abscess, with Exhibition of the Specimen.**—GORDON KING (New Orleans) stated that the peculiarities of this case were continued normal temperature and absence of other characteristic symptoms. Death was caused by rupture of abscess into dural space. The case was seen for chronic suppuration of middle ear.

**Proof of Efficacy of Treatment by Aseptic Drainage in Acute Suppurative Otitis.**—H. GRADLE (Chicago) claimed for the method that it would prevent a serous discharge from becoming purulent.

**The Great Value of Drainage and Ice in the Early Stages of Mastoiditis.**—SARGENT T. SNOW (Syracuse, N. Y.) stated that desirable conditions were acute cases without intracranial involvement, close observation of the patient, drainage maintained by supplementary incision if necessary, intelligent and faithful nursing. Application of ice must be constant.

**Discussion.**—J. T. BARNHILL (Indianapolis, Ind.) urged thorough asepsis of the external auditory canal, auricle, and drum membrane in all paracentesis procedure or other procedures on external or middle-ear. He endorsed Dr. Gradle's paper fully. He cautioned against too great conservatism in early mastoid inflammations in discussing Dr. Snow's paper. COBB (Boston, Mass.) agreed with Dr. Barnhill in opposing any great conservatism in acute mastoid conditions. D. A. KUYK (Richmond, Va.) related a case illustrating the dangers of conservatism—apply ice and hot water alternately in early stage of acute mastoid inflammation. In spite of inflammation and bulging of mastoid area in this case temperature remained normal, and the child apparently improved in every respect, but the operation disclosed a large amount of foul-smelling greenish pus. In concluding his paper Snow said he did not intend to advocate ultraconservatism.

**Deformity of the Nasal Septum in Atrophic Rhinitis: Shall We Operate?**—KATE W. BALDWIN (Philadelphia) urged correction of all deformities in these cases.

## Section on Cutaneous Medicine and Surgery.

### SECOND SESSION.

**Officers Elected.**—Chairman, H. G. Anthony; secretary, R. R. Campbell; delegates, J. Schamberg and G. W. Wende.

**Treatment of Leprosy.**—A. H. OHMANN-DUMESNIL (St. Louis) referred principally to chaulmoogra oil, which has long been in use, but only because, as a rule, it made some improvement. It never cured. He advises its administration by the mouth, hypodermically and locally. Reducing agents, such as ichthyol, do good, but do not cure. He referred to Carasquilla's serum and the antivenene of Calnette. He did not have much faith in them, but he did believe that serum therapy was the only hope.

**Discussion.**—SCHAMBERG (Philadelphia) reported having used antivenene in one case with no result. ROUSSEL (New Orleans) referred to one case in which potassium chlorate had apparently cured the patient. FORDYCE spoke of the spontaneous disappearance of the nodules of leprosy. He believes the prognosis better in anesthetic types.

**Some Notes on the Treatment of Lichen Planus.**—JOS. ZEISLER (Chicago) thought, as a rule, treatment should be based on the etiology. We know little of the cause of lichen planus. The frequency of the disease in his clinic was 3.10%. It was comparatively rare in dispensary practice. It is of most frequent occurrence in persons between 30 and 50 years. Most cases were in hard workers. Shock seems to play a great role in its production. Arsenic, while believed to be a specific by some, does not always succeed. He prefers tepid antiseptic baths, followed by cold douches along the spine. Protiodid of mercury alone, or combined with a general tonic treatment, gives good results. The x-ray also gives good results, especially in the hypertrophic form.

**Discussion.**—BAUM (Chicago) referred to the diminished urea elimination in these cases, and suggested that if the kidneys were looked after better results would follow the usual plan of treatment—elimination was what was wanted.

**Some Clinical Observations on Chickenpox.**—JAY F. SCHAMBERG (Philadelphia) was quite sure that variola and

varicella were not similar. He thought the vaccinal condition of patient and the existence of premonitory symptoms were important points in the differential diagnosis. The eruption of smallpox prefers exposed surfaces, the palms and soles being often affected, reports to the contrary notwithstanding. He referred to a case in an unvaccinated child with only a score of lesions and another with approximately 3,000 lesions. Though chickenpox is usually said to be rare in adults, he has seen a good many cases. The incubation period is longer in chickenpox than in smallpox—usually about 15 days.

**Diagnosis of Cutaneous Syphilis.**—ISADORE DYER (New Orleans) insists that the current method of classifying syphilis into the arbitrary divisions of primary, secondary and tertiary stages is wrong. They should be changed for teaching purposes. He never saw a student obtain a comprehensive idea of syphilis from the average textbook. The period of incubation is from 5 to 100 days. Dyer speaks of several types of chancre, many of which are double; the Hunterian chancre is the usual type and this varies much in size. He has seen them as large as a half-dollar piece. The excoriated lesion is next in frequency. The excoriated lesion with a tendency to breaking down at the edges is not unusual. Some forms cannot be distinguished from herpes. Postherpetic ulcers sometimes last two months. Has never observed the conventional copper color in early syphilis.

**Discussion.**—H. G. ANTHONY (Chicago) said that the copper color was often observable in early syphilids of the roseola type. He referred to a patient who had chancres on his penis, his tongue, and his fingers simultaneously. He said that one chancre did not follow the other in these cases. They all came out simultaneously, and glandular enlargement only occurred in connection with one of the chancres. He does not believe it possible always to make a diagnosis from the chancre alone. DYER, in closing, insists that the macular syphilid is never copper colored.

**A Case of Pemphigus Chronicus.**—WILLIAM FRICK (Kansas City) reported this case as occurring in a woman aged 52. The eruption was first seen on labia majora. Two years later a general outbreak occurred lasting two months, accompanied by chilly sensations and fever. He thought the condition rare. A large percentage of the cases recover temporarily, but the majority relapse, with a mortality of about 17%. His treatment consists of general tonics, light foods and baths rendered antiseptic by mercuric chlorid 1-5,000. The patients remained in this about 15 minutes three or four times a week. If absorption of mercury is feared baths of 1-20,000 should be used.

**A Case of Lupus Vulgaris.**—R. R. CAMPBELL (Chicago) reported this case, detailing certain interesting features. The case occurred in a woman 48 years old. The lesion appeared on the site of a papilloma which had been removed three months previously. It was not of the classical type of lupus. Looked much like tuberculosis verrucosa cutis. Campbell thinks that lupus is distinctly contagious; often comes from inoculation in various ways. He saw four cases in boys who had been circumcised.

**Discussion.**—ZEISLER (Chicago) called attention to the looseness in diagnosis of skin tuberculosis. He thinks we should stick to the classical types and not cover up shortcomings in diagnosis by the general term of tuberculosis cutis. He does not think it unusual for lupus to begin late in life. He says it is not difficult to differentiate lupus from tuberculosis verrucosa cutis. The latter usually appears on the backs of the hands. CAMPBELL, in closing, said that he does not believe that tuberculosis verrucosa cutis is always limited to the backs of the hands. This seems to be the classical type, but he has seen it on the patella and other places on the body.

[To be continued.]

## Section on Ophthalmology.

SECOND SESSION (CONTINUED).

**Pathology of the Cervical Sympathetic.**—JOHN E. WEEKS (New York) considered the appearance of the normal ganglia as compared with the appearance of the ganglia removed in cases of glaucoma. In the latter there was excess of pigment in the ganglion cells; the cells were not round, and even appeared shrunken; there were eccentric nuclei, with occasionally only the nucleolus visible; the cells were at times vacuolated and there were "mast" cells—evidences of degeneration. The author further referred to the methods employed in the examination of the tissue.

**Discussion.**—BLACK (Denver) believed that it could be concluded, from the statistics presented, that the operation was one of value. The operation, however, should not be tried as a last resort, but a first one in proper cases. He had some doubts as to the permanency of the results. FREEMAN (Denver) said that one of the surgeons of that city had operated on 10 cases, removing both the superior and middle ganglions, with no undesirable results following the proceeding, with the exception that sometimes a neuralgia resulted. He considered the operation one of value. SAVAGE (Nashville) believed that the sympathetic nervous system is the power that nature has given for the correction of

astigmatism. This power to correct a portion of the astigmatism, which certainly existed in every eye, was not in Muller's muscle nor in the third nerve, but in the sympathetic system. SUKER (Chicago) thought the consideration of the physiology of the sympathetic system in relation to glaucoma exceedingly interesting; the exact physiologic tract of the fibers was not yet known; if you excised the ciliary ganglia as well as the superior there would still be some sympathetic reaction from the rami communicantes coming down through the fifth nerve. There might be restitution through the crossing of the fibers, which might explain why some of the action is restored. From being very enthusiastic some years ago he had become quite conservative. JACKSON (Denver) thought we were not yet in a position to speak definitely as to the utility of the operation in glaucoma. He thought, with Dr. Black, that excision did most in the cases favorably influenced by eserin; it will do good in cases that would be benefited by iridectomy. It was of value in cases where one eye had been lost and it was difficult to get a patient's consent to operation upon the other eye. Where the patient will not submit to iridectomy, though indicated, sympathetomy may be expected to be useful. DESCHWEINIZ (Philadelphia) said it had been impossible to read in detail the experiments upon which his conclusions had been based; he had not attempted to go into the question of the pupil-dilating fibers which do not run in the sympathetic; a great many of these fibers do not run in the sympathetic at all, but in the trigeminal. He believed, with Suker, that it would not be right to excise the middle ganglia. He did not believe it was those cases in which eserin did good that the operation was of most value, because eserin does good where the filtration angle is closed, while sympathetomy has done good in the cases where there has been doubt as to whether the angle was blocked. WILDER (Chicago) said the ganglions excised did not show any increase in connective tissue, but increase in the adventitious tissue could be seen in the coats of the vessels. He thought there was doubt sometimes as to whether we should resort to sympathetomy first or iridectomy first in the cases of simple glaucoma. He was skeptical of the value of iridectomy in true simple glaucoma, where the anterior chamber was of normal depth; and it was in such cases that sympathetomy did good. BALL (St. Louis) said that in the examinations made of the ganglia excised for exophthalmic goiter the same pathologic changes had been found.

**Retinal Disease Limited to the Region of the Macula Lutea.**—HENRY GRADLE (Chicago) gave a description of various types of retinal disease sharply limited to the region of the fovea or that adjoining it. The reduced central vision corresponded to a well defined, but easily overlooked lesion. The paper included the report of five cases.

**Discussion.**—DAYTON (Lincoln) said the first two or three cases simulated the changes that might occur in senilia; that such changes did occur in the pigment and nervous epithelium of the retina in senile cases. The condition should also be carefully studied in reference to traumatism. Such changes might also be seen as the result of the electric light. COXOR (Detroit) had observed a somewhat similar case in a physician of 40. HAWLEY (Chicago) was reminded of three cases of a similar nature, which he reported, and referred to the influence of autointoxication from the intestinal tract as a factor in the trouble.

CASEY WOOD (Chicago), Chairman of the Committee on Pathologic Exhibit, made a few remarks on the various methods of preparing and preserving ophthalmic specimens for the museum, saying in part that back in the seventies these preparations were preserved almost entirely in alcohol which so contracted it that the proper relations of the parts were destroyed. Later it became the custom to make colloidal preparations. Then Priestly Smith, of Birmingham, had introduced the method of putting them up in gelatin. To this method there was the objection made by the pathologists that no sections could then be made. He considered the gelatin method, if one used great care, the best for the large specimens. Fluids, generally formalin, were used where one desired to be able to take sections. The most beautiful method of preserving the specimen in fluid was that of Greefe, where in a formalin solution the specimen is adherent to the jar. Dr. Brown had gilded refined gold by also making minute photographs of the specimen which were attached to the jar.

**Skiascopy as a Method of Precision.**—EDW. JACKSON (Denver) said the first step toward rendering skiascopy a method of precision was shortening the distance between the patient and the examiner. He deprecated the method of practicing skiascopy at a distance of a meter; it could not be exact; the correctness of measurements made at that distance could not be relied upon. He advocated working at a quarter of a meter, and for this distance the source of light must be reduced to 2.5 mm. or less; there must also be a reduction in the size of the sight-hole, which should not be more than one-half the diameter of the source of light. The correctness of measurements made at this distance depended upon precision and exactness in instruments and methods. Exact skiascopy meant working at a distance of a quarter or a half meter, the accurate measurement of that distance, the adoption of the source of light, and the sight-hole to the distance, and care to bring the source of light close to the conjugate focus of the retina.

[To be continued.]

## A CLINICAL REPORT OF NINE CASES OF FRIEDREICH'S DISEASE: HEREDITARY OR FAMILY ATAXIA SO CALLED, WITH COMMENTS ON NOTEWORTHY SYMPTOMS.

BY

JOSEPH COLLINS, M.D.,

of New York.

Professor of Nervous and Mental Diseases in the Postgraduate Medical School; Visiting Physician to the City Hospital; Consulting Neurologist to the Hospital for Ruptured and Crippled, etc.

The disease now commonly known as Friedreich's disease or hereditary ataxia has a history that dates back more than 40 years, nearly as long as the disease from which it was differentiated with so much difficulty—locomotor ataxia. In 1861 Friedreich, then professor of medicine in Heidelberg, presented at the Congress of Spire a report of three cases of locomotor ataxia which showed some remarkable features, particularly in regard to the time of the development of the disease and its occurrence in more than one member of the family. It was not until two years later when he published a report of autopsies made upon some of these cases that he contended for the separation of them from locomotor ataxia, and maintained that the disease was distinguishable not only in its etiology, but in its clinical delineation. Although in the beginning his teaching met considerable opposition both in his own country and abroad, 15 years later his claims were substantiated beyond question by his further contributions and by those of his pupil, Fr. Schultze, now of the University of Bonn. Since that time the contributions from Europe, America, and Australia have been very numerous, so that today the clinical features of the disease are as well recognized as those of locomotor ataxia and the morbid changes which are found in the spinal cord after death are as constant and typical as those upon which the latter disease is dependent. Despite the considerable literature of the subject, indicative of the study that has been given to it, there is still something to be learned of the disease from a clinical standpoint and vastly more of its causation. Cases of Friedreich's disease that show variation from the classic picture of the disease should be recorded as should those in which anything bearing on the etiology of the disease can be made out. It is for this reason that I publish a report of the cases that have been seen in my clinic during the past five years.

The most striking features of Friedreich's disease are (1) its occurrence in more than one member of the family, and (2) its development in early life, usually about the time of puberty. Aside from these two factors nothing is known of its etiology. If the present-day conception of the genesis of the disease is correct, or approximately so (that it is an evolutionary defect or teratologic manifestation), then very little further can be known.

Despite the fact that the commonest designation of this disease is hereditary spinal ataxia it is most exceptional to find any history of direct transmission from parents to offspring. In some instances a direct hereditary transmission can be traced through three generations. An example of this has recently been published by Hoffman.<sup>1</sup> However, the distinguishing feature of the disease from the point of heredity is its occurrence in several members of the same family, and for this reason the term "family ataxia," which is sometimes given to it, is to be preferred. The explanation of the fact that the disease is not transmitted directly may be that the vast majority of the victims of Friedreich's disease are incapacitated from procreation before they have reached a marriageable age. There must be other reasons, however, for there are a number of cases on record in which the disease did not develop until after early maturity;

for instance, Case VII of this series. The patient, a married man, has children, and his sister, a victim of the disease, is also married. In contrast to this there are many cases in which there is no evidence whatever of neuropathic taint of any kind in the family history, such as in Case III, a very intelligent young man who had carefully inquired into his ancestral history in order that he might be able to trace the origin of his own disease.

"Isolated" cases of Friedreich's ataxia, *i. e.*, cases in which no neuropathic taint in the ancestry or in the collateral family history can be obtained, are by no means uncommon. Ladame gave special attention to this in an excellent critical digest on Friedreich's disease published in *Brain* in 1890, and since that time a number of cases have been published. No adequate explanation of the occurrence of these isolated cases has as yet been given.

As in every other chronic disease, one hears now and then of contemporaneous event or occurrence attributed as the cause of the disease. Thus, exposure to cold, injury, fright, the occurrence of the specific fevers and infectious disease, have all been so attributed and spoken of by more than one writer upon the subject but scarcely any one attaches importance to them.

Friedreich was of the opinion that the disease developed at about the time of puberty in the majority of cases. Gowers states that the majority begin usually earlier than this, at the seventh or eighth year. There is no dearth of cases in the literature in which the disease began after 20. On the other hand, Fraser<sup>2</sup> reports a case with autopsy in which the signs developed first in infancy.

The distinguishing clinical features of Friedreich's disease are: 1. Ataxia of all purposeful movements and of station; incoordination due to the loss of the sense of equilibrium. 2. Loss of the tendon-jerks; diminished myotatic irritability and muscular weakness which may amount to paresis of the lower extremities. 3. Deformities of the spine, usually scoliosis, lateral curvature and deformity of the feet, commonly pes cavus, with extension of the big toe. 4. Nystagmus, static and dynamic. 5. Disturbance of articulation and intonation. 6. Features that distinguish it from tabes or locomotor ataxia: absence of lancinating pains, intactness of sensibility, normal pupillary reactions, no disturbance of vision and noninvolvement of the urogenital sphere.

The ataxia is the most striking feature, although not infrequently the deformity of the spine occurs before the ataxia. The ataxia of gait of Friedreich's disease is markedly unlike that of tabes. The patient with this form of disease walks with the feet wide apart, the steps varying in length with the amount of lateral deviation. When the patient attempts to walk a straight line a distinct reeling is added to the gait that patients with tabes do not have. In other words, the cerebellar element in the gait of Friedreich's disease is very conspicuous. Patients with Friedreich's disease manifest the ataxia in standing, but in many instances the instability is not increased by asking them to close their eyes. This is well illustrated in Case I. When the patient stands there is a constant attempt at balancing, the muscles of the different parts of the body being in a state of irregular contraction. To this condition of affairs the name titubation is usually applied.

The ataxia shows itself in the upper extremities nearly as often as in the lower, and in fact, every part of the body which manifests purposeful movement may show it. In the hands it is first made evident by the patient doing badly acts requiring fine coordination, such as threading a needle, buttoning the clothes, etc. It is more uncommon in the face than in other parts of the body. One very remarkable feature about the ataxia of Friedreich's disease is that it is made worse by protracted rest, and in one of my patients it is very much worse on arising than in the afternoon and even-

ing. I have not found involuntary jerking and choreiform movements in the cases reported herewith so frequently as one might suspect from the reported cases in the literature.

CASE I illustrates the typical family history. The patient is an Irish girl of 14, the sixth of seven children; four sisters and two brothers. Two sisters died in infancy. Of the five remaining children, three, one boy and two girls, have Friedreich's disease. The boy, now a man of 25, developed the symptoms when 12 years old. A girl, now 18, developed them when 12 years old, and my patient was quite well until her thirteenth year. The disease has run its customary course in the man, and he is now so crippled that he is confined to his bed or chair. The older girl is still able to get about, but she is much more uncertain in station and gait, it is said, than my patient.

The symptoms of Friedreich's disease in my patient, the youngest of the three who are affected in this family, began with a sensation of what she calls "faintness." This was of such severity that she consulted a physician, who told her it was due to oncoming puberty. After this she complained of pain in the back, a dull ache, not constant; of weakness of the legs; of staggering, which was at times associated with vertigo; of failing eyesight, and particularly of fatigue of the eyes when she read; and of girdle sensation. There was no disturbance of the sphincters, no paresthesia, no mental disturbance, no alteration of articulation. All the symptoms preceded the occurrence of menstruation, which came for the first time about a year after the initial symptoms of Friedreich's disease.

Examination shows that the gait is very ataxic, likewise the station. When the patient stands with the feet in apposition, with or without the eyes closed, the constant attempt of balancing, to which the name titubation is given, is very marked. It is not more pronounced with the eyes closed than with them open. There is slight but distinct ataxia of the upper extremities. The knee-jerks and ankle-jerks are absent and they cannot be elicited to the slightest degree on reinforcement. In this connection it may be stated that the ankle-jerks are best reinforced in my experience by having the patient read aloud while the tendon-jerks are being tested. The pupils are of moderate size, equal, and respond quickly to light and shadow. There is no nystagmus. The most striking feature of the face is its lack of mobility or action on emotional display, or on voluntary effort, such as talking. Tactile, thermal, and pain sensibility are undisturbed. The plantar reflexes are lively and of the flexor type. There is no loss of articulatory sense, no astereognosis. The spine presents in the dorsal region a pronounced convexity toward the right with slight rotation and a beginning compensatory curve toward the left in the lumbar region. This throws the right arm and shoulder upon a lower plane than the left. The feet have the characteristic deformity of this disease, usually spoken of as the "Friedreich clubfoot." The left foot in repose drops into a condition of moderate pes cavus. The great toe is flexed at the distal articulation, and extended at the proximal.

This case is in every way typical. The family occurrence of the disease, the development at puberty, the insidious onset and progressive course, and the characteristic clinical features all make it a typical case.

In the case about to be related there was no family history of similar or any other nervous disease, nor was the disease typical in any of the other respects above mentioned. Nevertheless, I venture to say that no one will deny that it must be put in the category of Friedreich's disease. It illustrates furthermore that although pain is not usually reckoned a symptom of Friedreich's disease, in some instances it is a cause of complaint.

CASE II.—L. G., a schoolgirl, aged 11, said when she first came under observation in March, 1898, that every evening about six o'clock she has pain in the feet and that this pain makes her weak, so that when she attempts to walk she staggers and falls if not supported. This has been coming on for about three years. In the beginning, her mother says, she hung her head because of weak eyes and after that she got very nervous and her head began to shake. The mother says there was no trouble with her eyes that could be seen. She recalls that Dr. Noyes, who lectured upon her daughter's case, said that the trouble came from lack of proper nourishment. She adds that she did not believe him because the child got the same food as the other children and they were well. It may possibly be inferred from this that paleness of the optic nerves was found at that time. Uncertainty of gait, staggering and weakness of the legs came on about one year ago, *i. e.*, when 10 years old. About two months ago she was sent home from school by the teacher, because her hand shook so much that she could not use a pen or pencil and because she was afraid that something would happen to her if she were allowed to go to and from school alone. At this time she was in the third grade of the grammar school, which indicates that she was as advanced in her studies as other girls of her age. For a few months before coming to me it was noticed that her speech had become slower and

somewhat indistinct. She is the fifth of a family of six children, all of whom are living and in good health. Her parents give no history of nervous disease and they have no knowledge of such disease in their relatives.

Examination March 31, 1898, reveals the staggering, uncertain gait; there is marked titubation of station even when the eyes are open, in fact, closing the eyes does not seem to increase it very much; the knee-jerks and ankle-jerks are absent; there is no wasting of the lower extremities; the plantar reflexes are sluggish and of the flexor type; the abdominal reflexes are absent; sensibility seems to be intact. The tremor and ataxia

Fig. 1.

of the upper extremities are pronounced. This is evidenced by the accompanying signature (Fig. 1). She is unable to button her clothes or to assist herself in any way. There is no deformity of the feet, unless it be that both feet are tending toward flatness (double-sided pes planus), nor is there any deformity of the spine. The ataxia of the head, or rotatory tremor, which is a better name for it, and the ataxia of the upper and lower extremities increased during the few months that she was under observation. She was not seen again until a few days ago, *i. e.*, after an interval of five years.

Examination April 7, 1903:

The patient can no longer stand without support, and she is unable to walk unless she is aided by two persons, one on either side (Fig. 2). When thus aided she gets about with difficulty. She drags the legs and has to raise the feet high in order to get the toes clear from the floor. In other words, when she lifts the foot from the floor the toe drops just as it does in a typical case of foot drop from neuritis. She seems to have strength enough in the legs to stand upon them, but when she attempts to do so she wobbles and staggers. There is no apparent atrophy in any of the muscles of the lower extremities. The most striking feature to the eye is the complete pes planus on both sides, there being no trace of arch left (Fig. 3). The knee-jerks and ankle-jerks cannot be elicited, nor is there any front tap. The plantar-jerks are lively, and both of the Babinski type. The left hand shows fairly advanced typical manus cavus (see illustration, Fig. 4). The direct myotatic irritability of the muscles of the upper extremities is prompt and rather fascicular, so that a tap over the common extensor of the fingers causes an extension of an individual finger where the blow is struck. The tendon-jerks of the wrists and elbows cannot be elicited. There is well-marked lateral curvature of the spine, the convexity being to the right. There is an irregular rhythmic movement of the head and of the extremities. The upper extremities are both ataxic, the left more than the right. The pupils are equal and respond normally to light and in accommodation. Ocular movements are free, but there is distinct nystagmus-like twitching when the eyes are put in extreme positions. The optic nerves and retinae, when viewed with the ophthalmoscope, are quite normal. There is no detectable error of refraction. The facial expression is lethargic, and it is apparent on emotional display that the right side of the face is innervated more sluggishly than the left. Speech is monotonous, slow, and some-

Fig. 2.

speech is monotonous, slow, and some-

times indistinct, the tendency being to lop off syllables. The musculature of the body is flabby, but there is no definite atrophy of any muscles or groups of muscles. The palm of the left hand seems thinner, but this is undoubtedly due to the deformity going on in the hand. The deep sensibility is profoundly impaired in all four extremities. Tactile, pain and temperature sensibility are normal, and there is no astereognosis. There is general hypotonia.

The patient makes no complaint now of pain, or in fact of any other symptoms. There is no disturbance of the sphincters except that occasionally she does not hold the urine so well as she did formerly. So far as can be learned there is no difficulty in starting the stream. The patient's intelligence is quite equal to the average girl of her age who has had no educational advantages.

The mental condition of all my patients was normal save, perhaps, in one, and in his case the deficiency was emotional rather than intellectual. He (Case IV) was irritable and explosive at times and below the normal mentally. Two of my

patients of this series were exceptionally bright. One, a young draughtsman, educated himself by his own efforts, and had taken a leading place in his profession. Another, a young girl, graduated from the grammar school at an uncommonly early age. The pure type of Friedreich's disease, as a matter of fact, involves no mental change. When symptoms of mental enfeeblement occur with symptoms indicative of Friedreich's disease, as they occasionally do, it may be taken for granted that we are dealing with a disease that involves the higher cerebral centers, and it is very questionable whether these cases should be

Fig. 3.

Fig. 4.

classified as Friedreich's disease at all. Such, for instance, are the cases reported by Norman,<sup>3</sup> under the title, "Three Cases of Friedreich's Disease Associated with Genetous Idiocy;" Bouchaud,<sup>4</sup> "Two Cases of Allied Diplegia of Friedreich's Disease;" Vinaj,<sup>5</sup> myself,<sup>6</sup> and Higier,<sup>7</sup> to name only a few of those who have placed atypical cases of Friedreich's disease on record. In hereditary cerebellar ataxia, if we admit that there is a group of cases to which this name should be given, mental enfeeblement is not infrequently present, but cases in which symptoms of Friedreich's disease occur in connection

with profound mental accompaniments should rarely be classified as Friedreich's disease. It seems to me that many of the cases so reported are cases of either hydrocephalus or infantile cerebral palsy.

The following case is worthy of note for several reasons, but particularly because it illustrates that the mode of advance of the symptoms may be quite unlike what they are usually stated to be, viz., a steady progress of the disease:

CASE III.—J. K., aged 26, of German birth, and by occupation a draughtsman, says that he or his parents first noticed the symptoms of his present disease when he was about 10 years old. The symptoms consisted of weakness and uncertainty of the left foot and of a gradually developing deformity, which went on until the present condition of the foot, viz., typical pes cavus, hyperextension of the big toe and flexion of the other toes developed. As a boy, and indeed up until the past two years, he has had attacks of "rheumatic" pain in the legs and occasionally in the upper extremities. The pain is described as a sudden sharp aching pain, which comes on first in one place and then in another, and is more or less paroxysmal in its manifestation. At times, however, he would be free from such pain for a month or more, at other times he would have it very frequently for two or three weeks. The pain was not of a darting lightning character such as tabetic patients describe, but an ache like a dull toothache. As a boy he was not able to participate in the games and sports of other children because of the uncertainty of gait and what he considered to be loss of strength in the left lower extremity. His disease, however, did not seem to make much progress until he reached 21 years, when he noted that his right foot was becoming deformed owing to the gradual development of a condition similar to that of the left foot. At this time he remarked that he stumbled and fell very frequently unless he kept his eyes carefully fixed on the surface on which he was walking, and it was necessary to hold the banister in going up or down stairs, and to have aid when walking on a narrow surface such as a plank. Two years before I first saw him tenotomies were done upon his feet by an orthopedic surgeon, and since then he thinks he has been much worse, especially the incoordination of the upper extremities. Until that time he had been able to follow his occupation, but since then he has very rarely been able to make sketches because of manual uncertainty. He says if he is alone and very quiet he can use the hands occasionally as well as at any time during the past five or six years.

Examination shows a markedly ataxic gait; distinct ataxia of station; absence of the knee-jerks and ankle-jerks; scoliosis and lateral curvature of the spine, the deformity being most conspicuous from the third to the seventh dorsal vertebrae; pes cavus of both feet, the left being very much more deformed; distinct lateral nystagmus; pupils equal, react, medium size, contract promptly on exposure to light; visual fields, optic nerves and retinas normal; ataxia of the upper extremities; tremor which is evidenced most exquisitely in the writing; slight disturbance of speech in the shape of indistinctness of articulation of words that contain many consonant sounds; mentality intact.

The patient's personal history was that he had had measles, scarlet fever, and whoopingcough as a child, but since his late childhood he had not been ill. He was wholly unable to account for the existence of his present trouble. His parents, in whom there was no consanguinity, were living and had had eight children, of whom this patient was the sixth. Nothing similar to the disease which the patient has was to be found anywhere in the family.

Ten years ago Marie<sup>8</sup> discussed some of the published cases of Friedreich's disease, especially those of Sanger Brown which, although it seemed necessary to classify under the heading of Friedreich's disease, were to be distinguished from it by certain important features, and especially by exaggeration of the tendon-jerks. He pointed out that these cases might legitimately be taken to indicate a lesion of the cerebellum, and possibly also of its afferent tracts, rather than disease of the posterior and lateral columns of the spinal cord as in Friedreich's disease. Marie proposed that the name "hereditary cerebellar ataxia" be given to these cases. The symptoms of this disease he maintained were in brief: Slow and gradual development of ataxia in the lower extremities; occasional pain in the legs and arms; ataxia of the upper extremities, which shows itself first about three years after the onset of the disease, and as a rule, contemporaneously with affection of vision and speech; preservation or exaggeration of the tendon-jerks, and in some cases mental enfeeblement. The disease runs a very protracted course, death occurring usually at an advanced age and from some intercurrent disease. It is

thought that hereditary cerebellar ataxia shows itself at a more advanced age than hereditary spinal ataxia, but like the latter, it is a family disease. The suggestion of Marie was that there is a similar degenerative process at work in hereditary cerebellar ataxia and hereditary spinal ataxia, the former involving the cerebellum exclusively or mainly and the latter the cord. There can be no doubt of the existence of cases that conform to the clinical description of Marie, Nonne, Londe, and others, and of such cases in which atrophy of the cerebellum is found postmortem, but it is doubtful whether they should be given other recognition than as a branch of a degenerative family disease. Although there have been a number of contributions made to this subject since Marie's article, such as those of Nonne, Brissaud, and Londe, to mention no others, the existence of hereditary cerebellar ataxia as a distinct disease has never been generally admitted. Of the following two cases one might put, if we subscribe to the views of Marie, the first in the category of hereditary cerebellar ataxia and the other in that of hereditary spinal ataxia. Yet no one can doubt for a moment, I think, that they are examples of the same disease:

CASE IV.—The first is that of a girl of 17, born in this country of Italian parents, who noticed when she was 15 years old that she was weak in the legs and could not walk straight. This weakness and uncertainty came on gradually, so that it was very difficult for her or her parents to fix the exact time of its first occurrence. In addition to the weakness of the legs and uncertainty of gait, she has complained during the past two years of "stinging pain" in the knees, in the back, the thighs, and the ankles. Sometimes this pain lasts for hours, creeping up from the legs through the back, and at times she complains of a sore feeling in the back of the head. Her most distressing symptom, however, is disturbance of locomotion. Her gait is profoundly ataxic. She staggers in a jerky, uncertain fashion in walking, and has difficulty in standing alone when the feet are in apposition, even when they are separated so as to give a wide base of support to the body. She is constantly going through balancing movements; in other words, titubation is a pronounced symptom. During the past six months ataxia has developed in the upper extremities. There is no functional disturbance of the bladder or bowels, and no complaint of girdle sensation or paresthesia. For a month or so before coming to me she had been getting deaf. Examination revealed, in addition to the ataxia of station and the incoordination of the upper extremities just mentioned, deformity of the feet and of the spinal column characteristic of Friedreich's disease, *i. e.*, pes cavus with hyperextension of the big toe and lateral curvature of the spine; lateral nystagmus; disturbance of articulation, best characterized by the word inebrious; and exaggeration of the knee-jerks with normal response of the ankle-jerks and front tap of the leg, and absence of objective sensory disturbances. In other words, she has the typical objective accompaniments of Friedreich's ataxia, save the exaggeration of the knee-jerks. While under observation she complained very much of attacks of vertigo, and when they came upon her she reeled and pitched very much like a person grossly intoxicated. This completely incapacitated her from moving about. These attacks occurred sometimes every day and sometimes not for several days, and were distinctively superadded to her other symptoms. Since their occurrence she has been getting progressively deaf. Examination of the ears by Dr. J. F. McKernon reveals that her upper tone limit is zero, and that there is marked diminution of lower tone; bone conduction is minus. Physical examination disclosed a moderately contracted drum membrane with an area of congestion over and around the oval window. In other words, a pseudo-Ménière's symptom-complex was engrafted upon the symptoms of Friedreich's disease. Under the administration of pilocarpin in moderately large doses and local treatment these symptoms abated.

CASE V.—Before commenting upon this case I shall recite briefly the history of her brother, a boy of 10, in whom the symptoms of Friedreich's disease are beginning to show themselves. Between the boy, whose history I am about to relate, and the girl just spoken of, there were two pregnancies, one of which resulted in a child that died soon after its birth, the other in a boy now aged 14, who is quite well. The symptoms of the disease showed themselves first in this boy when he was 9½ years old, and consisted of what he describes as weakness of the ankles and inability to walk straight. In addition to this he maintains that the right knee hurts him at times and that occasionally he has a disagreeable sensation "like electricity" going from the knees to the ankles. He cannot run as other boys do on account of turning over of the ankles and giving way of the legs, which causes him to fall heavily. His parents and his sister state that he is becoming progressively weaker and more uncertain. Latterly, his teacher has noticed that his handwriting has become tremulous. Examination reveals

ataxia of station and gait of the upper extremities; complete absence of the knee-jerks, both on ordinary tests and with reinforcement; absence of the ankle-jerks when they are tested in the ordinary way, but elicited on reinforcement; distinct lateral curvature of the spine in the dorsal region; lateral nystagmus, and slight but distinct disturbance of articulation. In other words, a most exquisitely developed picture of Friedreich's disease at its onset.

It is unquestionable that the tendon-jerks and ankle-jerks are usually absent in cases of Friedreich's disease; but it has been amply demonstrated that there are cases of hereditary spinal ataxia in which the knee-jerks are present or exaggerated. For instance, there can be no doubt, I take it, that these two cases of which I have just given a brief synopsis are two cases of the same disease. In the first the knee-jerks are slightly exaggerated and the ankle-jerks are normal. In the second the knee-jerks are completely obliterated and the ankle-jerks are absent, but can be elicited on reinforcement. The fact that the ankle-jerks are disappearing in the second case tends to show that the tendon-jerks will probably later be completely absent in both cases.

Tressider<sup>9</sup> has published the typical history of a family with Friedreich's disease in which the knee-jerks were completely absent in one patient and present in the others, which goes to show that the disappearance of the knee-jerks is sometimes not one of the early symptoms. There are a few other cases in the literature in which a similar condition has been made out. For instance, in Senator's<sup>10</sup> first case the knee-jerks were found to be present one year after the onset of the illness. A year and a half later the right knee-jerk was absent, the left could be elicited only on reinforcement. The sister of this patient who had had the disease for 27 years had no patellar tendon-jerks. Brock<sup>11</sup> has published a similar case of a man of 27, in whom the knee-jerks were present, but they were absent in the brother who is probably afflicted with the same disease. Erb,<sup>12</sup> Mendel,<sup>13</sup> and Ewart<sup>14</sup> have also spoken before medical societies of cases in which the knee-jerks were exaggerated.

Gladstone<sup>15</sup> has related a typical case of Friedreich's disease in which the knee-jerks were present and there was ankle-clonus on one side. A brother of the patient suffered from the same disease and in him the knee-jerks were absent. Nolan<sup>16</sup> has reported under the title of "Three Cases of Friedreich's Disease Associated with Genetous Idiocy" a form of family disease which has some of the clinical features of Friedreich's disease and in each case of which there was ankle-clonus and exaggerated knee-jerks. These cases have not been considered as belonging in the class of Friedreich's disease by those who have commented upon them and very properly so, as they were characterized by features that have no place in the symptomatology of the latter disease, such as enlargement of the thyroid, idiocy, and congenital manifestations of the disease.

Some writers are inclined to classify the cases presenting the symptoms of Friedreich's disease in which the ankle-jerks are exaggerated under the heading of hereditary cerebellar ataxia. For instance, Magnus<sup>17</sup> reports the clinical history of two brothers, in one of which he diagnosticates Friedreich's disease, while in the other, with exactly similar symptoms save that the tendon-jerks are exaggerated, he diagnosticates hereditary cerebellar ataxia. It is not easy to understand this, because there is an insufficient number of cases on record in which the knee-jerks are exaggerated to justify making such a diagnosis.

The occurrence of the symptoms of Ménière's disease complicated the clinical picture in the first of these two cases, but the superaddition was easily recognized, particularly as the manifestation of the latter changed the character of the symptoms so materially. Some days she could not walk at all without falling, and her efforts at walking were those of a person grossly intoxicated. At other times, and when under the influence of pilocarpin, this and the profound vertigo would disappear,

leaving the uncomplicated symptoms of Friedreich's disease. The occurrence of the Ménière symptom-complex in this patient may probably be looked upon as a coincidence.

As an example of the disease which does not develop until maturity, the following case may be cited :

CASE VII.—A. M., a farmer, aged 27, a native of Scotland, noticed about six years before consulting me that he inclined to wobble when he walked. This bothered him at first at inter-

*Ground the rugged rock  
The ravel rarr.  
The ragged ravel ran.*

Fig. 5.

vals only. He married when he was 23, and considered himself quite well at that time. He says later it was difficult at times for him to convince his wife that he had not been drinking. One year ago he came to this country, and from that time he dates his illness, which he describes as an uncertainty when standing and walking, and a slight "fulness" of speech. The uncertainty of gait and station is much worse in the dark and when he attempts to pass through narrow places or places where there are many people. During the past six months his right hand has become affected. When he goes to take up anything now he does it with a clutch, and oftentimes misses it. Examination shows that the knee-jerks are absent when tested ordinarily, but they can both be elicited very slightly on reinforcement. The left knee-jerk does not always respond to the blow of the hammer when reinforced, but the right does. Both ankle-jerks are absent. The plantars are elicitable and the right might be described as an atypic Babinski. The extension of the big toe and associated flexion of the small toe is abrupt,

Fig. 6.

otherwise it would be a typical Babinski. There is no disturbance of sensibility in any part of the body. The only deformity that can be made out is a lordosis of the spine. There is no pes cavus. The pupils are equal, of medium size, respond to light, and there is no nystagmus. There is marked ataxia of station and locomotion of the upper extremities, and distinct ataxia of the hand.

The patient's family history is that he has one sister with a similar disease, which came upon her in her youth, but which did not prevent her from working and getting married. After she married the symptoms of her disease increased rapidly,

and at the present time, in her twenty-ninth year, she is bedridden.

In some cases there is no history of a similar or dissimilar nervous disease in the family so far as the physician can make out, but in some of these cases the disease may develop later in other members of the family. An excellent example of such a state of affairs is furnished in the following history :

CASE VIII.—A butcher's boy, aged 14, came under my observation first in April, 1900. He was the eldest of three children, the other two being quite well and strong. Their ages are 6 and 4 respectively. One brother and one sister are dead, the sister having died of acute disease, the brother having been killed by an accident. The father and mother have no knowledge of any similar disease in their family.

He was born of a difficult labor without instruments or apparent untoward effect. He thrived as an infant and at 15 months was able to walk securely. When he was about 4 years old the parents remarked that he fell easily and frequently and that he was clumsy. This they attributed to fatness. This uncertainty and clumsiness increased as he grew older. He was never able to indulge in the feats and sports of other boys calling for equilibrium. He says he could not walk a fence, jump on one foot or learn to bicycle. When he was about 10 he first became aware that he could not walk as securely in the dark as in the light. His teacher remarked that he could not hold his pencil steady enough to make letters. Nevertheless he learned to write fairly well. Unsteadiness of the cephalic extremity was first noted when he was about 10. There has been no complaint of pain or functional disturbance of any kind save that of the extremities. The special senses functionate normally. There is no diplopia, vertigo, or ringing in the ears.

Examination shows absence of the knee-jerks, ankle-jerks, and triceps-jerks; pronounced pes cavus with hyperextension of the big toe; marked titubation on attempting to stand with the feet together and increased by closing the eyes; pronounced lateral curvature of the spine and projection of the left scapula; speech hesitating and drawling; mentally he is bright, of good memory, but his disposition is infirm. He is irritable and cranky and liable to explosions of temper; pronounced ataxia of locomotion, the feet are slapped on the ground, the stride is very irregular, and the feet are widely separated. The ataxia of the upper extremities is well marked. The accompanying illustration of his handwriting at this time gives an idea of the impairment of coordination in the upper extremities (Fig. 5). The pupils are equal, of medium size, and respond promptly to-

Fig. 7.

light. There is no nystagmus and no limitation of the visual fields. The left side of the face is innervated more actively than the right. The palatal, pharyngeal, abdominal, cremaster, and plantar reflexes are lively. Irritation of the sole produces lively extension of the small toes and flexion of the big toe. There is complete absence of cutaneous sensory disturbances, but the deep sensibility is profoundly disordered.

Examination of the patient, April, 1903, *i. e.*, three years after the above status was obtained, showed that there was only marked intensification of all the symptoms. No new symptoms had developed. He is now unable to get about without assistance and he can stand only by clinging to something. Ataxia of all four limbs in the dark. The patient did not complain of anything. There was no disturbance of the special senses or of speech. The functions of the bladder and bowels were normal, there being no hesitancy in starting the stream.

The deformity of the spine for which he has been wearing a corset has got very much worse (Fig. 6), and the deformity of the feet (pes cavus, retracted big toe, and flexed small toes) has intensified (see illustrations, Figs. 7 and 8). The reflexes and tendon-jerks remain the same as at the original examination. The patient is well nourished, the muscles are well developed, his circulation is vigorous, and he makes no complaint, save that the extremities, particularly those of the left side, are heavy as if they were loaded with lead. There is no indication of mental deterioration. Formerly his head seemed disproportionate in size to the body; now it does not. The asymmetry

of the face which was noted as being very slight three years ago is now striking, both in emotional display and when the face is in repose. Speech has become uncertain and characteristically inebrious. There is no disturbance of the sphincters or of the special senses. In brief, he presents now as he did three years ago the typical picture of Friedreich's disease.

About a year after this boy first came under my observation Dr. I. Abrahamson, my chief of clinic, in whose care he had been placed, noticed that a brother 7½ years old was afflicted in a similar fashion. I am indebted to Dr. Abrahamson for the history of the patient, whom I have recently examined.

CASE IX.—The only noteworthy thing about this boy's infancy is that he did not walk or talk until he was two years old. His emotional and intellectual possessions have always seemed quite normal. When he was 6½ years old it was noticed that he was becoming unsteady on his feet. This uncertainty was most evident in the morning on arising, on going downstairs, on walking. Speech is not affected. The disease is apparently progressive.

Examination shows a well-nourished, well-developed child, like the brother, whose history is related above; the head is rather large for a child of his years, has a number of somatic stigmata of degeneracy, the ears are particularly of a degenera-

Fig. 8.

tive type; the chest is of a rachitic type; the spine is irregular, scoliotic, and the feet are to a moderate degree in a state of equino varus, the right being more advanced. When he walks the feet are kept wide apart, and in locomotion they are brought down in a flapping way, and he inclines to walk on the outside of his feet. His station, which is unsteady, is made more so by closing the eyes. The knee-jerks and ankle-jerks are absent, both patellar and Achilles tendons are soft. The plantar-jerk is present on both sides, of a flexor type on the right side, and extensor on the left. The pupils are equal, responsive to light, there is no limitation of the visual fields, and the optic nerves are normal when seen with the ophthalmoscope, the discs being somewhat more red than normal. Lateral excursions of the eyeball are accompanied by nystagmiform twitching and a coarse tremor of the head consisting of a few jerks of the head in the same direction as the head is turned. There is a slight coarse, irregular twitching of the face and tongue. There is very little ataxia of the upper extremities. The special senses are normal. Tactile, thermal, and pain sensibility are normal, deep sensibility is disordered more in the upper than in the lower extremities.

These two cases offer little to comment upon save that they are fairly typical examples of Friedreich's disease occurring very early in life, the first as early as the fourth year and in the second at the sixth year. The

rapidity with which the elder brother has become incapacitated is greater than in the average case. These cases may all be looked upon as fairly typical examples of Friedreich's disease. They were observed in one neurological clinic and within a comparatively short time, which tends to show that the disease conforms to the classic type with some frequency. Although the literature contains the records of many atypical cases, histories such as those above related show how uniform the clinical features may be in one case after another. That the difficulties of distinguishing it from a few other diseases, such as Huntington's chorea, multiple sclerosis and congenital or early acquired inflammatory or sclerotic disease of the brain are often very great, there can be no doubt. That side of the subject I intend to take up later. I wish here only to point out the uniformity of the clinical manifestation of the disease and some uncommon clinical features, such as preservation of the tendon-jerks, pes planus, manus cavus and an uncommon complication, the Ménière symptom-complex.

### PRESENT STATUS OF CONGENITAL DISLOCATION OF THE HIP AND THE BLOODLESS REDUCTION.<sup>1</sup>

BY

VIRGIL P. GIBNEY, M.D.,

of New York City.

Surgeon-in-chief to the Hospital for the Relief of the Ruptured and Crippled, New York City.

The invitation to continue a discussion of this subject seems somewhat out of place, for so much has been said and written on this topic within the past six months. My friend, Dr. Wilson, however, thought that the Fairfield County Medical Society would be interested, and I am too keenly sensitive of the honor to decline.

Prior to the summer of 1902, the general profession took little interest in congenital dislocation of the hip, and simply accepted the teachings of the textbooks on surgery as final. For the past 10 years orthopedic surgeons themselves have leaned strongly toward the views thus expressed because of the difficulty of perfecting an operation that would yield satisfactory results. When cases have been presented to illustrate a cure, or at least a great improvement, there have always been a number of critical surgeons who scrutinize so closely that the reporter felt like apologizing for the work he had done. Those surgeons who have been contented with the deformity as it exists have always maintained that as the child grew older there was no increase in lameness or even in disability. The views were entertained that the child acquired a greater facility in walking, and apart from the lordosis, or in-curving of the spine, there was nothing to interfere with prolonged exercise. When the deformity was bilateral it was believed that the patient would, as the years went by, cultivate a grace of movement that was at times attractive.

In the early years of my own professional life I was assured by older orthopedic surgeons that a lady who

<sup>1</sup>Read at the annual meeting of the Fairfield County Medical Society, Bridgeport, Conn., April 14, 1903.

had double dislocation of the hip danced exceedingly well. During the last decade, however, very good men have claimed that as the patients grew older and heavier, the disability increased and that it was in evidence that patients who could formerly walk 8 or 10 city blocks with ease, could, as they grew older, walk only 2 or 3 blocks. It is true that these assertions have been maintained by men who were fond of operating, and those who maintained different views have obtained many histories of cases which would seem to prove their own views. It is a fact, however, that as adult life is reached, patients with unilateral and bilateral dislocations do tire more readily and seek relief on this account.

The Röntgen ray has aided materially in explaining these different histories, for we find all kinds of distorted femoral heads and femoral necks. Those heads that are pointed and necks that are almost continuous with the shaft of the bone, would naturally strain the gluteal muscles and cause greater disability as the patient's weight increased; while those heads which are well-formed and those necks which have not changed their relationship with the shaft would naturally cause less inconvenience in walking, so that it remains for the surgeon to determine in a given case what the prognosis is after a careful examination by means of the radiograph.

Professor Lorenz professed his ability to determine this by means of palpation and functional testing of the joint. It is quite easy to give a prognosis after so long a study of the subject as this distinguished surgeon has enjoyed. The extraordinary interest developed by his visit to this country last winter at least shows that the parents of these children are not as well satisfied as the profession is with a lifelong disability. Long before the bloodless method was demonstrable we found in the city of New York those who were willing to subject their children to the open method time and time again in the hope of reducing the lameness and the shortening. There are many parents today satisfied with the results, although the surgeons themselves feel that the best has not been attained. A hip partially ankylosed is sometimes better than one so much relaxed as the congenital hip.

The demonstrations made by Dr. Lorenz during his tour were looked upon by a great many physicians and surgeons with a certain degree of reservation. Even the dramatic slipping of the head of the bone from one position to another failed to convince, and men are waiting all over the country for the six or eight or ten months to elapse before the demonstration is accepted as satisfactory.

The details of the reduction have been so well taught by the champion of the bloodless method that it seems hardly worth while to repeat these on the present occasion. It may as well be repeated, however, in order to emphasize the facility with which the reduction can be accomplished in children of suitable age. Before we had an opportunity of witnessing the procedure we followed the earlier teaching, namely, firm traction with counter traction in the extended position, resorting to a folded sheet passed through the perineum and held over the head of the table while traction was made by one or two assistants for several minutes. The next step was the abduction of the limb and rotation outward, but in many instances, from my own observation, the adductors were not completely broken down, and the forced flexion of the limb was not carried to the extent which we learned later was a necessary factor in the reduction. We have learned that these later steps have been developed within the past two or three years, and at present the forced flexion, preceded by complete abduction of the limb until all the muscles are torn across or fully stretched, constitutes the main feature of the operation.

The cardinal principle, however, is to stretch thoroughly the capsular ligament after the muscles have been thoroughly broken down. There is in reality very little of the enormous traction employed, because the

other movements get the head down opposite the rudimentary acetabulum, enabling one, by strong leverage power with a wedge-shaped block just back of the trochanter major, to effect the reduction; that is, the appearance of the head under the femoral vessels midway between the anterior superior spinous process and the pubis. After this is accomplished it is necessary to stretch the capsule still further, and just here comes, in my own judgment, an element of danger. From the number of cases in which paralysis of the quadriceps-femoris and leg muscles have been developed it would seem that this final stretching is not only unnecessary, but extremely hazardous. It is true that a peripheral paralysis does, as a rule, yield in the course of a few weeks, yet I have in mind now one or two cases in which two or three months have elapsed, and yet the paralysis remains. The plaster-of-paris spica bandage can be just as well applied as soon as the head slips into position, and the use of the limb begun a few days later will contribute largely to the encapsulation. If the paralysis persists for a long time we lose the function-bearing factor so essential to the thickening of the tissues around the head in the new position.

Two weeks ago I removed the plaster from a patient operated upon by this method last July, and I found no slipping up or down, and the head of the bone is certainly in good position. This patient for the past six months has been walking very actively in his plaster-of-paris, and I am satisfied that a cure is established. The temptation to exhibit this patient, in order that you might see for yourselves how perfect a result is promised, was hard to resist. We have at present two or three patients in the wards of the Hospital for Ruptured and Crippled in a double plaster-of-paris bandage, applied in December and January after reduction of bilateral dislocation, and it would interest you very much to see them walking like an extravagant case of bowlegs. Our plan was to put these children at first astride a small chair on which were ballbearing castors, and they soon learned to wheel these chairs about the wards bearing their weight on both limbs.

The fear was entertained at the time Lorenz was giving his brilliant demonstrations that attempts would be made to reduce hips in patients beyond the age limit, namely, 7 or 8 years, and I am free to admit that I have yielded to this temptation with a few unsatisfactory results. The question, then, is what shall we do with these older patients? What was taught and what we are now doing at the hospital is to stop short of complete reduction, get an anterior reposition, contenting ourselves with placing the head under the anterior superior spinous process, and after the application of the plaster-of-paris in the adducted position of the limb, secure by the weight-bearing function encapsulation.

In some instances when plaster has been removed for observation we find that all is going well and the hope is entertained that the gait and attitude will be greatly improved. We certainly do away with this extreme lordosis and get a better lodgment for the head. Great improvement has been obtained in a child 12 or 13 years of age by enforced hyperextension of the limb a few hours every day. The procedure is as follows: The patient is placed prone in bed, the body and pelvis resting on a kind of swing, the anterior surfaces of the thigh resting on one another, while a weight varying from 2 to 10 pounds rests on the buttocks. We have constructed a pair of old-fashioned saddlebags with shot in each end, and in this way are enabled to carry out this principle with very little discomfort.

It is interesting to note that the surgeons on the hospital staff are admitting very few patients over 8, and when such patients are admitted we resort to a preliminary treatment of traction by weight and pulley in bed. We begin with 5 pounds and gradually increase this to 35 or 40 pounds, reaching this limit at the end of three or four weeks. Such a method enables us to drag

the head of the bone down nearer the plane of the acetabulum and make reduction at the time of the operation a little less difficult.

There is really no excuse for an error in diagnosis after so much has been said and done for congenital dislocation of the hip. It is only necessary for the practitioner to bear in mind that a history which tells him of lameness so soon as the child begins to walk and an absence of pain such as belongs to hip disease are sufficient to enable him to diagnose a congenital dislocation of the hip before the fourth or fifth year. I can readily understand how a poliomyelitis developing before the child begins to walk may mislead one and cause an error in diagnosis. Yet the history of poliomyelitis ought to be sufficiently well known by any physician to enable him to avoid an error. There is no other affection which is sometimes confounded with congenital dislocation, but even this, namely, an acute arthritis of infancy, has a history of acute pain and disability, even if suppuration is not present. When any reasonable doubt exists the Röntgen ray will assuredly help one in making a differential diagnosis. It is no compliment to the intelligence of physicians to insist on a thorough examination of every case of disability at the hip, and I am quite sure that all will agree with me that errors in diagnosis are very infrequent when the physician is in the habit of a routine, thorough examination of his patient.

In conclusion, I beg to present for your consideration a few points that seem to me paramount: 1. Do not rest content in a case of hip lameness in a young child until you have made a thorough examination of the patient and have obtained a full history of the case. 2. The diagnosis once established, aim to effect a reduction before the sixth or seventh year. It is fatal to postpone operation. 3. In patients beyond the age limit fortify yourself with a Röntgen ray picture in order to determine the exact position of the head, the shape of the same, and the relationship which the neck sustains to the shaft. 4. Do not make long attempts at reduction in patients over 10. 5. Bear in mind the dangers which Dr. Lorenz himself has warned against, namely, too extensive laceration of the soft parts, paralysis which may or may not yield to time and treatment, the fracture of the femur or the pelvic bones, rupture of an artery, sometimes the femoral.

## THE FORCIBLE REPOSITION OF CONGENITAL LUXATION OF THE HIP.

BY

GWILYM G. DAVIS,

of Philadelphia.

The attempts at forcible reposition of congenitally luxated hips have given rise to so many accidental traumatism that the question has arisen as to whether, in order to avoid bringing the treatment into disrepute, it is not appropriate to advocate more conservative measures.

That it is both desirable and proper to use a certain amount of force in this as in other orthopedic measures is self-evident, and its employment in the reduction of congenital luxations is just as necessary as it is in traumatic ones and, rarely perhaps, even with the greatest care, a femur may be fractured, but the question is, Has not the use of force been carried too far?

When Paci was evolving his method of forcible reposition from 1887 to 1894 he was evidently at times employing considerable force and fully appreciated its dangers. He laid much stress on using the greatest care and slowness in making the reposition, because he stated that fracture of the thigh might otherwise be produced, which accident he said had already occurred. When Professor Lorenz, after seeing Paci demonstrate his method of forcible (now sometimes called bloodless) reposition at

the time of the International Congress in Rome in 1894, published and demonstrated in 1895, and later, his own mode of procedure, it was characterized mainly by the great force advocated. What Paci attempted by comparatively mild and more or less gradual methods Lorenz sought to accomplish by violence. The earlier descriptions and reports of his manipulations showed that such an amount of force was used and so many serious injuries inflicted as to cause me to view his modifications of Paci's procedures with distrust and doubt their necessity. When in 1900 Professor Lorenz issued the second edition of his volume on congenital luxations of the hip he stated that in 450 cases he had had 3 deaths; 1 was from chloroform narcosis, the other 2 were apparently due to the manipulations, for they occurred 16 and 24 hours later. There were also 11 cases of fracture of the neck of the femur, 1 of the pubic bone, 1 of the ilium, 3 paralyzes of the perineal nerve, 7 of the anterior crural, beside some of the sciatic, and 1 total gangrene of the lower extremity. Minor traumatism causing stiffness of the joints and the serious ruptures described by Narath also occurred.

Heusner, of Barmen, has recently stated that he and Hoffa have had even more serious results. Hoffa in the German Congress of 1899 stated that he had had tearing of the soft parts, vulva, urethra, fractures and separation of the epiphyses, paralysis of the sciatic and anterior crural nerves, and suppuration of the hematomas which formed at the site of rupture of the adductors. He even lost one case, a child of 6 years of age. It may be urged that these injuries occurred early in the development of the method of forcible reposition and in old cases. This is only partly true, because Heusner's article appeared late in 1902 (*Zeitschrift für Orthopädische Chirurgie*), and it is a wellknown fact that the most difficult cases are not always the oldest ones; one of the worst in Philadelphia was only 4 years of age; also that these accidents appear to be still recurring and new instances are being continually brought to light. Wilson and Dinkelspiel state that in one of the cases operated on by Professor Lorenz himself in Philadelphia the child was seized with convulsions, went into a state of stupor, the pulse became weak and rapid and could not be counted. This child fortunately recovered. Professor Lorenz is quoted as saying of this case that he considered shock and traumatism as the cause of the symptoms. Others who have followed his teachings have not escaped. I have recently heard of two additional deaths and another case of fracture of one thigh and paralysis of the opposite leg in a bilateral luxation, besides tearing of the perineum and other traumatism. In order to appreciate what amount of force Professor Lorenz advocates and uses in his manipulations, the four cases operated on in his public clinic in Philadelphia will illustrate. His routine method, as accurately as I can describe it, on that occasion was first to place the child on König's block, and an assistant holding the pelvis the thigh was abducted and extended while pressure was made on the adductors near the symphysis until they were ruptured. The leg was then extended on the thigh and the thigh forcibly flexed on the abdomen until the heel laid alongside of the ear. Then the operator or his assistant made traction while the other held the pelvis. The child was then replaced on the block and forced abduction and hyperextension performed with the thigh at right angles to the body and the leg flexed on the thigh, the internal condyle pointing anteriorly and the toes laterally outward. This position I would call external rotation. These manipulations were repeated until the head moved to its new position. In the last case, after performing these manipulations in a child aged 4 years, and not succeeding, six times was extension made by assistants pulling on a skein of yarn attached above the ankle, while counter extension was accomplished by a sheet fastened to one corner of the table, the perineum being protected by a rubber pad. On one occasion there were

three assistants pulling, the operator was pushing on the trochanter, another assistant helped to steady the pelvis, another gave the anesthetic, and three were holding the table, a force of eight powerful men (exclusive of the anesthetist) who were exerting their strength, directly or indirectly, on the tender tissues of a child 4 years of age. Between the tractions the patient was repeatedly hyperextended over the block. On the last attempt the head moved slightly forward, and the operator stated that in this case he would be satisfied with a partial result. That the manipulations were not without a certain amount of risk, even to the operator, was shown by the reported sequel of his having sustained a sprain of the wrist as a result of his efforts.

While it is true that many of these severe injuries have occurred in the older cases, they are by no means confined to them. Their frequent occurrence apparently compelled Lorenz to abandon the use of his screw traction, and instrumental traction has been discontinued by nearly all operators. The great increase in the number of accidents and severe injuries following attempts at reduction which has occurred since Professor Lorenz has given public demonstrations in this country justifies a plea for a modification of the methods at present so generally used. Designating as "bloodless" a method that tears the soft tissues, breaks the bones, produces hematomas extending from the middle of the thigh below to the umbilicus above and at times kills the patient, seems to me to be a trifle facetious and certainly savors more of sophistry than it does of truth.

When we consider that the deformity is not a fatal one, and that in some it is not even a seriously disabling one, means of treatment which subject the patients to the serious risks of permanent injury or loss of life are not to be recommended.

It therefore becomes a duty to see if the objectionable and dangerous features cannot be eliminated. With this object in view, the following suggestions are offered: That the tendons of the adductor muscles at least be cut subcutaneously, and thus considerable traumatism and mauling of the soft tissues at this point be avoided. It appears to me to be unnecessary to resort to violent stretching movements in all directions as a routine practice to loosen up the joint. It is a serious question as to whether by rendering the joint loose and flail-like they do not increase the functional disability and favor the tendency to displacement. In many cases, particularly the younger ones, replacement can be accomplished, as has been my experience, without such extensive tearing and stretchings. Violent tractions for immediate replacement, I believe, should be totally abandoned. Everything that can be gained by violent traction can be gained without risk by weight traction, with the patient confined to bed for a variable period of time. This has been demonstrated by Pravaz, Volkmann, Brown, Mikuliez, and others. Lorenz<sup>1</sup> characterized his own method as a traction method and Paci's as a circinduction method, and he was right, but it is the latter which is the correct one. Forceful traction has no place in the immediate reduction of congenitally luxated hips. It is the agent which is mainly responsible for the traumatisms which are inflicted, and if we are to avoid them we must adhere more closely to the original teachings of Paci, which, as he stated, consisted simply in the application of the circinduction method of reducing traumatic luxations. In this the thigh is flexed on the abdomen followed by downward pressure on the knee with abduction, external rotation and gradual extension. Pressure is made on the trochanter posteriorly while the limb is carefully extended. Abduction is afterward maintained to an extent sufficient to prevent the head from escaping from its new position. Whether the thigh is completely flexed on the abdomen or only at right angles to the body, I think, is immaterial, but prefer the former. If

the adductor muscles prevent the desired abduction they can be tenotomized. This is not always necessary.

To make the pressure on the trochanter it can be done with the hand beneath or rested either on a hard roll, as did Pravaz; the edge of the table, as did Paci; or König's block, as does Lorenz. If serious difficulty is experienced in attempting reduction then instead of resorting to increased force I believe it better to confine the patient to bed with the limb abducted and with weight extension if desired for two to eight weeks or even longer and then again attempt reduction. The loss of time occasioned to these children is insignificant compared with the importance of avoiding the dangers of violence.

Rather than resort to the great force now at times employed I believe it to be much better to incise and clear a way for the head of the bone.

## ETIOLOGY AND TREATMENT OF RETRODEVIATIONS OF THE UTERUS.<sup>1</sup>

BY

CHARLES A. ROBERTSON, M.D.,

of Nashville, Tenn.

Professor of Gynecology, University of the South, Sewanee, Tenn.

The uterus under normal conditions occupies a central position within the pelvis, poised by certain suspensory ligaments or "guy ropes" which admit of considerable mobility and some variation of position in all directions with the movements of the body. Its relative position depends largely upon the degree of distention of the bladder and rectum. The long axis of the uterus, generally speaking, lies at right angles to a line drawn from the symphysis pubis to the promontory of the sacrum. This organ is normally in a state of anteversion, or very slightly anteflexed, with its anterior wall in close relation to the upper and posterior aspect of the bladder, and the cervix is directed toward the hollow of the sacrum. Any very decided variation from this position in any direction constitutes a malposition, and sooner or later is likely to take on pathologic significance.

Retrodeviations (versions and flexions) of the uterus are by far the most common, and coupled with downward displacement are, from a clinical and pathologic standpoint, the most important. The causes of retrodeviations of the uterus are many, and often complex in their nature. Congenital retrodisplacement is said to exist, but this condition is undoubtedly very rare. Anything which temporarily alters the normal position of the uterus, coincident with increased intraabdominal pressure, may produce backward displacement. Thus a distended bladder, tilting the fundus upward and backward, associated with a sudden jar or fall, might easily throw the fundus uteri backward into the hollow of the sacrum; intraabdominal pressure, spending its force upon the anterior wall of the uterus, being sufficient to keep it displaced.

Tight lacing, constant sitting, heavy lifting, constipation and straining at stool, are all means by which intraabdominal pressure may be increased, and operate as causal factors of these malpositions of the uterus, and this in great measure explains the frequency with which this condition is met in young and unmarried women.

Parturition, puerperal local infection and injuries to the uterogenital tract the result of childbirth are the most fruitful etiologic factors in the production of retroversion and flexion. Injudicious practices during the puerperal state, before the reparative processes of nature have established perfect uterine involution, are responsible for many cases. If the woman should assume the erect position while the uterus is yet heavy, or attempt some

<sup>1</sup> Revue d'Orthopédie, 1897, p. 143.

<sup>1</sup> Read before the Middle Tennessee Medical Association, November 21, 1902.

straining or laborious task before the uterus has had time to shrink, she is very liable to throw the organ out of position. Septic endometritis, through its interference with uterine circulation and involution, is not infrequently responsible for a retrodisplaced uterus. It is not without reason to say that this infection may, and often does, travel onward and inward, producing pelvic inflammation, acting not only as a contributing cause of the displacement, but being responsible for more or less dense adhesions which bind the uterus firmly in its new bed, adding much to the gravity of the situation.

The chief single cause of retrodeviation of the uterus is rupture of the perineum involving the levator ani muscle and its fascia, together with a heavy uterus. In some cases there may be no external evidence of a perineal rent, yet the very marked relaxation of the pelvic floor indicates clearly that the muscular and fascial functions have been greatly impaired or destroyed, allowing intraabdominal pressure to gain the ascendancy and general pelvic ptosis to result.

Impairment or destruction of the function of the pelvic floor, coincident with subinvolution, operates as a causal factor in retrodisplacement in the following mechanical manner: We know that the rectal ampulla is directed anteriorly against the perineal body at a decided angle, which on account of the anatomic shape of this body is again angulated in a backward direction for about two inches before the anal opening is reached. In the mechanism of defecation the fecal current and expulsive force strikes the posterior wall of the perineal body, which, if in possession of its full muscular strength and function, directs the fecal mass backward through the anus. Should the levator ani muscle, its fascia and the superficial perineal muscles be torn, or deprived of their function, then this pressure will not be counteracted, the rectovaginal septum gradually gives way by stretching, thinning, and the formation of redundant tissue, producing a rectocele. Each defecation, which in these cases is associated with increased intraabdominal pressure due to straining, causes a dragging upon the posterior vaginal wall, pulling the cervicocorporeal junction of the uterus downward, and somewhat forward, and coincident with intraabdominal pressure from above producing in time retroversion, prolapse of the uterus and vagina, with its consequent rectocele and cystocele.

Incidentally, I may remark that it is not unreasonable to conjecture that as a result of a lacerated perineum the patient will not only suffer the discomfort of the pelvic ptosis just mentioned, but on account of the cystocele will be unable to empty her bladder completely. The residual urine will cause cystitis, followed by suppurative changes, the infection finally finding its way through the ureters to the kidneys. Thus, a lacerated perineum may be indirectly the cause of death. While I have dwelt at length upon the causative influence of perineal lacerations, I do not wish to overlook lesions of the cervix as a contributing cause of subinvolution, nor am I unmindful of open wounds about the uterogential tract as avenues of infection through which metritis, parametritis and septic pelvic inflammation may have their origin.

#### TREATMENT.

This subject will be considered under three heads: Prophylaxis, nonsurgical, surgical.

*Prophylaxis.*—The proper appreciation and application of hygienic dress, the strict observation of the laws of health and intelligent parental control will do much toward preventing retrodeviations of the uterus in young girls. One of the most pernicious practices of today, especially among city girls, is the too early wearing of corsets and tight waists. In the majority of instances girls of 12 to 13 years wear tightly fitting corsets, at the expense of development. Displaced intraabdominal and intrapelvic viscera results, and in all probability a crippled life. I

do not believe a corset should ever be worn, but if worn, not until after full maturity and perfect bodily vigor has developed. During school life the young girl should be given ample opportunity for exercise in the open air. The college gymnasium is a valuable necessity, and should be utilized to the best advantage; but if possible, resort should be had by preference to nature's own gymnasium, the open lawn. An hour's fun and frolic here is more invigorating and refreshing than a week spent in a gymnasium.

The most important prophylactic measure, however, in forestalling this condition is the proper care of the parturient and puerperal woman. Nowhere in the whole domain of the healing art can skill and surgical dexterity accomplish more good than in the lying-in chamber. The strict observance of the established principles of asepsis is the bulwark against infection, and should be almost the chief aim of the obstetrician in the management of his cases. Perineal lacerations and all rents in the maternal soft parts should be closed by coaptation sutures at once, unless some very good reason exists necessitating postponement. Pelvic circulation should be promoted by proper care of the bowels and bladder, and sufficient rest should be enjoined to encourage proper involution.

In leaving the subject of prophylaxis, I am aware that much more could be said, but as space is limited, I have only thrown out hints which I have deemed of most importance.

*Nonoperative Treatment.*—Practically the only non-operative treatment at our command which offers any hope of cure is that by the pessary, aided with local treatment and the tamponade. Other measures, such as massage, electricity, tonic medication, etc., have been resorted to, but are of very doubtful efficacy.

In treating retrodeviations of the uterus by the pessary, one must remember that not all cases are suitable for this method, and that in suitable cases there is a certain amount of preliminary attention necessary before introducing the supporter. For married women, who have never borne children and in whom retroversion is the sole pathology and the uterus freely movable, the pessary will not infrequently bring about an anatomic and symptomatic cure, at the same time favoring conception. For a multiparous woman with a heavy uterus, free from adhesions, adnexal disease, lacerations of the cervix and perineum, with more or less engorgement and discomfort within her pelvis, judicious treatment by rest in bed, glycerin tampons, and depleting measures, will within a short time make her a suitable subject for the pessary.

There are a great number of cases which distinctly belong to the surgeon, but in which the patients persistently refuse operative treatment. In this class of cases much good can be done by local treatment and the introduction of a properly fitting pessary. An anatomic cure is impossible, but not infrequently a symptomatic cure will obtain so long as the support is worn.

In resorting to the pessary in a given case it is of great importance (1) to determine if the case is a suitable one; (2) to mold and fit the instrument to suit the case, and (3) to replace the organ before introducing the supporter.

A properly fitting pessary should be worn without the slightest discomfort to the patient, and for a period of at least two years when a permanent and curative result is expected. It is important to remove the supporter about once a month, when it is cleaned and reintroduced.

*Operative Treatment.*—The indication to be fulfilled by surgical treatment is to replace the uterus to as near its normal state of anteversion as possible and fix it there with a minimum amount of subsequent physiologic disturbance. Many operative procedures have been suggested and practised with varying degrees of success within the past 20 years; some have successfully stood

the test of time and experience, others are now upon trial, while a few have fallen by the wayside. They may be divided into three classes: 1. Shortening the round ligaments. 2. Ventral fixation or suspension. 3. Vaginal fixation.

Shortening the round ligaments was first suggested in the year 1840 by Alquié, of France, but the honor of its practical application is due to Alexander, of Liverpool, whose monograph was published in 1884. The Alquié-Alexander-Adams operation, with some slight modifications in technic, is now established upon a firm basis and has but few opponents in this country. Like the pessary, the Alexander operation is not suited to all cases, but in suitable and well selected cases it is undoubtedly the best of all surgical procedures for the cure of uterine retrodisplacements. It is comparatively easy of performance, free from danger, leaves an insignificant scar, a minimum danger of postoperative hernia, does not interfere with subsequent pregnancy or make menstruation more painful, and offers as much hope of success in suitable cases as any other operation.

Simple uncomplicated cases, free from adhesions and adnexal diseases when the uterus is freely movable, are the ones best suited for this operation, although if the adhesions are slight they may be broken up by manipulation, if need be through a vaginal incision. This procedure, however, is not entirely devoid of risk, and I do not like it.

In the presence of rather firm adhesion, or adnexal disease, abdominal section and intraperitoneal shortening of the round ligaments after the method of Gill Wylie or Mann is preferable, or if both ovaries are removed there is no objection to ventral fixation or suspension. Intraabdominal shortening of the round ligaments was first proposed by Wylie in 1886 and has since been modified by Mann, Dudley, Polk, and others. Shortening the round ligaments through the vagina and at the same time dealing with adhesions and adnexal disease was first done by Wertheim in Austria, subsequently modified and advocated by Byford, Goffe, and Vineburg in this country. In the hands of surgeons who have a special fondness for the vaginal route this operation has given good results. Goffe<sup>1</sup> reports 130 cases with only 3 failures. Fixation of the uterus to the abdominal wall for the cure of backward displacements was first performed by Lawson Tait in February, 1880, and subsequently modified by Kelly, who proposed the operation of suspension of the uterus April 25, 1885. It has met the approbation of many operators and is very popular, but as advocated by Kelly, in all cases demanding surgical interference, irrespective of future procreative possibilities, intrapelvic disease or adhesions, is not free from objection. The influence of suspension of the uterus and ventral fixation upon pregnancy and labor is not very great, yet serious and fatal dystociae have been reported. Troublesome irritation and invalidizing conditions have resulted therefrom.

Among the objectionable features of this operation may be mentioned the following:

*Postoperative.*—Inherent danger of celiotomy (2% to 3%); constant pain in the hypogastrium in many cases; dysmenorrhea ensues in many instances and if it existed previously is often made worse; marked retraction of the scar may occur due to the tugging adherent uterus which may cause persistent nausea.

Artificial suspensory ligaments invite ileus. Kelly reports 1 case; Dickinson, 1 case; Jacobs (Brussels), 1 case; Olshausen reports 1 case of Leopold's; Hall (Cincinnati), 2 or 3 cases; Dr. Richard Douglas, 2 cases; Goldspohn knows of at least 15 authentic cases, and many others may be found by a careful search of literature.

*Obstetric.*—Renders conception less likely. There were 56 conceptions out of 808 cases in Noble's collec-

tion, less than 7%. Favors abortion (perhaps only slightly, 10.7%). There is retraction posteriorly and ascent of the cervix during pregnancy. Gives an obstetric mortality of 2% to 3%. Out of 133 cases collected by Noble from French and German operators there were 3 deaths (2.25%). Out of 56 cases collected by Noble from American sources there were 2 deaths (3.57%). There is danger of too firm attachment of the uterus to the abdominal wall with subsequent hypertrophy of the anterior uterine wall, forming an obstruction to labor, as in the case of anterior mural fibroid (Noble 2 cases) or uterine inertia (Bloomhardt,<sup>1</sup> Altoona, Pa., 2 cases). There is danger of great thinning of the posterior wall of the uterus to accommodate the growing fetus and rupture of the uterus may occur.

It favors malpositions and obstetric surgery, often of a capital nature, such as cesarean section.

The uterus may be torn away from its moorings during pregnancy or labor, producing intraperitoneal hemorrhage.

It favors postpartum hemorrhage and uncontrollable vomiting.

Dr. Ochsner, of Chicago, says: "I do not advise celiohysteropexy at any time, because I have frequently seen a great amount of irritation in these cases, necessitating a second operation for the purpose of loosening the adhesions. . . . I have seen troublesome results following ventral fixation and suspension in subsequent pregnancies."

With these facts before me I am forced to take the position that in uterine retrodisplacements without adhesions, the tubes and ovaries being normal and functioning, suspension of the uterus or ventral fixation is an unjustifiable operation. I am borne out in this opinion by Mann, Ochsner, Reed, Clement Cleveland, Goldspohn, Vineburg, and to some extent by Noble, as well as many others. In other cases when the tubes and ovaries are removed for diseased conditions and extensive adhesions broken up, leaving a large amount of raw surface, in my opinion suspension of the uterus is a good operation, and from a purely gynecologic standpoint is quite satisfactory. It is, however, far from ideal, inasmuch as the artificial suspensory ligaments will always menace life by inviting ileus.

Ventrofixation or suspension falls short of the surgical indications in the treatment of backward displacements of the uterus in replacing the organ to as near its normal position as possible, and fixing it there with a minimum amount of subsequent physiologic disturbance. This normal position of the uterus refers to its position within the pelvis, and I am sure that none will argue that ventrofixation or suspension will accomplish this result. It is well known that celiohysteropexy lifts the uterus out of the pelvis into the abdominal cavity, which, in my opinion, is but the substitution of one pathologic condition for another. I will not condemn the operation as unjustifiable in well-selected cases, for apparently it has a field at the present time, but if I can interpret the signs of the times properly, its popularity is upon the wane.

In doing an abdominal section for intrapelvic disease associated with retrodeviation of the uterus, without removal of the ovaries, if the patient is of childbearing age I repeat that intraperitoneal shortening of the round ligaments should be the operation of choice. Vaginal fixation of Mackenrodt and Duhrssen has been abandoned by its originators because of disastrous dystocia which so often followed, therefore I will not take up time with the discussion of this operation.

Fixing the cervix uteri back in the hollow of the sacrum has been attempted by shortening the uterosacral ligaments. Bovée, of Washington, reports 12 cases, 8 by the vaginal route, 4 by celiotomy, all successful, which speaks well for the future of this method.

<sup>1</sup> Am. Gynecol., November, 1902.

<sup>1</sup> American Medicine, January 11, 1902.

With the same object in view, Pryor endeavors to form adhesions between the posterior surface of the cervix and rectum, but the number of patients operated upon is yet too small; they are, therefore, still considered *sub judice*.

In conclusion, I will say that no operative procedure designed to cure retrodeviations of the uterus is complete without the proper application of the principles of plastic surgery to the restoration of the function of the pelvic floor. Old cervical tears should be repaired, and septic endometritis relieved by a thorough curetage.

There is, perhaps, no department of surgery which requires more skill and judgment in the diagnosis and selection of cases for a particular operation than the one under consideration, as practically all methods have something specially meritorious and worthy of serious consideration.

## STRONGYLOIDES INTESTINALIS IN TEXAS, WITH REPORT OF A CASE.<sup>1</sup>

BY

JOHN T. MOORE, M.D.,  
of Galveston, Tex.

Associate in Clinical Medicine, Medical Department of the University of Texas, Galveston, Texas.

In the *Journal of Experimental Medicine* of November 29, 1901, Thayer reports three cases of *Strongyloides intestinalis* occurring in Johns Hopkins Hospital. Strong, who is now in the Philippines, is given credit for the discovery of the first case occurring in North America, and Thayer, who reported this and two other cases, has gone very carefully into the literature and found that these are the only cases that have been reported in the United States.

While doing postgraduate work at Johns Hopkins Hospital in 1900 I heard something of these observations, but thinking I would never see the parasite in our part of the country did not fix the matter on my mind. However, on May 14, 1901, a patient came to my clinic complaining of cramps in the abdomen and a diarrhea of a very obstinate type. Upon examination of the stool I found an actively moving parasite that I had not seen. I therefore submitted the specimen to Dr. A. J. Smith, who returned me the report that it was *Anguillula intestinalis*. It seems important enough to report, as I believe this makes the fourth recorded case in this country. It is, however, quite a common parasite in many parts of the world, and is, no doubt, more common in the Southern States than at present thought.

J. S., a colored male, aged 28, is a resident of Galveston, his occupation being that of laborer on the wharf. He was born in Galveston, and has lived in Houston, Texas, part of the time. He was admitted to the outpatient clinic of John Sealy Hospital May 14, 1901. He went to Santiago, Cuba, in 1898, and has been in San Luis and other parts of the island. He was in the army, and many of the men had diarrhea, some of the cases terminating fatally. He drank all sorts of water, very often obtaining it from standing ponds. He returned home from Cuba May 22, 1899.

*History.*—He drinks beer moderately, smokes tobacco, but has no other drug habit. Hygienic surroundings were good except while in Cuba.

*Family history* is unimportant.

*Previous Diseases.*—He had measles when a child; malarial fever while in Cuba. He was attacked with dysentery about three weeks after his arrival in Cuba, passing much mucus and blood in the stools. He gained weight while in Cuba, notwithstanding the chills and fever and diarrhea. He had clap 13 years ago.

*Present Disease.*—He complains of pain in the abdomen and in the back. The pain has been present at irregular intervals for some time, but is worse when an attack of diarrhea comes on. These attacks are periodic, lasting for a day or two, then he gets better and the bowels will move only once a day for a while. His appetite is good and he sleeps well at night.

*Examination.*—He is a well-nourished man, 5 feet, 7 inches in height, and weighs 150 pounds. Heart and lungs are normal, liver and spleen apparently normal. There is slight tender-

ness over the abdomen. An intestinal parasite was suspected, and therefore the next day (May 15) a stool was examined while fresh. It was thin, mushy and of foul odor, dark in color, but no macroscopic elements of abnormal character were seen. Microscopic examination showed many actively moving worm-like bodies. No ova of parasites were present and no amebae were found.

As I had never seen such parasites before, I sent the specimen to Dr. A. J. Smith, professor of pathology, University of Texas, for identification, and he made the following report:

"Referring to specimen of stools submitted to me for examination containing parasitic worms, I wish to report that these worms are examples of *Anguillula intestinalis*; formerly supposed to cause the diarrhea of Cochin China, but at present regarded as unimportant intestinal parasites, embryos of parent worms in the intestines not often obtained. I have encountered these a number of times in specimens of fecal matter used in class demonstration, or otherwise, since the opening of the school in 1891, and believe them comparatively common in this part of the country."

The patient was put on thymol and an examination of the stool made May 28, 1901, showed many embryos still present. Thymol was again given in full doses. The patient improved while taking 4 grains (60 grains) a day, but an examination December 21, 1901, showed parasites present. An examination April 15, 1902, showed many embryo strongyloides.

The monographs of Strong<sup>1</sup> and Thayer<sup>2</sup> go quite fully into the history of this parasite, and from these authorities I have obtained much of my knowledge of *Anguillula intestinalis*.

Normand, a French army surgeon, is credited with the discovery of this parasite in 1876. It was found in the stools of patients suffering from diarrhea of a severe character. These patients had been in Cochin China, where the parasite is found in large numbers. Bavay, who made a close study of this intestinal worm, gave it the name of *Anguillula stercoralis*. Normand in 1877 found another worm present in the small intestine of a patient dying from Cochin China diarrhea. Bavay, who in the same year found a number of this form of parasite, described it as *Anguillula intestinalis*. The fact of the parasite manifesting itself in two forms and having received separate names has led to some confusion, but at present it is held by most observers that *Anguillula intestinalis* and *Anguillula stercoralis* are the same. Grassi and Parona, who made a close study of the parasite, gave a careful description of the mother worm, of the eggs, and of the embryos developing from the ova. Grassi in 1879 proposed the name of *Strongyloides intestinalis*, and Thayer says that most authorities now accept this classification.

Many persons in different parts of the country have studied this parasite, and those who feel enough interest in this worm will find in the monographs mentioned the bibliography of the literature complete to 1901. I made repeated examinations of the stools of my patient, but failed to find anything pathologic except the embryos of *Strongyloides intestinalis*. These were quite numerous, and measured .26 mm. to .40 mm. in length by 20 to 25 microns in width. They were quite actively moving bodies, going either backward or forward. The cephalic end was slightly smaller in diameter than the body, while the parasite tapered to a point at the tail. The digestive canal could be easily made out running from the depression seen at the cephalic end. If there were any lips as described by Strong as seen in the larger forms I could not make them out. The enlargement of the esophagus about one-fourth of the length of the parasite from the mouth, the narrowing back of this, and the enlargement could be very easily made out. The anal end of the digestive tract is situated one-eighth to one-tenth of the length of the worm from the tip of the tail. Between the outer covering and the digestive tract is a granular material extending the entire length from the mouth to the anal opening. The outer covering of the worm is of a clear hyaline structure, but after applying some weak formalin solution I noticed a fine transverse striation of the skin.

I repeatedly tried to grow the adult male and female

<sup>1</sup> Read at the meeting of the South Texas Medical Association, at Beaumont, Texas, 1902.

<sup>1</sup> Johns Hopkins Hospital Reports, Vol. x.

<sup>2</sup> Journal of Experimental Medicine, Vol. vi.

worms by keeping the thin stools in the incubator, but I failed to observe any other than filiform larvæ which measured .495 mm. in length and 22 microns in breadth. The esophageal enlargements were lost in this form as noted by Thayer and the body of the worm was more uniform in thickness throughout its entire length. The anal opening was seen just a short distance anterior to the tail end. These two observations were made five days apart.

Repeated examinations were made for the ova, but none was ever found either in fresh stools or those kept at incubator temperature. As I found no adults I have adopted the description of RAILLET, a French author, who describes them as occurring in two forms:

1. *The Intestinal Form.*—The female is 2 mm. in length by 34 microns in breadth. The body is somewhat attenuated at the head end, terminating at the posterior extremity by a conical tail. The end is somewhat rounded and even a little dilated. The integument is finely striated transversely. The mouth has three small lips, giving access to an esophagus almost cylindrical and which occupies about one-fourth of the length of the body, and continues without transition into the intestine, the color of which is different. The anal opening is a transverse slit, situated near the base of the tail. The vulva is about one-third from the posterior end of the body. The uterus contains 5 to 9 eggs greenish-yellow in color, and ellipsoid in shape, 50 to 58 microns in length and 30 to 34 microns in width.

2. *The Stercoral Forms.*—The individuals are both male and female. The females are smooth, cylindrical, drawn out at the extremities, especially at the posterior end. The mouth has two lips, which are indistinct, followed by a short and rather large vestibule. The esophagus is dilated into two cone-shaped cylinders, which are separated by a narrowed portion. The anterior one is elongated, the posterior one is pyriform, with a chitinous armature in the shape of a Y. The intestine is a little dilated at its beginning. The anal opening is at the base of the tail on a slight elevation or nipple, turned to the right by the development of the uterus. The male is 7 mm. in length by 34 microns in thickness. The tail is curved back in the shape of a hook, with two curved in spicules, which have openings 38 microns in length. There are a few preanal papillae. The female is 1 mm. in length by 50 microns thick. The tail is drawn out to a long point, slightly wavy. The vulva is a little to the back of the middle of the body. The eggs are ellipsoid, of a yellowish shade, with a thin shell and 70 microns in length by 45 microns wide. The eggs sometimes hatch in the uterus.

*Distribution.*—The parasite is very broadly scattered. It is said to be found in pretty nearly all of the Asiatic torrid zone and in the Indian Archipelago. It has been observed and studied in Italy, Germany, Egypt, Ceylon, Brazil, the West Indies, and Martinique. Strong has observed it in the Philippine Islands. He and Thayer report three cases in Baltimore. My patient probably contracted the parasite in Cuba, as he had not noticed any diarrhea previous to going there. Dr. Smith states that he has several times seen the embryos in fecal matter examined by the class. This parasite has been noted in frequent association with *Uncinaria duodenale*. Lutz in Brazil found strongyloides in one-half of the cases of ankylostomiasis.

*Significance.*—This is a much disputed question. Many writers hold that it causes great inflammation of the bowel, even causing destruction of the epithelial coat of the intestine; while others hold that the diseased bowel only furnishes a suitable habitat for the parasite. They have been observed in persons otherwise healthy. My patient suffered periodically with cramps in the belly and with diarrhea. His digestion at times is more or less disturbed, and he has a moderate anemia.

*Treatment.*—I gave my patient thymol without ridding him of the worms, though he seemed to improve

while taking it. Normand and Perroncito advise the use of extract of male fern, and Davidson advises the continual administration of thymol and tr. ferri chlorid.

## STREPTOCOCCI INFECTIONS.

BY

LEONARD K. HIRSHBERG, A.B., M.D.,

of Baltimore, Md.

Assistant in Bacteriology and Hygiene, College of Physicians and Surgeons; Assistant in Nervous Diseases and Assistant Neurologist to the Baltimore City Hospital, Baltimore, Md.

The number of actual pathologic conditions to be laid at the door of the streptococcus are rarely given the consideration they deserve. Not even that protean destroyer, the tubercle bacillus, causes such various conditions as this little coccus which grows in chains. Perhaps there are more than one species of Koch's bacillus, each of which differs from the other, one forming scrofula, another causing Pott's disease, a third causing various pulmonary lesions, acute, subacute or chronic; a fourth being the cause of hydrocephalus, a fifth exciting gastrointestinal tuberculosis, another osteomyelitis, and so on. But why should there be different species of the tubercle bacilli to cause these conditions? The pathologic lesions are the same, though their situation is different. The tubercle of the brain and spinal cord is exactly like the tubercle of the pleura or peritoneum. In one of the newest volumes on bacteriology<sup>1</sup> the streptococcus, which we know as a small, round-celled bacterium occurring in chains, long or short, and nonmotile, is subdivided into 35 or more species. The majority of these, 18, or more than half, were isolated from various pathologic lesions of man, the other 17 were obtained from decomposing saccharin solutions, cattle and sheep disease, blighted sorghum, water, milk, potato blight, sewage, diseased dogs, bitter cream, feces from healthy children, and decayed meat.

Of the 18 species of streptococci pathologic for man there are only two divisions morphologically, cocci which occur unpaired but in chains, and diplococci occurring also in chains. Under the latter, however, is included *Diplococcus pneumoniae*, described as two species, viz., *Streptococcus pneumoniae* and *Streptococcus weichselbaumii*.

Of the remaining 16 species of streptococci, the only morphologic means of differentiation given is, do they stain with or without capsules. There is one, *Streptococcus capsulatus* given with a capsule. This was isolated also from a pneumonia (peribronchial) and may be only a variety of Weichselbaum's diplococcus.

The remaining 15 species given are about the same morphologically, but differentiated in the classification by cultural (biologic) characteristics.

The first class, those not growing at room temperature or poorly, are subdivided into (a) discernible growth in agar, and (b) scarcely discernible growth in agar.

The second class, those growing at room temperature and liquefying gelatin, are subdivided into (a) poor growth in gelatin; (b) viscid softening in gelatin; (c) good growth and slow liquefaction of gelatin; (d) good growth and rapid liquefaction of gelatin.

The third class, those growing at room temperature and not liquefying gelatin, are subdivided (a) with capsule and (b) without capsule. Under (a) are *Streptococcus pneumoniae* and *Streptococcus weichselbaumii* before

mentioned and already excluded from this list because of morphologic differences.

Under (b), streptococci without capsules, are included (among pathologic forms) the following means of differentiation: 1. Conglomerate chains. 2. Free chains. 3. Little growth in depth of gelatin. 4. Much growth in depth of gelatin. 5. Growth in gelatin not described (three species). 6. Pathogenic to animals. 7. Non-pathogenic to animals. 8. Pathogenic to plants. The fourth class is not included in the 15 species mentioned, for it contains chromogenic streptococci not concerned in human pathologic conditions.

Here are 15 species described which, as regards motility, morphologic appearances, staining reactions to basic anilin dyes and Gram's method, are in every respect exactly similar, and which must be differentiated one from the other by the temperature of best growth, visible or invisible growth on agar, poor or heavy growth in gelatin (in three species this is not mentioned), pathogenicity or nonpathogenicity to animals, and of more importance negative, slow or rapid liquefaction of gelatin.

Five of our 15 selected streptococci are given as variously liquefying gelatin. These are *Streptococcus brightii* described in 1839 by Mannaberg<sup>2</sup> and isolated from urine in acute Bright's disease; *Streptococcus enteritidis*, isolated from stools, organs, and lymphatics of intestines by Escherich<sup>3</sup> in 1887; *Streptococcus septicus* taken from the blood of a child dead of septicemia, by Babes<sup>4</sup>; *Streptococcus liquefaciens* of Sternberg<sup>5</sup> from a yellow fever cadaver; *Streptococcus fischeli* isolated by Fischel<sup>6</sup> from the blood of two influenza patients.

Of the remaining 10 all are nonmotile, occurring in short or long chains inconstantly; take Gram's stain and the basic anilin dyes and can only be differentiated by slow or rapid growth in agar and gelatin, pathogenicity or nonpathogenicity to animals, visible or invisible growth. *Streptococcus enteritidis* of Hirsh<sup>7</sup> from stools of infant diarrhea has invisible growth on agar, very little growth on gelatin; causes diarrhea in white mice. *Streptococcus conglomeratus* associated with scarlet fever by Kurth<sup>8</sup> is very pathogenic to mice and is said to differ from *Streptococcus erysipelatis* only by forming very white scales at the bottom of bouillon cultures. *Streptococcus erysipelatis* (pyogenes) is the only one perfectly and completely described and which has stood the test of Rosenbach's<sup>9</sup> original description continuously since. Three varieties of this organism are given and the statement of their probable identity made. These differ about as greatly as the other streptococci given as distinct species, do not liquefy gelatin.

*Streptococcus enteritidis* of Libman<sup>10</sup> seems to differ but slightly from the one described later by Hirsh. And so on through the entire list. Variations in cultural characteristics are so frequent among the same species and the degree of pathogenicity of bacteria is so variable that to differentiate 15 species of streptococci upon such a slender basis would seem to be indeed frail.

The *B. tuberculosis* which is so difficult and slow of growth upon glycerin agar and glycerin bouillon might upon the same grounds include 15 different species. For we have as yet been unable to grow it upon the very media employed to make so many streptococci species.

In the literature which I have attempted to follow as completely as possible, there are many pathologic conditions associated unquestionably at all times with streptococci. No attempt has been made, as a rule, to describe a special species of streptococci for each separate process.

Of erysipelas, Osler<sup>11</sup> says: "The specific agent is a streptococcus growing in long chains, which is included under the group name *Streptococcus pyogenes* with which *Streptococcus erysipelatis* appears to be identical.

Streptococci are isolated in pure culture from all uncomplicated cases of erysipelas, and by injecting bouillon cultures of these cocci into animals pathogenic effects are produced, the animal dying in a few days.

Holt<sup>12</sup> states that croupous tonsillitis can be differenti-

ated with certainty from diphtheria only by means of cultures. "Croupous tonsillitis is nearly always due to the streptococcus." In five cases of acute follicular tonsillitis which developed in the bacteriologic class of sixty odd students at the College of Physicians and Surgeons\* cultures made by me showed the streptococcus in pure growth four times, and in association with *Staphylococcus albus* once.

Sahli, Choostels, and Singer<sup>13</sup> in their researches upon acute articular rheumatism show very convincingly that it is an infectious disease, and Singer's work points very conclusively to the streptococcus as one of the most important etiologic factors concerned in its production. He found over 42% of his cases beginning with tonsillitis. Last year Clupman<sup>14</sup> reported the cure of a patient with antistreptococcal serum, and Kollman<sup>15</sup> and Meuzer<sup>16</sup> reported other patients similarly treated.

Two patients with chronic rheumatism who have been under my observation for some time have suffered with a subacute nasopharyngeal catarrh for many years. Always just preceding the development of the articular disturbances, the sore irritating feeling in the posterior nares and pharynx has appeared. To me this led to the theory that there might be the possibility of a focus of infection there which might occasionally flare up and pour the toxins into the general circulation, causing the discomforts and joint pains occurring in chronic rheumatism. The portion of the pharynx which was accessible was therefore curetted and cultures made from both cases. Streptococci were obtained in both instances, although the second case showed a bacillus resembling a pseudodiphtheria bacillus which may have been present in the mouth.

There is no *a priori* reason why we should not find chronic streptococcal infections just as we find chronic tuberculosis, syphilis, leprosy, influenza and diphtheria. In fact, there is considerable presumption in its favor, when we consider the frequency of recurring tonsillitis, rheumatism and erysipelas.

The most malignant and most frequent cause of child-bed fever is undoubtedly the streptococcus. Williams's<sup>17</sup> method of obtaining cultures from the infected uterus in the puerperium should be followed in every case, for the treatment and therefore the life of the patient depends upon the results of these cultures. The streptococci can be seen to have grown down deep into the muscular walls of the uterus, for the most part much beyond the reach of antiseptic douches.

Streptococci are often obtained in pure culture from traumatic cases of cerebrospinal meningitis, as in the case recently brought to the Baltimore City Hospital. Dr. West,<sup>18</sup> the resident surgeon, made a lumbar puncture the day after the patient was admitted and obtained an uncontaminated culture of the streptococcus. Subsequently the cultures at autopsy verified the finding.

Streptococci have been so often found associated with scarlet fever that the announcement of Prof. Adolf Baginsky, of Berlin,<sup>19</sup> that during the past 12 years he had treated 701 patients with an antistreptococcal serum prepared by Herr Aaronson with the mortality reduced to 8% is not surprising. He states that scarlet fever, like erysipelas, is due to the streptococcus.

It is somewhat more astonishing, however, to learn that streptococci have been found circulating in the blood of chorea patients. P. A. Preprojensky<sup>20</sup> obtained pure cultures of the streptococcus very easily from the circulation of two patients suffering with chorea. In a third case pure cultures of streptococci were obtained from all the viscera at autopsy. This led him to employ antistreptococcal serum and after two weeks the movements entirely ceased.

Of the many skin diseases besides erysipelas only two show the streptococcus in etiologic relationship. Thibierge and Bezançon<sup>21</sup> made a great many cultures from

\* Three other private cases gave pure cultures of the streptococcus.

beneath the scabs in ecthyma and obtained the streptococcus every time in pure culture. Gilchrist<sup>22</sup> verified these findings.

Gilchrist<sup>22</sup> in 17 cases of impetigo contagiosa varying much in severity obtained pure cultures of *Streptococcus pyogenes* in ten cases. In the remaining seven there was a contamination with *Staphylococcus aureus*, but the proportion of the number of colonies of the streptococcus was as hundreds to one of the staphylococcus. Smear preparations from the impetigo vesicles demonstrated the chain cocci very easily in every case. These results verified the work of Leroux,<sup>23</sup> Balzer, and Griffen.<sup>24</sup>

Dr. William Royal Stokes<sup>25</sup> states that in his pathologic records he has notes of two cases of malignant endocarditis which yielded pure cultures of streptococci at autopsy; another case of cerebrospinal meningitis following trauma, gave pure cultures of streptococci from the brain and cord. Stengel<sup>33</sup> states that the streptococcus is occasionally found in ulcerative endocarditis. Miss Thomas,<sup>37</sup> working under the direction of Prof. Stokes, found streptococci in ice-cream sold in the public streets.

Through the kindness of Dr. William Royal Stokes I was able to find among his autopsy records of the Baltimore City Hospital eight instances of pure streptococci infections and three combined with the colon bacillus. Among these were No. 6, acute endocarditis; No. 56, tuberculosis; No. 79, retropharyngeal abscess; No. 85, peritonitis; No. 111, septicemia; No. 122 (by Dr. Ruhrah), pneumonia; No. 142, cerebrospinal meningitis; No. 141, pericarditis. Stokes<sup>26</sup> cautions against cow's milk for infants, and reports the presence of streptococci in it, and its relation to summer diarrheas. Acute gastrointestinal intoxications, indigestions and diarrheas have been shown by Escherich, Baginsky, and Booker<sup>27</sup> to be frequently associated with streptococci. Septicemia, pyemia, local abscesses, wound infections and appendicitis have shown pure cultures of streptococci so often that they need only be mentioned among the associated disease processes.<sup>28</sup>

As to the ability to make distinct species of streptococci with our present knowledge, Petruschky<sup>29</sup> has shown that the streptococcus obtained from pus may cause erysipelas in the human subject. In one case of purulent peritonitis he obtained a pure culture of streptococci, the patient never having suffered from erysipelas. With this culture he produced typical erysipelas in two women with cancer.

As to its difference of pathogenicity, Muir and Ritchie<sup>30</sup> state the wellknown fact that even highly virulent cultures, if grown under ordinary conditions, lose in time all pathogenic power, while passage from animal to animal may increase the virulence again, as in the case of most pathogenic organisms.

Marmorek<sup>31</sup> showed that the same culture of streptococcus may at one time produce redness, at another local suppuration, again spreading erysipelas, or again general septicemic infection, according as its virulence is increased. He also showed that the same streptococcus which originally grew in long chains may grow in short, and again be made to grow in long chains. This again destroys a means of differentiating species.

Widal and Bezançon<sup>32</sup> also showed a nonpathogenic streptococcus to become virulent when inoculated with *Bacillus coli communis*.

These authors anticipated the recent findings of the Americans in the constant presence of the streptococcus in the lesions of smallpox cases found at autopsy. They isolated the streptococcus from the circulating blood of a patient with smallpox and found it to be quite virulent, while the streptococci cultivated from the mouth of the same patient were nonvirulent. They explained this upon the ground that the streptococcus of the mouth entered the circulation of the diseased individual and thus became virulent.

Ziegler<sup>36</sup> states that infections with streptococci arise

in healthy individuals, occasionally by injuries or associated with or terminating other infections, as tuberculosis and diphtheria. He states that septicemia and pyemia are dependent upon the virulence of the organism.

In conclusion, then, it would seem that there is little warrant, with the paucity of our present means of differentiating bacterial species, for dividing the streptococcus into 18 or more species. From the multiplicity of pathologic processes concerned, in which the streptococcus is undoubtedly found always, it is quite likely there are distinct species, or at least varieties of streptococci involved, but our present means of separating them proves it is open to considerable doubt.

**Injunctions Keep City Dirty.**—Commissioner Blocki, of Chicago, who has entered upon a crusade for clean streets, complains that he is unable to keep the downtown sidewalks clear of fruit stands from the fact that so soon as a fruit vender is notified to vacate a sidewalk he immediately applies to an attorney, who gets out an injunction restraining the authorities from moving the dealer, and this causes unnecessary delay and litigation, which practically ties the hands of the commissioner. It is hoped that the new City Council will be much more careful in issuing permits for these nuisances in the streets and on the sidewalks.

**Minnesota State Hospital for Crippled and Deformed Children.**—According to the surgeon's report to the board of regents of the University of Minnesota since the first appropriation was made for this hospital there have been treated 167 patients. Of these 125 have been discharged as cured or improved. There have been 7 deaths and 35 are still under treatment. Most of the patients come from remote districts where there are no hospital facilities. It seems almost impossible to get these children in the early stages of disease, as their parents will not permit them to go until all home measures have failed, so that generally when a child is admitted to the hospital it is in a desperate condition and in imperative need of proper care. Experience with these children has shown that it is most important to have a hospital abundantly provided with wards and a building separate from the main wards for the isolation of suspected contagious diseases, as it has been found that patients are brought to the institution with beginning scarlet fever, measles, chickenpox and diphtheria. It has, therefore, been found advisable always to isolate a child as soon as it arrives until it is demonstrated that it is not suffering from any of the above diseases. It is asserted that even with this extreme caution a case of contagious disease occasionally appear in the wards. There have been 3,762 dressings made, 115 plaster-of-paris casts applied, and 18 operations performed. During the past year 30 new patients were admitted. There remained from the previous year 44 patients, making the number treated in the hospital during the past year 74.

METHOD OF INSTRUCTION IN SURGICAL PATHOLOGY.<sup>1</sup>

BY

J. C. BLOODGOOD, M.D.,  
of Baltimore, Md.

Clinical instruction in the out-patient department and in the hospital wards has and will always have certain defects and limitations as a complete method of instruction.

The question to be solved is, Can these limitations and defects be removed?

The method of instruction in the surgical pathologic laboratory of the Johns Hopkins Hospital has reached a sufficiently satisfactory development to at least justify its presentation as a possible solution of the problem of teaching surgery.

Clinical instruction in the out-patient department and in the wards must to a very large extent be limited to the observation of the patients treated. The usual time spent by a student in the hospital dispensary and wards is two years. During this time many important surgical diseases are seen not at all or so seldom that the student does not get a clear or lasting clinical picture of the disease. Of necessity examples of the various surgical diseases present themselves in no systematic order, and are so scattered that the student seldom, if ever, can observe in the dispensary or even in the ward at the same time the different varieties of affections of a single organ or part. Even in the ward it is very difficult to arrange that the student follow the patient from his admission through the operation and after-treatment, to present to him the diagnosis confirmed in the pathologic laboratory and the result of the treatment when the patient leaves the hospital, and never the ultimate result many years afterward. Although the time between the admission and discharge of the patient is frequently but an interval of a few weeks, nevertheless it is a very difficult problem to keep all the students in the group familiar with even the important details in the history of each patient.

These limitations and defects can be remedied to a very large degree by the method of instruction in the surgical pathologic laboratory.

We may describe this method briefly as follows:

The instruction to the third year medical class in the surgical laboratory is divided into two parts. The first may be called the systematic part, in which the instruction is given by pamphlets, museum specimens, microscopic sections, and illustrations. The second part may be called the routine instruction, which is limited to the fresh material sent to the laboratory from the operating or the autopsy-rooms.

*First Part.*—For the systematic work the third year student in the beginning of the year comes to the laboratory one afternoon each week. The class is divided into groups of not less than five and not more than ten. Each group is given a pamphlet and a box of microscopic slides stained and labeled. Near each group on a table, a rolling table if possible, are placed the museum specimens discussed in the special pamphlet given to this group. The pamphlet corresponds somewhat to a chapter in a textbook on surgery; for example, Tumors and Inflammations of the Breast, Malignant Tumors of Bone, Inflammations and Tumors of the Thyroid, etc.—i. e., each pamphlet discusses the various affections of a special organ or part. The pamphlet is divided into two parts. In the first part of the pamphlet, for example, Inflammations and Tumors of the Breast, the student is given the number of cases treated during the life of the clinic in relation to the total number of surgical patients. This gives him at once an idea of the relative frequency of the diseases of this organ or part. Then follows a classification of the various diseases with the number of cases admitted for treatment in the surgical clinic. Here the student learns the relative frequency of the various affections of this organ. When no examples of certain rare affections have

come to the clinic for observation it is so stated. The pamphlet then proceeds to give a summary of the clinical history and picture treatment, gross pathologic appearance, and microscopic study of the various diseases of the organ discussed in the pamphlet which have been observed in the clinic, and most important, the ultimate result after leaving the hospital. This general summary corresponds somewhat to what is written in a chapter of a textbook on surgery. It has the advantage, however, similar to that of a monograph, in that it gives the summary of a certain number of specific cases, in each of which the diagnosis has been confirmed by a pathologic study and in which the ultimate result is known from a few months to many years. Descriptions of rare diseases not observed in the clinic can be made from the literature with illustrations. The second part of the pamphlet gives the clinical history, the treatment, the description of the fresh specimen which is preserved in the museum and which the student can find on the table near the group to which he belongs. Then follows the microscopic description, and the student will find in his box of slides a section taken from the specimen he has just examined.

The general part of the pamphlet the student can read at home in connection with his textbook on surgery. When he comes to the laboratory he is advised to take a museum specimen, selecting the various diseases of the organ in a certain natural sequence. This specimen has a surgical and pathologic number which is indexed in the pamphlet, so that the student can quickly turn to the clinical history of this case, and, as in the majority of instances some years have elapsed since the patient has left the hospital, the pamphlet is able to give him the ultimate result. Each museum specimen, therefore, is one identified with an individual, the clinical history and ultimate result of whom the student can read, and he can examine the microscopic section of the museum specimen by which the diagnosis was confirmed. By a careful reading of the pamphlet the student is brought in contact with the relation between the clinical, the gross pathologic and the confirming microscopic diagnosis. In addition, in the pamphlet he will find photographs of the patient illustrating the clinical appearance, diagrams, photographs of the fresh specimen, x-ray photographs, if made, and in some instances photographs of microscopic drawings, and quite frequently photographs of the ultimate result.

Each group, as stated before, is given a pamphlet and a box of microscopic slides, and near the group are the museum specimens discussed in the pamphlets. From time to time the groups exchange material, so that by the end of the third year a large field of surgery is covered.

I believe this method presents surgery to the student in just as systematic a manner as a didactic lecture, with the great advantage that he reads instead of listens, and with his reading he has object lessons illustrative of the text. I have found that very little demonstration is necessary. The student works quietly by himself, just as he should in the dissecting-room or chemical laboratory. He is brought in close contact with the disease, with each specimen he can get in a few minutes the entire history of the case and the ultimate result. This is impossible with the patient. While this work in the laboratory is going on the third year student observes patients in the out-patient department and in the surgical clinic. When, for example, he sees a patient with the clinical appearance of an exophthalmic goiter, he will have read in his pamphlet a summary of the clinical history, treatment, and ultimate results of all the cases of exophthalmic goiter treated in the hospital up to that time, he will have examined the museum specimens of the thyroids removed and the microscopic sections; he will have seen numerous photographs before and after operation. In the fourth year he will be much better prepared to observe his patients clinically in the wards; when, for example, he sees a case of exophthalmic goiter in the ward, he can go to the library in the hospital and in a few minutes review his third year instruction on this disease. If during the third and fourth year it is his misfortune to see few or no examples of various important diseases he will at least in his third year have read the clinical history, seen the photographs, examined the museum and microscopic sections of one or more examples. This systematic method, therefore, prepares the student to take

<sup>1</sup> Author's abstract read before the American Surgical Association in Washington, May 14, 1903.

better advantage of the patients he sees clinically in the dispensary and in the ward, and it fills the gaps which cannot be avoided in clinical teaching.

Although such a course is called surgical pathology its ultimate aim is really clinical diagnosis taught, however, from the museum specimen and microscopic section instead of the patient. Clinical instruction should and must always be considered the most important part of medical teaching, and the object of this laboratory course is by no means a substitute, but a supplement; its only object to better prepare the student for instruction in the dispensary or at the bedside.

Such a laboratory course has the great advantage that it utilizes the material accumulated during the entire life of the surgical clinic. The student is brought in contact not only with the patients observed during his two years' course of instruction, but with the entire experience of the surgical clinic. This method stimulates better record, more careful descriptions of the fresh tissue removed at operation and autopsy, and their preservation in the museum. It becomes necessary to keep track of the patients treated in the surgical clinic; one is stimulated to get better illustrations; the history of every important case, every museum specimen, microscopic sections and photographs, similar to a book in a hospital library, are accessible to the student.

The preparation of the pamphlets is not specially difficult. Once made, they can be added to from year to year. The photographs necessary for a set of five to ten pamphlets and the microscopic sections will last for years. The museum specimen is practically indestructible.

In addition to the systematic course just described the fresh material from the operations and autopsies is used. In the first part of the year each fresh specimen is assigned at once to a third-year student. The probabilities are that he has seen this patient in the dispensary or in the surgical clinic; in any event he is instructed to make a summary of the clinical history and record the clinical diagnosis. He examines and makes a description of the fresh specimen and makes his own naked eye diagnosis. The afternoon on which the entire class meets in the laboratory those students who have been assigned fresh material meet the instructor in a small room. The cases are discussed, frozen sections are exhibited. After the first of January the class meets on two afternoons in the week. By this time the students have had an opportunity from the systematic course and from the study of a certain number of fresh specimens to acquire a certain amount of familiarity with surgical diseases, and for this reason the demonstration of the fresh material is made before the entire class. The cases are presented by the student to whom the specimen was assigned. By this time the student has been brought in contact with the various surgical diseases from different standpoints. He has studied quite a number systematically in the pamphlets, illustrated by the museum specimen and microscopic section. He has examined personally a number of fresh specimens in conjunction with the clinical history. He has a certain number of cases clinically in the surgical dispensary and clinic. For this reason the student can better appreciate now a general demonstration and discussion on the routine fresh material, so that while he is continuing to study by himself the experience of the surgical clinic of the past, he is brought more and more in contact with the material of the present. It is my rule to exhibit those specimens which the student has seen as fresh material again when it has become an alcohol museum specimen, so that he can compare the difference between the fresh and the alcohol specimen. As much as possible the student is informed of the ultimate microscopic diagnosis.

About once a month a lantern-slide demonstration is given. The first demonstration, for example, on inflammations and tumors of the thyroid is given the class, after this pamphlet has been studied by each group. I am quite positive that the time necessary to give such a course is no more than that which would be taken by a course of didactic lectures. The properly-prepared pamphlet is certainly better than any notes of a lecture which can be taken by a student. He can digest most surely what he reads better than what he hears, especially if during his reading object lessons in the shape of photographs, museum specimens and microscopic sections are before him. The

instructor can conform his talking to the demonstration of fresh specimens, to general remarks on certain more difficult problems, and to a certain amount of personal instruction. The method of teaching is not only more satisfactory to the student, but infinitely more so to the teacher.

Such a course may be difficult to establish, but when once established it can be maintained with a minimum of labor and a maximum of results. The good results are not only to the student, but to the teacher and to the surgical clinic.

2.—See *American Medicine*, Vol. V, No. 20, p. 773.

3.—See *American Medicine*, report of fifty-fourth annual session of American Medical Association.

4.—**Serum Diagnosis of Tuberculosis.**—L. M. Loeb discusses different methods advocated for the diagnosis of incipient tuberculosis, together with the objections to them. He describes the agglutination reaction according to the method of Arloing and Courmont. With their cultural methods some observers claim a motility equal to that of *B. typhosus*, but the writer has never found more than an active Brownian motion in the hanging drop preparation. He gives the modifications in technic made by other investigators, and his personal observations in 52 cases, and reaches the following conclusions: Under various conditions animal sera agglutinate homogeneous cultures of human tubercle bacilli in liquid media. Such sera may be obtained from the body without the presence in it of *Bacillus tuberculosis*, and it is doubtful whether the agglutinative powers are ever due to the specific action of the latter. The presence or absence in adult human blood-serum of agglutinative properties for tubercle bacilli is no decisive evidence of the presence or absence of tuberculous lesions in the body. [H.M.]

5.—See *American Medicine*, Vol. V, No. 21, p. 819.

6.—See *American Medicine*, Vol. V, No. 21, p. 819.

7.—**Combined Intrauterine and Extrauterine Pregnancy.**—G. J. Hagens and J. J. Moorhead briefly review the literature of the subject, which is very scanty, indicating that this form of gestation is infrequent. In the case reported a perfectly formed fetus was removed from the right broad ligament by vaginal section, and 20 hours later a second was expelled from the uterus. [H.M.]

Boston Medical and Surgical Journal.

1. A Study of 534 Operations Upon the Gallbladder and Bile Passages, with Tabulated Report of 547 Operated Cases. WILLIAM J. MAYO.
2. The Germicidal Action of Alcohol. CHARLES HARRINGTON and HAROLD WALKER.
3. Report of Five Cases of Fracture of the Hip in Children. H. M. CHASE, JR.
4. A Glass Urethral Irrigator. DAVID D. SCANNELL.

1.—See *American Medicine* report Congress of American Physicians and Surgeons, Washington, May 12-14, 1903.

2.—**Germicidal Action of Alcohol.**—Harrington and Walker, after a series of experiments, come to the following conclusions: 1. Against dry bacteria absolute alcohol and ordinary commercial alcohol are wholly devoid of bactericidal power, even with 24 hours' direct contact, and other preparations of alcohol containing more than 70% by volume are weak in this regard, according to their content of alcohol—the stronger in alcohol the weaker in action. 2. Against the com-

moner, nonsporing, pathogenic bacteria in a moist condition, any strength of alcohol above 40% by volume is effective within five minutes and certain preparations within one minute. 3. Alcohol of less than 40% strength is too slow in action or too uncertain in results against pathogenic bacteria, whether moist or dry. 4. The most effective dilutions of alcohol against the strongly resistant (nonsporing) bacteria, such as the pus organisms, in the dry or moist state, are those containing from 60% to 70% by volume. 5. Unless the bacterial envelope contains a certain amount of moisture it is impervious to strong alcohol; but dried bacteria, when brought into contact with dilute alcohol containing from 30% to 60% of water by volume, absorb the necessary amount of water quickly, when the alcohol can reach the cell protoplasm and destroy it. 6. The stronger preparations of alcohol possess no advantage over 60% to 70% preparations, even when the bacteria are moist; therefore, and since they are inert against dry bacteria, they should not be employed. 7. Provided the skin bacteria in the deeper parts can be brought into contact with disinfectants alcohol of 60% to 70% strength may be depended upon usually, but not always, to destroy them within five minutes. [A.B.C.]

**3.—Fracture of the Femoral Neck in Children.**—H. M. Chase, Jr., states that this accident is not so rare as is commonly supposed. The ages of five reported cases varied from 11 to 16 years. A noticeable feature in several of the cases is the mildness of the symptoms. The author says these cases illustrate the early age at which fracture occurs, the possibility of fracture following rapid increase in weight, the occurrence of fracture from slight trauma, and the possibility of relatively slight disability following fracture of the femoral neck. They emphasize that the bone may be fractured, giving rise to slight symptoms, the pain developing a number of weeks or months afterward without known cause; and that depression of the femoral neck from fracture predisposes to further depression and a consequent gradual increase of disability. In contrast to the effects of fracture of the femoral neck in later life, we see in childhood less marked immediate effects, while the remote effects are more disabling; and if recent cases of fracture pass unrecognized, danger lies in confounding their late results with hip disease. Attention is called to the necessity for care in diagnosis. Other affections of the hip-joint are to be ruled out, and a skiagram should make positive the true condition. [A.B.C.]

**4.—Glass Urethral Irrigator.**—D. D. Scannell found the repeated sterilization of rubber catheters very destructive and somewhat expensive in a large clinical practice. He devised a curved glass irrigator 14 cm. (5½ inches) long, and in size equal to a No. 13 of the French scale. This tube is perforated by several openings and it terminates in a blunt conical perforated end. The other end is suitable in shape for a rubber-tube attachment. The author commends it after extensive trial, and holds that it possesses the following advantages: Cheapness, durability, ease of sterilization, cleanliness, facility of use, volume of injected fluid, and adaptability for posterior irrigation by Janet's method. An illustration accompanies the article. [A.B.C.]

#### Medical Record.

May 23, 1903. [Vol. 63, No. 21.]

1. Some Unusual Cases of Appendicitis. ROBERT F. WEIR.
2. On a Case of Complete Fibrous Obstruction (Congenital?) of Both Superior and Inferior Vena Cavae in a Young Man of 18 Years: First Case Recorded. ALFRED MEYER.
3. Total Respiratory Failure from Ether: Artificial Respiration for Over Four Hours; Recovery. H. H. EVERETT.

**1.—Unusual Cases of Appendicitis.**—Robert F. Weir says the unusual cases of appendicitis should be reported. Conforming to this view he reports several unusual and interesting cases: 1. Internal intestinal strangulation from an elongated inflamed appendix. In this instance the distal end of the appendix was adherent to the side of the lumbar vertebra and through the loop thus formed some 10 inches of the small intestine had passed and become strangulated. Operation resulted in recovery. Several somewhat similar cases are reported by the writer. 2. Strangulated hernia with gangrenous appendix.

The patient was a woman of 67. She had noticed pain and a tumor in the right groin for a week. Operation showed a strangulated hernia including the appendix, which was gangrenous. Recovery followed. Again several similar cases are reported. 3. Tumor of the cecal wall following removal of the appendix. The patient was a young woman who had recurring attacks which simulated appendicitis after her appendix had been removed for several months. Operation revealed a hard tumor 2 cm. (¾ inch) in diameter at the site of the appendiceal stump. It was removed and a microscopic examination showed it a chronic inflammatory condition of the stump. 4. Appendicitis with general peritonitis; operation; repeated infusion and recovery. The patient was a man of 32, operated upon for appendicitis of three days' duration. A ruptured gangrenous appendix, with general purulent peritonitis, was found. Free irrigation and free drainage. On the second day there was persistent vomiting and high temperature. Venous infusion of 1,000 cc. of saline solution and lavage frequently repeated for some three days were believed to have saved the patient's life. 5. Cancer of the appendix. Fourteen cases have been reported since 1896. The few that have been followed since operation show as yet no recurrence. Weir's patient was a man of 23, who had 13 attacks of appendiceal pain. Microscopic examination of the removed appendix showed adenocarcinoma. No recurrence after three years. [A.B.C.]

**2.—Complete Fibrous Obstruction of Both Superior and Inferior Cavae.**—Alfred Meyer reports the case. The patient was a young man of 18, with personal and family history which threw no light on the condition. He had never been strong, had general enlargement of the lymph-glands and was poorly nourished. Three weeks before death he presented the general symptoms of cardiac insufficiency from a general adherent pericardium. Necropsy showed the true condition. The report in part says: Superior cava ends at a distance of 6 cm. (2½ inches) above auricle. Near the termination of the cava the wall is somewhat thickened. Above the atresia, for distance of ½ cm. there is only some fibrous tissue in which both innominate veins end. There is no evidence of any inflammatory process at or near the atresia of the cava. The vena azygos major quite large, opens into the cava at the usual location and below the atresia. The inferior cava shows atresia at the diaphragm; there is fibrous tissue about 1 cm. or 1½ cm. thick about its termination. The upper end of the cava is rather conical, the wall quite thickened, the atresic part is surrounded by the area of perihepatitis on the upper surface of the liver, but the vein does not appear to be affected by the perihepatitis. All return circulation had been carried on by the enlarged vena azygos. The author has found no similar case reported. Various theories are advanced to account for the condition. [A.B.C.]

**3.—Respiratory Inhibition from Ether: Artificial Respiration for Over Four Hours; Recovery.**—H. H. Everett reports the case. While under ether anesthesia for an appendiceal operation the patient, a man of 20, suffered complete respiratory inhibition, became cyanotic, and death seemed imminent. Strychnia and atrophin had proved unavailing. Artificial respiration was instituted and 30 minims adrenalin chlorid were given. Soon the cyanosis disappeared and the pulse dropped from 120 to 96. Thereafter any cessation of artificial respiration resulted in cyanosis and threatened death. Most of the many measures resorted to for combating such conditions were tried without avail. Nothing seemed to be of service except the artificial respiration and the adrenalin chlorid. The latter after the first and second doses of 30 minims each was given in 10-minim doses every hour during artificial respiration, and for the next day the same dose was repeated every two hours. There was no effort at voluntary respiration for 4 hours and 20 minutes after artificial means were adopted. During all this time the pulse was good and the skin pink and warm, showing the circulation good. This is attributed by the author to the excellent effect of the adrenalin chlorid, but for which he thinks patient had surely died. The respirations, which were 20 for some hours, gradually rose to 26, where they remained for some days and then subsided to normal. The patient's recovery was complete. [A.B.C.]

1.—See *American Medicine*, Vol. V, No. 20.2.—See *American Medicine*, Vol. V, No. 19.

3.—**Cholelithiasis and Pancreatitis.**—Joseph Wiener, Jr., gives a brief review of the literature of 32 cases of acute pancreatitis associated with cholelithiasis and reports a case in full. He believes that in many, if not all, the cases there is a causal relationship between the two conditions. In not a few of the cases positive proof was found at the autopsy that the duct of Wirsung had been occluded by a gallstone. In the case of Dieckhoff a biliary calculus had actually found its way into the pancreatic duct. In Thayer's case we have a history of several attacks of biliary colic followed by jaundice. Then came the fatal attack of acute pancreatitis. At the autopsy the common duct was found enormously dilated, and in the duodenum was found the large calculus which had undoubtedly caused the duct occlusion. The cases of Day and Cutler presented similar features. The author urges early operation in these cases. The case reported by Wiener is that of a woman of 41, who was suddenly seized with violent pain in the epigastrium. She was nauseated and there was moderate tenderness over the entire abdomen, and some rigidity over the right rectus. Later the pain became colicky in character. The pulse-rate and temperature gradually increased. An exploratory incision was made. The gallbladder was found distended, and there was a large stone in the cystic duct. This was milked back into the gallbladder and a cholecystectomy performed. The head of the pancreas felt hard, but it was not enlarged. Complete recovery followed the operation. [C.A.O.]

4.—**A long case of relapsing typhoid fever** is reported by W. L. Stowell in a young woman of 30. The first three weeks was what might be called normal typhoid, the temperature reached normal and the patient felt well. Suddenly the temperature ran up and the first relapse was on. After that the temperature fell rapidly, but not quite to normal. After an interval of six days it went up again. These fluctuations were more or less irregular, so that it would seem that there were in all about six relapses; each one of these seemed to be shorter and less severe than the predecessor. The disease lasted 20 weeks. Calomel was used early and freely, and later. Naphthalin, salol and guaiacol were given almost continuously. Cold sponging did not avail much. The cold pack in the wet sheet was better, as the patient would fall asleep while so enveloped and the temperature would fall, delirium cease, and the thready pulse become stronger. [C.A.O.]

May 23, 1903. [Vol. 82, No. 21.]

1. Fracture of the Spine: Three Cases. HOWARD J. WILLIAMS.
2. Rheumatic Tonsillitis in Children. JOHN STEWART.
3. Notes on Blood-pressure in Man. S. S. GOLDWATER.
4. The Circulation in Puerperal Eclampsia. DOUGLAS H. STEWART.
5. Some Interesting Phenomena of Specific Immune Sera. ARTHUR P. HITCHENS.

1.—**Fracture of the Spine.**—H. J. Williams reports three cases. They are discussed under the following headings: Case I.—Fracture of the sixth cervical vertebra; bilateral paralysis of the wrist, fingers and intrinsic muscles of the hands; bilateral anesthesia of the inner border of the forearm and ulnar side of the hand, and complete paraplegia below the third rib; sudden death after 27 hours. Case II.—Gunshot fracture of the fifth dorsal vertebra; complete transection of the cord; paraplegia; laminectomy; death after 90 days. Case III.—Fracture of the first lumbar vertebra; motor paralysis below the great tro-

chanters; sensory paralysis below the knees; laminectomy; death after 19 days. Concerning operative treatment he says: Instead of waiting we should operate earlier in all cases of spinal fracture and oftener in the severer cases; knowing that even if the cord is completely crushed the destroyed zone may be removed and the ends approximated with hope of successful union. The absence of the deep reflexes should now be the most urgent reason for prompt exploratory operation, for it demonstrates that the cord is severed and if possible its continuity should be restored at once. Early operation would antedate the stage of secondary degeneration and take advantage of the possibilities of early regeneration. This will apply with equal force to the employment of myelorrhaphy in spinal crushing and to laminectomy in spinal compression. [A.B.C.]

3.—**Blood-pressure in Man.**—S. S. Goldwater concludes an exhaustive research in this interesting field, many experiments were made and blood-pressure was studied in a number of normal conditions and positions and under the influence of drugs. Various pathologic conditions were studied in relation to blood-pressure, particularly aneurysms, arteriosclerosis, nephritis, organic heart disease, various nervous and mental conditions, fevers, etc. Such a wide and varied field is covered by the investigation that the article should be read *in toto* to be appreciated. He says in conclusion: We are able to recognize at least one distinct service which blood-pressure has done. It has proved that arterial tension may be extremely low during the early stage of high fevers, when the pulse is full and bounding; relaxation of the arterial walls is no doubt the cause. A question which suggests itself is whether treatment having in view a better control of the circulatory apparatus during this period might not prove of some benefit. The clinician must not be surprised to find abnormalities of pressure during convalescence; blood-pressure is at this time as sensitive and changeable as the frequency of the pulse, and may rise or fall 20 mm. or 30 mm. in the course of an hour without apparent cause. [A.B.C.]

4.—**The Circulation in Puerperal Eclampsia.**—D. H. Stewart asserts that some substance in eclamptic blood favors reabsorption to such a degree that stercoremia gravidarum appears an exact term to designate a blood poisoned by its own excretions and then irritating the nerve centers until convulsions arise. In eclampsia the left ventricle is hypertrophied. We might have dilation were it not for the hypertrophica gravidarum which makes the heart wall of the pregnant woman thick and strong. The pressure on the arterial side is more than 10 to 1 on the venous. This pressure falls after venesection because poison is withdrawn and not because blood is drawn. To diminish arterial tension one would bleed from an artery, not from a vein. Removal is better than antagonism, and theoretically, a daily loss of 4 ounces of blood is worth the whole list of cardiac depressants from aconite bromid and chloral down to veratrum. In venesection consider the age of the patient. The pulse will soften as heart-irritation and heart-effort is relieved by extracting poison. Less blood in the coronary arteries will weaken the heart stimulus, arterial resistance will fall with decreasing dilation, and tension and friction in the arterioles will abate as expansion lessens. If the kidney is not excreting properly the waste products already in the vena cava are fortified by those in the renal stream, broadly speaking, the caval blood, is made thoroughly venous and consequently the heart is overimpelled. Finally, as the thorax aspirates the venous so it drives the arterial flow, and as the arterial circulation is already overfilled, in puerperal eclampsia calm respiration is decidedly desirable. [W.K.]

5.—**Specific Immune Serums.**—A. P. Hitchens discusses the phagocytic theory of Metschnikoff and the alexin theory of Buchner, also Pfeiffer's reaction, together with the researches of Bordet, Morgenroth, and Ehrlich, in regard to cytolysins, and finally the agglutination reaction of immune sera, noting its value in diagnosis, especially in regard to the cause of death in medicolegal cases. He also calls attention to the delicacy of the precipitin test in albuminuria as well as in differentiating blood, and concludes with a review of observations as to immunization against immune serum. [H.M.]

6. Upon the Local Use of Cocain in the Nose. WM. G. B. HARLAND.

**1.—Third and Final Report of a Case of Presystolic Mitral Murmur, Complicating Pregnancy, Etc.**—James Tyson gives the third and final report of this case. The previous reports have been abstracted in *American Medicine*. The woman died May, 1902. The autopsy revealed mitral, tricuspid, and aortic stenoses. [F.C.H.]

**2.—The Present Treatment of Puerperal Infection.**—E. P. Davis lays stress upon the necessity of absolute asepsis and antiseptics as an important role in the prevention of puerperal infection. Aseptic and simple cleanliness are not sufficient; the thorough use of antiseptics upon the hands of the physician and nurse and upon the external genital organs of the patient are requisite. The blood loss must be reduced to a minimum, as loss of blood distinctly predisposes to infection. Upon the development of septic infection the first duty of the physician is to thoroughly cleanse the uterus and vagina. Curetment should be done gently and with a dull curet. For the abdominal pain a turpentine stupe should be applied and over this is laid an ice-bag; he considers this method of application the best for this purpose. Medication should be limited to those drugs which act most efficiently as tonics and stimulants to the nervous system and which produce contraction of the uterus. Strychnin and ergot are the most valuable. Good nursing and liberal feeding are very valuable. Collections of pus occurring during puerperal infection should be emptied in whatever situation the collection occurs and in whatever organ. The following methods of treatment must be considered at present as experimental: The use of antistreptococcic serum (he has seen brilliant results follow its use in some cases and in others absolute failure); the use of nuclein to produce increased leukocytosis. Practically it is impossible at present to assert that such is the case; the employment of Credé's silver ointment; the intravenous injection of formalin (he thinks no adequate evidence has been presented to warrant the further employment of this method); écouvillonnage, which is at present peculiar to the French. The écouvillon is a swab containing bristles, by which the uterine cavity is vigorously brushed by rotating the swab. The question of hysterectomy for puerperal septic infection and hysterectomy during labor in infected cases is detailed. Methods of treatment which must be considered injurious are the administration of drugs to a septic patient to reduce fever; useless drugging in over anxiety to stimulate the heart; the effort to check the purgation in septic cases which nature often sets up, and the mistake of repeated intrauterine manipulation. The methods that should be employed instead are detailed. [F.C.H.]

**5.—A Fatal Case of Anthracosis.**—T. S. Githens details the history and postmortem findings of a case of anthracosis. The reader is referred to the original article. In a careful review of the literature of the subject he has not been able to find any mention of the disease in the United States, and only one from this continent. [F.C.H.]

**6.—The Local Use of Cocain in the Nose.**—W. G. B. Harland believes that the accidents which occur from the use of cocain in laryngology are due to errors of dosage. The usual dangers can be summed up as follow: Drug habit, secondary congestion and hemorrhage, local subjective sensations, and effects attributed to the so-called idiosyncrasy, each of which is detailed. He considers that adrenalin has proved a most valuable aid in lessening the dangers and in enhancing the powers of cocain. Cocain may be safely used in spray form in the strength of a 1% aqueous solution. If used on a cotton applicator, 5% should be the maximum strength employed. [F.C.H.]

A. O. J. KELLY

## REVIEW OF LITERATURE

**The Bacteriologic Diagnosis of Typhoid Fever.**—In a preliminary communication Z. F. Orloffsky<sup>1</sup> summarizes the result of his investigations as follows: 1. A convenient and safe method of bacteriologic blood examination consists in drawing blood from an arm vein, and making a bouillon culture. 2. The blood in typhoid fever contains bacilli in almost all cases. 3. The appearance of bacilli in the blood seems to be an early one; twice they were found on the sixth day when other symptoms were indefinite. 4. The cultures develop about the third day. It is necessary to take at least 1½ cc. to 2 cc. of blood and 200 cc. or more of bouillon to ensure success. 5. In doubtful cases it is imperatively advisable to make this bacteriologic blood test. If a positive result is obtained the diagnosis becomes certain; otherwise a second test is requisite before typhoid can be excluded. [L.J.]

**The Occurrence and Mortality of Typhoid Fever in Children.**—Henry Koplik<sup>2</sup> says that typhoid fever in the newborn runs an atypical course, the infection partaking of the nature of a hematogenous one. Evidence of cases occurring later in infancy, before the age of 12 months, and also up to the age of 2, is constantly multiplying. The frequency of the disease in this class as compared with older children and adults cannot be stated in figures until a sufficient number of cases have been observed and diagnosed with modern methods. Statistics from a host of observers are given by Koplik in order to determine the mortality rate, the frequency of perforation, etc., in patients between the ages of 2 and 10. From a study of these statistics and from his own cases he states that the mortality of this class varies from 6.6% to 13%, neither his own series nor the collated cases supporting the view that typhoid fever is always a mild disease during that period of life. As to perforation he has had two cases in his series of 100. The severer forms of myocarditis and endocarditis are rarer than in the adult. [A.G.E.]

**Accessory Pock Marks in the Course of Vaccination and of Postvaccinal Exanthems.**—A. Groth<sup>3</sup> considers the accessory pock marks in the immediate neighborhood of the field of vaccination to be rudimentary vaccinations, and to be due in most cases to transference of germs by way of the lymph paths from the point of vaccination. These germs are not necessarily such as carry the vaccine virus. These vaccinole are rarely typical pustules; they are usually very small, and appear and disappear in the course of about four days. In a few cases they are probably due to superficial lesions of the skin being infected directly from the pock. Generalized vaccinia—a general pustular eruption with the typical characteristics of the pocks—is the result of an infection of the organism with vaccine. The pustules must be formed from within, that is, the poison must be carried along the blood paths before the eruption can be considered as generalized vaccinia. Wherever multiple eruptions are the cause of numerous local infections the condition must be considered as one of postvaccinal local infection, probably due to scratches. Whether such a state is in any way connected with generalized vaccinia has not been determined as yet. He warns against permitting children with skin disease to be vaccinated, as they are very liable to severe postvaccinal eruptions. [E.L.]

**Oliver's Sign in Aortic Aneurysm.**—Though 25 years have elapsed since Oliver described his sign, its value is still far from being universally acknowledged. While some authors dwell on its positive significance, others emphasize its negative features. P. T. Grosdowski<sup>4</sup> reports 10 original cases of aneurysm, and infers from a detailed study that Oliver's sign of tracheal tugging is not pathognomonic of thoracic aneurysm. The sign may be present in the mediastinal tumors as well. Furthermore, the sign can no longer be considered as conclusive evidence of aneurysmal dilation of the beginning or lower posterior concavity of the aorta since it has been observed

<sup>1</sup> Russki Vrach, March 1, 1903.<sup>2</sup> Archives of Pediatrics, May, 1903.<sup>3</sup> Münchener medizinische Wochenschrift, January 20, 1903.<sup>4</sup> Russki Vrach, February 22 and March 1, 1903.

in aneurysm of the entire thoracic portion, and even in aneurysm of the descending part. Nevertheless, in conjunction with other indications of aneurysm, Oliver's sign has a distinct value as additional evidence. Tracheal tugging is not a constant factor, but depends on the cardiac activity; it is well marked when the heart is beating strongly, and it may become indistinct or disappear with the onset of heart failure. [L.J.]

**Inversion in the Treatment of Acute Pulmonary Edema in Young Children.**—T. S. Southworth<sup>1</sup> reports the case of an infant of 13 months, which was suddenly seized with acute pulmonary edema one month after an attack of pneumonia. The child was inverted and held in that position while firm, steady pressure was made over the lungs, with stroking pressure over the bronchi toward the head. A little frothy fluid tinged with blood ran out of the mouth and nose. Decided relief of the infant was immediately noted by those in attendance. The child was then placed in bed with the foot considerably elevated and the usual medicinal treatment instituted. Rapid recovery followed. As several previous cases in the same hospital had died despite the same medication it seems that the expression of the accumulating serum in this instance was a life-saving measure. The undigested and offensive stools which resulted after purgation in this case are considered as suggestive of acute indigestion as one of the possible etiologic factors in acute pulmonary edema of young children. [A.G.E.]

**Behavior of the Chlorids in the Stomach and the Cause of the Absence of Hydrochloric Acid in Gastric Carcinoma.**—A number of clinicians are of the opinion that the secreted hydrochloric acid is destroyed by substances contained in the carcinomatous stomach, others believe that less hydrochloric acid is secreted; they find the cause of the latter was believed to be the gastric catarrh so frequently associated with carcinoma, especially as atrophy of the mucous membrane and the glands of the stomach have been found in this disease. But since free hydrochloric acid may be absent at a very early stage, and can reappear after removal of the cancer, it must follow that the cause of the absence of the acid is removed with the carcinoma, and that the glandular atrophy is only secondary. Reissner's<sup>2</sup> examinations of cancer patients have moreover shown that the total chlorids are relatively high, due to an increase of the combined chlorids. The chlorids found in the stomach are derived from the following sources: 1. The neutral chlorids of food and saliva. 2. The free hydrochloric acid secreted by the gastric glands and that combined with albumens. 3. The combination of chlorin with ammonia. Reissner believes that the total chlorids are increased because a portion of the secreted hydrochloric acid is neutralized by an alkali derived from the fluid discharged from the ulcerating surface of the carcinoma and which in itself possesses a large amount of chlorin. He states that a cancer produces changes in the chemistry of the gastric secretion only after it has ulcerated, and that the free hydrochloric acid is absent because its actually secreted amount is diminished and the existing quantity has been neutralized by the alkali mentioned. The cause for both is ulceration of the cancer. [E.L.]

## GENERAL SURGERY

MARTIN B. TINKER

A. B. CRAIG

C. A. ORR

### EDITORIAL COMMENT

**Foreign Bodies Left Within the Abdominal Cavity.**—Many instances in which this accident occurs are obviously not reported even when recognized, and it is fair to assume that a considerable number are never recognized. The various devices resorted to by surgeons minimize but do not render improbable this danger, so long as any article is placed wholly within the abdominal cavity. We can recall several instances coming

within personal knowledge in which a sponge or pad was left within the abdominal cavity, or else operation was done to remove such a foreign body. Seemingly few cases are reported, and yet Schachner<sup>1</sup> collected 155 reported cases of this kind. He says a foreign body left within the abdomen may remain for years without causing symptoms; usually, however, it seeks the route of least resistance and not infrequently causes a sinus which persists until the body escapes or is removed. The more serious fatal termination occurs too frequently. It is somewhat refreshing to read the admission of Robert Weir<sup>2</sup> that once in his practice an unremoved sponge caused the death of his patient, and on two other occasions postoperative removal of a pad saved the patient's life. That the accident is somewhat more common than is usually supposed is evidenced by Weir's statement that on five occasions he has been called to remove a sponge or pad left within the abdomen by fellow surgeons, several of them men of high repute for painstaking care. He now permits no pad or other piece of gauze to remain in the abdomen unless in the grasp of a forceps or to which clamps have been attached. To obviate the use of clamps, which are somewhat cumbersome, he has substituted ordinary harness-rings, which are sewn to the tape attached to the gauze with which they are sterilized. Sanger<sup>3</sup> holds that dry sponges should not be used in abdominal operations, since their roughness injures the delicate peritoneum and causes subsequent adhesions. He moistens the sponges in a solution of sodium chlorid and calcined sodium carbonate. Lilienthal<sup>4</sup> holds there is but one safe procedure, and that is to make it an absolute rule to place no packing or other substance entirely within the abdominal cavity. His practice is to cut gauze of such length that two-thirds of a piece may be packed within the abdomen leaving the remaining one-third entirely outside the cavity. From the number of reported cases and the doubtless greater number which are not reported, it is evident that the leaving of foreign bodies within the abdominal cavity is a danger to be reckoned with in every case of laparotomy. Too great care cannot be exercised by surgeons in this particular. Prudence would certainly indicate that no sponge, pad or packing should be placed within the abdominal cavity unless secured by tapes, clamps or other means to minimize the danger of their being left.

### REVIEW OF LITERATURE

**Ectopia of the Kidneys.**—O. Engstroem<sup>5</sup> reports three cases of congenital displacement of the kidneys. The first case was one of horseshoe kidney, situated below the normal level. In the two other cases one kidney only was displaced, in the last instance being associated with rudimentary uterus. The ectopia is explained by interference with the course of development of the primitive kidney. These ectopic kidneys rarely functionate normally, and often present anomalies of form. The diagnosis is usually made by laparotomy or autopsy. The condition has been mistaken for various pathologic conditions of the pelvic organs, or for an abdominal tumor, and the kidney has even been removed under such misapprehension. Recently it has become possible by catheterization to determine the length of the ureters, and this offers a means of more accurate diagnosis. Dangerous complications may arise as the result of ectopic kidneys, among the most important being injury due to exposure of the organ, pressure of the ectopic kidney on the large veins with resulting thrombosis, serious rectal obstruction by the displaced organ, and difficult or impossible labor. [B.K.]

**Gastrotomy for Hemorrhage Following Traumatic Rupture of the Gastric Mucosa.**—F. v. Winiwarter's<sup>6</sup>

<sup>1</sup> Annals of Surgery, November, 1901.

<sup>2</sup> Medical Record, May 23, 1903.

<sup>3</sup> Zentralblatt für Chir., 1896, p. 191.

<sup>4</sup> Medical Record, October 18, 1902.

<sup>5</sup> Zeitschrift für klin. Med., Bd. xlix, p. 25.

<sup>6</sup> Wiener klinische Wochenschrift, December 25, 1902.

<sup>2</sup> Zeitschrift für klinische Medizin, 1902, Vol. xlv, p. 71.

patient run against the elbow of a friend while playing football. It struck violently over the region of the stomach. He recovered from the blow and continued the game. Frequently during the next two weeks he complained of abdominal cramps, was nauseated, and vomited several times. He then began to vomit blood, also passing considerable blood in his stools. After medical treatment had failed, and as the patient seemed to be approaching death, Winiwarter opened the stomach and found as the cause of the hemorrhage two tears in the gastric mucosa—one 5 cm. (2 inches), the other 12½ cm. (5 inches) long. The tears were sutured and the abdominal wound healed by primary intention. On account of the severe anemia and the great irritability of the stomach the patient's recovery was slow, and he was not discharged from the hospital for four months. [E.L.]

**Thirty-three Cases of Cancer of the Tongue.**—S. Boyd and W. H. Unwin<sup>1</sup> give a table summarizing 33 cases of undoubted cancer of the tongue, with brief history, operation, and result. Of the patients 30 were males and 3 females. The mortality was 5. Six patients have remained free from cancer for periods varying from 11 years to 11 months; 16 recurred within a year. The writers have reason to think that some recurrences were due to direct inoculation of raw surfaces from the growth as it was dragged past them. Wrapping the growth to prevent this is not satisfactory, and they propose in the future to wipe over the surface of the growth with a cautery before beginning the operation. The removal of the mylohyoid and anterior belly of the digastric muscles is advisable in advanced cases. Tracheotomy is performed only for dyspnea. [A.G.E.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### REVIEW OF LITERATURE

**Gonorrheal Puerperal Fever.**—F. J. Taussig<sup>2</sup> gives a full history of five cases of gonorrheal puerperal fever, quotes the opinions of several authors, advises against curetment as involving too much risk of general infection, and summarizes the essential points in regard to this condition as follow: The gonococcus is the etiologic factor in about one-sixth of all cases of puerperal infection. Although almost invariably secondary to a gonorrheal process elsewhere, this trouble involves an infection of the puerperal wounds, and hence must be classified under the head of puerperal fever. The gonococcus may gain access to the uterine cavity without any internal examination being made, though more frequently this results from digital examinations and operative manipulations, particularly intra-uterine, in the delivery of the child and placenta. The infection shows itself about the sixth or eighth day by rigors, a temperature of 103° and severe abdominal pains. The fever is usually of short duration and the course of the disease mild, but liable to become chronic. Cases in which the temperature begins to rise as early as the sixth day, and runs up to 102° and 104°, are not necessarily caused by mixed infection but may be due to gonococcus alone. The diagnosis is based on the rather late onset, the slow regular pulse, the moderate and steady elevation of temperature, the profuse purulent, glairy discharge, and, above all, the presence of gonococci in the lochia. Prophylaxis is of more benefit than treatment. All pregnant women having gonorrhea should be delivered so far as possible without internal examination. Treatment should be limited to one or two intrauterine douches, frequent vaginal irrigations and rest in bed for a prolonged period of time. [w.k.]

**Puerperal Insanity.**—R. Jones<sup>3</sup> reports the statistics of 259 cases personally observed. The insanity of pregnancy is more common in first confinements among single women, disgrace being an important factor. During pregnancy melancholia is commoner than mania, and suicide must be guarded against. The nearer to confinement the more acute the symptoms. Insanity of the puerperium comes after the first confine-

ment in 33% of the cases. Cases occurring during lactation show marked physical exhaustion, and are more of the depressed than maniacal form, and are more likely to become chronic than in other periods, and there is a tendency to low forms of inflammation, thrombosis, gangrene, and phthisis. When insanity commences more than six weeks after confinement suicidal and infanticidal promptings are commoner than in puerperal cases. A previous record of hysteria is frequent in puerperal insanity. The pathology is that of heredity and stress. Cases of insanity in early pregnancy improve toward the end of pregnancy, whereas those of late pregnancy become worse at the puerperium. Puerperal insanity is markedly recoverable, requiring from three to five months. All cases presenting headache and sleeplessness must have absolute rest. Home treatment is desirable. Presence of the husband aggravates the symptoms. The diet should be liberal and stimulating. Change is indicated when the patient becomes stuporous. Menstruation is a sign of improvement. [H.M.]

**Tetanus After Perineorrhaphy.**—L. Goth<sup>1</sup> reports a case of tetanus occurring after repair of perineal laceration. The patient had been delivered four months and had nursed the child until she entered the hospital. Ten days later, after the cessation of milk secretion, the perineorrhaphy was performed under chloroform anesthesia. Repeated vomiting followed and the next day a typical tetanus set in, involving both hands and feet. The cramps were repeated two or three times an hour, causing intense pain. Bromid was ordered in moderate doses and in three days the attacks became less frequent and less extensive. On the eleventh day after operation the sutures were removed, the wound having healed by first intention, and on the thirteenth day the last attack of tetanus occurred, the patient leaving the hospital on the sixteenth day. The tetanus in this case, Goth says, cannot be ascribed to any of the usual known causes. It followed the operation immediately, had occurred neither just before the operation or at any earlier date; further, the symptoms abated with increased rapidity after the removal of the sutures. Hence Goth thinks the operation was the cause of the tetanus. [w.k.]

**The Bossi Dilator in Accouchement Forcé.**—J. B. De Lee<sup>2</sup> has made a careful study of reported cases of the use of this instrument, and has used it three times. He reaches these conclusions: (1) There is a small field of usefulness for this instrument in cases in which rapid dilation of the cervix is necessary after effacement. Before effacement the colpeurynter should be used. It will be more successful in multipara; (2) the instrument will be useful in dilating the cervix in those cases where manual dilation would be successful. It possesses advantage over the hand in the aseptis in that it is not so tiring, so that the operator may carry out the subsequent delivery comfortably; (3) the instrument is not safe, but requires careful and skilled watchfulness, and one must search for and be ready to repair more or less extensive lacerations. These are greater in primipara; (4) it should never be used in placenta prævia; (5) it does not replace the colpeurynter, the use of the hand, or cervix incisions in all cases. [A.G.E.]

**Congenital Absence of the Uterus.**—W. A. Dorland<sup>3</sup> thinks probably the true percentage is nearer one case in 5,000. A description of four cases is given, and a discussion of their cause. This congenital defect is probably caused by the action of traumatism, microbes, or toxins upon the embryo in utero. The variety of the congenital defect will depend upon the time in embryogenesis at which the disturbing factor becomes operative. If this occurs after the ducts of Mueller have attained their full maturity, but before they have fully coalesced to form the generative organs, the various forms of double uteri and vaginæ are thus evolved. If, however, the arrest of development occur prior to the formation of the uterus by the fusion of these ducts, or prior to the development of the ducts of Mueller themselves, either one or both of these structures fail to appear. Owing to their distinct origin, ovaries may be present in the absence of uterus and vagina. [w.k.]

## TREATMENT

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPELMAN

## REVIEW OF LITERATURE

**A Case of Septic Meningitis Treated with Intravenous Injection of Formalin.**—This case is reported by W. H. Corrigan,<sup>1</sup> the patient being a boy of 14, with the typical signs of meningitis, following influenzal otitis media. After the temperature had been abnormally high for 60 hours, 10 ounces of 1-4,000 formalin solution was injected into the left median basilic vein. The temperature fell in five hours from 106.4° to 99.5°, the pulse from 140 to 84, respirations from 32 to 22. Delirium was followed by sleep and convalescence, ending in recovery; it being interrupted temporarily by a metastatic abscess. [A.G.E.]

**Pertussin in Whoopingcough.**—H. Barasch<sup>2</sup> advises the use of pertussin (extractum thymi saccharatum) in whoopingcough. It should be administered in doses of one teaspoonful every three hours. [W.E.R.]

**Respiratory Gymnastics.**—While it is true that general exercises, which increase the pulmonary respiration by increasing the elementary respiration—that is, the interchanges that take place in the structural elements—constitute the most perfect form of respiratory gymnastics, it must be added that they presuppose the ability to perform a greater amount of work than can always be demanded of the very patients who are most in need of increasing the functional activity of their lungs. It is in these cases that local pulmonary gymnastics, properly so called, find their greatest usefulness. The guiding principle in this method is altogether different from that which underlies the use of general exercise for the purpose of increasing the functional activity of the lungs. No attempt is made to create a desire for air, a need for more active respiration. The patients are, in fact, already incapable of completely satisfying the normal respiratory demands, and an endeavor is therefore made to stimulate function without fatiguing the organ. Chiefly the procedures employed in the Swedish movements are resorted to for this purpose. An attempt is made to facilitate either inspiration alone, or expiration alone; or, possibly, both phases of the respiratory rhythm at the same time. Among the procedures intended to increase the amplitude of inspiration, the so-called "respiratory movement" should be given particular prominence. This "respiratory movement," which is commonly employed by Swedish trainers to satisfy the air-hunger induced by the training exercises, is described as follows: The patient raises his arms to the vertical position, at the same time taking a deep inspiration. He then brings the arms backward and downward, thus describing a large movement of circumduction. The result of this maneuver is to raise the chest with the muscles that are attached to the ribs and to the humerus. These movements may be practised either in the erect or in the recumbent posture. In the latter position the resistant plane formed by the bench on which the patient reclines tends to obliterate the normal curves of the vertebral column, so that the upward movement of the ribs is greatly facilitated. In order to obtain the same extension of the spinal column in the erect posture, the patient supports himself on his toes, inclining his body backward during the entire period of inspiration. Expiration is ordinarily passive. Under certain circumstances, however, it may require the aid of the expiratory muscles. Among the latter the abdominal expiratory muscles are most frequently called into action. One of the procedures in the Swedish movements consists in permitting these muscles to remain inactive, and calling into play exclusively the thoracic expiratory muscles. This is accomplished by making it impossible for the abdominal expiratory muscles, particularly the recti, to act. The patient lies prone upon a bench and contracts the extensor muscles of the vertebral column and of the head in such a manner as to raise the head and shoulders. The recti muscles in this position being tense and unable to contract, the patient calls upon all his thoracic expiratory

muscles in his efforts to make a forcible expiration. Swedish movements yield excellent results in the treatment of chronic emphysema. One of the most efficacious procedures consists in passive movements having for their object the mobilization of the ribs. For this purpose direct pressure upon the ribs may be employed; or the muscles that move the ribs may be subjected to various manipulations, especially to a movement that appears exceedingly strange to the observer who witnesses it for the first time. This movement is designated in Swedish "scrufridning," which practically signifies a screwing motion. The patient being seated astride a bench to which his thighs are fixed, two attendants, grasping him by the shoulders, forcibly rotate the trunk upon its axis, alternately from right to left and from left to right. These movements are repeated a certain number of times in succession, and the shaking to which the various bones that compose the thorax are subjected has for its object to cause one bone to play upon another and thus to mobilize, by this general shaking, the vertebrocostal articulations, upon which it would be difficult to act separately. The maneuver designated "*fente en arrière*," is intended to facilitate both phases of respiration: During inspiration the patient thrusts the chest backward in forced extension, brings the arms forcibly to the horizontal position in abduction, and carries one of his legs back to steady himself. During expiration he lowers the arms, inclines the body forward, and brings the legs in line in such a way as to favor mechanically the expulsion of air from the chest. At the same time the patient is instructed to rise on his toes during inspiration, and to flex the knees during expiration. When the vertical position is a source of fatigue to the patient, he may be made to assume the recumbent posture upon a resistant surface—a bench, for example—as in performing the "respiratory movement" already described. This is to obliterate the curves of the spine and to give the ribs a direction which better enables them to attain the maximum degree of elevation.—Tissier's Pneumotherapy (System of Physiologic Therapeutics, Vol. x).

**Concerning the Therapy of Croup.**—Leopold Bayer<sup>1</sup> treats croup by the administration of  $\frac{1}{2}$  grain doses of calomel, alternating every hour with  $\frac{1}{16}$  grain of apomorphin, until the maximum dose is reached of calomel 8 grains, and of apomorphin  $\frac{1}{2}$  grain. The author obtained very favorable results in 20 patients treated in this manner. [W.E.R.]

**Guacamphol in Night sweats.**—Ladisl<sup>2</sup> considers guacamphol the best means of stopping night sweats. The dose is 3 to 4 grains, and should be continued over a period of two weeks. Guacamphol splits into guaiacol and camphoric acid in the alkaline medium of the intestine. [W.E.R.]

**Pertussin in Laryngitis.**—A. Model<sup>3</sup> reports the favorable and rapid effects of pertussin (extractum thymi saccharatum) in acute laryngitis, bronchitis and the dyspnea of emphysema. One hundred grains should be taken in the course of a day. [W.E.R.]

## FORMULAS, ORIGINAL AND SELECTED.

**Snuff for Rhinitis.**—In acute coryza Cates<sup>4</sup> considers the following snuff almost a specific:

Aluminium acetate,  
Menthol,  
Acetanilid, of each . . . . . 1 grain (0.06 gram)  
Bismuth subnitrate . . . . . 1 dram (4.0 grams)  
Dispense in a vial, labeled Catarrh Snuff.

A bit of this snuff the size of a grain of wheat is poured into the palm of the hand and snuffed up each nostril. [H.C.W.]

**For Administering Quinin Hypodermically.**—Aufrecht<sup>5</sup> recommends the following formula:

Quinin hydrochlorate . . . 0.5 gram (7½ grains)  
Urethane . . . . . 0.25 gram (3¾ grains)  
Distilled water . . . . . 5 grains (80 minims)  
For one injection.

He believes that unpleasant after effects are less likely to supervene than when the drug is given by the mouth. [H.C.W.]

**Changes in the Medical Corps of the U. S. Army for the week ended May 23, 1903:**

**BRECHEMIN**, Major LOUIS, surgeon, is relieved from his present duties and will proceed to Camp Stotsenburg, Angeles, Province of Pampanga, for assignment to duty as post surgeon, relieving Major Daniel M. Appel, surgeon.

**APPEL**, Major DANIEL M., surgeon, will proceed to San Francisco, Cal., reporting by telegraph to the adjutant-general of the army for instructions.

**LAMBERT**, First Lieutenant SAMUEL E., assistant surgeon, will proceed to Fort Keogh for temporary duty. Upon the departure of the Second Squadron, Thirteenth Cavalry, from San Francisco, Cal., en route for Manila, P. I., he will report to the squadron commander for duty as medical officer to accompany the squadron to its destination.

**PINKSTON**, OMAR W., contract surgeon, now at Kansas City, Mo., is relieved from further duty in the division of the Philippines, and will proceed to Madison Barracks for duty.

**RAFTER**, JOHN A., contract surgeon, is relieved from duty at Madison Barracks, to take effect upon the arrival at that post of Contract Surgeon Omar W. Pinkston, and will then proceed to his home, West Winfield, N. Y., for annulment of contract.

**HOWELL**, First Lieutenant PARK, assistant surgeon, is granted leave for eighteen days from about May 14.

**SHEPARD**, First Lieutenant JOHN L., assistant surgeon, is relieved from further duty at Fort Apache and will proceed to San Francisco, Cal., and report for assignment to duty at the U. S. General Hospital, Presidio.

**MILLER**, J. E., contract surgeon, is granted leave for twenty-three days.

**PETTYJOHN**, JOSEPH, contract surgeon, is relieved from duty at Fort Gibbon, Alaska, and will proceed to Vancouver Barracks for further instructions.

**GREENLEAF**, First Lieutenant HENRY S., assistant surgeon, is granted leave for one month, beginning May 15, with permission to apply for an extension of one month.

**BLOOMBERG**, First Lieutenant HORACE D., assistant surgeon, leave granted January 12 is extended one month.

**PEASE**, F. D., contract surgeon, is granted leave without pay, to include June 30, and to take effect upon the expiration of the extension of leave granted April 14.

**Changes in the Medical Corps of the U. S. Navy for the week ended May 23, 1903:**

**WEIBER**, F. W., surgeon, granted sick leave for two months—May 15.

**MORRIS**, L., passed assistant surgeon, ordered to the Minneapolis—May 16.

**MICHEL**, R. H., assistant surgeon, ordered to the Asiatic station via the Solace—May 16.

**BROWN**, E. M., assistant surgeon, detached from the Naval Hospital, Norfolk, Va., and ordered to the Naval Hospital, Newport, R. I.—May 18.

**HOLLOWAY**, J. H., assistant surgeon, ordered to the Baltimore—May 19.

**GEIGER**, A. J., assistant surgeon, appointed assistant surgeon from May 6, 1903—May 19.

**Changes in the Public Health and Marine-Hospital Service for the week ended May 21, 1903:**

**VAUGHAN**, G. T., assistant surgeon-general, detailed to represent the service at the meeting of the Association of Military Surgeons at Boston, Mass., May 20—May 21, 1903.

**PERRY**, J. C., passed assistant surgeon, to report at Washington, D. C., for special temporary duty—May 17, 1903.

**DECKER**, C. E., assistant surgeon, granted extension of leave of absence, on account of sickness, for fourteen days from April 24—May 15, 1903.

**WILSON**, R. L., assistant surgeon, granted leave of absence for seven days from April 28, 1903, under provisions of paragraph 191 of the regulations.

**MCLAUGHLIN**, A. J., assistant surgeon, granted leave of absence for two months from May 1—May 15, 1903.

**WARD**, W. K., assistant surgeon, granted leave of absence for three days from May 14, 1903, under provisions of paragraph 191 of the regulations.

**FORD**, C. B., acting assistant surgeon, granted leave of absence for fourteen days from June 3—May 15, 1903.

**FRASER**, A. C., acting assistant surgeon, granted leave of absence for forty-five days, on account of sickness, from April 27—May 15, 1903.

**MARSH**, W. H., acting assistant surgeon, granted leave of absence for seventeen days from May 8—May 15, 1903.

**WETMORE**, W. O., acting assistant surgeon, granted extension of leave of absence for fourteen days from May 15—May 15, 1903.

**WIGHTMAN**, W. M., acting assistant surgeon, granted leave of absence for three weeks from June 7—May 19, 1903.

**WILSON**, W. W. W., acting assistant surgeon, granted leave of absence for fourteen days from May 14—May 19, 1903.

**SCHLAAR**, W. F., pharmacist, granted leave of absence for three days from May 10, 1903, under provisions of paragraph 210 of the regulations.

**War Waged by Means of Bacilli.**—Held to be of sufficient credibility to justify cabling, the newspapers say that the revolutionary leaders in Bulgaria have obtained a quantity of plague bacilli and are determined to infect the people of Constantinople, Salonica, and even Berlin, unless the Powers interfere in their behalf. Gunpowder, dynamite, and other explosives have been thought of as conservers of the capitalistic, governmental and educated classes, and of civilization itself, because of the inability of the masses to secure these means of malevolent destruction. In some parts of Europe the pollution of the wells, etc., with disease germs has been credited to some wicked unfortunates. The popularization of knowledge and mechanical skill will perhaps make the control of revolutionary and inferior peoples by the engines and explosives of war no longer possible, or only so with increasing difficulty. We have long wondered if bacteriology would not be seized upon as an implement of war by private or public vengeance. Once at least in old Europe, as history tells, venereal disease was consciously used as a destructive agent for enemies, and its effects on Spain and Europe brought by the returned Columbians was a full repayment, however unintended, for the wrongs done them by the renegades of the discoverers of America. Perhaps the foregoing press dispatch is only a canard, or only a preliminary hint of a new agency to be thrown into the hates and wars of mankind. One must confess that the method could easily be used in some such a way as that suggested. The thought is worth more than a passing smile of incredulity.

**The war against bad milk** now being waged by the profession of the cities of the nation is a fine proof of the union of science and benevolence, and as the summer approaches far-sighted preparations are being made by every competent health board to strike at the root of the abuse. An indication of how watchful the officers must be is shown in the results of recent "milk raids" carried out in New York under Dr. Lederle's direction. In one out of 162 samples only 44 were above the legal requirement, according to tests made at the laboratory of the Department of Health. In another raid 124 samples were taken, and out of this number only 18 were found to be wholesome. The Sunday raids showed clearly that dealers were taking advantage of

the lax inspection on this day by reducing, watering, and adulterating milk to a greater extent than was done on week days. The value of pasteurized milk is shown in the records of the Infant Asylum at Randall's Island. In 1897 the deathrate among the waifs picked up in the streets of New York and taken to this hospital was 44.36%. A year later a pasteurizing plant was installed and the deathrate dropped to 19.80%. In 1901 it was 18.09%.

**A Strabismic Veto.**—As indicative of the power of "politics" in some States we recently called attention to the veto of the medical practice act by the Governor of Colorado. That is also noteworthy of the Governor of Illinois of the act regulating "the examinations of those who desire to practise any other system of treating human ailments who do not use medicines internally or externally and who do not practise operative surgery." Both the concocters of this legislative nonsense and their vetoing Governor seem to think that only drugs are "medicines" and that manipulations, massage, etc. (as, *e. g.*, in setting a dislocated hip-joint), are not "operative surgery." Under the old law the osteopaths were enabled to practise their "system of healing" in Illinois, as, according to the Governor, 350 are now doing. Consequently the discriminating chief executive says: "No hardship is imposed upon this class of practitioners and they are deprived of no legitimate privileges." The inference is plain that had such hardship been desired, even by the osteos themselves, the befriending Governor would have interposed to save them from themselves. His especial objection to the bill, however, is that it would have "subordinated the entire machinery of the State government to societies." National Guardsmen should not control admission to the National Guard; the State bar, the pharmacists, the teachers, etc., should not prescribe the conditions as to those desiring to practise law, pharmacy, or school teaching. That is to say, those knowing nothing of a subject should make laws for and govern those who do. In the same way, the logical conclusion must be that those who know nothing about statesmanship and government should be legislators and Governors! The sting is in the tail: "I am far from any intention of casting any aspersions upon the practice of osteopathy, or the practitioners thereof. I believe those who pursue this practice are doing great

good, and are rapidly earning, and justly earning, the confidence of the people." He should have added that some democracies are slowly learning, "and justly learning," lack of confidence in their Governors.

"The Infant Index" is the name of a new system devised by Dr. Lederle, of New York, for the purpose of reducing the mortality among infants from "summer complaint." Already an index of 20,000 infants has been made—this number having been born since January 1—but the records will be carried back to October of last year. In the case of each infant, the name, date of birth, number of birth certificate, the number of the house in which it lives, and the name and nativity of its father, have been written on a card, and to the father will be sent a circular describing in simple terms the proper method of caring for babies in hot weather. The circular will be printed in English, German, Italian, and Yiddish. The city will be laid out in districts, and to each district one or more inspectors will be assigned. It will be the duty of the inspectors to visit continually all children under their charge, and where children are sick to make immediate reports of the cases. In his reports the inspector will state whether the child has been nursed by its mother or whether it has been fed on loose or bottled milk. He will also state the amount of each feeding, the air space of the living-rooms, whether the rooms are clean and the child well cared for, and whether raw fruit has been given to the infant. The health board has in its employ six physicians who are specialists in the diseases of children, and these men will take charge of cases reported by inspectors. The doctors will report on the family history of the infant from a medical standpoint, the character of the sickness, the treatment, and the kind of food which the infant has been taking. Coupled with the crusade against bad milk the board will still further greatly lessen the infant mortality of the city. Could the plan not be adopted by the boards of other cities?

**Economy in Nutrition.**

—After careful laboratory tests, Professor Chittenden, of Yale (*Popular Science Monthly*, June, 1903), finds that a man who weighed 165 pounds was able to keep up his weight and health on a self-chosen diet at an average food-expense of 11 cents a day. This, moreover, was during a period—a short period, it should be noted—in which he undertook "drastic and fatiguing" exercises. His only food was "a prepared cereal food," milk and maple sugar, taken twice a day, in the quantities desired. Professor Chit-

tenden's work is most scientific, valuable, and suggestive. He rightly contends that the problems of nutrition demand scientific investigation; that they lie at the basis of our social and personal life, that there is an evident and enormous waste in our common diet, that the influence of the mind on digestion and nutrition need the most careful study, etc. Such a preliminary or suggestive investigation is illustrated by this 13-day laboratory test of "H. F." In view of the millions of dollars invested in "breakfast foods" we cannot help being suspicious of the term "a prepared cereal food," used by Professor Chittenden and his subject. Even if the commercially cunning Yankee's head never becomes visible in the wood newspaper pulp, and on the wooden billboards, there are at least the greatest individual variations in the demands of the organism for food. One must doubt the ability of American men generally to keep up their weight and health, while undergoing "drastic and fatiguing" physical exercise, upon 11 cents' worth of maple sugar, milk, and "a prepared cereal" a day, even if the latter were force itself. Radium is a very rare metal. Will the radium-man supplant "Sunny Jim"?

**Thermometric Readings.**—By the courtesy of the editor of *Science* and of Professor S. W. Dudley we reproduce herewith a diagram which gives at a glance the differences in the three thermometers in common

use. Professor Dudley says that the diagram affords a convenient method of transferring one reading to another provided a high degree of accuracy is not desired. The relations between the three systems are given by the following formulas:

$$F.^{\circ} = \frac{9}{5} C.^{\circ} + 32^{\circ} = \frac{9}{4} R.^{\circ} + 32^{\circ}.$$

Fahrenheit degrees being plotted along a horizontal axis and Centigrade or Réaumur degrees along a vertical

axis, the graphs of the two equations above give two straight lines, as shown, from which, having given a reading in one of the systems, the corresponding reading in either one of the other two may be obtained. Thus to find the equivalent of 80° R. the horizontal from the 80° division on the vertical axis is followed to its intersection with the line marked Réaumur, thence downward where the corresponding Fahrenheit reading (212° F.) is found on the horizontal axis; or upward to "Centigrade" line and thence horizontally to left where the corresponding Centigrade reading (100° C.) is found on the vertical axis. Both lines cross the horizontal, or Fahrenheit, axis at the same point, 32°; the Réaumur line having a slope of  $\frac{9}{4}$ , the Centigrade line a slope of  $\frac{9}{5}$ .

"Education Not the Cause of Race Decline" is the title of a masterly article by Dr. Engleman, of Boston, in the current issue of *Popular Science Monthly*. There can be no doubt as to the proofs adduced that although the average graduate family does not reproduce itself, neither does that of any other group of our native American population. The graduate's family is even larger than that of his uneducated brother. As has been emphasized in these columns, the startling truth is that of all the civilized nations, the American has the lowest rate of reproduction. The alumnus of the American college is even more obedient than the foreigner alumnus to the primal command to increase and multiply, for although the child birthrate has been decreasing in our college families, it has been decreasing to a still greater extent in those families abroad. The inattention to this is because the fecundity of the foreign elements in our population is from 2 to 2½ times that of the native. The native American is therefore disappearing, and rapidly, with a birthrate of 17 per 1,000, and less than 2 children to the family. Dr. Engleman contends that the cause of the rapid decline of the formerly high birthrate of the native American is not physical, not due to venereal disease, nor to late marriage, but to the deliberate avoidance by couples of the obligation because of the strenuous, nerve-racking life of the day, and the struggle for luxury. As in the ancient Rome of Juvenal, so now, "Few children are born in the gilded bed to the wealthy dame, so many artifices has she, and so many drugs to render women sterile and destroy life within the womb."

"The Graveyard of the Human Race"—such is a melodramatic description of the city which has often served to point a moral and adorn a tale as to the relative mortality of city and country. There has never been any doubt in the minds of the quoters of the *mot* that in a general way the city was as much fed by the country with men as with food. But the need of extreme caution in the use of statistics is illustrated by Professor Jordan (*Popular Science Monthly*, June), who shows that it is unnecessary that the city's mortality rate should be higher than that of the country. If we can only get the known laws of preventive medicine carried out, if we can stop the unnecessary waste of city life, the deathrate and sickness expense can be made as low as that of the country. But the further fact is

brought out that in the last few years this urban expense has been vastly lessened and that the relative difference is being reduced to zero. Professor Jordan gives the following table:

EXCESS OF URBAN OVER RURAL DEATHRATE.		
Registration State.	1890.	1900.
Connecticut . . . . .	3.9	.1
Massachusetts . . . . .	2.7	.8
New Hampshire . . . . .	1.0	1.3
New Jersey . . . . .	7.9	3.3
New York . . . . .	9.3	4.0
Rhode Island . . . . .	1.1	.4
Vermont . . . . .	3.0	.7

Gratification over the fact herein disclosed will not lessen effort, and one may even go so far as to say that there is every promise and speedy possibility that the new science of city sanitation will soon reduce the death-rate below that of the country.

The increase of age of college graduation, according to Professor Thomas (*Popular Science Monthly*, June) has been greatly exaggerated, and he says that at best it exists only for certain institutions, others showing even a decrease. As our school system is at present constituted, the normal age is between 22 and 23, and the gradually organizing secondary education tends to make the percentage graduating within this age increasingly large. It was formerly possible, though not often happening, for a boy to graduate at 16; but this is not so now. The young man now leaves college but little older than did his father or grandfather, but, of course, with higher academic attainments. If entrance into professional life is later than formerly, the cause is not in the college or its preparatory school. The trend of opinion and of practice is in some way to drop a year of the college course, and to make the medical college course longer and more thoroughgoing. In this connection we call attention to the thoughtful and most noteworthy article of Dr. Dearborn, published in *American Medicine*, April 11, 1903.

**A University President on Football, Rowdyism, and Scholarship.**—The champions of a bastard athleticism have as a chief argument relied upon the contention that football prevented worse evils, such as those of bloodless and diseased scholarship, idleness, and depraved sports. President David Starr Jordan puts the matter in another way:

It is the spirit of advertising that leads some institutions to tolerate a type of athlete who comes as a student with none of the student's purpose. I am a firm believer in college athletics. I have done my part in them in college and out. I know that the "color of life is red," but the value of athletic games is lost when outside gladiators are hired to play them. No matter what the inducement, the athletic contest has no value except as the spontaneous effort of the college man. To coddle the athlete is to render him a professional. If an institution makes one rule for the ordinary student and another for the athlete it is party to a fraud. Without some such concession half the great football teams of today could not exist. I would rather see football disappear and the athletic fields closed for ten years for fumigation than to see our colleges helpless in the hands of athletic professionalism, as many of them are today.

The same methods which cure the aristocratic ills of idleness and cynicism are equally effective in the democratic vice of rowdyism. With high standards of work, set not at long intervals, by formal examinations, but by the daily vigilance and devotion of real teachers, all these classes of mock students disappear.

The football tramp vanishes before the work-test. The wealthy boy takes his proper place when honest, democratic brain effort is required of him. If he is not a student he will no longer pretend to be one and ought not to be in college. The rowdy, the mucker, the hair-cutting, gate-lifting, canerushing imbecile is never a real student. He is a gamin masquerading in cap and gown. The requirement of scholarship brings him to terms. If we insist that our colleges shall not pretend to educate those who cannot or will not be educated we shall have no trouble with the moral training of the students.

**Science and Materialism.**—There has of late been a great deal of discussion as to the origin of life and the attitude of scientific thinkers concerning the subject. The matter has of course a decided medical bearing, as the influence of a belief in materialism, whether openly or secretly held, will undoubtedly affect the subjects and trend of investigation of the laboratory worker and even the therapeutics of the practicing physician. A noteworthy contribution to the subject is made by the man whom all agree is the world's greatest scientist. The highest authority in physics says that physical laws and forces cannot explain the origin and actions of organic beings. His words, from a recent letter to the *London Times*, are:

... but I desired to point out that, while "fortuitous concurrence of atoms" is not an inappropriate description of the formation of a crystal, it is utterly absurd in respect to the coming into existence, or the growth, or the continuation of the molecular combinations presented in the bodies of living things. Here scientific thought is compelled to accept the idea of Creative Power. Forty years ago I asked Liebig, walking somewhere in the country, if he believed that the grass and flowers which we saw around us grew by mere chemical forces. He answered, "No, no more than I could believe that a book of botany describing them could grow by mere chemical forces."

Every action of human free will is a miracle to physical and chemical and mathematical science.

**A preparatory course for nurses' training schools** is announced by the Drexel Institute of Philadelphia and the plan deserves the serious interest of the professions concerned and of the public. The rapid development of training schools for nurses in this country has led of late to serious discussion as to the kind and amount of scientific education which ought to be given to the nurses in training. The question has been before the American Society of Superintendents of Training Schools for Nurses, and the drift of opinion is evidently in favor of increasing the amount and raising the standard of the instruction given in those studies which might be characterized as auxiliary to the strictly professional training given in the hospitals. The conviction among those who have given the matter special attention appears to be that this scientific knowledge could be more advantageously acquired if given independently of the professional work; and the general conclusion which has been reached is that if a preparatory course of training in the scientific branches, a knowledge of which is essential to a fully equipped nurse, should be provided relief from the pressure upon the women in the first year of the training schools would be obtained, while the standard for the education of nurses would be raised. Particulars concerning the course, etc., can be obtained by addressing the president of the Drexel Institute, James McAlister, Philadelphia.

## AMERICAN NEWS AND NOTES.

### GENERAL.

**Drug Stores in Havana Closed.**—The drug stores have all closed in consequence of the enforcement of the Havana Provincial Council's tax on the sale of patent medicines, and free prescriptions are again in vogue at the public dispensaries. The Druggists say that, rather than continue to be fined for the privilege of selling patent medicines, they prefer to remain closed until Congress passes on the pending bill providing that the government shall collect the internal revenues and appropriate the same among the provinces.

**New Rules for the Hypochondriac Health Seeker.**—Drink water and get typhoid. Drink milk and get tuberculosis. Drink whisky and get the junjams. Eat soup and get Bright's disease. Eat meat and encourage apoplexy. Eat oysters and acquire toxemia. Eat vegetables and weaken the system. Eat dessert and take to paresis. Smoke cigars and die early. Smoke cigars and get catarrh. Drink coffee and obtain nervous prostration. Drink wine and get the gout. In order to be entirely healthy, one must eat nothing, drink nothing, smoke nothing, and even before breathing one should see that the air is properly sterilized.—[*Southwestern World*.]

**Miscellaneous.**—ANN ARBOR, MICH: It is reported that Dr. J. Playfair McMurrich, professor of anatomy at the University of Michigan, has accepted a commission from the Royal Academy of Prussia and the government of Holland to examine and identify certain species of animal life. ATLANTIC CITY, N. J.: Dr. C. Radcliffe Johnson has recently accepted an appointment as Missionary Physician to the Philippines, and will be stationed at Manila. NEW YORK CITY: Dr. Eugene Hodenpyl has been elected president and Dr. Simon Flexner vice-president of the American Association of Pathologists and Bacteriologists. CHICAGO: Dr. J. Rollin Slonaker, associate in neurology, University of Chicago, has accepted the position of assistant professor of physiology in Leland Stanford, Jr., University.

**Hospital Benefactions.**—BROOKLINE, MASS.: The Free Hospital for Women has received a bequest of \$20,000 from the estate of the late Robert C. Billings. This sum is given to establish a permanent fund called the Robert Charles Billings Fund, the income of which is to be used for general hospital purposes. RICHMOND, IND.: Daniel G. Reid, formerly of Richmond, now of New York City, recently notified the trustees of St. Stephen's Hospital that he would give \$50,000 to the city for a new hospital provided \$25,000 is raised by the trustees of the present hospital as an endowment fund. The gift has been accepted. PHILADELPHIA: According to the will of the late Hannah B. Fry, of this city, the sum of \$5,500 will revert to St. Timothy's Hospital to establish a free bed after the death of the testatrix's sister. CAMBRIDGE, MASS.: It is reported that James Stillman, the New York banker, has given \$50,000 to the Stillman Infirmary of Harvard University for the purpose of establishing a ward for the treatment of contagious diseases. YONKERS, N. Y.: The late Warren B. Smith, of this city, bequeathed \$50,000 to St. John's Hospital.

**To Prohibit Adulterated Wines and Meats.**—It is reported that a conference has been held at the Bureau of Chemistry and the Department of Agriculture in Washington to determine upon a plan for the execution of the new law which places a ban upon adulterated wines, meats, etc., from foreign countries, particularly from Germany and France. The wines from France and the meats from Germany are the two articles which will be discriminated against most severely. This will probably result in a very much restricted importation of these articles into this country. During the last fiscal year there were imported into the United States from France champagne and sparkling wines to the value of \$4,529,000, and still wines to the value of \$1,073,159, whereas from Germany came sparkling wines to the value of \$1,273,227. The American consuls abroad will be directed to notify shippers that the new law will be enforced. It is known from analyses that have been made that foreign meats coming into this country are chemically treated. French wines imported into this country are proverbially impure. False brands are much used by foreign shippers as well as domestic dealers and manufacturers in California. It is asserted that a mixture consisting of 10% alcohol, 3% of sugar and glycerin, a trace of tannin, a red coloring material, a few drops of essential oil, a little burnt sugar, will make a mixture which the average person can in no way distinguish from claret. This fraudulent mixture is said to be sold in large quantities. Anilin dyes and logwood are said to be used to color wines. The primary purpose of the law is to safeguard the health of consumers, but it is also said that it will serve as a powerful means for retaliation on countries like Germany which have carried the exclusion of our products to an extreme degree. The new law is comprehensive and will be easy to execute, and it is believed that the officials are thoroughly in earnest in their determination to restrict the importation of many fraudulent products.

## NEW YORK.

**Socalled Doctor Fined.**—A person practising medicine in New York City has been fined for illegal practice. He claimed to be a specialist in diseases of men. Although he had no license to practise in the State it is estimated that his income was upward of \$20,000 per annum, while the pharmacist, a one-time baseball player, to whom his prescriptions were sent and who had no license to practise pharmacy, derived an income equal to that of the socalled specialist. The fine was \$50.00, a small deterrent when \$20,000 per annum is at stake.

**Consumptives in Tents.**—The present issue of *Charities* discusses at some length the plan of treatment for consumptives inaugurated during the present summer in New York. It says that June marks the beginning of the third year of tent treatment for special classes of the insane at Manhattan State Hospital, East, Ward's Island, New York City. Stakes are being driven and floors laid for new tents, and not less than 170 patients will be under canvas. The Hospital for Consumptives, opened by the New York Commissioner of Public Charities in connection with the Metropolitan Hospital, Blackwell's Island, on January 31, 1902, which has quickly become the largest hospital for consumptives in or near the city of New York, is adding to its equipment a series of tent cottages. Three of these are already occupied, four others are in process of construction, and still others will be erected as rapidly as practicable. There will be provision for at least 100 men before the end of the summer.

## PHILADELPHIA, PENNSYLVANIA, ETC.

**New Dean at Hahnemann Medical College.**—Dr. Charles M. Thomas, who at present holds the chair of ophthalmology in Hahnemann Medical College, has been elected dean of that institution, to succeed Dr. Dudley, resigned.

**Hospital in Need of Funds.**—The Orange Memorial Hospital is in serious financial straits, and the Finance Committee of the Board of Governors has issued an urgent public appeal for funds. The cost of running the hospital is constantly on the increase, but the income has remained stationary for many years.

**Phipps Institute.**—A second ward has been opened in the Phipps Institute for the cure and prevention of tuberculosis. This will provide a total of 30 beds for the present capacity of the institute. It is asserted that many more beds are needed, and those in charge are pushing the work of extending the institute as rapidly as possible.

**College of Physicians.**—After a protracted discussion the College of Physicians has decided to purchase for \$80,000 the property at the northwest corner of Twenty-second and Chestnut streets, Philadelphia. The purpose is to dispose of by sale and abandon the historic old building at Thirteenth and Locust streets, and build a handsome and extensive structure on the new property acquired, and thus establish an entirely new home for the college. The generous donation of \$50,000 from Andrew Carnegie has enabled the College of Physicians to take this new departure.

**Typhoid and the Schools.**—Director Martin has taken steps which it is hoped will materially decrease the prevalence of typhoid fever in Philadelphia. His work in this particular is directly mainly toward the securing of water free from germs for the public schools. Investigation has shown that many of the schools are unsupplied with filters and that such as are supplied have filters practically worthless. The director has suggested that school children be not permitted to drink water coming directly from the hydrants or spigots about the school-yard and that the knowledge of the efficacy of the boiling of water be impressed upon the school children and their parents.

**Encourage the "Index Medicus."**—The College of Physicians has adopted the following resolutions:

WHEREAS, Through the generosity of the Carnegie Institution, which has pledged \$10,000 a year for three years, the *Index Medicus* has been revived; and

WHEREAS, The *Index* is invaluable to the profession not only of America, but of the whole world, and its permanent establishment is of the utmost importance to the profession at large; and

WHEREAS, If the profession does not support this publication by a general subscription, it cannot be expected that the Carnegie Institution will continue to defray nearly the entire expense of its publication; therefore

Resolved, That the College of Physicians requests each Fellow, if within his power, to subscribe to at least one copy, at an expense of \$5 a year, by check or postal money order, to the *Index Medicus*, care of Carnegie Institution, Washington, D. C.

## SOUTHERN STATES.

**Cambridge Hospital.**—The corner-stone of the new hospital of the United Charities in Cambridge, Maryland, was laid with imposing ceremonies on May 26. The chief guest and prime benefactor of the hospital was John E. Hurst, from Baltimore, and a native of Cambridge. The length of the building is to be 136 feet by 51 feet in width, with wings at each end 36 feet wide. There will be three stories and a basement.

## WESTERN STATES.

**Tornado Wrecks Hospital.**—At Glenwood, Ia., a tornado struck the State Hospital for Feeble-minded on May 25. Two persons were killed and 11 injured.

**Colony for Vegetarians.**—It is said that Edgar Wallace Conable, of Colorado Springs, has purchased 8,000 acres of timber and fruit land in Benton county, Ark., where he will found a vegetarian colony. Colonists will be forbidden to use meat, alcoholic stimulants, or tobacco. The land is favorably situated in the Ozark fruit belt.

**Osteopaths and Vaccination.**—The *Cleveland Medical Journal* for May says: "Dr. Metz, of Cincinnati, applied to the State Board of Health for a decision in reference to the authority of an osteopathic practitioner in vaccinating school children. He claims that an osteopath has no right to perform surgical operations even of minor form. He has been sustained in his claim."

**Contaminated Ice.**—The Bulletin of the Health Department of Chicago says: "Recent ice analysis has shown some of the lakes from which ice has been cut during the winter are contaminated. The ice companies have been notified and are using great care to protect their customers. When contamination is found the ice is sold only for cooling purposes. Typhoid fever was widely spread last year, and the summer hotels situated on these lakes may have had visitors who were convalescing or suffering from the fever. As the sewage sweeps into the lake its waters become contaminated."

**Money to Secure Better Milk Supply.**—An appeal for \$5,000 to cover the expense of inspecting, standardizing, and distributing milk as suggested by the Children's Hospital Commission was authorized by the milk conference, which was held May 27 at the Chicago Women's Club. Dr. Reynolds states that the campaign for purer milk in Chicago had its inception in 1892, when the inspection ordinance was passed. At that time 45% of the milk analyzed was below grade. At the depots only 8% was below grade, indicating that the contamination occurred in the city. There has since been a great improvement in the milk supply of Chicago, though it is far from what it should be at the present time.

**Improving the Milk Supply.**—The Bulletin of the Health Department of Chicago for the week ended May 23 states that notwithstanding the high temperature of the week the effect of the work begun by the department three weeks ago relative to the impure milk supply has been to check the increasing mortality among infants. The daily deaths under one year were as follows: Sunday, 23; Monday, 23; Tuesday, 24; Wednesday, 10; Thursday, 10; Friday, 9; Saturday to noon, 4; a total of 103. During the corresponding last four days of the previous week there were 45 deaths among the same class, the decrease for the present week being 26.6%. The inference is that the agitation has borne fruit and mothers are taking more precautions in the care and feeding of milk furnished. The work on the part of the health department is still in active progress and circulars are being furnished to all homes in the afflicted districts, with specific instructions as to the proper means of preserving and feeding the milk furnished.

## FOREIGN NEWS AND NOTES

## GENERAL.

**Paris Académie des Sciences.**—There is only one German among the members of the Paris Académie des Sciences—Professor Robert Koch, who was elected in place of the late Rudolf Virchow. Of the other six foreign members Austria and America contribute one each—Suess and Newcomb, and England four—Kelvin, Lister, Stokes, Hooker.

**To Use Plague Bacilli as Revenge.**—From London comes a communication that the following has been received from a correspondent in Constantinople: The revolutionary leaders have at the present moment in their possession a large quantity of the Indian plague bacilli, with a dire determination to infect Constantinople, Salonica, and even Berlin. "If within eight days after the warning," they say in effect, "the great Powers do not grant the execution of the Berlin treaty, then we die, but we shall not die alone, for there shall follow us into the grave myriads of people in Europe—Europe which robbed us of our liberty."

**Fish Cause of Leprosy.**—Dr. Jonathan Hutchinson, former president of the Royal College of Surgeons, who has recently returned from a tour of investigation in India as to the cause and prevention of leprosy, has written a letter in which he gives it as his opinion that fish eating is the cause of leprosy. Catholic fast days are responsible, he says, for a great deal of the spread of leprosy. The eating of unsound fish should be prohibited. Wherever Catholic missions are successful, says Dr. Hutchinson, leprosy increases. His calculation is that the risk to a

Catholic convert is twenty-fold that to one who remains in the Hindu faith. He says the Jain, who is a vegetarian, rarely if ever has leprosy, while the Catholic converts suffer fearfully, and he expresses the opinion that this is proof that the disease is noncontagious. Among other measures of prevention he urges the abolition of the salt tax in India to enable the Hindu to render fish wholesome.

#### CONTINENTAL EUROPE.

**Mothers of Large Families.**—Senator Piot has written to Premier Combes proposing that the government accord decorations to mothers of families. The senator says the depopulation of France is a serious menace, and urges that mothers of large families are entitled to equal consideration with firemen, gymnasts, and others who have recently been decorated. M. Piot expects to propose in parliament the creation of a mother's decoration, consisting of a ribbon and cross.

#### OBITUARIES.

**E. C. Wendt**, of New York City, died in Paris, France, May 27. He was an authority on sanitation, and during the past seven years has devoted nearly all his time to studying the methods of sanitation in Europe, especially in Southern Italy. He has written many papers on the subject. He was an editor of the *Medical Review*. After going to Europe Dr. Wendt continued to contribute valuable papers to medical publications in this country.

**John P. Bryson**, of St. Louis, Mo., died recently. He was graduated from the Humboldt Medical College, St. Louis, Mo., in 1868. He was professor of genitourinary surgery in the medical department of Washington University, and surgeon to the St. Louis Mullanphy Hospital. He was a member of the American Association of Genitourinary Surgeons and of St. Louis Medical Society. He was a Founder of *American Medicine*.

**Florence W. Hunt**, in Milwaukee, Wis., May 27. She was graduated from the Northwestern University Woman's Medical School in 1891. She was formerly a member of the Illinois State Board of Health, the American Medical Association, the Chicago Medical Society, and the Illinois State Medical Society. She was neurologist to St. Joseph's Hospital.

**Octavius A. White**, of New York City, May 25, aged 78. He was graduated from the South Carolina Medical College in 1848. He served as surgeon in the Confederate Army during the Civil war. In 1876 he received an appointment by the American Medical Society to go to Savannah and report on the yellow fever epidemic in that city.

**John Reid**, in London, Eng., May 14, aged 80. He first practised his profession in Rochester, N. Y., and then in St. Louis, Mo., afterward going to Chicago, where he stayed a number of years and served several terms as health officer. He subsequently removed to New York City, where he resided several years.

**A. T. Tagert**, of Chicago, Ill., May 27, aged 57. He was graduated from the medical department of the University of Vermont in 1866. He was a member of the American Medical Association, the Chicago Medical Society, and the Illinois State Medical Society. He was president of the Kedzie Hospital.

**H. G. Latham**, in Lynchburg, Va., May 5, aged 72. He was graduated from the University of Virginia, Charlottesville, in 1851. During the Civil war he was in command of the famous Latham battery. He served several terms as president of the Virginia Medical Board.

**Jacob R. Plank**, of York Springs, Pa., May 24, aged 76. He was graduated from the old Washington University School of Medicine, Baltimore, in 1873.

**H. C. McLaurin**, of Brandywine, Miss., May 25, aged 42. He was graduated from the medical department of the Tulane University of Louisiana in 1888.

**Ethan A. Riggs**, of New Orleans, La., May 28, aged 42. He was graduated from the medical department of the Tulane University of Louisiana in 1869.

**Robert M. Euders**, a contract surgeon in the United States Army, died at Manila, May 24.

**John Van Harlingen**, of Brooklyn, N. Y., May 18, aged 57. He was graduated from the medical department of Columbia University in 1869.

**Alfred B. McChesney**, in Chicago, Ill., May 7, aged 75. He was graduated from the University of Michigan, Ann Arbor, in 1853.

**Walter B. Morrison**, in Muskegon, Mich., May 2, aged 65. He was a graduate of the Long Island College Hospital, Brooklyn.

**William Deegan**, in Chicago, Ill., May 6. He was graduated from the College of Physicians and Surgeons, Keokuk, Ia., in 1884.

**James C. Rhodes**, in Stillwater, Minn., May 1, aged 79. He was graduated from the Geneva (N. Y.) Medical College in 1847.

**T. C. Rich**, at Williamsport, Pa., May 27, aged 60. He was graduated from the Jefferson Medical College in 1878.

**James E. Hyslop**, in Keller, Va., May 15, aged 27. He was graduated from the University of Maryland in 1900.

**Andrew J. Lauer**, of Canton, Ohio, May 20, aged 30.

## SOCIETY REPORTS

### SIXTH TRIENNIAL CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

Held in Washington, May 12, 13 and 14, 1903.

[Specially reported for *American Medicine*.]

Sessions of the Congress.

SECOND SESSION.

The subject of this session was the medical and surgical aspects of the diseases of the gallbladder and bile ducts.

**Diagnosis of Affections of the Gallbladder and Bile Ducts.**—JOHN H. MUSSEY (Philadelphia) pleaded for the early recognition of the primary inflammation of the gallbladder and ducts. In his opinion there would be very little seen of the secondary stages if the early ones were recognized. He laid great stress upon laboratory methods of diagnosis, and referred to the presence of leukocytes in these conditions. Among other things with which gallbladder disease is confused, he mentioned cholelithiasis, congestion of the liver, perforation of the intestinal tract, subdiaphragmatic abscess, pleurisy, pneumonia, pancreatic disease, syphilis of the liver, simple abscess of the liver, and primary cancer of the gallbladder. In his opinion there is still much to be learned about hepatic function, and one must rely very largely upon the urine.

**Differential Diagnosis of Diseases of the Gallbladder and Bile Ducts.**—GEORGE E. BREWER (New York) claimed that much of the information obtained in reference to this disease has been due to the conditions found at the time of operation. He divided the subject into (1) calculous disease; (2) inflammatory disease; and (3) newgrowths; and called especial attention to the pain in impacted gallstone. The presence of the gallbladder near the median line, as well as its congenital absence, was referred to, and the cause of the pain in gallbladder disease was believed to be due to inflammatory conditions, although it may be due to pressure and spasm. The most characteristic symptom of cholelithiasis was considered to be the pain, while the most conspicuous symptoms of stone in the common duct were mentioned as jaundice, pain and fever. In the author's opinion inflammation of the gallbladder is present in most cases coming under the surgeon's hands, but a tumor of the gallbladder was rarely found. The three chief symptoms of obstruction were given as (1) pain, (2) tumor, and (3) jaundice, and the fact that gallstones are rarely found in young persons, say under 20, was alluded to.

**Etiology and Pathology of Gallstone.**—C. A. HERTER (New York) first considered the chief constituents of gallstones, which in his opinion are cholesterol and bilirubin. He showed a table giving the results in the formation of cholesterol after injections into the gallbladder, and after mentioning that cholesterol is increased in pneumonia stated that the quantity of this substance in the blood was very little in relation to the quantity in the bile. As to bacteria in gallstones reference was made to the work of Welch, who found *Streptococcus pyogenes*, or the colon bacillus, while a bacterial nidus was found in one-half of the stones. In reference to the artificial production of stone the principal obstacle to its accomplishment was believed to be the flow of bile. Inflammation of the gallbladder, superinduced by ascites and unaccompanied by any infection, is not itself sufficient to give rise to a very marked increase in the percentage of cholesterol in the bile. The author stated that gallstones may be produced, experimentally, by the introduction of bacteria, although he felt there was considerable evidence that we are going a little too far in assuming that all cases of gallstones are due to bacteria and nothing else.

**Diseases of the Gallbladder and the Bile Ducts, with Especial Reference to Diseases of the Stomach and Intestines.**—C. A. EWALD (Berlin). This will be published in a future issue of *American Medicine*.

**A Study of 534 Operations Upon the Gallbladder and Bile Ducts.**—WILLIAM J. MAYO (Rochester, Minn.) commenced his paper with the statement that in nature's defense against infection within the abdominal cavity there are three weak situations, the fallopian tube, the appendix, and the gallbladder, of which the first to gain an accepted surgical position was the infective lesions of the tube. While he considered that the appendix had reached an assured place in surgery he considered that the gallbladder had been slow to receive that attention from the medical public which its importance deserved. He compared the similarity between the appendix and the gallbladder and explained why perforation and sudden death are less frequent in diseases of the gallbladder than the appendix. He showed the relative preponderance of the two conditions according to the age of life of the patient and also the relative frequency of operations upon the appendix, gallbladder, ovaries and tubes, and stomach. The 534 operations upon the gallbladder and bile passages, which formed the basis of this paper, were performed upon 518 patients, with 19 deaths, a mortality of 3.5%. Of the total number 510 were for gallstone disease, with a mortality of 3%. Considering stones in the gallbladder as uncomplicated, there were 208 cases with 2 deaths, a mortality of less than 10%. While in his opinion the colic is

the standard of measure in the diagnosis of gallstones, yet it is but a small part of the clinical picture and is readily diagnosed. While it is known that the large majority of adults with gallstones never suffer it is equally true that these stones only slumber, with the possibility of a painful awakening. The ideal operation, which is complete closure of the gallbladder incision, has been successful in many of these cases of slumbering stone, while the hope of the patient that the stones will pass down and out through the common duct frequently materializes; usually, according to the author, there were more behind, and he has never operated upon a patient who has passed calculi without finding more in the gallbladder. Commenting upon the safety of operations upon the common duct, he claimed that the mortality depended more upon the condition of the patient than any difficulties in the technic, and gave Dr. Robson the credit for the great improvement in the technic. He has met chronic pancreatitis 18 times in connection with gallstone disease and in 4 of them cholecystoduodenostomy was successfully performed, while in the remaining 12 no special treatment was adopted. The average stay in the hospital was slightly less than three weeks, the attempt being to remove all of the stones at the primary operation. Malignant disease of the gallbladder and bile duct was met 24 times, in some of which the exact origin could not be determined. As the presence of gallstones only occurred in 15% of secondary cancers of the gallbladder and in over 80% of primary cancers it was concluded that they were the chief etiologic factors in the production of malignant disease.

## ASSOCIATION OF AMERICAN PHYSICIANS.

[Specially reported for *American Medicine*.]

FIRST SESSION (CONTINUED).

### Artificial Immunity in Experimental Tuberculosis.—

E. L. TRUDEAU (Saranac Lake) referred to the recent attempts at producing artificial immunization against tuberculous infection, and spoke of the work of Koch, Falk, Martin, Dor, Behring, and others. The attainment of a certain degree of toxin immunity did not protect against reinfection, and whatever degree of immunity had been obtained experimentally was due to a bacteriolytic immunity. A living germ was necessary to produce whatever immunity had been obtained experimentally. The great majority of mankind had to some degree a natural immunity against tuberculosis, but it was only relative and maintained only so long as the person was in a good state of health.

**Studies of Mammalian Tuberculosis III: Description of a Bovine Bacillus from the Human Body: A Simple Culture Test for Distinguishing the Bovine from the Human Type of Bacilli.**—THEOBALD SMITH (Boston) described tubercle bacilli isolated from men, cattle, dogs and cats. Some were isolated from the mesenteric lymph-glands of children; one identified as belonging to the human type of bacilli, the other differing from it very much and agreeing in all its characteristics with the bovine type. A test was described for differentiating by means of bouillon cultures these different types. The writer concluded that the bovine bacillus does invade the human body, but that such invasion is rare.

**Discussion.**—OSLER (Baltimore) inquired if any macroscopic differences between the mesenteric glands in the two cases were observed. Creighton had suggested 25 years ago that some cases of human tuberculosis might be of bovine origin, because of the similarity of lesions, whereas really the lesions were unlike those of bovine tuberculosis. SMITH, in closing the discussion, said that he had not seen the autopsies, but thought no macroscopic differences were observed. The case of bovine tuberculosis, however, showed numbers of the bacilli in the mesenteric glands, while the other case did not.

**The Transmission of Bovine Tuberculosis in Milk.**—GEORGE M. KOBER (Washington) said that a number of cases of tuberculosis supposed to be due to infectious milk had been collected and the evidence indicated the agency of the milk of tuberculous cows in the spread of the disease, especially in children, but the writer thought the degree of danger was apparently not so great as was usually supposed. He thought the subject demanded much more study before Koch's conclusions that bovine and human tuberculosis are different and that human tuberculosis can not be conveyed to cattle and that man is insusceptible to bovine tuberculosis, could be accepted, for much of the recent investigation seemed to disprove the claims of Koch.

**Discussion.**—THEOBALD SMITH (Boston) said it was pretty well agreed that there was a difference between the tuberculosis of man and animal, though it was slight, but it remained to be determined how great the difference was. Pathologic difference certainly existed and the immunizing qualities had not established their identity.

**Tuberculosis of the Tonsils, the Tonsils as Portals of Tuberculous Infection.**—HENRY KOPLIK (New York) called attention to the work of Cohnheim, Orth, Strassman, Schlenker, and Kruckmann in this connection, and thought the cases might be divided into those observed clinically and those in

which postmortem examinations had been made. Primary tuberculosis of the tonsil was rare; secondary forms, especially those occurring in pulmonary tuberculosis, were common. With tonsillar tuberculosis there was constancy of occurrence of the cervical lymph-nodes. The writer referred to a number of cases of tuberculosis of the lymph-nodes occurring in children, and said the secondary enlargements of these nodes was of interest only as a complication of tuberculosis elsewhere. Owing to the greater activity of growth of lymph-tissue in children they furnished the largest percentage of cases of tuberculosis of the tonsils. At first it had been thought that these lymph-nodes were infected from below, from the bronchial nodes, and that might exceptionally occur, but as a rule the tubercle bacilli entered the tonsil and infected the nodes from above. Cases of Friedman demonstrated this fact. The writer detailed a number of cases in conclusion.

**A Skin Lesion Associated with Rapid Growth of Long Bones (Les Vergetures de Croissance, Jules Comby).**—W. P. NORTHROP (New York) said that he considered the conditions producing this lesion to be adolescence, typhoid fever, prolonged rest in bed with excessive growth of the long bones. These conditions resulted in fraying, welts, or wales of the skin over the epiphyses of the long bones. Photographs were exhibited illustrating the condition.

**Discussion.**—JACOBI (New York) considered the case as but an example of an excess of what was frequently seen after cases of typhoid fever in a growing child. Epiphyseal hyperemia produced an exaggeration of the normal process; he did not think lying in bed had anything to do with it; it was just the reverse of what was seen in rachitis. OSLER said the condition might not always be attributed to rapid growth, inasmuch as it frequently occurred in adults after typhoid fever. He referred to a friend who had welts come on his back after typhoid, causing considerable deformity.

**The Visceral Lesions of the Erythema Group of Skin Diseases; Third Series.**—WILLIAM OSLER. (Read by title.)

**Dermatomyositis.**—F. FORCHHEIMER (Cincinnati) presented another case of this rare disease and dealt with the classification and etiology of the affection.

**Observations Upon Results Obtained in Infant Feeding with Various Forms of Milk in Tenements and Institutions in New York: Clinical Report.**—L. EMMETT HOLT (New York). **Bacteriologic Report.**—WILLIAM H. PARK (New York). A report upon 600 infants, observed in their homes for a period of three months, was made by the writers. Two-thirds of the observations were in the summer and one-third in the winter. This work was conducted with a view to ascertaining how much the results depended upon the factors of care, surroundings, atmospheric conditions, sterilized or raw milk, and the number of bacteria present in the milk.

## AMERICAN SURGICAL ASSOCIATION.

[Specially reported for *American Medicine*.]

SECOND SESSION.

**The Surgery of the Gastrointestinal Tract.**—Prof. JOH. V. MIKULICZ RADECKI (Breslau) divided his subject into the following topics: 1. Cardiospasm and its treatment. 2. Peptic ulcer of the jejunum. 3. The operative treatment of severe forms of invagination of the intestine. 4. Operation on malignant growths of the large intestine. ZENKER considered the cardiospasm an idiopathic dilation of the esophagus. It consists mainly of a sacculated or fusiform dilation of the esophagus, most pronounced in the lowest portion. The chief characteristic of the lesion is difficulty in swallowing either liquid or solid food; until, in the advanced stage of the affection, only very small amounts of food can reach the stomach. The cause of this difficulty lies in the fact that the esophagus retains a portion of the ingesta, instead of being completely emptied during each act of swallowing, as is normal. In advanced stages this residue amounts to a quarter or even half a liter; and the patient finally dies of inanition. The author has observed about twenty cases. Twenty years ago he showed that in all these cases there exists an abnormal occlusion of the cardiac orifice of the stomach, which he regards as owing to a muscular spasm. While under normal conditions during the act of swallowing the cardiac orifice opens automatically and easily admits the food into the stomach, it remains closed in case of cardiospasm; and this spasm must be overcome by the contraction of the muscular wall of the esophagus. This leads to an eccentric hypertrophy of the esophageal wall; and the organ becomes more and more dilated as the free passage of the food is interfered with. Another consequence of this impeded passage of the food is a chronic esophagitis caused by the decomposition of the contents of the esophagus. Cardiospasm can be definitely diagnosed in the living subject only by means of the esophagoscope. The affection which the author describes is a primary cardiospasm, if no other lesions are demonstrable. There is, however, a secondary cardiospasm which he has occasionally observed in case of carcinoma of the cardiac end of the stomach. This secondary cardiospasm is originally entirely different from the secondary dilation of the esophagus in consequence of actual esophageal carcinoma. Two cases of which he had charge were peculiar in that they

were followed by secondary carcinomas. In each case the carcinomatous growth was found in the first thoracic portion of the esophagus, above the dilation. In view of the insufficiency of all therapeutic measures for the relief of this affection, Prof. Mikulicz advises the following operation:

The stomach is exposed by laparotomy, and in the anterior wall is made an incision long enough to allow the entire left hand to pass into the stomach. Under the guidance of the fingers, which are pushed forward toward the cardiac end, an instrument resembling a glove-stretcher is introduced into the cardiac orifice. Dilation is gradually effected to such an extent that the blades of the instrument are about 7 cm. apart. Thus is caused a blunt dilation of the cardia similar to the dilation of the sphincter and in case of anal fissure. Then the wounds in the stomach and in the parietal walls are closed.

Professor Mikulicz suggests that it would perhaps be better not to make so large an incision into the wall of the stomach, but to introduce the dilator through a small gastric fistula; or an instrument might be constructed which could be introduced into the cardia through the mouth and act as a dilator. 2. *Peptic ulcer of the jejunum* has only recently been observed by surgeons, and only as a sequel to gastroenterostomy performed for benign affections of the stomach, such as gastric ulcer or pyloric stenosis. Moreover, it appears only after anterior gastroenterostomy according to Woelfer's method—but it does not after von Hacker's posterior gastroenterostomy. It may develop during the first weeks after the operation, or it may delay for several months. The general picture of the disease closely resembles that of gastric ulcer; hence most cases were formerly regarded as a recurrence of the original trouble. The ulcer lies either at the point of junction between the stomach and the jejunum, *i. e.*, at the artificial anastomosis, or some centimeters away from the anastomosis, sometimes 10 cm. Peptic ulcer of the jejunum can be explained only by the prolonged presence of gastric juice, which reaches the jejunum without having been normally diluted and neutralized by bile and by the pancreatic secretion. The author believes that after these observations we are not entitled to perform anterior gastroenterostomy any longer—at least, not for benign affections of the stomach. For carcinomatous stenosis of the pylorus it may be considered, being technically the more simple operation. For the benign affections of the stomach we must choose an operation which does not expose the jejunum to the immediate action of the gastric juice, *i. e.*, an operation which restores so far as possible normal physiologic conditions. The most rational method is the pyloroplasty operation. If this is not feasible, we have to choose between gastroduodenostomy, which recently has been advocated by Kocher, and von Hacker's posterior gastroenterostomy. 3. *The operative treatment of severe forms of invagination of the intestine*, when disinvagination is impossible, as advised by Prof. Mikulicz, is that which he first performed in Breslau in March, 1902.

In this case the anterior surface of the distended, edematous, descending colon was sutured into an incision of 20 cm. in the left rectus abdominis. The colon was then opened longitudinally for 12 cm., exposing the intussusceptum, which consisted of two tubes, the outer being colon, the inner ileum. These tubes were in contact with each other on their serous surfaces. In order to avoid all danger of infecting the serous surfaces, the outer and inner layers of the intussusceptum were cut away step by step, and a deep catgut suture was immediately put in to close the peritoneal pocket as soon as it was opened. The mesentery was separated by multiple ligatures. A small strip of iodoform gauze was inserted here, in order to drain the mesenteric pocket into the gut. The resected portion was then drawn out through the abdominal wound, after an unsuccessful attempt to draw it out through the rectum. There was no peritonitis, and the large artificial anus which was left was closed in about eight weeks. The patient left the clinic cured. The same method was used with equal success in the case of a second patient, a woman of 35 years.

4. *As to operation on malignant growths of the large intestine.* Statistics collected up to the present time show that the prevalent method of excision of the tumor and immediate suture of the intestine give very bad results, the mortality varying between 30% and 50%—most patients succumbing to peritonitis. The cause of this phenomenon is found mainly in the secondary changes which take place in the intestinal walls under the influence of carcinomatous stenosis. For a number of years the author has invariably performed the operation at 2 sittings. Of 24 cases operated on only 4 died after the operation; but in none of these cases can the method of procedure be held responsible for the fatal termination. One patient died of pulmonary embolism; 1 of pneumonia; a third, 6 weeks after the operation, of general carcinomatous; and the fourth within 2 days, of peritonitis, caused by rupture of the carcinomatous gut during the enucleation of the tumor.

As regards the technic of the two operations performed by the author, the primary incision, the enucleation of the tumor, the removal of the lymphatic glands—in short, the entire operation—are performed exactly as when one operation only is done. After the tumor has been freed and completely enucleated, it is drawn out of the wound, the loop of gut is stitched to the parietal peritoneum with sutures including only the serous coat, and the abdominal wound is closed, leaving only room enough for the loop of the gut. Now only, after the abdominal cavity is completely closed, is the tumor excised, and an artificial anus is established, which is closed in two to four weeks, according to the usual methods.

In compiling the joint statistics of the author's clinic and that of Körte, it is found that in 24 cases which have been under observation more than 4 years, there are 9 cases without any recurrence.

[To be continued.]

## AMERICAN GYNECOLOGICAL SOCIETY.

[Specially reported for *American Medicine*.]

SECOND SESSION (CONTINUED).

**Ureterocystotomy.**—J. W. BOVÉE in a previous paper had recounted 80 cases, which, together with his own, had been reported. He now brings the number to 111, and reports three cases of his own, all of which were successful, and all done by the abdominal route. Indications for the operation are ureterovaginal fistula from whatever cause, abnormal orifices, resection of the ureter for malignant disease, etc. Should fistula develop after operation for malignant disease 8 to 12 months should elapse before operation for its cure should be undertaken, as recurrence of the disease is probable, and the operation would have been useless. If the proximal severed end of the ureter is below the ileopectineal line it should be implanted into the bladder; if above, it may be implanted into the other ureter; if but slightly above, the kidney of the same side may be depressed to permit implantation into the bladder. The principal complication is infection. The mortality in the 80 cases was 8%; in the 111 cases 6%. Continuous drainage from the bladder is very essential. GEORGE H. NOBLE (Atlanta) called attention to the firmness with which the ureter is held in the areolar tissue beneath the peritoneum. Ordinarily it can be drawn down but little. In a case detailed he incised the peritoneum for 6 cm. (2½ inches) on each side of the ureter, loosened the same, and was thereby able to gain about 2½ cm. (1 inch). Important points are secure implantation, a tight joint, and continuous bladder drainage.

**Discussion.**—POLK said that bladder implantation of the ureter must inevitably lead to constriction and stenosis, and result in pathologic renal changes. Ureteral anastomosis is to be preferred to ureterocystotomy whenever possible. REUBEN PETERSON reported that he operated for an intraligamentous fibroid and without his knowledge injured the ureter. A fistula developed, and a ureterocystotomy was done, which resulted in the death of the patient. We should warn our patients that the operation is attended with danger. BOVÉE closed by stating that insisting on peritoneal drainage whether we operate by the transperitoneal or extraperitoneal route. He described the technic of several operations.

**Occurrence of Gallstones in Insane Women.**—W. P. MANTON stated that sedentary life, bodily inactivity, and supposedly torpid livers of the insane should theoretically conduce to the formation of gallstones. He began to investigate the subject some five years ago, but as yet his statistics did not embrace numbers sufficiently large to be of value. Among 133 deaths among insane women in the hospital with which he is connected he could obtain but 23 necropsies owing to the ignorance and prejudice of relatives of the deceased. State laws should permit autopsies to be held on the dead bodies of all who have been gratuitously cared for by the State. He found gallstones in 26% of those autopsied.

**Excision of the Proximal Ends of the Fallopian Tubes at Their Origin in the Uterus the Operation of Choice for the Extremely Rare Cases Wherein Sterility is Desirable.**—PHILANDER A. HARRIS said this is to take the place of the Porro operation, of bilateral removal of the ovaries, and of bilateral excision of healthy tubes. Menstruation will not be sacrificed. Every advantage arising from retention of the ovaries will be preserved to the individual, excepting the single item of impregnation. Tubes thus disconnected from the uterus will probably remain immune from future gonorrhoeal infection of the endometrium. A patient thus sterilized can doubtless be cured of her sterility by implantation of the tubes through the uterine cornua to the uterine cavity. While there are doubtless cases which are characterized by certain conditions of the body, mind or nervous system calling for the voluntary production of sterility, there must necessarily be a very limited field for the employment of this operation. If a case is to be surgically sterilized it should be effected in such manner that the patient and her friends may feel that she can be restored to fertility should the pathologic factors of her case so abate or disappear as to render impregnation and pregnancy permissible. No attempt will be made to present the indications for an operation which produces sterility for temporary purposes, although such instances are believed to be within the range of possibility, and if so, they emphasize the advantage of doing the primary operation in the manner proposed.

**Operation on Diabetic Patients.**—C. P. NOBLE (Philadelphia) reported that he had operated on 7 women with diabetes mellitus, of whom 6 recovered and 1 died of diabetic coma. So far as his experience goes, no preoperative treatment appears to reduce the danger of diabetic coma which, however, occurs less frequently than would be supposed. He has collected 62 cases from literature, operated upon; 14 of these were breast cases, 17 abdominal cases, and 31 were pelvic cases; of these 52 recovered and 17 died (25%), the chief cause of death being diabetic coma.

**Officers Elected.**—President, Edward Reynolds, Boston; first vice-president, Whitridge Williams, Baltimore; second vice-president, E. P. Davis, Philadelphia; secretary, J. Riddle Goffe (re-elected), New York; treasurer, J. M. Baldy, Philadelphia. Retiring president Joseph E. Janvrin was elected a member of the council. The next meeting will be held in Boston.

[To be continued.]

## AMERICAN ASSOCIATION OF PATHOLOGISTS AND BACTERIOLOGISTS.

Third Annual Meeting, Held in Washington, May 12, 13 and 14, 1903.

[Specially reported for *American Medicine*.]

### THIRD SESSION.

**Blood-plates and Their Possible Relation to Coagulation of the Blood.**—F. H. PRATT (Boston) has used a modification of Vierordt's apparatus for the determination of the coagulation time, and has used a solution in water of sodium metaphosphate to permit of the counting of the blood-platelets. The study has shown a marked variation in the number of the plates in blood taken at different times from the same individual. No relation between number of plates and time of coagulation could be ascertained. The plates disappear at coagulation and disappear from the blood of an animal injected with albumose.

In the *discussion* LOEB (Montreal) says that normal lymph will coagulate, and yet it contains no plates. This coagulation of the lymph is also inhibited by the injection of peptone.

**Some Experiments Relating to the Influence of Innervation Upon the Course of Inflammation.**—S. J. MELTZER and CLARA MELTZER (New York) dealt with the influence upon the course of an inflammation of section of the sympathetic as compared with the influence of the extirpation of the third cervical ganglion. An interesting detail of technic is the use of subcutaneous injections of adrenalin chlorid to produce the inflammatory reaction. The conclusion of the paper is that the sympathetic carries nerve fibers which control the anabolic processes in the ear, while the ganglion carries the fibers presiding over the katabolic processes. Therefore, when the sympathetic is cut the katabolic fibers can continue in their function, unopposed by the action of the anabolic fibers, and the course of the inflammation is favorably influenced by the increased tendency to katabolism.

**A Preliminary Report of an Experimental Study on the Action of the Pneumococcus in Animals, with Special Reference to the Pneumonic Processes.**—AUGUSTUS WADSWORTH (New York). The difficulty with all inoculation experiments heretofore has been that the pneumococcus has set up a general septicemia in the inoculated animals. After many control experiments Wadsworth has tried the ingenious idea of immunizing animals against the pneumococcus and then subjecting them to intratracheal infection, with the idea of giving the animals a sufficient resistance to escape the septicemia. His experiments have thus far been successful, if the proper relation of immunity to virulence of the inoculation culture was observed. Wadsworth demonstrates the lungs of several rabbits thus treated, which show apparently a typical pneumonic infiltration.

**Tuberculosis of the Placenta and the Occurrence in the Fetal Circulation of Thrombi Containing Tubercle Bacilli: Microscope Demonstrations.**—A. S. WARTHIN and D. M. COWIE (Ann Arbor) detailed the case of a woman with acute miliary tuberculosis, in whom abortion occurred the day before death in the seventh month. Placenta and fetus showed no macroscopic lesions, but the microscopic examination showed that the placenta was filled with thrombi, composed of red blood cells or possibly of blood-plates, which thrombi contained great numbers of tubercle bacilli. The thrombi occurred chiefly in the intravillar spaces. Of interest was the behavior of the syncytial cells, which seem to have been especially resistant to the tuberculous process, since in many instances they had grown over and around the thrombi. The giant cells of the thrombi Warthin thinks were composed of leukocytes. Great numbers of the tubercle bacilli were found in the bloodvessels of the liver of the fetus. The fetal tissues seemed especially resistant to the growth of the organism. Warthin thinks that congenital tuberculosis is possible, and should be considered as a possibility. In this case the presence of the bacilli was demonstrated both in sections and in inoculation experiments.

In the *discussion* BALDWIN (Saranac Lake) touched upon the behavior of the bacilli in immunized animals, and suggests the possibility that this fetus was immunized.

**The Bacteriolysis of the Tubercle Bacillus.**—E. R. BALDWIN (Saranac Lake) has used a method of saturating the sera to be tested with emulsions of tubercle bacilli, and then testing the hemolytic value of the serum. The theoretic possibility of such a procedure was not made clear. Baldwin thinks that he has evidence of the existence of a specific immune-body in his immune sera.

**Morphology of the Tubercle Bacillus, with Lantern Slide Demonstration.**—S. B. WOLBACH and H. C. ERNST (Boston) gave a detailed description of the methods used in the cultivation of seven bovine and four human strains. In the lantern demonstration, especial attention is called to the presence of certain round bodies, occurring side by side with the ordinary vacuolated appearance of the tubercle bacillus.

**A Hitherto Undescribed Fibrillar Substance Produced by Connective Tissue Cells Illustrated with Diagrams.**—F. B. MALLORY (Boston), by the use of a special method, has been able to demonstrate the presence in rapidly growing con-

nective tissue of a new form of fibril, which seems to lie upon the exterior of the cell; these fibrils extend in all directions, and are of interest in their relation to the basement membrane. These fibrils follow the development of the connective tissue, are acidophile, and do not branch.

In the *discussion* WELCH (Baltimore) emphasized the work of Mallory in extending our knowledge of the connective tissue substances, and asks regarding the possible value of these fibers in the differentiation between certain types of tumors. MALLORY replied that his studies have not been carried far enough to enable him to say if any diagnostic value is to be attached to them in pathology.

**A Case of Gigantism with Leontiasis Ossea, with Lantern Demonstrations.**—PETER BASSOE (Chicago). This was reported by E. R. LECOUNT. The case is one which has been brought before the medical profession several times before—that of the giant Wilkins, reported in 1893 by Dana. Lamberg next reported the case, and considers it a case of akromegaly. Sternberg opposed this diagnosis, and again later in his article in Nothnagel's work, where he states his view that the case is one of pathologic growth, but not akromegaly. Wilkins was admitted to the Presbyterian Hospital, Chicago, for surgical relief for blindness, but died soon after admission of amebic dysentery. Bassoe reports as a matter of interest that the small intestine was 60 feet in length. The autopsy showed a soft tumor of the base of the skull, which nearly filled the anterior fossa. The brain shows a corresponding atrophic area. The tumor is a spindle-celled sarcoma. The hypophysis was not enlarged. COPLIN (Philadelphia) demonstrated a lantern slide of an endothelioma of the pituitary body.

**Demonstration of Specimens from a Case of Dermatitis Gangrenosa Infantum, with Microscopic Specimens.**—E. R. LECOUNT (Chicago) gives the history of the case and discusses certain of its bearings. *Staphylococcus pyogenes aureus* was isolated from all the skin lesions, also obtained from the kidney, the pleural cavity, and the peritoneal cavity.

**Observations on the Distribution and Culture of the Chaneroid Bacillus, with Lantern Demonstrations.**—L. DAVIS (Boston) discusses the cultural characteristics of the bipolar staining organism first described by McCrae as occurring in soft chancres. Davis succeeded in obtaining pure cultures from eight cases by cultivating upon media which contained fresh blood or by cultivating in fresh human blood. Old media do not give results. Davis reports positive inoculation experiments on the monkey. Two interesting cases were of chancre of the hand, independent of genital affection.

**The Nonidentity of Agglutinins Acting Upon the Flagella and the Bodies of Bacteria.**—THEOBALD SMITH and A. L. REAGH (Boston) have made a comparative study of the sera produced by immunizing an animal with a motile specimen of the hog cholera bacillus and of the serum of an animal immune against a nonmotile bacillus of the same group. Their conclusions are, in short, that there are two different agglutinins, one acting upon the flagellas and one acting upon the bodies of bacteria. A serum produced by immunization with a motile form will not agglutinate a nonmotile form, unless used in a much greater quantity than that necessary to produce agglutination of the motile form.

In the *discussion* BERGEY (Philadelphia) thinks that his own work would not justify any such conclusion.

[To be continued.]

## AMERICAN ORTHOPEDIC ASSOCIATION.

[Specially reported for *American Medicine*.]

### SECOND SESSION (CONTINUED).

**Observations on Hip Diseases as Seen in Hospital Out-patients.**—AUGUSTUS THORNDIKE (Boston) is of opinion that the poor results obtained from hospital out-patients are due largely to their ignorance and poverty. Patients come for treatment in homemade apparatus consisting of straps, buckles, etc., and return for continued treatment at their own good pleasure rather than at regular intervals. Of 55 cases coming to the children's out-patient clinic 11 years ago 17 had involvement of the right hip, 36 the left, and 2 both. All under 12 years of age are received; the favorite age for development being from 2 to 7 years. Symptoms are usually noticed early by the family and the patients are usually brought to the hospital at once or before a month or so has elapsed, while in former years children were frequently left untreated for years, thus proving the rapid advance of orthopedics. The length of time treatment lasted ranged from 18 months to 11 years, the splint being withdrawn intermittently. It is safer to leave the splint on too long than risk relapses by too early removal. The Taylor long-traction splint was used in the majority of cases, the author preferring the Thomas double splint in a few cases, and these discarded later for the convalescent splint. There was no prolonged recumbency. Bed frame and traction were used for a few weeks mostly. Results were as follows: Permanent deformity and shortening in 20%, the average shortening being 1½ inches, and all those over a shortening of 3 inches were due to some peculiar condition as a long trochanter, etc. Motion usually resulted even in the irregular patients and began as a rule after discarding the apparatus. Amount of motion in 32 was over 20° and in 23 less than 20°. None was

deprived of walking, but did so without aid. These good results he believes were due to early recognition and treatment (thus avoiding suppuration); employing traction and persistence in looking after details of the treatment.

**The Forcible Reposition of Congenital Luxation of the Hip.**—GWILYM G. DAVIS (Philadelphia). To be published in *American Medicine*.

**Peripheral Palsies Following Manual Replacement of the Congenitally Dislocated Hip.**—HENRY LING TAYLOR (New York) is of opinion that since Lorenz's visit to this country more force has been used to reduce the dislocation and stretch the contracted tissues, and the position of retention is more extreme. In many cases observed by him it was noticed that some patients did not get up and walk. This, upon examination, was found to be due to paralysis of the quadriceps. As Lorenz says, this is not an uncommon sequel of the operation, and in fact occurs in all for the first few weeks. The paralysis is easily overlooked if the patient is not made to walk or tested for this condition by placing in the vertical position, allowing the leg to hang. He has observed 12 cases of palsy of the quadriceps, only 4 being in patients over 6 years of age; all recovered completely; 2 sciatic palsy, 1 in a patient 10 years old who recovered; the other, 13 years of age, shows a faint trace of returning power. These peripheral palsies are a common cause of the difficulty in walking experienced by some patients, the sciatic being less common and less favorable as to recovery.

**Discussion.**—RIDLON (Chicago) reported 27 cases operated upon, with 6 failures, including 2 cases in which fractures occurred. Palsy of the sciatic nerve was found in 1 case in which the patient has not recovered. Of 4 casts removed the results have been good; these were mostly anterior transpositions. Three other Chicago cases have been equally successful. MCKENZIE (Toronto) states the prognosis as double dislocations, 25%; single dislocations, 50%, and therefore recommends not being too ready to operate, for patients are often greatly benefited by nonoperative methods. STREELE said that Lorenz uses traction for a considerable period prior to operating, and thought his success in America would have been greater had this been possible.

**The Scoliotome, a Machine for Elongating the Spine and Lessening the Rotation in Lateral Curvature.**—COMPTON RILEY (Baltimore) says the external oblique is the principal muscle figuring in this deformity, the other muscles by their attachment and nearness being unable to cause the condition. In all lateral curvatures there is noticed a marked inequality of the sides of the pelvis, the anterior superior spines and the crests always differing. This may be due to numerous conditions, such as rickets, short leg, faulty attitude, etc., but in every case lateral curvature is a secondary condition, the primary cause making the pelvis unequal, overstretching the muscles on one side, which in turn pull the ribs with them. Treatment: (1) Overcome the cause; (2) stretch the weakened muscles (Swedish movements); (3) use the scoliotome, which consists of a square frame, a rack for the patient, and a weighted strap to overcome the deformity. With it any amount of force can be used at any desired angle without any exertion on the part of the physician.

**Discussion.**—R. W. LOVETT (Boston) exhibited an ingenious folding board for home use in lateral curvatures. It answers the purpose of more complex apparatus at a small cost, and is used in the home by the patient. It consists of a folding board with three belts worked by pulleys and ropes. The patient lies prone and uses any amount of force necessary to produce the correction. N. M. SHAFFER (New York) believes the cause is due to: (1) Anterior poliomyelitis; (2) unequal development; (3) growth following in the line of least resistance. Treatment: Ankylosing the articular processes, thus preventing further development though not curing already deformed spine. LOUIS A. WEIGEL (Rochester) treats the condition by straightening with force, and holds the position thus gained by an enameled paper cast.

## AMERICAN DERMATOLOGICAL ASSOCIATION.

[Specially reported for *American Medicine*.]

FIRST SESSION (CONTINUED).

**Syphilis and the Medical Secret.**—P. A. MORROW said that from the ethical standpoint it is necessary that the physician keep the medical secret of his profession to the utmost in most diseases, and especially is this true when dealing with syphilis because of the private nature of the disease. Only by so doing and by virtue of this does the patient have the utmost confidence in the physician. The law has made the failure to keep this confidence an offense, and at the same time the physician is obliged to report all cases which are dangerous to public health. Syphilis certainly comes under this classification. In order to treat the case correctly the physician must direct his conduct in the line of duty. The interests of others must be considered as well as that of the patient, and especially is this true if the patient is a married man. The wife and children as well as those with whom he comes in contact must be protected. In many cases when the patient is a young man he goes to the physician for advice in regard to marriage, etc. It is distinctly

the duty of the physician to tell the patient of the dangers of the disease in marriage and he should use every means possible to prevent such marriage. Until he has done such he has failed to do his duty and is committing a moral and legal crime. It is his duty on the one hand to protect his patient and on the other hand to defend the innocent woman from the disastrous injury to herself and offspring. Here is a crime contemplated but not completed and the physician is the only person who can prevent it. The physician very often stands back and says nothing. His conscience as well as his professional code should guide him in his conduct. There are no circumstances in medical practice so painful as to see a syphilitic man infect an innocent woman in marriage. It is a sanitary duty to keep syphilis and marriage apart and the law backs up the sanitarian. The medical man feels the situation and his conscience makes him feel as an accomplice in the crime. Few patients when enlightened and warned on the subject postpone marriage. The physician owes it to his profession to use every available means and many patients could be brought to see the dangers and act accordingly. While some criminal monster may endanger the physician as to practice, and even as to life, yet in the face of all this the physician should be loyal to his profession. In many instances it is best to inform the innocent woman of the situation, and an understanding can usually be brought about. After marriage the physician should not tell the wife of the nature of the disease; it will spare mental anguish and worry. The patient should not confess either, but should persist in the treatment. The syphilitic child introduces a dangerous contagion, which is generally multiple. In France the wetnurse must be notified by the attending physician of the nature of the child's disease; it must then be insisted that the syphilitic child's mother nurse her offspring. When this is impossible, artificial nourishment must be resorted to. The drynurse is also exposed to danger, but not so much as a wetnurse. She should also be informed of the danger so that greater care may be taken on her part and those with whom she comes in contact. The child may be healthy and the nurse syphilitic, so the physician should examine both wetnurse and drynurse for evidence of the disease and if found they should give up their employment and situation.

**Discussion.**—T. C. GILCHRIST said that syphilis should be taken on the same standpoint as variola, for it is certainly a contagious disease. The sooner we can educate the people to recognize the danger of the contagion the better off the community will be. EUGENE FULLER said the specialist looks out for himself and does not regard others. He did not think it was good policy for the physician to interfere in marriage, as he gets very little thanks for his painstaking. Very few take it kindly. He thought legislation should take a hand in regard to marriage as well as to syphilitic servants and nurses. H. W. STELWAGON thought that before hospitals get their appropriation they should be bound to receive and treat syphilitic patients. This is a means of spread of the disease. He also thought the physician was to blame, as he very often belittles the disease; the patient is laughed at and made the subject of a joke. The contraction of syphilis is anything but a joke.

SECOND SESSION.

**Dermatitis Venenata: A Supplemental List.**—JAMES C. WHITE (Boston) said that this is a partial list of the substances noted since he had published his book which have been known to produce dermatitis: Chlorhydratparaphenyldiamin, orthoform, salol, aristol, ichthyol, resorein, dermatol, euprophen, pyocetanin, creolin, iodvasogen, kerosene, electricity, "aurantia," coccuswood, guaiaicum, humulus, heracleum, angelica, hyacinth, ginkgo tree, cotoneaster, humea; while among the suspected agents are tecoma and ampelopsis. He reported a case of dermatitis from ginkgo tree which he saw in November. This tree is a native of China, and is grown in this country for its foliage. In this case a woman gathered the fruit, which was let stand for four days, when she washed the fruit in water, roasted it and gave it to the children to eat. While she was washing the fruit she noticed some itching of the hands and arms; on the second day the itching became intense and appeared on the face. A marked dermatitis could be seen. She was treated with lead acetate, and relief was obtained. There was no rhus toxicodendron about the yard or house, and no firewood was handled by the woman. Later another case with similar symptoms occurred under similar circumstances. In the Southern States the Virginia creeper has produced marked dermatitis. The trumpet vine has also produced it, and the dogwood has been accused in different instances as a cause, also the small laurel. Other cases are reported from handling green fruit of pawpaw, dog fennel, various molds, and radish tops, pollen of life everlasting. He was of the opinion that blonds were more susceptible than brunets. Homatropin, as used by amateur photographers, has been known to produce a dermatitis of the hands.

**Report of a Case of Symmetrical Gangrene.**—E. B. BRONSON (New York) reported the case of a young lady aged 17, of neurotic family and of nervous temperament, ambitious, but distinctly no hysteria, who 3½ years ago had an affection of her legs; various pains, at times severe, or vague, or burning, but at times lancinating in character. These came on at varying periods, and were always accompanied by erythema. The lesions remained at the same place and were at same

area on both legs, occupying a space  $1\frac{1}{2}$  inches long, oval, at the middle and lower third of anterior surface of tibia dusky red in appearance, looked more like venous than arterial congestion, and was of a deeper hue in the center. Later it looked "bleb-like," as if it had been blistered, was kept under observation for one month, and no change whatever was noticed. She then disappeared and came back in three years with the same symptoms, and the same area was involved, except that it was a little larger and showed more evidences of cyanosis, especially at the center. The patient stated that four months previous to her return she had gone to a surgeon who exposed the areas to moderate x-ray, making six exposures, with the result that the lesions were worse and the pain was worse. About this time decided evidences of gangrene began, beginning on the outskirts of the ulcerated area, which gradually spread until the space occupied was exactly the same on both legs. After waiting for four weeks a papular erythema appeared over the entire body with intense pruritus. The gangrenous area was operated upon, the sloughs removed and the legs treated with silver foil. The area began to heal, and several skin grafts were made. The area healed perfectly, and since then there has not been any pain or erythema. Hysteria is distinctly contraindicated in this case. Raynaud's disease was thought of, but was doubtful because of the peculiar area involved, absence of the prominent symptoms and no pallor. Only the cyanosis in its favor.

*Discussion.*—S. POLLITZER thought this should be classed in a subdivision of Raynaud's disease—the cyanotic form—the cyanosis bringing about thrombi, thus accounting for the gangrene.

[To be continued.]

## THE AMERICAN OTOLOGICAL SOCIETY.

[Specially reported for *American Medicine*.]

SECOND DAY.

**The Effects of Increased Intratympanic Pressure: A Possible Explanation of Tinnitus Aurium.**—H. O. REIK (Baltimore) called attention to a paper which he read before this society at its last meeting, presenting some physiologic experiments to show the cardiac and vascular effects of operations upon the middle ear. These experiments tended to show that operations upon the membranes or ossicles always produced a depressor effect, an unusual result to follow the stimulation of a sensory nerve, and that the lowering of blood-pressure and the duration of the period of depression was always in direct proportion to the amount of injury inflicted. This fall of blood-pressure that immediately follows any injury to the tympanum was shown to be due to the disturbance of the vasomotor apparatus and to account for that cardiac depression and syncope that so often accompany operations upon the middle ear; phenomena that had been erroneously attributed to disturbed equilibrium due to increased intralabyrinthine pressure. Following in this line of work Dr. Reik had attempted to determine the effect of increased intratympanic pressure as measured by changes in the pulse-rate and blood-pressure. The method of procedure was to inject fluid into the middle ear through a catheter fastened in the mouth of the eustachian tube. A mercury manometer was attached to the tube so that the pressure exerted within the tympanum at any given moment could be accurately recorded. At the same time the kymographion was registering the pulse-rate and blood-pressure. Charts were exhibited to show that any increase of pressure upon the fluid within the tympanum, in fact even the weight of that fluid, so small in amount, immediately causes a falling of the blood-pressure and of the pulse-rate and the greater the pressure exerted the greater will be the degree of depression and the longer will the effects be felt after withdrawal of the pressure. It seemed fair to conclude that any foreign substance, such as a pathologic exudate, whether it fills the tympanum or merely irritates the mucous surface of the tympanic membrane or tympanum walls, will produce a vasomotor disturbance. Dr. Reik then called attention to a suggestion made long ago that tinnitus aurium might be due to the appreciation of sounds produced by the circulation of the blood in the vessels in or bordering upon the tympanum and quoted from a paper on "Tinnitus Aurium," published some years ago by Dr. Samuel Theobald, who said: "I have been led to the conclusion that in almost all cases tinnitus aurium is to be attributed to the existence of vibrations excited in the walls of the bloodvessels by the friction attending the circulation of the blood." Both Dr. Theobald and Dr. Reik expressed the conviction that the generally accepted theory of increased intralabyrinthine pressure failed to explain the etiology of tinnitus in the majority of cases, since there is no reason to assume that in the majority of cases of tinnitus increased pressure in the labyrinth exists. Dr. Reik believed that his experimental work substantiated the hypothesis put forward by Dr. Theobald many years ago and that tinnitus aurium is the result of vasomotor disturbances in the middle ear and labyrinth produced by irritation of the tympanic mucous membrane, the blood supply of both regions being intimately associated by anastomosis and controlled by the same nerves.

**A Case of Thrombosis of the Sigmoid Sinus, with Unusual Complications.**—GORHAM BACON (New York).

The most interesting point in the discussion of this subject turned upon the question of ligation of the internal jugular, in cases where the sigmoid sinus is involved.

*Discussion.*—JACK and CROCKET advocated the early ligation of the jugular in every case of sinus thrombosis, believing it to be an easy operation, which affords greater safety to the patient in diminishing the chances of conveying infection to other parts of the body and an operation that should be performed too soon rather than too late. Bacon believed that the operation was often more difficult than is generally supposed, and that in many cases it was not necessary, since the patient would recover without it, and he was not sure that its performance did not occasionally detract from the chances of success.

**A Study of the Surgical Relations of the Facial Canal.**—B. ALEX. RANDALL (Philadelphia) said that an examination of 500 skulls showed but a single instance in which there was a notable outward deviation of the canal. There was a group in which an apparent outward deviation was due solely to overlapping of the paramastoid process upon the stylo-mastoid, giving the canal an apparent outward course, although it was really vertical. In 60% of all cases no deviation from the vertical could be detected, and he felt warranted in reiterating his claim that in the vast majority of cases the descending portion of the facial canal is exactly or practically vertical, and that variability of course, as claimed by Schwartz, is of extreme rarity, if, indeed, it actually occurs in any degree demanding surgical consideration. The course of the canal was found to have no relation to the edge or cranial index of the skull.

**A Case of Aural Fibroma.**—BRYANT (Boston) said that this patient had been seen by several physicians and different diagnoses made, varying from a ceruminous plug to an exostosis. The mass in the canal was removed, and microscopic examination proved it to be a fibroma having rather large cells with elongated nuclei, the cells being arranged in columns and some of them undergoing hyaline degeneration.

Under the heading, **exhibition of new instruments**, BULLER (Montreal) exhibited a new contrivance for the more perfect and satisfactory inflation of the middle ear by Politzer's method; and JACK (Boston) exhibited a new mastoid retractor which he believed of value, because it could be quickly adjusted, easily kept in place, and holds the lips of the wound wide open.

**Officers Elected.**—President, B. Alex. Randall, Philadelphia; vice-president, Wm. H. Carmalt, New Haven, Conn.; secretary and treasurer, Frederick L. Jack, Boston.

## AMERICAN OPHTHALMOLOGICAL SOCIETY.

[Specially reported for *American Medicine*.]

FIRST SESSION (CONTINUED).

**Why Not Employ Intracapsular Irrigation in the Extraction of Cataracts?**—H. O. REIK (Baltimore) called attention to the very slight references to this operation in the recognized textbooks, and to the fact that these references were generally of a discouraging character, while a review of the literature showed that every operator who had properly employed the method was on record as an enthusiastic advocate of its employment as a routine measure. He stated the belief that many operators had feared to employ the method solely on the ground of theoretical objection, and that those who had condemned it had either failed to properly employ the apparatus and the method as set forth by McKeowen or had made an unsatisfactory attempt at the operation with inefficient apparatus. He called attention to the monograph published by McKeowen in 1898, and described the operation as performed by that surgeon. It has been claimed for intracapsular irrigation after extraction of the lens nucleus that it improves the chances of securing a successful result, diminishes the probabilities of concurrent iritis or keratitis, and lessens the number of secondary capsular cataracts, and consequently the number of dissection operations. Dr. Reik stated that he brought the question forward in order to ascertain whether there were any well-grounded objections to the employment of this measure, and after quoting from the published experiences of McKeowen, Lippincott, and others, he stated that his own experience with the operation had been entirely satisfactory and led him to believe that the employment of intracapsular irrigation properly was an improvement in the technic of cataract operations.

*Discussion.*—LIPPINCOTT referred to several papers he had published on this subject, and said that after 15 years' experience he now used irrigation for the removal of cortical matter in 90% of his cataract operations; in other words, in all cases except those in which there was threatened or actual escape of vitreous, or where the lens came out in its capsule. He had met with no disadvantages from the use of irrigation, and believed that its employment secured more benefits even than were mentioned by Reik. He quoted statistics from an additional 100 cases, not previously reported, showing the same good results as he had heretofore claimed for the operation. Dr. Lippincott exhibited an instrument which he had himself devised for the operation and which he believed had served him better than the original McKeowen apparatus. GRUENING said that the operation had never appealed to him, that he

believed he could empty the anterior chamber without irrigation, and that there was some danger in its use. HOLT replied that he had used irrigation for 14 years and could not agree with Dr. Gruening that it was at all dangerous. "With proper manipulation of the apparatus there is no danger to come from it, and I still think that by the use of irrigation you not only lessen the amount of irritation about the eye, but secure better results." RISLEY said that he had in the past made some adverse criticism of the operation, but that he was going to try it again, inasmuch as he was convinced that he had not given it a fair trial because he had not been employing the proper apparatus.

**An Interesting Case of Retinitis Pigmentosa.**—WALTER L. PYLE (Philadelphia). This will appear in future issue of *American Medicine*.

**Leukosarcoma of the Choroid.**—T. R. POOLEY (New York) exhibited a specimen of nonpigmented sarcoma of the choroid occurring in a man aged 35. When he first came under observation he presented the typical features of absolute glaucoma, and an iridectomy was performed. Later a fresh hemorrhage into the anterior chamber occurred, accompanied by pain and increased tension, and enucleation became necessary. Microscopic examination showed a typical small rounded sarcoma of the choroid.

**Discussion.**—MARPLE said that he had seen a case of leukosarcoma situated near the papilla in a patient only about 35 years of age. Both the situation of the tumor and the age of the patient were contrary to the general rule.

**Are Tenotomies for Hyperphoria Necessarily More Uncertain in Their Results Than Those for Esophoria and Exophoria?**—SAMUEL THEOBALD (Baltimore) related a number of case histories to show the varying results following the same operation, as nearly as he could regulate it, for hyperphoria. In some instances a tenotomy of the verticle muscle would secure a change of only four or five degrees, while in another instance it would amount to as much as 15° to 18°. He had sometimes found, too, that a slight over-correction gave the patient more discomfort than the original trouble operated for.

**A Case of Panophthalmitis Following Dissection of a Capsular Cataract.**—L. H. TAYLOR (Wilkes-Barre) had operated upon this patient for cataract in both eyes, and later performed a dissection operation upon the capsule. He believed his technic had been perfect in every respect, and yet infection followed necessitating enucleation.

**Discussion.**—MATTHEWSON, BRUNS, KNAPP, and RISLEY all reported somewhat similar cases, and Knapp called attention to the fact that there must be in such cases some infective material on the cornea just at the point where the knife is entered and thought that the operator should not blame himself since it is impossible to sterilize the eye perfectly, and there had been no fault in his own technic. LIPPINCOTT suggested the advisability of closing the puncta in all such cases by filling the conjunctival sac with a melted ointment of mercuric chlorid, since infection might come from the nose.

**Officers Elected.**—President, Chas. Steadman Bull, New York; vice-president, Arthur H. Matthewson; secretary and treasurer, S. B. St. John. A committee was appointed to confer with a similar committee from the Otolgical Society to determine the next place and time of meeting.

## AMERICAN MEDICAL ASSOCIATION.

Fifty-fourth Annual Meeting, Held at New Orleans, La.,  
May 5 to 8, 1903.

[Specially reported for *American Medicine*.]

### Section on Practice of Medicine.

FIFTH SESSION (CONTINUED).

**The Passing of Chronic Rheumatism.**—J. J. WALSH said most persons under 40 think they have had rheumatism, when in fact few have had. Doctors are to blame for this prevalent error. Osteopaths depend for their clientele upon those who have been erroneously treated for chronic rheumatism. The latter arises only from repeated attacks of acute rheumatism. Four different painful conditions are often erroneously diagnosed chronic rheumatism: 1. Relaxed ligaments, as in flat-foot, at the shoulder or knee joint. 2. Occupation neurosis; almost any occupation may lead to some form of neurosis, and the pain is usually worse in rainy weather. 3. Neuritis; as for instance in the group of shoulder muscles, when they are exposed or overworked, pain will be felt in the joint because the circumflex nerve sends trophic fibers into the joint. 4. Gout is often mistaken for rheumatism, and it is much more common in this country than is generally supposed. It is only about 25% less frequent here than in England, and is especially common in lead-workers and beer-drinkers; and arthritis deformans, which is also more frequent than is commonly supposed. It assumes three forms: 1. Those cases with Heberden's nodes, which is an osteitis at the ends of the bones, with early pains. 2. Osteoarthritis, which is more common in young women and in old men—in the latter often a spondylitis. 3. Acute rheumatoid arthritis. The term "rheumatic diathesis" has no real meaning in medicine and should be expunged from the medical vocabulary.

**Discussion.**—JAMES TYSON said the subject is a difficult one because it has no definite pathology. He thinks more cases are called gout than should be. We cannot positively say a case is gout unless there has been a well-defined previous attack or unless Heberden's nodes are present. Uric acid diathesis is a much abused term. If we have a persistent condition of scanty urine, high specific gravity, with uric acid sediment, we may speak of it as a uric acid diathesis, but even then we do not know the pathology of the condition. THOMAS McCRAE said we know little more about this condition than was known 100 years ago, when Heberden wrote exhaustively upon the subject. LAMBERT said cases frequently occur, especially in young women, which begin as acute rheumatism, but which are arthritis deformans. There is much more gout in New York than formerly, and he is of opinion there is more chronic rheumatism than Walsh apparently believes. Uric acid diathesis is a poorly-understood condition. Athletes have been observed to have much uric acid in their urine at times, yet certainly with them there is no great tendency to rheumatism or gout.

**Albuminuria in Diabetes.**—A. R. ELLIOTT said there are no typical renal lesions in diabetes. Hyaline degeneration of the tubular epithelium is observed in most severe cases. In some mild cases there is a chronic interstitial nephritis; in most, however, there is a combined interstitial and parenchymatous nephritis. About 43% of the cases have albumin. A toxic albuminuria always eventually arises in all severe forms of diabetes, but it is never severe. A degenerative albuminuria arises as a result of the irritation produced by the sugar. It begins as a local inflammation, but finally cardiovascular changes arise, and interstitial and parenchymatous changes in the kidneys. Coma is always preceded by albumin and casts. Kidney alterations are always antecedent to and often the cause of coma; yet this is not the coma of uremia.

**Arthritis Deformans.**—THOMAS McCRAE gave an analysis of 110 cases. We know little about this disease. Broadly speaking, there are two groups of cases: (1) Those exhibiting bony changes, and thus producing osteoarthritis; (2) those exhibiting changes in and around the joint, the rheumatoid group. Another method of grouping, without reference to the pathology, give us: (1) Those exhibiting Heberden's nodes—clinically it has been observed that these are apt to escape involvement of the larger joints; (2) polyarticular involvement; (3) nonarticular involvement; and (4) spondylitic cases. Ninety-four of the analyzed cases were of the polyarticular type, 30% being before the twentieth year and 50% being before the thirtieth year. Of the 110 cases 106 were white, 4 were colored, and 96 were native born. The disease is often mistaken for chronic rheumatism; it bears no relation to acute rheumatic fever, nor to a preceding gonorrheal infection. The attack was gradual in onset in 45 cases, and acute in 41 cases. The cervical vertebrae are at times involved; nearly 25% of the cases had involvement of the temporomaxillary articulation, and one or both knees were involved in 80 out of 92 cases. The temperature runs from 99° F. to 100° F., while the pulse-rate is high, averaging about 96. These differentiate it from acute rheumatic fever. There may be periods of latency; the heart is not involved. The spondylitic cases were 22, 20 being in males and 2 in females, and in 15 the whole spine was involved. Pain in the spine and legs resembles sciatica. We can differentiate from Pott's disease by the use of tuberculin and the Röntgen rays.

**Discussion.**—J. J. WALSH said no other affection gives so much scope to quacks as the so-called chronic rheumatism, but which in reality is too often arthritis deformans. This disease is common in this country, while true chronic rheumatism is rare. J. J. MOORE said he had found a large number of these cases in the dissecting-room, which in life had rarely been recognized. Investigation of this disease is much needed. McCRAE closed by stating that the disease is probably some form of infection. Treatment should be along general lines—plenty of nourishment, iron, arsenic, massage; rest is indicated in the osteoarthritic cases, and exercise in the articular group is indicated. Massage and exercise prevents contractures and atrophy.

[To be continued.]

### Section on Surgery and Anatomy.

FOURTH SESSION (CONTINUED).

**Epithelioma Under the X-ray: A Preliminary Report of the Histologic Changes.**—J. CLARK STEWART (Minneapolis) reports the case of a patient whose finger was cut by a bottle, epithelioma afterward developing in the wound. It was treated by exposure to the x-ray and successive blocks of tissue were cut during the treatment until the growth seemed entirely cured. In all seven blocks of tissue were cut. The more important changes which were noted in the tissues microscopically examined were fatty degeneration, which was found in the pearls of epithelial cells in all the blocks. Later on vascular changes occurred, new bloodvessels being formed, which were tightly packed with polymorphonuclear leukocytes. In the later sections necrotic changes were noted in the cells and in the latest section nothing was left, the cells being entirely destroyed by coagulation necrosis, and only fat, broken down epithelium, and polymorphonuclear leukocytes could be seen. Different patients and different tumors no doubt vary in their susceptibility to the x-rays. In this case the subsequent history

was of progress of the growth beneath the skin, the exposed tissue melting away entirely.

**Discussion.**—CHRISTIAN (Boston) mentioned a case of epithelioma of the hand in which he had had an opportunity of examining microscopic specimens before treatment and during treatment by the x-rays. In this case the epithelial cells were found dead and surrounded by giant cells. There was no effect noted on the connective tissue cells, though neighboring epithelial cells were killed. Few, if any, polymorphonuclear leukocytes were seen and no inflammatory changes were noted. Not too much stress should be laid upon fatty degeneration in Stewart's case, for the reaction employed is open to some objections, osmic acid staining several other tissues beside fat. Fat is also always present in cases in which polymorphonuclear leukocytes are present, and these are always present in ulcers of whatever sort. Another source of doubt was that Stewart's tumor was not examined microscopically before the x-ray treatment was begun. Christian considered the bloodvessels which were seen in Stewart's case probably those which are usually found in all granulation tissue. NICHOLS (Boston) has seen a number of cases in which epithelioma has skinned over after treatment with the x-rays, but the disease was still present in the deeper tissues. The changes noted in the cases treated under the observation of the Cancer Commission of Harvard were not characteristic. Probably the action of the x-ray is to be explained by the changes which it produces in epithelial cells of low vitality where the more resistant cells are not affected. Epidermoid-carcinoma may be produced by the action of the x-rays. Nichols mentioned one case in which death resulted from epidermoid-carcinoma in a man who had worked a great deal with the x-rays and had suffered from severe x-ray burns. RIDLON (Chicago) doubts if sunlight alone is of great advantage in the treatment of tuberculosis. The value of sun and fresh air is most noticeable in the case of city children, and is probably caused by the change from their accustomed environment, for country children are not correspondingly benefited by such treatment. A number of cases of tuberculosis have been under treatment by the x-rays by his associates, but it is too early to say anything definite about the results. Ridlon has the impression, however, that the benefit is more often seen in tuberculosis of superficial joints, not of the deeper joints, such as the hip and vertebrae. LUND (Boston) called attention to the fact that most of the cases of the carcinoma which have been successfully treated by the x-rays were the nonmalignant epithelial variety. Many surgeons are premature in saying that the day of the knife has passed. The local disease is frequently cured in these cases, but the glands are already affected and x-ray treatment has not proved successful in the treatment of glandular involvement. Lund believes that such growths should be excised early in every case, while radical operation is still possible, and that we should not tamper with the x-ray. THOMPSON (Scranton, Pa.) mentioned a case of carcinoma of the pylorus with obstruction in which excision of the growth seemed impracticable. Posterior gastroenterostomy was performed and 48 hours later the wound was reopened, gauze was packed about a tumor of the size of an orange and the x-ray treatment was tried directly on the growth. A gastric fistula resulted from sloughing, but by gauze packing food was retained. Temporary improvement resulted, but death occurred in a month after the operation. WILLARD, in closing, said that he advocated the use of light and the x-ray simply as adjuvants to other recognized methods of treatment. The x-ray at least relieves pain in certain cases and may prove of considerable help. He has found fresh air and sunlight as valuable in treating country children as city children. Frequently the sanitary conditions in the country are as bad as in the city. STEWART, in closing, stated that the vessels in his specimens were real vessels and not such as are to be found in granulation tissue.

**Varix of the Inferior Mesenteric Vein Complicated by Chronic Ulcerative Colitis; Operation.**—JOHN E. SUMMERS, JR. (Omaha). The varix of the inferior mesenteric vein in the case reported was either an effect or cause, most probably the former, of a chronic ulceration of the rectum and sigmoid flexure of the colon. The ulceration was accompanied by the usual clinical signs and demonstrated by ocular inspection. An incision in the left inguinal region, made for the purpose of establishing a temporary artificial anus, disclosed an intense dilation of all of the radicals going toward the formation of the inferior mesenteric vein. The project of the establishment of an artificial anus was abandoned. At a subsequent operation an attempt was made to discover any interference with the return circulation. These operations were without benefit to the patient. A gastroplasty and in addition a Morrison operation were carried out with the purpose of relieving the congested circulation; much benefit followed. Two months later an artificial valvular fistula was formed in the cecum and the colon irrigated daily, the patient gaining 20 pounds in weight. Another experience in which an artificial valvular fistula in the cecum for the purpose of irrigation in the case of chronic colitis was mentioned.

**Discussion.**—SMYTHIE (Memphis) stated that in the hospital to which he was the attending surgeon all cases of colitis, such as had been reported by Summers, are now referred to the surgeon. Operation is simple in these cases, and the results have been very favorable.

**Congenital Dislocation of the Radius.**—CHARLES A.

POWERS (Denver) reported in careful detail a very interesting case of this kind. The position of the hand in extreme pronation and grasping motion were quite characteristic. The motions of pronation and supination were absolutely wanted, and flexion and extension of the elbow were limited. Operation was refused by the child's parents without assurance could be given of much benefit, and from the results in the cases previously reported Powers was not prepared to give this. Details of the few cases which have thus far appeared in the literature were given.

**Discussion.**—BOTTOMLEY (Boston) reported two cases which had occurred in the service of Cotton, at the Massachusetts General Hospital. In one case both elbows were involved. Excision was performed, followed by early passive motion with a perfect result on the right side, and improvement on the other side. WILLARD (Philadelphia) has seen several cases of this kind, in which the extreme pronation and grasping motion of the hand noted by Powers were present. He would advise resection of the elbow and division of the muscles, if necessary, to relieve the extreme pronation. The improved appearance of the arm would repay one for operation, if nothing else.

**Acute Epiphysitis of the Head of the Femur Causing a Condition Subsequently Simulating Congenital Misplacement.**—JOHN P. LORD (Omaha) reported a case in which all of the appearances of congenital dislocation of the hip were present. An abscess had appeared over the hip-joint following an attack of pneumonia, and Lord thought that the infection was possibly from the pneumococcus. An unsuccessful attempt was made to remedy the deformity by the Lorenz method. The Hoffa cutting operation was then tried, and considerable improvement resulted. Lord believes that a perfect cure of the condition would be impossible.

**Discussion.**—RIDLON (Chicago) has had no personal experience in the treatment of these cases until a short time previously, when two cases came under his care. He believes that the condition is rare. Both cases were operated upon. The only treatment is to operate, pull the bone down in position, abduct the leg and fix it in this position for a number of years if necessary. TOWNSEND (New York) considers abduction all important in the treatment of these cases. Either casts or traction may be used to produce it. In some cases after forcibly pulling down and abducting the patient should be allowed to get about on a high shoe to return for treatment if necessary.

[To be continued.]

## Section on Obstetrics and Diseases of Women.

### SECOND SESSION (CONTINUED).

**Discussion.**—MARCY (Boston) had contented himself by modifying Sims' operation for cystocele. He thanked the essayist for pointing out the anterior vaginal plane. THIENHAUS (Milwaukee) cited various forms of cystocele. If in a woman 50 years of age, the uterus must usually be fixed, especially if the uterus is in the axis of the vagina. He uses vaginal suspension, thus retaining the uterus in the pelvis, where it belongs. BOVÉE (Washington, D. C.) considers it rational to treat cystocele as a hernia. He practises resection, always passing the sutures transversely. Unless the operation is skillfully done it will pull the cervix forward. REYNOLDS, closing, stated that his method brings the vaginal walls together from side to side, narrowing the vagina.

**An Investigation as to the Proper Time for Repair of Lacerations of the Cervix Uteri.**—DANIEL H. CRAIG (Boston). This paper involves an investigation covering one year and five months. As a basis of study the results of 100 tracheloplastic operations performed at the Free Hospital for Women were tabulated. A majority of these operations were trachelorrhaphies. The cases include those in which from two to five years have elapsed since the operation. The first desire was to prove tracheloplasty a necessary and justifiable procedure. To consider an operation necessary symptoms must exist which fail of relief by palliative treatment, and to be justifiable it must relieve these symptoms without causing sterility, miscarriage, or dystocia. Another justification is that it serves as a prophylactic against cervical carcinoma. A circular letter was sent asking certain questions. In the answers received complete relief from symptoms had resulted in 78 cases, great relief followed in 11 cases, no benefit accrued in 11 cases. There were 37 pregnancies subsequent to trachelorrhaphy, and of these 24 (80%) went to full term. Twenty-three of the 100 cases were past the child-bearing period. Therefore, a proper tracheloplasty does not engender sterility. Inquiry made as to relaceration at the time of delivery, about one-half the cases reported showed a relaceration; this, then, cannot be considered a serious contraindication to tracheloplasty when definite indications for it exists. Regarding subsequent womb trouble inquiry showed that 67% women have, after the lapse of two to five years, been entirely free from "womb trouble." Craig has learned that 12 of the 33 not permanently cured owe their symptoms to adnexal lesions, fibroids, etc. There has been no instance of malignancy. Having satisfied himself that a proper tracheloplastic operation after proper palliative preparation was curative and justifiable he turned his attention to its prophylactic influence as regards cervical carcinoma. Fifty gynecologists were addressed. In addition 78 cervical carcinoma cases treated in the Free Hospital for

Women were investigated. In no single instance was a history of a previous tracheloplastic operation found in a carcinomatous cervix. Answers received in connection with investigation convince Craig that at least 90% of the cases of cervical carcinoma occur in previously lacerated cervixes remaining unrepaired. From information gathered he is convinced that a properly repaired cervix reverts in labor to about the condition of the primiparous cervix as regards laceration. The following conclusions are reached: 1. Immediate repair of the cervix is indicated only in exceptional cases, aside from the control of hemorrhage. 2. Mediate repair is contraindicated, except it be in some unusual cases. 3. Secondary repair is indicated so soon as symptoms are definitely due to the laceration, such symptoms failing of relief by palliative measures or recurring after apparent palliative cure. 4. Operations on women past 35 give better permanent results than in younger women. 5. Repair of the cervix is indicated as prophylactic of malignancy in a woman approaching the cancer age, if the cervix manifests locally evidence of cellular irritation, whether or not causing subjective symptoms. 6. Lacerations in which operation is not indicated should be kept under close observation as the cancer age approaches. 7. Obstetricians are obviously unable to avoid lacerations of the cervix in many cases, but if the above deductions are correct a far more strict asepsis will, by favoring spontaneous primary union of such lacerations, do much toward lessening the number of secondary tracheloplastic operations.

**The Hygiene of Young Girls.**—J. H. CARSTENS (Detroit) considered the conditions of girls during puberty, and included the care of both body and mind. In some walks of society girls are required to do hard work with poor food, bad air, general bad hygiene; they may have strong but ungraceful figures. In other social conditions the mental training is far beyond the physical strength. We desire equal development of body and mind. Predisposition to nervous affections was dwelt upon. The influence of the mother often intensifies neurasthenic or hysterical tendencies. The mother imbues the daughter with the belief that the latter is nervous and cannot help it, and the belief becomes established. Often it is necessary to take away the daughter for a time from the baneful influence of the mother when a wonderful change for the better may result. The mother suggests a train of pelvic troubles. Poor girls undergo hardships of physical strain and the ignorance on the part of the mother as to hygiene is often at fault. The physician can usually manage the latter cases. He can regulate the kind of work, and control in various ways. The State should regulate the hours of labor and ventilation, should see that proper toilet facilities are provided. Diet above all should be regulated. Gymnastics and sports of girls should be encouraged and directed. So guiding the girl, the menstrual function will take care of itself. As to the mental development of girls there is greater difficulty. The rich are ever ready to stop school when advised by the physician. With the poor or middle classes there is the greater difficulty. Often a girl is ambitious, or feels that she needs an education to aid in supporting herself and others. If she continues in school, the nervous system will collapse; if she marries, she becomes a burden to her husband. In many such cases mental work should be stopped to be resumed perhaps in a year. The hygiene of girls is a problem most difficult. There is no general rule, but each case should be studied. Heredity, environment, assimilation, elimination, the nervous system, etc., must each be considered. The physician must have tact sufficient to manage both the patient and family, and he must work out each case for himself.

**Pelvic Disease in Young Girls.**—F. LAWRENCE (Columbus, Ohio) says that prejudice has often been met in the laity and among general practitioners against the pelvic examination of young girls. He wishes to direct the attention to the fallacy and injustice of such a position. The young have equal rights with the old to relief and protection. Many, if not all, pelvic diseases are curable. Displacements destroy functions of tubes and ovaries, render the patient sterile, and, therefore, demand relief. A chaste man will not excite any impure thought in the mind of a patient. Sound physical organism is the surest protection against degradation. Nymphomania, he believes, occurs only in diseased conditions of the genital organs. The recto-bimanual method should be used except in rare conditions. Sterility may be the result of neglected pathologic conditions in the girl. Tuberculosis is not infrequent, leukorrhea is common. Symptoms often direct the attention to the nervous system or circulatory system. Symptoms of irregular menstruation or menstrual pain point to disease and should lead to investigation. Displacements, infantile uterus, metritis, fibroids, endometritis, ovaritis, prolapse, septic salpingitis, all occur in the young girl.

**Discussion.**—MCMURTRY (Louisville) considered that these subjects have been too much neglected by the section. It is common for the gynecologist to be consulted by young women neurasthenics, a condition that could have been avoided by proper prophylaxis. They were apt to pass in rotation through the hands of the general practitioner, the oculist and gynecologist, and finally as nervous wrecks into the care of the neurologist. It is often essential to protect and prevent too much being done in these cases. If in conditions of neurasthenia the environment could be altered in the incipency the greatest advance in therapeutics would be made. ETTA GRAHAM (Chicago) has treated girls for gonorrhoea at 4, 6, and 14 years of age.

The latter was in the hands of a physician for six weeks without improvement. He had failed to make an examination. Better examine 100 girls free from gonorrhoea than by failure to examine miss one who has the disease. This case had been infected by the nurse. The case of a girl of 18 was cited, in which retrodisplacement existed, and the fact emphasized that whenever disease exists the patient has reached the age to cure the disease.

[To be continued.]

## Section on Diseases of Children.

### FOURTH SESSION (CONTINUED).

**Management of Catarrhal Pneumonia in Infants and Young Children.**—CHARLES GILMORE KERLEY (New York) said that the first step should be to establish a sick-room régime. The value of fresh air was not sufficiently appreciated in connection with the management of this disease. The necessary change of air was most easily and effectively secured by the use of the wellknown window-board. Coddling and over-clothing these children were the rule, and should be prevented. The food should be reduced one-third or one-half and the intervals between medicines and external applications should be arranged, particularly at night, that the sick child was disturbed as little as possible. Among distinctly remedial measures steam and creasote inhalations deserved a prominent place. Ten drops of creasote should be added to one quart of water in a croup kettle, and the vapor conducted to the crib for about 30 minutes every three hours. Revulsives should be found very useful. Among the best were the mustard plaster and an embrocation composed of oil with one-third turpentine. The mustard plaster should not be applied longer than enough to produce reddening of the surface, and not oftener than two or three times in the 24 hours. Expectorants must be given with care lest they disturb the stomach. For a child of one year he would prescribe  $\frac{1}{15}$  of a grain of tartar emetic and  $\frac{1}{10}$  of a grain of ipecac, and if the cough were teasing small doses of sodium bromid might be advantageously added. Syrups should be avoided. If the fever ran high and bathing was not well borne, or the attendant could not give them properly, a child of one year might be given  $\frac{1}{4}$  of a grain of caffeine, and  $\frac{1}{2}$  grain of phenacetin at intervals of four to six hours, and if there were great restlessness one might even give cautiously a little Dover's powder. Heart stimulants should only be prescribed when there were distinct indications of failing heart power; then he would give one drop of strophanthus every three or four hours. Strychnin was a useful adjuvant, but whisky or brandy, because of their disturbing action on the stomach, should be strictly reserved for occasional emergencies. When employed, it should be given in doses of  $\frac{1}{2}$  dram to 1 dram, well diluted with water, every two hours to a child of one year. For the relief of marked cyanosis  $\frac{1}{15}$  of a grain of nitroglycerin could be given every three hours to a child of one year. A sponge bath at 90° should be given daily. When the temperature showed a tendency to go above 104° F., the temperature should be controlled by sponging off the body surface with one part of alcohol and four parts of water. The child should be sponged under the blanket for 10 or 15 minutes at a time, and then the skin briskly rubbed with the hand. He had not found tub baths a desirable antipyretic measure in these children; a far better and more potent method was by the use of the wet pack. The child should be covered with a bath towel from the neck to the middle of the thighs, and a hot-water bag placed at the feet. At first the towel should be moistened with water at 95° F., and then after a few minutes with water at 85°, the temperature being gradually lowered to 80°. After a half an hour, if the temperature had been very little reduced, and had originally been at about 105°, the temperature of the pack might even be gradually lowered to 65° or 60° F. The aim should be to keep the body temperature between 102° and 103.5° F.

**Discussion.**—C. F. WAHRER (Fort Madison, Iowa) described graphically some of the conditions met with in rural private practice, and said that undoubtedly some of these children were smothered to death by the treatment employed. He added that it was not always easy to differentiate in children between a pure bronchitis and a pure pneumonia. WILLIAM CARVER WILLIAMS (Chicago) said he wished to still further emphasize that very important part of Dr. Kerley's paper which pointed out the necessity in carrying out our treatment—to disturb the child as little as possible and husband its vitality. R. B. GILBERT (Louisville) said that when an emetic was indicated he was of the opinion that turpentine mineral should be given the preference, as it produced emesis promptly and the subsequent nausea was of short duration. THOMAS D. PARKE (Birmingham, Ala.) spoke of the asthmatic element often associated with bronchitis, and which was frequently not recognized and treated. He made it a rule in the treatment of bronchopneumonia in children to watch for tympanites and endeavored by appropriate regulation of the diet to prevent it, and so avoid one of the common causes of respiratory embarrassment. Among drugs, his main reliance was on strychnia, given in solution as a rectal enema. He did not hesitate to give a child of 1 year  $\frac{1}{10}$  of a grain, and if necessary even more. He was not alarmed if this dosage caused some twitching, for he had never seen any harm from it. HUGH A. LEAVELL (Louisville)

said there could be no doubt that much could be accomplished by the use of inhalations, yet it was possible to carry this treatment too far, and in the later stages smother the child in its own secretions. Much could be done in the way of controlling the fever by occasionally emptying the stomach and promoting the activity of the bowel. Heart stimulation he considered of the greatest importance, and consequently began early the use of strychnin. BARBOUR, closing, said that he avoided cough syrups and made use of strychnin from the beginning to the end of bronchopneumonia, giving it in doses sufficient to cause muscular twitching. He also held belladonna and aconite in high esteem.

## FIFTH SESSION.

**The Safranin Reaction in the Urine of Children.**—W. S. CHRISTOPHER and A. C. CROFTAN (Chicago) presented this paper in abstract. The test was new, and consisted in a color change produced by the presence in the urine of a substance, which Dr. Christopher considered to be sugar. The following were some of the conclusions from this study: (1) Safranin is a reliable and convenient test agent for sugar in the urine in quantities too small to be detected by the copper test; (2) safranin is decolorized by sugar, but not by uric acid; (3) the "safranin index" is the number of cubic centimeters of a 1-1,000 solution of safranin solution which are decolorized by 1 cc. of urine; (4) the normal safranin index is low during the first year of life, but gradually increases until it reaches a maximum between the third and fourth years, after which it slowly decreases for a number of years; (5) during the first 10 years of life boys have a constantly higher safranin index than girls; (6) at the age of 11 years the index curves of the two sexes cross, the girls becoming superior; (7) both the safranin and acid toxemias play an important role in infancy, and are responsible for many of the difficulties in infant feeding.

**The Treatment of Scarlet Fever, Its Complications and Sequels.**—H. M. MCCLANAHAN (Omaha) insisted upon the importance of keeping all scarlet fever patients on a liquid diet for not less than four weeks, in order to prevent renal complications. For hyperpyrexia associated with great restlessness he found hydrotherapy particularly useful. Oily applications or bathing the skin with a 1% carbolic acid solution was comforting to the patient and served to limit contagion.

**Discussion.**—R. B. GILBERT (Louisville) was accustomed to prescribe iron ammonio-citrate in all these cases. The physician who prescribed baths for his private scarlet fever patients must meet many difficulties and assume additional responsibilities, chiefly because of the prejudices and ignorance of the laity. B. R. SHURLY (Detroit) spoke of the treatment of scarlet fever by the use of antistreptococcal serum, and stated that he had used it rather late in two malignant cases, but death had occurred nevertheless. He wished to emphasize especially the great importance of irrigation of the nose and throat in the early stage.

**Prolonged or Retained Intubation Tubes, With a Method of Treatment Leading to Their Extraction.**—B. R. SHURLY (Detroit) described a number of cases, reviewed the literature, and spoke of the danger of metal intubation tubes. A large dose of diphtheria antitoxin as a preliminary to extraction of the tube was a great aid. The treatment advocated consisted in the use of small or modified tubes coated with alum ointment or gelatin. This treatment had been successful in all of his cases.

**Pseudohydronephrosis or Paraneuritic Cyst in a Boy of Three and a Half Years; Operation; Recovery.**—SAMUEL W. KELLEY (Cleveland) sent the report of this case, together with photographs.

**Officers Elected.**—Chairman, Charles G. Kerley, New York City; secretary, Charles F. Wahrer, Fort Madison, Iowa. Henry E. Tuley was reelected to the House of Delegates.

## Section on Sanitary Science and Hygiene.

## SECOND SESSION (CONTINUED).

**The Present Status of the Filtration of Water.**—GEO. G. FULLER (New York) stated that the composition of the water supplies of the different cities in the United States varies considerably. Lawrence, Mass., has 10 parts solid matter per million parts of water in the water supplying it; Allegheny has 50 parts per million; Cincinnati has 230 parts per million; Louisville has 350 parts; New Orleans has 650 parts, and St. Louis has 1,000 parts per million. It is possible to purify any water into a potable water by filtration. The varieties of filtration of water for the supply of large cities was described. The mechanical method is the cheapest. At New Orleans the Mississippi river water contains small submicroscopical particles of clay suspended. The hygienic condition of the water at New Orleans is good, containing only three *Bacilli coli communis* per one cubic centimeter. The sewage from 45,000 persons empties into the river above New Orleans within 250 miles of the city, but none within 130 miles. There are no records to show that harmful results follow the use of sulfate of aluminum. It is used in cities with an aggregate population of 2,000,000. Present status: Any water may be purified by some one or by a combination of the methods of filtration.

**Discussion.**—SWARTS (Providence, R. I.). There is no danger in using aluminium sulfate, and people should not

object to it. Nature employs chemical methods as well as sand filtration in the artesian wells. He is glad to know that the mechanical method is cheaper than the sand filters. All inland cities suffer from bad water supplies, and he is of the opinion that filtration will do much toward mitigating this evil. He is glad that Mr. Fuller emphasized the fact that aluminium sulfate does not prevent the use of the sand filter also. In Providence they were unable to use the alum method, as the citizens did not wish "doctored" water. Ozonization of water destroys bacteria. The treatment of surface water, he is glad to know, will give a potable water. The mechanical method he thinks is best, as it is the simplest and there is less likelihood of contamination. CHAPMAN (Toledo): Ignorance as to filtration is very prevalent. The masses need education along this line. Most people consider the water of the Great Lakes a pure water, but the water of Lake Erie is not a potable water. Toledo has established a plant for its purification. He believes that the mechanical method is excellent. The water-supply of Toledo is at times muddy, and in these instances he uses aluminium sulfate as a coagulum. E. B. BORLAND (Pittsburg) thinks any contaminated water can be purified by filtration. The laity have no ideas or appreciation of the value of filtration. The real value is in the gelatinous film which forms on the top of the filter. By experiments carried on in Pittsburg it was found that 98% of the bacteria were removed in the first two filters. Fifty-seven thousand bacteria were found in 1 cc. of water, but all of these were gotten rid of by filtration without the aid of a coagulum. S. G. EGBERT (Philadelphia) thinks that the regions to be especially taught are the rural districts. Physicians should be taught the value of filtration. The cost of maintaining a filter plant is less than the cost of illness to the community. F. J. MAYER (Lafayette, La.) wished to emphasize the importance of educating the public to the value of pure water: The majority of the water in the State of Louisiana is unfit for drinking. This is especially the case in the rural districts. The Mississippi river water is the most potable water in Louisiana. In the inland parishes it is especially difficult to obtain potable water. Many so-called artesian wells in Louisiana are merely surface wells and are not potable. It is absolutely necessary to educate the masses. W. G. OWEN (White Castle, La.) has found several cases of typhoid traceable directly to drinking cistern water. FULLER, in closing, said that the gelatinous layer on the surface of the sand filter is the real filter. The organic matter in the water forms a gelatinous coating around each granule of sand or clay and this catches the bacteria. In order for a mechanical filter to be effective the gelatinous material must be supplied if not present. Mechanical filtration is best suited for some waters, and sand filters for others.

A resolution was submitted by Dr. F. J. MAYER, of Lafayette, La., and passed unanimously by the section, to submit a resolution to the House of Delegates requesting the establishment of a section on medical jurisprudence in the American Medical Association.

Stereopticon slides of the proposed purification plant were then shown.

[To be continued]

## Section on Nervous and Mental Diseases.

## SECOND SESSION (CONTINUED).

**Neurasthenia, and Its Treatment by Actinic Rays.**—ALBERT E. STERNE (Indianapolis) summarized his paper as follows: (1) Actinic rays are chemic in their quality, but of small calorific value; (2) they exist mainly in the ultraviolet zone of the spectrum; (3) actinic rays derived from high power electric light are similar or identical to those of solar radiation; (4) their use is as rational as that of sunlight itself; (5) their value lies in their decomposing but at the same time reconstructive molecular action upon the body tissues, mainly the fluid elements; (6) by the method herein spoken of their activity is enhanced by the generation of ozone in free and nascent form; (7) their ultimate effect is one of oxidation, and consequently they increase the metabolic changes, thereby augmenting the natural processes of regeneration within the system; (8) the germicidal action is especially pronounced on account of the fact that few germs can exist in the presence of free or nascent oxygen.

## Symposium on Relation of Public School Methods to Psychoses.

**Relation of the Public School to the Seminary and College as to Psychoses.**—F. SAVARY PEARCE (Philadelphia) emphasized the fact that there was not sufficient correlation between the various institutions of learning, and that the desire of the teacher for originality had led away from fundamentals, and for this reason students were often overworked. The subject chiefly concerned not the boy on the farm but the citybred youth, who among the comforts and confinement of city life too frequently neglected his physical training. It had been his experience, in observing the average American boy or girl who passes from the city grammar school to the high school and finally to the academy or college, that there was a wide variance in the methods of instruction, brought about largely in some instances by the fact that too much stress was

laid upon particular methods of instruction. Of course, the greatest trouble lay in the fact that growing children were often put to tasks which their brains could not compass. In many instances psychoses in children and early adult life could be laid at the feet of the general practitioner, who did not prove to be a wise guard, as he should be, and had failed to advise against the evils of overstudy on the one hand, and overtraining in gymnastic exercises on the other.

**Best Methods of Counteracting Psychoses Due to Strain and Stress Incident to Our Public School Methods.**—WILLIAM JAMES HERDMAN (Ann Arbor, Mich.) summarized his paper as follows: 1. A careful medical inspection of school children at the beginning of their school life and at stated intervals thereafter, covering both their physical and mental capacities. 2. All teachers should be well instructed in the physiology and psychology of the child and in the principles of school hygiene. 3. School buildings and their environments should be made to comply with all the requirements of modern school hygiene as to light, pure air, temperature, seating, decorations, playground facilities, etc. 4. The curriculum should be so flexible as to allow more opportunity for the exercise of the individual judgment of the teacher as to the best method to adopt for each child in order to secure for it the greatest educational value, and the curriculum should include facilities for appealing to the mental faculties along every sensory pathway, among which facilities he would mention nature study, rational kindergarten, manual training, and physical exercise. 5. The number of pupils assigned to any one teacher should be only such as he or she can care for to the best advantage. Time should be allowed the teacher for a careful study of the physical and mental needs of each pupil. 6. A closer relationship between the parent and teacher, with a view of securing the end sought—the highest and most useful development of the child. 7. The removal so far as possible of all conditions within or without the school-room that interfere with the accomplishment of this purpose.

**Discussion.**—H. N. MOYER (Chicago) said he felt convinced that the psychoses of childhood were largely incidental to the developmental period *per se*, and were the result of bad heredity and primary defects in the nutritional processes rather than of overwork and the stress and strain of school life. They were manifestations of impaired nutrition during the growing period, when nutrition represents such a vastly more important factor than it did after the age of puberty. The nutritional factor was the broad, underlying principle of pedagogy and education. All other factors, such as eyestrain, etc., were supplemental to it. All organs of the body could only be strengthened by use, but we must stop short of strain. The early breakdown of the athlete was due to the fact that there was a maladjustment of the organs resulting from the decay and atrophy of those organs upon which there was no longer any strain after youth had gone. JOHN PUNTON (Kansas City) said there was a great need of a consensus of medical opinion in reference to the relation of school education to nervous diseases, and up to the present time nothing of a tangible nature had been done in that direction. The appointment of medical inspectors in the public schools was in the line indicated, but much still remained to be done. He referred to the value of anthropometric measurements as a guide in estimating the mental and physical capacity of school children, and stated that if they were systematically carried out they would go far toward preventing the occurrence of psychoses in early life. Certain definite standards of weights and measures in relation to the height of pupils would be of vast importance. Under the present system pupils of the same age were assumed to possess like mental capacity, and this was plainly a misleading criterion. Standards should also be fixed by which the normal child could be separated from the abnormal. J. H. McBRIDE (Los Angeles) said he did not believe that many persons broke down as the result of overwork. The evil effects of so-called overwork among school children were really due to the faulty methods employed in teaching; to too long hours, the multiplicity of the studies, etc., and to bad hygiene. ALBERT E. SIERNE (Indianapolis) emphasized the fact that the school period was the growing period, the evolutionary period, both physiologic and mental, and this no doubt accounted, to a certain degree at least, for the peculiar psychoses occurring at that time. D. R. BROWER (Chicago) in speaking of the importance of this general subject, said that during the past few years, according to his experience, the number of cases of insanity among adolescents had at least doubled in the city of Chicago. They were rapidly increasing in that strenuous city, as they probably were elsewhere in this country. T. A. WILKINS (East Bernard, Texas) said that many of the psychoses among school children could doubtless be traced to their bad hygienic surroundings. The effects of defective ventilation reacted upon circulatory activity, and eventually led to the impaired digestion of food, constipation, and other evils. A thorough reconstruction of our school system was necessary. School teachers should be as incapable as violating a hygienic law as they are supposed to be of violating a social or moral law, or as a surgeon is of violating an antiseptic law. The entire subject under discussion was much simpler than it appeared on the surface, when studied in connection with the physiologic laws of the growth of children, both physical and mental.

[To be continued.]

## Section on Cutaneous Medicine and Surgery.

### THIRD SESSION.

This took the form of a clinic by ISADORE DYER at the Charity Hospital, with presentation of the following: **Three cases of leprosy.** One case of multiple cystic epithelioma involving the face. This latter case is of 15 years' standing, and for 10 years was of the benign type. One case of herpetic dermatitis, exhibiting many features of impetigo contagiosa, was of two years' duration and somewhat unique. One case of psoriasis in a tuberculous patient. The condition was of long duration and very refractory to treatment. MCGOWAN suggested the use of iodipin. He claimed good results in these cases from its use. A unique case of nevus lateralis in a child of 5 years was exhibited. The disorder had existed for three years. Dr. DYER was of the opinion that no interference was best in these cases. He thought it better to wait, as a great many of the vessels would contract in time. Later those remaining might be treated by electrolysis or some other means. A very interesting case illustrating the use of thiosinamin in scar formation was presented, showing marked improvement. He used the soap and the plaster. A case of infantile eczema of reflex origin was presented. Dr. DYER was of the opinion that these cases always recover and with the simplest applications, if the cause was once discovered and removed. A case of pediculosis capitis followed by impetigo contagiosa involving face and vulva in a girl about 10 years of age was then shown. The lids were especially involved and resembled very much a sycoosis. ZEISLER thought the case one of staphylococcus origin. MENAGE reported that the case did not yield to the usual treatment of impetigo contagiosa. ROUSSEL suggested the use of the ultra violet ray. He had seen a very similar case recover under its use when the other agents had been faithfully used with no results. A case of psoriasis and one of chloasma in the negro were exhibited. These exhibited no special features.

### FOURTH SESSION.

**Pityriasis Rosea.**—LUDWIG WEISS (New York) thought the disease still of uncertain classification. Its etiology is not known, but he thinks it is entirely due to internal causes—to absorption of toxins from the intestines. External irritants, chemical or mechanical, are also etiologic factors. Some may possess latent disposition to develop pityriasis rosea. He did not think it in any way parasitic, others to the contrary notwithstanding. Macules of pityriasis rosea are clinically as well as pathologically pure erythemas. He thought the scaling of a recent patch of the disease upon scraping with the nail was pathognomonic of the disease. Little treatment was necessary.

**Discussion.**—ANTHONY (Chicago) was of the opinion that the disease was distinctly on the increase. He thinks it parasitic in nature. BULKLEY (New York) thinks it impossible to confound this with ringworm. He has always thought it was parasitic in nature from the way it spreads. He thinks that treatment is very important, and insists on the use of such agents as salicylic acid, mercuric chloride, etc., in always obtaining cure by their agency. DE FORDYCE saw a case in which the lesions were confined to the legs. He thinks it is parasitic.

**The Influence of the Menstrual Function on Certain Skin Diseases.**—DUNCAN BULKLEY (New York) thought with Jacobi that women passed through periods in life of which the menstrual period was but one. He thought that such diseases as acne, eczema, psoriasis, herpes and urticaria, etc., were usually worse just before or during the period, sometimes even without any pathologic symptoms in the ovaries. Nervous affections attributable to such conditions arose. Of acne one-third of his cases were worse at menstrual period. Acne on the chin is usually due to menstrual disturbance. The hands are also often affected in this form. In all of these affections the treatment should be directed toward removing the cause, though, of course, some local applications also should be made.

**A Case of Blastomycetic Dermatitis from Accidental Inoculation in a Physician.**—NEWTON EVANS (Battle Creek, Mich.) stated that the case appeared about a week after he had held a postmortem on a case of the same disease. Inoculation took place in a small cut on his forefinger, the disease appearing as a small pustule, which became rapidly worse. A lymphangitis involving the lymphatics of the hand and arm followed, with enlargement of the axillary glands. Microscopic examination revealed budding organisms similar to those revealed in the fatal case. The case is particularly interesting as being the only case in which the source of infection was positively known. Potassium iodid is the best medicinal remedy known so far, but excision is still better.

**Discussion.**—BRAYTON (Indianapolis) referred to boring pain as frequent in this disease. He thinks it easy to diagnose. DYER would like a cure for a case in his practice. The lesions are located on the leg of a man of 70 years. He has given him potassium iodid in 120 grain doses with no results. Irrigation with 2% argyrol does best of the remedies used, but none does very well. HEIDINGSFELD (Cincinnati) does not believe that the yeast fungus is the cause of the disease. He believes the presence of the fungus is accidental. It may be a form of tuberculosis. DYER believes that clinically yaws and blastomycetic dermatitis are similar. DE FORDYCE has seen many cases that clinically appeared to be blastomycetic dermatitis, but was not

able to find the fungus. He thought that the fact that the fungus did cause the disease was well established.

[To be continued.]

### Section on Ophthalmology.

#### SECOND SESSION (CONTINUED).

*Discussion.*—GRIFFIN (Ann Arbor) considered that subjective tests were very unreliable, and there was great necessity for some exact method that we might not have to depend upon the patient's judgment. The method should be followed in all its details in order to get the desired results. He was somewhat surprised at Dr. Jackson's view that accurate results could not be obtained at one meter, and believed himself that at that distance one could diagnose within a quarter or even an eighth diopter. GIFFORD (Omaha) thought we should speak of the visual area and not "zone." WILDER (Chicago) thought that while the method was very exact it was in most cases an unnecessary refinement. He felt satisfied when within a quarter diopter of the actual truth; it was close enough for practical purposes. He thought it increased the difficulties without proportionately increasing the good results obtained. HAWLEY (Chicago) considered the method very scientific but hardly necessary for practical work. Most ophthalmologists used a distance of one meter. He spoke of the necessity for the examiner to correct his own error of refraction, especially if presbyopic.

#### THIRD SESSION.

**Some Points in the Pathology of Neoplasms of the Conjunctiva, Illustrated by the Present Exhibit of Morbid Growths.**—EDW. A. SHUMWAY (Philadelphia) gave a review of our knowledge of tumors of the conjunctiva, and exhibited stereopticon illustrations showing the various growths which are found on this membrane. He considered the growths on the conjunctiva of great interest pathologically because of their great variety, although they were, relatively speaking, infrequent. He showed illustrations of carcinoma, sarcoma, and of the benign growths, specimens of dermoid tumor, lipoma, cystoma, lymphangioma, telangiectasis, fibroma, granuloma, papilloma, adenoma, hemangioma, etc.

CASEY A. WOOD (Chicago) gave a lantern exhibition and talk, showing the comparative appearance of the fundi of various of the lower animals, including the bat, duck, skunk, snake, chimpanzee, Nubian negro, rabbit, sheep, goat, etc. He called attention to the close resemblance of the fundus of the chimpanzee and the Nubian.

**The Bacteria Concerned in the Production of Eye Inflammations.**—ROBERT L. RANDOLPH (Baltimore) spoke of the occurrence, cultural properties, and morphology of the bacteria concerned in the production of the eye inflammations, illustrating his talk with lantern slides. He said, among other things, that we had not yet found any bacteria that were pathogenic only for the eye. That the possibility of there being such bacteria was suggested by such diseases as sympathetic ophthalmia and trachoma. He was sometimes tempted to think that the bacteria so often found in the normal conjunctival sac performed important functions in the life of the normal conjunctiva and should not be destroyed. He thought that with increasing knowledge of the subject we would be compelled to take a different position and perhaps to regard some of the bacteria, at least, as benefactors.

**Bacteria in the Conjunctiva, Cornea, Iris, Ciliary Body and Choroid, and Changes Caused Thereby.**—(Illustrated by projection with a lantern of sections and lantern slides.) BROWN PUSEY (Chicago) gave a lantern lecture in which many sections were shown and the interesting and instructive features pointed out, especially pertaining to the bacteriology of the conjunctiva, cornea, iris, ciliary body, and choroid, and the pathologic changes resulting from the invasion of bacteria. He also showed specimens of the Weeks' bacillus, diphtheria bacillus, gonococcus, streptococcus, typical bacilli in the tissues. The author said we were handicapped by the fact that many of the organisms that produce conjunctivitis in man do not lend themselves to experimentation in animals; such being the case with the Weeks' bacillus and that of Morax-Axenfeld.

**The Essentials and Unessentials of Ophthalmic Asepsis.**—HAROLD GIFFORD (Omaha) briefly discussed the bacteriology of the conjunctiva, edges of the lids and eyelashes and gave the results of experiments in disinfecting the same. The writer thought a certain share of the precautions taken by the general surgeon could be dispensed with for the ophthalmic operator. The preparation of the conjunctiva should be conspicuous for its simplicity; simple irrigation with sterilized normal salt solution or boric acid solution. He deprecated the use of the preparatory bandage as increasing the number of germs in the normal sac. The best application was one of the shields composed of an arch of some firm material. Instruments should be boiled 8 to 10 minutes in a closed vessel; the collyria should be sterilized at each operation. He thought that for the oculist no preparation of the hands beyond a good scrubbing with sterile soap and water and careful drying on a sterile towel was necessary.

*Discussion.*—CASEY WOOD (Chicago) advocated the method of tying off the canaliculi by simple suture in cases of infective

daercycystitis where the eyeball was to be opened, filling up the sac and canaliculi with argyrol prior to tying the suture. DUDLEY (Easton) called attention to the great value of making bacteriologic examinations of the conjunctival secretion as a routine practice in the office. FRICKS (Louisville) thought the ophthalmic surgeon should prepare for operation just as the general surgeon. He did not believe that boiling the instruments dulled the edges as much as was generally supposed; it was the operation that dulled them. BAKER (Cleveland) said it had been his custom for a long time to place his instruments in boiling water; he did not boil his knife long and while waiting wiped the knife with bits of sterile cotton held in the forceps in the boiling water. ELLETT (Memphis) referred to a method he had recently used to prevent infection in a cataract extraction where there was an incurable conjunctivitis. Previous to the extraction he incised the conjunctiva and dissected it up from the eyeball all around the cornea; he then picked up the edges of the conjunctiva and bringing them up over the cornea, sutured them there, after having extracted the lens. The sutures were removed on the fourth day, when the corneal wound was healed and the conjunctiva slipped back to its natural position. Patient got vision of 20/30 without needling operation. PARKER (Detroit) had operated on one case after the method employed by Ellett with good result and vision of 20/40. CLAIBORNE (New York) called attention to the fact that the health and vitality of the patient had a great deal to do with the matter of healing of the corneal wound, citing a case of nonclosure for a long time although there was no infection. GIFFORD (Omaha) said that a number of years ago DeWecker had recommended the covering in of the corneal wound in these cases with membrane and the use of a flap from above had been recommended. For several years he had been using the flap method.

**Development of the Fusion Center in the Treatment of Strabismus.**—NELSON M. BLACK (Milwaukee) designated the fusion center as the dominant center of the visual apparatus and said that from it must emanate all the impulses to the various subsidiary centers for all changes in the accommodation, position of the visual axes and position of the head and body that are required to bring corresponding retinal points into focus. Any disturbance or condition of nondevelopment of this center is the cause of those heterophorias or heterotropias not due to abnormalities in the anatomic relation of the orbit and extrinsic muscles or their paralyses. He considered the various causes of the nondevelopment of this fusion center; the method of developing its function with the amblyoscope during the existence of strabismus. He considered that if treatment did not result in parallelism of the visual axes and operation had to be resorted to the fusion center, being in a developed condition, could better proceed with its function as soon as the visual axes were made parallel.

**A set of charts for stereoscope to be used for an amblyopic eye or for treatment of squint** was shown and explained by A. B. HALE (Chicago.)

*Discussion.*—SAVAGE (Nashville) did not believe in the existence of a fusion center, but in volitional centers controlling the recti and oblique muscles, and basial, or reflex centers, all being under the control of the fusion faculty. WOOD (Chicago) said that binocular single vision is a thing that every child has to acquire; he doesn't possess it at birth. He strongly advocated the use of the Worth instrument for exercising the children. He used practically only three pictures, one of which was the bird and cage, which the child would always recognize. The child should be exercised three or four times a day with the stereoscope at home and at least three times a week in the office. JACKSON (Denver) called attention to the advantages of the fusion tubes suggested by Priestly Smith, and thought the child would be easily induced to keep up the use of that instrument, more so than with the pictures. STEVENSON (Akron) had found the Worth instrument of great service in the cases of squint. He thought the term "fusion faculty" preferable to that of "fusion center" and that it was the principal factor in binocular vision.

**Cramp of the Ciliary Muscle Due to Eyestrain.**—J. W. WRIGHT (Columbus, O.) referred to cramp in other parts, as in the fingers and hands of telegraphers, pianists, typewriters, etc., due to prolonged contraction of certain muscles and said that similar conditions occurred in the muscles of accommodation; that it occurred in emmetropia as well as in refractive errors. He spoke of the frequency of this cramp and considered that the etiology was particularly enforced near work: ametropia, especially hypermetropia and astigmatism. He referred to the differential diagnosis between this cramp and hypertrophy of the ciliary muscle. As to treatment he thought that cycloplegics were of only transient value and should be supplemented by internal treatment. The writer had found gelsemium of considerable value in these cases.

*Discussion.*—JACKSON (Denver) said as to treatment that the important consideration was the discovery and removal of the cause, which was generally uncorrected ametropia or some overuse of the eye. When that had been thoroughly attended to the condition generally cleared up very quickly. DONOVAN (Butte, Mont.) had found homatropin more or less unreliable in the treatment of these cases and preferred the use of hyoscin hydrobromate. RYAN (Galesburg) said that as Dr. Wright had made the statement that he was never able to get relaxation of the spasm by the use of the gelsemium alone he thought that would militate against its employment.

## FOURTH SESSION.

**Some Observations on the Eye Complications of Small-pox During the Recent Epidemic in Cleveland.**—A. R. BAKER (Cleveland, O.) exhibited a chart showing the character of the complications and referred to a number of cases in which loss of the eye resulted. The total number of cases occurring was 1,248, with 224 deaths, 17.9%. He referred to the fact that one-third of all the cases of blindness in Europe before Jenner introduced vaccination were due to smallpox. The infection is carried into the eyes from the skin. The eye complications were greatly to be feared. As to treatment no specific treatment had been found. Frequent washing of the eyes and the use of such antiseptics as were not harmful were indicated.

[To be continued.]

## AMERICAN PROCTOLOGIC SOCIETY.

Fifth Annual Meeting, Held in New Orleans, May 5-6, 1903.

[Specially reported for *American Medicine*.]

**The Qualifications for Membership in the American Proctologic Society.**—After the transaction of preliminary business President EARLE (Baltimore) among other things said: "Now is the time that our foundation is being laid and the life and success of the Association depend upon the wisdom and discretion with which it is laid. And just at this time and juncture it seems to me that our attention should be called to a matter of the gravest importance to the continued life and usefulness of our Association. The profession, and especially general surgery, is already prophesying that no great good can be accomplished in such a restricted field, and where work to be done is so near the surface and within reach of the simplest observer. It is certainly expected that if we are to be recognized as leaders in this line of work we must use as our foundation the cardinal principles that underlie both general surgery and medicine. When fairly upon its feet there is nothing more important to the perpetuity and usefulness of an association than the character and ability of the members it gathers in, and upon whom the position to be taken by the association depends. It is quality, not numbers, that we most need; neither the one whose usefulness in proctologic work is interfered with by his interest in other departments of medicine or surgery, nor the pseudoproctologist, should apply for membership in this Association. The principal object the members of this Association have had in keeping it a separate and distinct organization from the American Medical Association has been that we might control the character of its membership, not from any selfish or narrow motives, as is evidenced by the welcome we have always accorded to those who are not members to attend our general meetings, but for the broad and worthy object of enrolling upon our list of members only men of ability, learning, and with the avowed purpose of bending all their energies to advancing their knowledge of rectal medicine and surgery. Candidates for admission to the American Proctologic Association should be specialists in that line of work, meaning thereby that they devote their energies chiefly to it. If men in the various specialties of medicine would only be sufficiently honest and unselfish as to confine themselves strictly to their special work, there would be no necessity for these suggestions that I am now making. I do not mean to say that our work is so complicated that others than rectal surgeons cannot perform such operations. A general surgeon can perform iridectomy, but who would be so foolhardy as to go to a general surgeon for such an operation when a competent oculist is at hand? So it is in ours, and in all other specialties; the man who confines himself to one line of work must be far below mediocrity if he cannot perform the operations in his line better than the general surgeon or those in other special lines of work. In order to be recognized by this organization one should be something more than a mere itinerant vender of a pile ointment, or a pile doctor whose only armamentarium consists of a hypodermic syringe and a bottle of carbolie acid. We need well educated, well trained, and well equipped men to carry on this work. We have submitted to us operations that require the most perfect surgical technic and the greatest skill, the coolest head and deftest hand."

**X-ray Therapy in Anorectal Diseases.**—J. RAWSON PENNINGTON (Chicago) dwelt upon the importance and efficiency of this agent in the treatment of pruritus and when the cause is local. The society asked Dr. Pennington to continue his researches.

**Tuberculous Ulceration of the Rectum and Anus.**—L. A. ADLER (Philadelphia). This paper will appear in a future issue of *American Medicine*.

**Primary Tuberculosis of the Rectum: Report of Cases.**—LEON STRAUS (St. Louis) presented a very interesting paper.

**Atony of the Rectum and Anal Sphincters: Its Etiology, Pathology, Diagnosis and Treatment.**—WILLIAM BODENHAMER (New York) said: "Atony of the rectum and colon is most commonly met in delicate women of a lax muscular fiber, and in those whose sedentary occupations lead to a neglect of the necessary measures to ensure the regularity of the functions of the organ. It is also frequently met with in delicate children. In the treatment of rectal atony the first consideration is to enjoin a strict observance of regular habits respecting a daily evacuation of the rectum, and this may be

aided and often attained by simple means, such as the injection of half a pint of cold water into the rectum at the regular time of going to stool; cold being tonic, stimulant, and astringent, and acts somewhat similarly to nux vomica, by exciting the sensibility and contractility of the organ; but it should be discontinued as soon as the object of its use has been attained. In the more obstinate cases, however, the chief remedies should be nux vomica, alone or combined with some other ingredients, together with the employment of rectal injections composed of powerful astringents and tonic substances, with the intention of inducing contraction, corrugation, and condensation of the relaxed and weak muscular fibers of the rectum, by which they become shorter and firmer, and thus aid in diminishing the morbid organ to its normal dimensions and tone.

**Obstipation: Its Causes, Effects, Diagnosis, and Treatment.**—JOHN L. JELKS (Memphis, Tenn.) stated: "Obstipation is the term used by proctologists to denote mechanic obstruction of the bowel, and is preferred to the generic term, of which obstipation is one variety." He classed the causative factors as (1) extravisceral; (2) perivisceral; (3) visceral; (4) intravisceral. One of the chief facts which the author wished to forcibly express is that other factors may and do cause obstipation or obstructive constipation, and a careful discrimination should be made before an operation is performed upon a supposed obstructing rectal valve.

B. MERRILL RICKETTS (Cincinnati) called the attention of the society to **cautero-angiotribe** as an efficient agent in the treatment of hemorrhoids and first degree rectal prolapse.

This subject, together with that of **hemorrhoids**, by GEORGE J. COOKE (Indianapolis), elicited considerable discussion, and Dr. Ricketts was instructed to make further report on the use of the angiotribe in the treatment of hemorrhoids. The discussion disclosed the approval of various methods of treatment of hemorrhoids, but none of them ideal.

**The Treatment of Anal and Rectal Diseases Without General Anesthesia.**—WILLIAM L. DICKINSON (Saginaw, Mich.) said: "The treatment of anal and rectal diseases has been so long associated with that of general anesthesia, that when a patient presents himself and we have made an examination, we unconsciously begin to solve the mental problem of how he will take the anesthetic, and the number of days he will be confined to the house after the operation. The time-honored treatment of anal fissure by dilation, under chloroform, was both effective and speedy, but we can accomplish the same results in a little longer time by the use of cocaine or eucain. Superficial fistula, ischioanal abscess, external hemorrhoids, and many cases of internal hemorrhoids can be operated upon under filtration just as well as general anesthesia. We owe it to our patients, and also to ourselves, to keep patients from going to the irregular practitioner, for as regular, educated physicians, we ought to be able to cope with all diseases of the rectum in an intelligent manner, and thus give entire satisfaction to our patients. Our students should be taught that the greater number of our patients seek our advice and aid for ailments that respond readily to office treatment that can be given without general anesthesia."

**A Unique Case: Molluscum Fibrosum of the Rectum in a Patient the Subject of the Typical Skin Lesion.**—A. BENNETT COOKE (Nashville): "The feature of the case which justifies the adjective 'unique' is not the skin diseases nor the occurrence of the multiple filroid tumors in the rectum, but rather the association of the two conditions in the same individual, and the further fact that the mucous and cutaneous tumors are identical in structure. He described the patient as emaciated, sallow, nervous, and despondent; at least a dozen calls to the stool in 24 hours; sphincters relaxed and perianal integument excoriated from the irritating discharges; anal canal patulous, in spite of numerous successive abrasions. The protoscope revealed the rectum almost completely filled with polypoid tumors, many of them ulcerated and bathed in a mucopurulent blood-stained secretion of exceedingly offensive odor. The growths began in the lowest rectal chamber, varying in size from a bird shot to an almond; the largest were uniformly pedunculated; those intermediate in size had sessile attachments, and the smallest appeared as mere elevations under the mucous membrane, well bedded. It was found that the lesions extended well into the sigmoid colon, smaller in size, and were attended by less inflammation of the mucosa. Beginning below, the tumors were removed by torsion with the forceps, and by biting them off with a curet against the sharp end of the protoscope. The hemorrhoid was rather free, so that it was possible to remove only a small number at a sitting. The operation was repeated from time to time during a period of three weeks, when the bowel, as high as could be seen, was clear of all but the smallest tumors. Sixty of the growths were removed. No anesthetic was employed. Dr. Cooke appended a report from the pathologist, which demonstrated the identity of the skin and rectal lesions. The production was considered a valuable contribution to proctologic literature."

**Officers Elected.**—President, William M. Beach, of Pittsburgh; vice-president, Leon Straus, of St. Louis; secretary-treasurer, A. Bennett Cooke, of Nashville; executive council, Samuel T. Earle, of Baltimore (retiring president), chairman; George B. Evans, of Dayton, O., and John L. Jelks, of Memphis, Tenn. The society adjourned to meet in Atlantic City, N. J., in June, 1904, on the first and second days of the meeting of the American Medical Association.

## ORIGINAL ARTICLES

## THE SYMPTOMATOLOGY AND DIAGNOSIS OF DISEASES OF THE PANCREAS.\*

BY

REGINALD H. FITZ, M.D.,†

of Boston.

The consideration of the symptomatology and diagnosis of diseases of the pancreas may appropriately be introduced by referring to the memorable communication on this subject by Friedreich<sup>1</sup> nearly 30 years ago. According to this authority "no single symptom which may occur in diseases of the pancreas is pathognomonic, and the concurrence of several does not always result in a positive diagnosis. Fatty stools, mellituria, epigastric pains with the characteristics of the celiac neuralgia and a palpable tumor lead among the symptoms most useful in diagnosis," and (p. 223) the presence of undigested, striated muscle fibers in the feces "is worthy of every consideration, and may, perhaps, prove of diagnostic value."

For awhile no material additions were made to our knowledge of the clinical pathology of the pancreas, but in 1887 the investigations of Müller,<sup>2</sup> and especially those of v. Mering and Minkowski<sup>3</sup> in 1889, excited a renewal of interest in the matter. Since then physiologists and pathologists, physicians and surgeons in various parts of the world have made numerous contributions to the knowledge of the functions and lesions of the pancreas, and this gland has become recognized as of the greatest importance in maintaining and promoting a healthy state of the body. Within the past five years have appeared the notable treatises of Körte, Oser, and more recently that of Mayo Robson and Moynihan. These are the authors now to be consulted for classified knowledge of the questions under consideration. From them is to be learned in what respects the clinical characteristics of pancreatic diseases are now more sharply defined than in the days of Friedreich and his predecessors.

It is generally agreed that the symptoms especially suggestive of pancreatic disease are dependent largely upon the resulting disturbances of its functions and upon the situation of the organ. The former include the various modifications in the composition of the urine and feces; the latter comprise the localized resistance, tenderness and pain, and the evidence of obstruction of the gastrointestinal and biliary tracts. Unfortunately for diagnostic purposes the functions of the pancreas are not the exclusive property of this gland, but are possessed to a greater or less extent by other structures and other agencies.

For more than a century it has been known that diabetes may be associated with disease of the pancreas. More than 80 years ago visible fecal fat was found to hold a like relation. Forty years later the presence of undigested muscle fibers in the feces first attracted attention. These observations have since been repeated with sufficient frequency to lead the physician to suspect, often to assert the presence of, disease of the pancreas when one or more of these conditions have been determined. The comparison, however, of the results of anatomic investigation with clinical observation makes it evident that diseases of the pancreas much more frequently occur without the recognition of glycosuria and fat and muscle in the feces than when these abnormalities are apparent.

The physician, therefore, wishes to know if one or more of these conditions are present in some diseases of the pancreas, why are they not present in all? If found in a certain instance of a single variety, why are they not

present in all or in most of the cases of this particular affection. Morbid changes of the pancreas are found frequently after death without symptoms having been observed during life to indicate their presence. On the other hand, the diagnosis of probable pancreatic disease, perhaps of the gravest sort, has been made from the recognition of one or more of the symptoms or signs which, at times, have been found associated with alterations of the pancreas, and the patient has recovered or the gland when exposed has presented no abnormal appearance.

From the data collected by Oser it is evident that the symptoms attributable to disturbed pancreatic function are almost invariably connected with chronic lesions productive of extensive destruction of pancreatic tissue or with interference to the passage of its secretion into the intestine. The pancreatic lesions usually associated with diabetes are those in which the common element of interstitial inflammation exists with a corresponding destruction of the parenchyma of the gland. This may occur in the form of the genuine, granular atrophy of Hausemann, in calculous pancreatitis, or in the sequence of chronic suppuration, cysts, and tumors.

Visible fecal fat and azotorrhea on the contrary are oftener associated with chronic conditions interfering with the flow of pancreatic juice into the intestine as obstruction of the ducts from calculi, stricture or tumors, than with those causing destruction of the secreting cells of the gland. Rarest of all is the presence of alterations which are associated with diabetes, and fat and numerous muscle fibers in the feces. The case reported by Fles<sup>4</sup> is almost unique in these respects. His diabetic patient ate much bacon and fat meat, and evacuated so much unabsorbed fat that it could be scooped by the ounce from the feces. The latter contained also large numbers of undigested, striated muscle fibers. The autopsy showed that the pancreas was represented only by fragments of the fibrous framework and scarcely recognizable traces of the gland substance. The duct could not be found. Nevertheless, it is evident from human pathology that extensive destruction of the pancreas may take place without observable modification of function. Franke<sup>5</sup> extirpated a cancerous pancreas, and although the patient lived five months after the operation, there was glycosuria merely for a few days, and the stools appeared normal. The patient of Trafoyer<sup>6</sup> was well 17 years after a pancreatic slough was discharged from the bowel.

The inference from such observations is that in extensive destruction of the pancreas without obvious disturbance of function enough of the gland is left intact, or an accessory pancreas or other organs or agencies are present to assume the pancreatic functions. Even when the pancreas presents an apparent integrity and fatal diabetes exist the researches of Ssoboleu<sup>7</sup> and Opie<sup>8</sup> make it evident that destruction of the islands of Langerhans may have taken place. Their investigations, and those of other observers directed to this possibility, add force to the suggestion that in the destruction of these islands may lie the important factor in explanation of diabetes in certain of the cases in which the gross appearances of the pancreas are normal. Hence with the recognition of various causes of glycosuria and diabetes, these affections, in the light of our present knowledge, are attributable to disease of the pancreas only in those instances in which there is extensive degeneration or destruction either limited to these islands or affecting also the parenchyma of the gland.

If the diabetes is associated with long-continued bronzing of the skin and enlargement of the liver, in the absence of jaundice and the characteristic distribution of the pigment in Addison's disease, the suggestion is direct that chronic, fibrous pancreatitis is present. Since the original publication by Hanot and Chauffard<sup>9</sup> on this subject, the bronzed diabetes of French writers, Apschutz<sup>10</sup> has tabulated 24 cases of this combination.

\* Read at the Congress of American Physicians and Surgeons in Washington, D. C., May 12, 1903.

† The writer wishes to acknowledge his indebtedness to Dr. J. H. Pratt, of Boston, for assistance in reviewing the literature of the subject.

The view of us that the affection of the pancreas is the remote result of the deposition of the pigment in the hemochromatosis of v. Recklinghausen has repeatedly been favored by recent writers.<sup>11</sup>

Steatorrhea is next in importance to glycosuria and diabetes as evidence of disturbance of pancreatic functional, though the views concerning its significance are somewhat divergent.

The presence of oil readily attracted attention, but it soon became apparent that the fat might assume a solid as well as a liquid form. It was considered that the presence of visible fat represented an increase of this constituent, the absorption of which was interfered with in consequence of the disease of the pancreas. Müller,<sup>12</sup> however, called attention to the frequent concurrence of disturbance of biliary secretion in the cases reported. He emphasized the importance of a lack of bile in the intestine as interfering with the absorption of fat, and considered it doubtful if a lack of pancreatic juice could cause steatorrhea. He endeavored to show that a deficiency of split fat the proportion of total fecal fat

fatty transformation in 3, in which there was also either obstruction or obliteration of the duct. Of the 17 cases of steatorrhea without jaundice, in 7 the lesions were tumors, chiefly cancer; in 6 calculi were present; 2 were fatty and 2 were single examples of cyst and atrophy.

It was considered interesting to note also the relation of diabetes or glycosuria to the steatorrhea. Diabetes was present in 11 cases and absent in 18. The lesions present in the former series were tumors, chiefly cancer in 4, calculi in 4, a cyst in 2, and fatty degeneration in 1 instance. Among the 18 cases of steatorrhea without diabetes were 11 of tumors, chiefly cancer; 2 of calculi, 2 of fatty transformation, and 1 each of atrophy and induration. Visible fecal fat, jaundice and diabetes were present in 3 cases only, 2 of tumor and 1 of cyst. This table, therefore, does not support the view that jaundice is an important factor in the origin of the fatty stools connected with disease of the pancreas. It suggests that in about three-fifths of the cases of steatorrhea attributable to pancreatic disease there is neither dia-

being normal, was the chief feature when there was lack of the pancreatic juice, and that interference with the flow of bile was the main cause of pathologic steatorrhea. Müller reported but three cases of pancreatic disease in support of his views. Jaundice was present in one only. In another the actual condition of the pancreas and its duct was not to be determined, as the patient was seen after having been operated upon for "cyst" of the pancreas.

In order to obtain further clinical evidence on this point, a table has been prepared to show the relation between visible fecal fat, jaundice and pancreatic disease. Only those cases are included which give anatomic evidence at an autopsy, a laparotomy or by the passage of a pancreatic calculus that there was actual disease of the gland.

Twenty-nine cases of steatorrhea are the basis of this table. Jaundice was present in 12 and absent in 17. Among those with jaundice, tumors, chiefly cancer, were present in 8. The lesions existing in the remaining 4 cases were a cyst in 1, and induration rarefaction and

betes nor jaundice, that in two-fifths there is either diabetes or jaundice, in about equal proportion, and in but few instances is there a combination of diabetes and jaundice.

Müller's researches were of value in another direction by calling attention to the clinical importance of a chemical analysis of fecal fat in cases of suspected disease of the pancreas. A table has been prepared showing the analyses given by him and others of fat extracted from the feces in health, catarrhal jaundice and in diseases of the pancreas with and without jaundice. The last mentioned include only those actually demonstrated either by the knife or by the passage of a typical calculus.

It is evident from this table that the feces of the healthy individual contain about 20% of unabsorbed fat and that in catarrhal jaundice this ratio may be doubled. In affections of the pancreas the percentage of unabsorbed fat is generally not much increased, except when jaundice is an accompaniment, thus sustaining the position of Müller.

In health this extracted fat contains from 20% to 30% of neutral fat, and from 70% to 80% of split fats, namely, fat acids and soaps. In 10 cases of disease of the pancreas the neutral fat ranged from 17.50% to 91.6%. In but 2 of these was the percentage of neutral fat below normal, while in 9 of them it was largely or greatly increased. That of split fat, on the contrary, was decidedly diminished in 9 out of 11 patients. In the remaining 2 it was as high as in health. The table thus bears out the view of Müller, though not without exceptions, that in pancreatic disease there is less splitting of the fat and consequently an increase of the neutral fat, thus giving a satisfactory explanation of the oily stools of the older observers.

On the other hand, there is a sufficient lack of anatomic control to permit his conclusions to be accepted without question. Enough pancreatic juice may have been supplied to effect the results of chemical analysis in many of the cases of obstruction of the duct of Wirsung by a flow through the duct of Santorini. If both ducts were closed and the pancreas extensively diseased an accessory pancreas may have existed. Müller himself recognized the influence of intestinal bacteria and gastric contents<sup>13</sup> in splitting fat, although he regarded their importance as slight. It is obvious also, as stated by him, that the feces may contain an excess of fat not only in cases of jaundice, but also when there is a super-

cases have been found which fulfil the demanded requirements. In 6 sugar was present in the urine; in 5 there was visible fecal fat, and jaundice was present in 2 instances. In Lichtheim's case the diabetic patient's diet was composed largely of meat, but diarrhea existed, a combination sufficiently explanatory of azotorrhea without the assumption of the presence of disease of the pancreas. The relative frequency of steatorrhea as compared with azotorrhea indicates that proteids are better digested than fats if the supply of pancreatic juice is notably diminished. Any significant increase of undigested muscle fibers in the stools would be expected only when there was extreme diminution of pancreatic juice in the bowel, gastric digestion was relatively normal, the diet contained no excess of meat, and there was no diarrhea.

Bulky stools are mentioned by Oser<sup>15</sup> as suggestive of disease of the pancreas. These are notably excessive in quantity as compared with that of the food taken, and are composed of unabsorbed muscle fibers, fat and carbohydrates. He has met this condition in a number of cases in which the suspicion of pancreatic disease was confirmed.

The various possible disturbances of function in pancreatic disease have usually been sought by inspection and microscopic examination, and by the use of the simplest chemical and physical methods. It must be

RELATION BETWEEN DIABETES OR GLYCOSURIA, STEATORRHEA, AZOTORRHEA AND JAUNDICE IN DISEASES OF THE PANCREAS.

abundance of fat in the food and when there is disease of the absorbents within or without the intestinal wall.

Steatorrhea, therefore, is to be regarded as evidence of disease of the pancreas only when other causes of its presence can be excluded, the most important of which is interference with the flow of bile into the intestine. Its recognition depends not merely on the presence of fat resembling oil, butter, lard or tallow, but in doubtful cases requires the skill and facilities of the chemist trained in physiologic methods.

The probability that steatorrhea is due to extensive disease of the pancreas and may exist for years without disturbance to the general health is suggested in the communication of Walker.<sup>14</sup> His patient, a physician, free from jaundice, passed for 20 years large colorless stools of a peculiar putrid odor, occasionally accompanied by free oil, or fat, liquid or solid. During this period he was in perfect health and in the active pursuit of his profession. He died at the age of 90. There was no marked absence of fat. The pancreas was large, apparently composed of nearly purely fat. The duct was rendered almost absolutely impermeable within an inch of the duodenum by a very irregular calculus.

Despite the attention which has been given since the time of Friedreich to azotorrhea, as manifested by the presence of numerous undigested muscle fibers in the feces, but little clinical evidence has been offered that this sign is likely to prove of especial value in the diagnosis of diseases of the pancreas.

In the preparation of the accompanying table but 8

recognized, however, that any considerable disturbance in the digestion and assimilation of fat, muscle, and carbohydrates from affections of the pancreas has almost invariably been connected with extensive and protracted lesions. It is obvious, therefore, that feeding with an increased quantity of one or the other of these constituents of diet in suspected cases of pancreatic disease might be followed by appreciable changes in the secretions and excretions earlier than otherwise would have been the case. It is clear, also, that disturbances in the digestion of fats, starches and proteids, relieved by the addition of pancreas or its preparations to the diet, provided disease of the digestive glands could be eliminated, might furnish additional evidence in favor of the pancreatic source of the disturbance.

It has been repeatedly noted that the fecal fat has been observed when the patient was eating abundantly of fat. It is desirable, therefore, in possible cases of pancreatic disease to increase the quantity of fat in the diet nearly to the limit which is to be reached without producing steatorrhea in healthy persons or in patients not suffering from disease interfering with the absorption of fat. It is particularly desirable to determine the toleration of fat in those cases of diabetes in which the pancreas presents no abnormal conditions. These limits are not sufficiently known at present, especially as the thorough appreciation of this method of investigation demands the use of especial training and a properly equipped laboratory.

For the immediate future, however, observations are

more important which can be made simply with the eye, at the most aided by the microscope. Hartsen<sup>16</sup> gave eight to ten teaspoonfuls of cod-liver oil to two diabetic patients, in each of whom extreme atrophy of the pancreas was found, but there was no unusual quantity of fat observed in the feces. Müller<sup>17</sup> despite an almost exclusive milk diet in his case of cyst of the pancreas, found only a trifling increase in the fat extracted from the feces, and but little variation in the split and neutral fats from that observed when a mixed diet was taken. Herter gave to Northrup's patient with probable cancer of the pancreas an exclusive milk diet. Although the feces probably were fatty before this test was applied, no chemical analysis of their condition was reported. While the milk diet was being taken (see table) there was a large excess of fat in the feces, although there was no considerable modification in the percentage of neutral fats. The especial change seems to have been an increase in the percentage of fat acids and a diminution in that of the soaps. The reported cases are few in which pancreatic disease has been found after death, and properly controlled dietetic tests with fat have been made during life. Important additions to our knowledge are likely to be made by further observations in this direction.

In like manner should be tested the capacity of the

urine of the patients was collected every two hours after the glucose was taken. In 15 of 77 patients who died glycosuria occurred, and the postmortem examination showed alterations of the pancreas. In certain instances the changes were slight, and ascertained only by microscopic examination. The test was positive in three out of four cases of cancer of the pancreas. Unfortunately, the ease with which a similar result is obtained with this test in a great variety of conditions in which there is no reason to suspect disease of the pancreas makes it of little value in diagnosis under present conditions.<sup>19</sup> The comparison of the quantities of glucose necessary and the percentages of sugar obtained may lead to further information.

The functions of the pancreas may be tested also by the use of agents which demand largely the action of the pancreatic juice to promote their absorption and elimination. Salol was first suggested for this purpose by Ewald and Sievers.<sup>20</sup> It had been stated by Nencki that salol was split by pancreatic juice into salicylic acid and phenol, and that the former could readily be detected in the urine. It was recommended that the salol be given in capsule or in pills coated with keratin. A delay in the cleavage would suggest retention in the stomach or deficiency of pancreatic juice.

patient for digesting muscle in the intestine as compared with that of the normal individual or with one suffering from affections in which there is no reason for supposing that the pancreas or intestine is diseased. For this purpose it is important first to determine the condition of the gastric functions and then to introduce into the intestine the muscle fiber, as free as possible from the influence of gastric digestion. It may be that the glutoid capsules of Sahli, to be mentioned later, will suffice for the latter purpose, or that other more satisfactory means may be devised.

Müller found well preserved muscle fibers in his case of cyst of the pancreas when the patient was not eating more meat than a healthy adult could easily digest. A similar appearance was observed during several days while the patient was taking but little meat. The evidence furnished by this patient has only a relative value, since the nature of the lesion was determined by a surgical operation, and the condition of the pancreatic duct was known.

The possibility of testing the efficiency of the pancreas by attempting to produce an alimentary glycosuria also demands consideration. The researches of Wille<sup>18</sup> in this direction are especially significant. This observer gave at breakfast to each of 800 patients  $\frac{1}{100}$  gr. of glucose in a half liter of tea or coffee. This quantity was selected with the view that the limit of physiologic glycosuria lay between doses of 150 and 250 gr. The

Sahli<sup>21</sup> has suggested the use of "glutoid" capsules containing iodoform to determine the presence of pancreatic secretion in the intestine. It is claimed that these capsules are sufficiently hardened in formaldehyd to withstand powerful gastric digestion for at least 12 hours, although rapidly digested in pancreatic juice. If there is normal motility of the stomach, the iodine reaction will appear in the saliva in from four to six hours after the capsule containing the iodoform is swallowed, provided there is a satisfactory pancreatic digestion and there is no interference with intestinal absorption. Sahli<sup>22</sup> reports a number of cases in which the reaction was delayed for 24 hours or more, and obstruction of the pancreatic duct from cancer of the gland was found.

The late reaction is evidence of defective pancreatic digestion only when there are normal gastric motility and intestinal absorption. If the latter is defective and there is diarrhea the undigested capsule may be found in the feces. Fromme<sup>23</sup> applied this test in a case proving to be one of inoperable sarcoma of the omentum. Visible fecal fat was present, but neither jaundice nor glycosuria. The reaction did not appear till the end of 27 hours. In a patient who was found to have a "cyst" of the pancreas the glutoid capsule test gave only a slightly delayed reaction, from seven and a half to nine hours. Although these cases were reported to illustrate the inaccuracy of the test, the evidence given

is insufficient to exclude closure of the pancreatic duct in the first, and it is possible that the "cyst" of the pancreas was an omental bursitis, or, if of the pancreas, that there was no considerable interference with the passage of the pancreatic juice into the intestine.

The suggestion is obvious that if symptoms attributable to disturbed functions of the pancreas be present and other conditions, especially jaundice, be absent, the use of pancreatic preparations or of minced pancreas might favorably affect these disturbances and thus indirectly confirm the diagnosis of pancreatic disease. Fles<sup>24</sup> gave daily a calf's pancreas to his patient with atrophied pancreas and unrecognizable duct. The fat and muscle fibers disappeared from the feces, to return again when the pancreas was omitted from the diet. Repeated instances of the disappearance of visible fat from the feces and of improvement in diabetics have followed the use of pancreas and its preparations, but they are not included in this consideration as lacking the control of anatomic investigation.

The examination of the urine for pentose has attracted attention since the statement by Hammarsten<sup>25</sup> that the pancreas contained a nucleoprotein, the cleavage of which produced pentose. Salkowski, who had discovered the condition pentosuria, recognized the identity of the pentosazon in the pancreas and that in the urine, and suggested that pentosuria might be regarded as an affection of the pancreas. Blumenthal<sup>26</sup> showed that the condition might be persistent during a period of five months. Pentose was usually sought with phenylhydrazin, acetic acid and heat. Mayo Robson<sup>27</sup> states that Cammidge obtained yellow crystals in sheaves and rosetts from the urine of a patient with chronic pancreatitis by boiling it for a short time with an oxidizing agent and adding phenylhydrazin. Urine from a case of catarrhal jaundice gave a negative result when similarly treated. It was suggested by him that this test might prove useful in diagnosis. If these crystals were an osazon it is possible to find them even in normal urine, and further evidence is needed before any diagnostic importance in connection with pancreatic disease is to be attached to their presence. Blumenthal,<sup>28</sup> moreover, was able to isolate nucleoproteids from various organs and find pentose in them, which obviously excludes the pancreas as the necessary place of their origin.

It is known that the putrefaction of the proteid contents of the intestine is caused by bacteria and that their action is enhanced by the presence of pancreatic juice. In consequence, the aromatic compounds—indol, skatol and phenol—are formed, and the quantities of indican and of ethereal sulfates in the urine give evidence of the extent of the proteid putrefaction and indirectly of the condition of the pancreas. Gerhardt<sup>29</sup> observed an absence of indican in the urine in a case of obstruction of the small intestine, in which condition, according to Jaffé, it should have been increased. After the patient's death acute hemorrhagic pancreatitis and an obstructed pancreatic duct were found. Gerhardt suggested that the absence of indican when the small intestine was obstructed might be regarded as evidence of disease of the pancreas. Two confirmatory and one contradictory observations have been made. Oser, however, maintains that variations in the excretions of indican may have no direct relation to disease of the pancreas, hence be of no diagnostic value.

The quantity of ethereal sulfates eliminated seem to have a more constant relation to the extent of intestinal putrefaction and to the secretion of pancreatic juice. The clinical observations on these points, especially those sufficiently controlled, are few. Herter found increased indican and an increased ratio of ethereal to preformed sulfates in Northrup's case, in which disease of the pancreas, though not the condition of the duct, was ascertained. Edsall<sup>30</sup> concludes in his communication on this subject "if, with suspicion of pancreatic disease, factors which usually cause an increase of the ethereal sulfates

be present and yet the values be found low, the test would at present appear to be of distinct practical importance in diagnosis. Constipation, gastric hypoacidity or anacidity, icterus, grave anemia, and cachexia are very likely to cause an increase in the relative or absolute values of the ethereal sulfates."

Finally, Opie<sup>31</sup> has suggested the possibility of discovering in the urine the fat-splitting ferment set free in acute pancreatitis. He endeavored to determine its presence in one case by following the method proposed by Cassell and Loevenhardt which is based upon the decomposition of ethyl butyrate by the ferment and the production of butyric acid. The urine neutralized with potassium hydroxid was divided into two portions, one of which was boiled for the purpose of destroying the ferment. Ethyl butyrate was added to each specimen. That unboiled after 24 hours gave an acid reaction, while the boiled specimen showed little if any change.

The symptoms which have proved most useful in diagnosis are those which call attention directly to the region of the pancreas. They are the epigastric pain, tenderness, tension and tumor, with or without obstructive jaundice, and evidence of mechanical interference with the motility of the stomach and duodenum.

Pain, when present, usually is manifested early in the course of the disease and may be the initial symptom. It often suggests gastric cramp or intestinal or biliary colic. It is occasional, paroxysmal or persistent, dull or sharp, squeezing, tearing or piercing, mild or severe, even agonizing and not infrequently is associated with signs of collapse. It may be clearly defined near the median line, midway between the ensiform cartilage and the navel or may shoot laterally especially toward the left side. It occasionally is continued upward into the thorax or downward into the lower abdomen.

Tenderness is a frequent accompaniment, especially of persistent pain. It often is described as sensitiveness and although usually limited to the epigastrium, may be found in the region of the spleen or in the left groin. Ultimately tender spots may appear in remoter parts of the abdomen, especially when disseminated foci of fat necrosis accompany the pancreatic affection. Epigastric tension often is observed, and may be apparent at the outset or develop later in the course of the disease. When an early symptom it is followed soon by a circumscribed, tympanitic, epigastric swelling, evidently due to gaseous distention of the stomach.

The resistance found late in the course of pancreatic disease is due to the formation of a tumor. When the latter is the result of disease of the pancreas its characteristics depend largely upon the nature of the affection. Small, circumscribed, dense tumors result from chronic inflammation or neoplasms, usually of the head of the gland, while large, tense tumors of pancreatic origin in the left half of the epigastrium or symmetrically involving more or less of the upper abdomen are indicative generally of cysts of the pancreas or of collections of fluid in the omental bursa, more common than the former and generally confounded with them.

Jaundice, commonly slight and of short duration, is occasionally encountered in acute affections of the pancreas. Then it is oftener seen in the course of a few days after the onset of the attack than as an earlier symptom. Prolonged jaundice is a frequent accompaniment of chronic affections of the head of the pancreas, especially of fibrous inflammation and neoplasms. The association of the jaundice with distention of the gallbladder is sufficiently frequent as noted by Courvoisier and others to make this combination suggestive rather of disease of the pancreas than of affections of the biliary tract.

Motor disturbances of the stomach and intestine are among the usual symptoms associated with pancreatic disease. Vomiting, sometimes frequent or incessant and often distressing, is customary among the early symptoms of acute pancreatitis, and constipation, at times

obstinate, is the rule. So constant are these motor disturbances that the frequent diagnosis in cases of acute pancreatitis is acute intestinal obstruction.

The prolonged motor insufficiency of the stomach mechanically induced by chronic affections of the pancreas, especially from enlargement of the head of the gland, not infrequently give rise to dilation of the stomach. In consequence frequent or persistent vomiting may take place late in the course of pancreatic disease.

Although the diagnosis of diseases of the pancreas in the light of our present knowledge practically depends more on the symptoms calling attention to the locality of the organ than upon the evidence of disturbances of its function it is reached eventually by the exclusion of other sources than the pancreas of the local symptoms.

The differential diagnosis lies first between acute and chronic affections and second between the several varieties of chronic pancreatic disease. The former include pancreatic hemorrhage and the hemorrhagic gangrenous and suppurative varieties of acute pancreatitis, all of which are characterized by similar symptoms and some of which presumably represent stages of the same affection. The latter include chronic pancreatitis with or without calculi, cysts and tumors.

Of acute pancreatitis it may be said now as in 1889<sup>22</sup>: "The symptoms are essentially those of a peritonitis beginning in the epigastrium and occurring suddenly, during ordinary health, without obvious cause. The diagnosis, therefore, is based on pain, tenderness and tympany limited to the region of the pancreas, and on the gradual development of a deep-seated peritonitis in the same place."

#### DIFFERENTIAL DIAGNOSIS.

The differential diagnosis lies practically between an irritant poison, perforation of the digestive or biliary tracts, and acute intestinal obstruction. An irritant poison is excluded by the history of the case and by the examination of the vomit. Perforating ulcer of the stomach or duodenum is to be excluded by the absence of pain after eating, hemorrhages from the digestive canal and cachexia. Acute perforation of the transverse colon is rare, and the resulting peritonitis progresses more rapidly and is likely to be general. Perforation from gallstones is usually preceded by attacks of biliary colic and jaundice, while the seat of the pain is rather in the region of the gallbladder than in that of the pancreas. Acute intestinal obstruction is most likely to give rise to doubt. It is to be eliminated by determining the patency and capacity of the large intestine, by the rarity in the epigastrium of an obstructed small intestine, by the immediate presence of localized tenderness and by the usual absence of conspicuous, general tympany or limited distention of intestinal coils.

In the cases of acute pancreatitis thus far reported no new evidence, unless that of Opie be confirmed, has been furnished which gives to the diagnosis more than a variable degree of probability. Certainty has been reached only by a laparotomy or a postmortem examination. The former has made clear the condition of the pancreas by the usual disclosure of multiple areas of disseminated fat necrosis, a condition occurring on an extensive scale only in the sequence of acute pancreatitis, or by the demonstration of the enlarged, hemorrhagic or necrotic pancreas as the focus of the surrounding peritonitic manifestations.

Fortunately the exploratory laparotomy in an increasing number of cases has proved the most satisfactory method of treatment, and, like most abdominal operations for the relief of acute symptoms, is the more helpful the earlier in the course of the disease it is performed.

The diagnosis of chronic pancreatic affections is based usually on the occurrence of localized pain and upon the presence of a tumor. The pain may exist without the tumor, but the latter is rarely present without the former at some time during its formation. The pain of chronic pancreatic affections is often a deep-seated discomfort; when severe it is likely to be paroxysmal, and then is suggestive of biliary colic, but is referred rather to the region of the pancreas than to that of the biliary tract. The tumor is of slow or rapid growth, large or small, perhaps distinctly palpable only in narcosis, fixed or slightly movable, with or without symptoms of pressure upon the surrounding parts. Its position behind the stomach and above or behind the colon is made apparent by inflation and percussion of these portions of the alimentary canal. Evidences of disturbance of pancreatic function are to be sought along the lines previously mentioned, but experience has shown that definite and convenient additions to our knowledge must be made before functional disturbances of the pancreas can be ascertained sufficiently early and with sufficient certainty to render assured the pancreatic source of the disease. The discovery of sugar in the urine should lead to the examination of the feces for fat. The presence of the latter should suggest the search for undigested muscle fibers and for glycosuria, and alimentary and therapeutic tests should be applied to all suspected cases.

The differential diagnosis lies between chronic pancreatitis, with or without pancreatic calculi, cysts, and tumors.

The association of jaundice with tumor has led to the diagnosis of chronic pancreatitis and to its effective treatment by Mayo Robson and others. The relatively rapid formation of the tumor in the sequence of symptoms suggestive of gallstones may serve in certain instances to differentiate this condition from malignant neoplasms.

The discovery of characteristic calculi in the feces has made clear in a few instances the source of discomforting or severe symptoms without tumor in the region of the pancreas, and exploratory laparotomies have confirmed or suggested the diagnosis of neoplasms of this organ.

The various possibilities of a more accurate study of the symptomatology and diagnosis of diseases of the pancreas suggest an early advance in our knowledge of the subject. With the increase of clinical laboratories in our general hospitals and with the more frequent addition of biologic chemists to the force of pathologists the errors of the past are likely to be avoided and new lines of research are sure to be planned.

THE MEDICOLEGAL TEST OF BLOOD-STAINS.

BY  
E. N. LAYTON, A.B.,  
of Chicago.

One of the chief problems in forensic medicine presented to the medical expert is the identification of human blood-stains. Many methods for proving the presence of blood have been presented. The only tests which are now recognized as reliable are these: 1. The finding of the red blood-corpuscles. 2. The proof of the presence of hemoglobin. 3. The demonstration of hemin crystals. 4. The formation of the characteristic hemato-porphyrin spectrum. In the first two the blood must be fairly fresh; in the last two it may be fresh or old.

The identification of blood as such has been exhaustively treated and final conclusions reached by which it is now possible to say absolutely whether or no a given stain was made by blood; the further question, that relating to the source of the blood, has been before the profession for years, but only since 1896 has material advance been made toward its solution, while the greatest success has been attained during the past 18 months.

All efforts at differentiating blood-stains have been directed along one of two lines, *first*, tests based upon microscopic findings, and *second*, tests based upon processes which may be demonstrated by test-tube reactions.

It has been the object of the work herewith presented to answer as adequately as possible the following questions:

1. A given stain having been proved to be blood by one of the absolute methods above cited is it possible to prove whether or no the stain was made by human blood?
2. If so, is the proposed test always specific?
3. Is its accuracy modified by (a) the age of the stain or (b) the admixture of other blood or foreign matter?
4. Is the proposed test sufficiently accurate and invariable for medicolegal purposes?

Before entering into a discussion of my experiments a consideration of the work already done in the same field is appropriate.

THE MICROSCOPIC TESTS.

Birchmore<sup>1</sup> claims that he can distinguish human from animal blood microscopically, and moreover that the blood of individuals can be distinguished by the same means. His method is to measure the red blood-corpuscles in a given specimen of blood and compare these dimensions with those of corpuscles of known origin. The diameters are taken by means of a micrometer eyepiece and are tabulated and finally plotted as curves. The measurements in each specimen vary widely, of course, but the author says the curves so plotted are so very similar that having examined a given specimen of blood and constructed its curve he can say positively to which "curve-group" the blood belongs. This method has not been employed by any other writer in the literature. It is limited to the examination of fresh blood.

Moser<sup>2</sup> believes he can differentiate the blood of man from that of lower animals by a microscopic examination of the hemoglobin crystals. For a successful test the blood must be fluid and fresh, or at least not very old, that the characteristic crystals may be obtained. However, on one occasion<sup>3</sup> he did obtain the characteristic reddish-brown crystals when applying the test to some stains he found on the ground. The age of the stains in this instance was unknown. This method, at best, is not generally applicable for medicolegal purposes, because questionable stains are so apt to be very old.

A very promising method is that suggested by Ziemke.<sup>4</sup> He tests the solubility of the hemoglobin of

different bloods in the various alkalies. He reports that human hemoglobin was invariably dissolved sooner than that of lower animals. The following tabulation shows the average of his results:

Animal.	Dissolved in minutes.	Ratio.
Man .....	5.6	1.0
Cat .....	28.8	5.0
Dog .....	36.5	6.5
Rabbit .....	38.1	6.8
Mouse .....	61.1	10.9
Horse		
Sheep		
Ox		
Pig		
Calf	More than 120.0	?

The chief objections to the microscopic tests are these: (1) The large amount of blood required; (2) the great variability of the red blood-corpuscles, even in fresh blood; (3) the absence both of red blood-corpuscles and of hemoglobin crystals in old stains.

THE SERUM TESTS.

The serum test for blood originated with Bordet,<sup>5</sup> who in 1898 published his first observations. In this paper he announced that as early as 1896 both he and Gruber had demonstrated the agglutinating and hemolytic power of the sera of different animals, and that "the converting and agglutinating property does not belong entirely to the animal injected, but is increased many fold by the injection of the serum of another animal." In his later work, Bordet began by testing the agglutinating power of various animal sera against cholera vibrios, colon bacilli, typhoid bacilli, tetanus bacilli, and the action of these same sera upon the red blood-corpuscles of other animals. He found, for example, that fresh chicken serum agglutinated and then destroyed the red globules of rabbit blood. If the serum was heated to 55° C. during the test the agglutination occurred, but there was no destruction of the globules. He says that it is possible, by frequent injections of a given serum into a susceptible animal, greatly to increase the agglutinating and destroying power of the animal's serum for the particular blood injected. To demonstrate this, he injected guineapigs intraperitoneally five to six times with 10 cc. each of defibrinated rabbit blood. A rapid and positive reaction was obtained with a dilution of 1 to 18 in two or three minutes, the tested blood becoming red, clear and limpid. His test serum lost its destroying power but not its agglutinating property when heated one-half hour to 55° C. The destroying power was reestablished if to the serum which had been heated to 55° C. a certain amount of serum of a normal uninjected guineapig was added.

He then modifies his statement regarding the inaction of the heated serum, declaring that it is not quite exact to say that "defibrinated rabbit blood remains truly intact. A destruction of red blood-corpuscles does occur, slow and imperfect, it is true, but sufficient to impart a red tinge more or less visible. This is due to the fact that the defibrinated blood contains not only corpuscles, but also serum charged with a certain amount of alexin. And so we come to see that the alexin of a new rabbit acts on the corpuscles of the same animal when these are impressed with the agglutinating substance of active serum. But the proportion of alexin is not sufficient to destroy the enormous quantity of globules present. And this is why, in the mixture, the destruction of the corpuscles is slow." He obtained no reaction when the serum of a normal noninjected animal was used. The serum immunized with rabbit blood did not react to the serum of the pigeon, but there was a reaction to the serums of rats and mice, which latter were also affected by the serum of a normal guineapig, though to much less degree. The same reaction occurred in a living immunized animal, when rabbit serum was

injected intraperitoneally, and to a less extent when it was injected subcutaneously. The serum of a normal guineapig so injected was not altered. He found that the serum thus elaborated by the guineapig after injection with rabbit serum was toxic for the rabbit, killing it when injected in doses of 2 cc.

He concludes that these reactions are due to two distinct substances, the one existing only in the serum of the immunized animal, the other an alexin existing in the normal animal. The latter has very little agglutinating power, but becomes very powerful when mixed with the first substance.

It remained for Tchistovitch<sup>6</sup> to perfect the work of Bordet. He used the same methods employed by Bordet, and treats in his paper largely of the theory of the precipitation obtained by the injections. In most of his experiments he injected rabbits and guineapigs with the serum of eels, the rabbits being much easier to immunize, and obtained a reaction when some of the homologous serum was mixed with the immune serum. The reaction consists of two parts, first, an agglutination and dissolution of the red blood-corpuscles, and second, a coagulation and precipitation of a substance insoluble in water, neutral salts and alkaline carbonates, but soluble in alkalies and acids. These two processes are distinct because the agglutination can be produced in sera which do not cause coagulation. The coagulation is the specific reaction desired and will occur only when the homologous serum is used. Heating the test material prevents the precipitation.

The next work of any importance was done by Schütze<sup>7</sup> in 1900. He followed the plan adopted by Bordet and demonstrated that when an animal is injected with the serum of a different species, a toxin is generated which has the power of destroying or dissolving the red blood-corpuscles of the species whose blood was injected.

In the first experiments of Uhlenhuth<sup>8</sup> he administered per oram and injected intraperitoneally into rabbits the albumen of hens' eggs. When the blood of the treated animal was drawn and mixed with some of the same egg-albumen solution, a reaction occurred. He obtained a similar though a fainter reaction when the test serum was mixed with the albumen of pigeon eggs. But when pigeon-egg albumen was injected in the first place the relation of the two reactions was reversed. All other albumens gave negative results. The reaction was unchanged when the tested serum was heated to 60° C. He then injected test animals with chicken blood, instead of with the albumen. In this case also the test was positive with the chicken's blood and negative with all others. He claims that he is able with one drop of his test-serum to obtain a positive reaction in a solution of egg-albumen diluted 100,000 times.

Friedenthal<sup>9</sup> makes an exhaustive review of the literature regarding the blood-relation of allied species, but makes no medicolegal application of the test.

Somewhat later Uhlenhuth<sup>10</sup> experimented with injections of rabbits with cow's blood, obtaining an absolutely specific reaction. He does not, however, mention any reaction with the blood of monkeys. Dried blood, he found, was as active as if fresh.

Nuttall and Dinkelspiel<sup>11</sup> give the introductory abstract in the paper here cited of the extended report published by the former in the *Journal of Hygiene*, which report is abstracted below.<sup>12</sup> This is the first and most extensive work on the subject recorded in English.

The experiments were made with rabbits, injecting successively the blood of the dog, horse, sheep, ox, and of man. Using the sera of these injected animals as bases, the sera of 35 different animals were tested, and specific reactions obtained with the blood of the sheep, ox, and horse. The test with human blood also responded strongly with the human blood and gave a faint cloudiness with horse, ox, and sheep blood. These

results were unaltered by the use of fresh or old, putrid or septic blood, and were not changed by the mixing of several bloods, when testing for a given one. No reaction was obtained unless the mixture contained the blood sought. Nuttall concludes that "in this test lies the most delicate means of detecting and differentiating bloods, and we may hope," he says, "that it will be put to forensic use." Later in the same year<sup>13</sup> Nuttall made more extensive experiments, especially with monkey's blood, but adds nothing more conclusive.

Wasserman and Schütze<sup>14</sup> published their results one week later than did Uhlenhuth, although they claim to have been working on the problem some time before. At any rate, with precisely the same methods as those employed by Uhlenhuth, they reached the same conclusions. However, they made a strong point of the fact that they obtained a slow, indistinct, but positive, reaction with the blood of apes. If the blood of monkeys can be excluded, they believe the test may then become reliable for medicolegal purposes.

Stern<sup>15</sup> reviewed the experiments of Uhlenhuth and made similar tests, injecting rabbits subcutaneously with human blood. He was able to obtain a positive reaction, even when the test-serum was much diluted. Albuminous human urine gave a similar, though a weaker reaction. His results were negative with the blood of the ox, horse, wether, and hog. He believes the test is not absolutely specific, since he was able to obtain a reaction with certain of the apes. This fact, he says, is an obstacle to the forensic use of the test.

Mertens<sup>16</sup> began as did Uhlenhuth, by injecting rabbits intraperitoneally with egg albumen, and later introduced human serum. His reactions were positive with human blood and with albuminous urine, although weaker in the latter and quite negative with normal urine. During his experiments one of the test-rabbits gave birth to a litter of three young ones on the seventh day of the injections. One of these was bled, and its serum was also found to react positively with human blood and albuminous urine.

The results obtained by Dieudonne<sup>17</sup> were identical with those of Mertens. He used human blood, albuminous urine and pleural exudate, obtaining positive results in each case. The human blood injections produced the strongest antiserum, and the reactions were always more frank when the substance injected was employed in the test; *i. e.*, if blood was originally injected, the reaction was better if blood was used in making the test. He believes with Mertens that the blood of the young of the injected animal also possesses the same antibody.

Deutsch,<sup>18</sup> following the plan of Bordet, employed the hemolytic test, obtaining a certain amount of hemolytic power after the injection of 30 cc. of human blood. The tests of human blood were darker than the control tests, which fact he attributes to his mistake of allowing some of the plasma to be injected with the serum. He decides that the serum which will dissolve the red cells most readily indicates the species of animal to which the injected cells belong.

Ziemke,<sup>19</sup> after the manner of Wasserman and of Uhlenhuth, tested 18 different bloods. He says the reaction is positive for human blood and negative in the case of all the lower animals, except the monkey. With this blood a positive reaction occurred, but it was slower and less intense. He was able to identify fresh human blood in soapy water, in urine, or when soaked into linen and dried. The reaction from the serum of animals injected with serous exudates was positive, but weaker than when blood was used.

In the summer of 1901, Uhlenhuth<sup>20</sup> made further experiments, using old, dried blood-stains of known and of unknown origin, and says he made positive diagnoses in each case. He also made tests for the identification of blood in solutions of carbolic acid, corrosive sublimate, borax and soapy water, and in earth. He succeeded in

diagnosing each variety of blood. He states, however, that the blood of allied species gave reactions when mixed together, although these reactions were weaker than in the case of the species whose blood was injected. He believes this method might be employed as a means of demonstrating the relation of species; for example, the test shows the sheep to be more nearly related to the goat than to the ox, because the reaction obtained with the blood of the former, when "antigoat" serum is used, is stronger than that with the latter. He says the age of the stain is immaterial, but that the reaction, to be positive, must be immediate. This last clause is questioned, as will be brought out in the record of these experiments.

Corin<sup>21</sup> reviews the literature and repeats the earlier experiments of Uhlenhuth with practically the same results; but he believes the test is not sufficiently invariable for absolute reliance.

In the same volume containing the report of Corin, Frenkel,<sup>22</sup> after reviewing the literature on the subject, concludes that in the method of Uhlenhuth or of Wasserman and Schütze we possess a new serum reaction which is exact, specific, very sensitive, and one which permits of an absolute diagnosis of human blood, with the one exception of monkey blood.

In November, 1901, Nuttall<sup>23</sup> read a paper before the Royal Society, in which he described in detail his methods, and reported his tests made with some 230 bloods, obtaining with human serum a negative result in all cases except in those of human and monkey blood. He cites the fact that the test is adequate for mixtures of different bloods containing human blood as well as in the case of human blood in earth. He says the reactions for human and for monkey blood differ only in degree. His tests on several species of monkey blood showed that the Old World monkeys are more nearly related to man than are the New World monkeys. This conclusion is based upon the amount of precipitate obtained in each case. He also made similar comparative tests with dog and ox antiserum, and mentions the existence of a possible blood relation between all allied species. Later<sup>24</sup> he describes some 50 additional experiments, and states that if monkey blood can be excluded the test may be called specific, and "is capable of medicolegal application for the detection of blood-stains." Moreover, he believes it possible by this means to study the relation of different allied species by the degree of the serum reaction in each case. He concludes his paper by a postscript, scoring Uhlenhuth for taking to himself the credit of having discovered the serum test, whereas Nuttall believes the credit of discovery is due to Tchistovitch, and only that of the elaboration of the method to Uhlenhuth.

Grünbaum<sup>25</sup> notes the work of Nuttall, just cited, and reports his own similar experiments. He believes the fact that human blood causes a quicker and more marked reaction than monkey blood is sufficient to constitute a differential test, and suggests that the reaction should be studied microscopically, after dilution, while it is occurring.

Linossier<sup>26</sup> says the biologic test is not specific, as formerly thought, but only relatively so. The reaction is more marked with the homologous serum. When using rabbit serum immunized with human blood, he obtained strong reactions when human blood was tested, and fainter reactions with the blood of the cow, horse, dog, guineapig, pig, fowl, the reaction diminishing in intensity in the order named. He also obtained similar comparative results when other sera were injected. He believes that a dilution of 1 to 1,000 might allow of a precipitation only in the case of the homologous serum. This fact he believes renders the test only relatively specific.

Nuttall<sup>27</sup> again reports the progress of his experiments, showing the reaction of the biologic test in homologous and other sera. He believes the exact degree of

relation of all species can be tabulated when the test is sufficiently worked out and perfected. He still believes the test is specific, because the degree of reaction is so much greater in the case of the homologous serum that mistakes are unlikely. He describes in this article an apparatus he has constructed for measuring the amount of precipitate after it is drawn up into capillary tubes.

The first report of any work on the serum test in the United States was made in April, 1902, by Whitney,<sup>28</sup> of Boston, who describes minutely the method of the intraperitoneal injection of rabbits with human serum. He obtained uniform results whether blood or the various exudates or transudates were employed in the injections. In one case he attempted to hasten the formation of the antiserum by giving a single injection of 100 cc., but the blood of the rabbit so treated was negative. He makes the somewhat remarkable suggestion that in case of a suspected murder the expert making the test of the blood-stains should also make a parallel test of the blood of the victim, obtained at autopsy, "that any doubt as to this individual's blood giving the serum reaction can be set at rest." As a matter of fact human blood always gives the serum reaction with properly elaborated antiserum. Hence the above statement is, to say the least, remarkable.

Herewith is given a detailed account of my experiments, conducted between April 1 and May 25, and between November 1 and December 30, 1902, in the Bacteriological and Research Laboratories of the Northwestern University Medical School, under the direction of Professor F. Robert Zeit.

#### PRODUCTION OF THE IMMUNE SYSTEM.

RABBIT No. 1.—April 9: Weight, 2,855 gms.; temperature, 100° (normal). Injection, 10 cc. hydrocele fluid, subcutaneously.

April 11: Weight, 2,855 gms.; temperature, 100°. Injection, 10 cc. hydrocele fluid, subcutaneously.

April 14: Weight, 3,027 gms.; temperature, 99.4°. Injection, 10 cc. hydrocele fluid, subcutaneously.

April 16: Weight, 2,987 gms.; temperature, 100.8°. Injection, 5 cc. hydrocele fluid, subcutaneously.

April 18: Weight, 2,900 gms.; temperature, 100.8°. No injection.

April 21: Weight, 2,753 gms.; temperature, 100°. Injection, 5 cc. hydrocele fluid, although the loss of weight had been considerable.

April 23: Weight, 2,795 gms.; temperature, 100°. Injection, 10 cc. hydrocele fluid. Condition good.

April 25: Weight, 2,669 gms.; temperature, 100°. Injection, 5 cc. hydrocele fluid.

April 30: Weight, 2,730 gms.; temperature, 100.8°. Injection, 10 cc. hydrocele fluid.

May 5: Condition apparently good, but shows some stiffness and sensitiveness when handled. No injection given.

May 7: Found a small necrotic area on abdomen near point of injections. Has lost 250 gms. in weight in five days.

May 9: Rabbit died.

Total injection, 65 cc.

RABBIT No. 2.—April 11: Temperature, 100°; weight, 1,750 gms. Injection, 10 cc. defibrinated placental blood.

April 14: Temperature, 99.8°; weight, 1,572 gms.; loss, 178 gms. Injection, 10 cc. blood.

April 16: Temperature, 99.6°; weight, 1,495 gms.; loss, 87 gms. Injection, 5 cc. blood.

April 18: Temperature, 102°; weight, 1,455 gms.; loss, 40 gms. No injection.

April 21: Temperature, 103°; weight not taken. There is a necrotic area two inches in diameter on the abdomen. No injection.

April 23: Condition very bad. No injection.

April 25: Condition unchanged. No injection.

April 30: Condition unchanged.

May 5: Rabbit died.

Total injection, 25 cc.

RABBIT No. 3.—April 23: Temperature, 100°; weight, 1,672 gms. Injection, 5 cc. hydrocele fluid.

April 25: Temperature, 101°; weight, 1,690 gms.; gain 18 gms. Injection, 5 cc. hydrocele fluid.

April 30: Temperature 100.4°; weight, 1,600 gms.; loss, 90 gms. Injection, 5 cc. hydrocele fluid.

May 2: Temperature, 102.2°; weight, 1,602 gms.; gain, [2 gms. No injection.

May 5: Temperature, 100.4°; weight, 1,622 gms.; gain, 20 gms. Injection, 5 cc. hydrocele fluid.

May 7: Temperature, 103°; weight, 1,570 gms.; loss, 52 gms. No injection.

May 9: Temperature, 102.8°; weight, 1,585 gms.; gain, 15 gms. No injection.

May 14: Temperature, 100.8°; weight, 1,592 gms.; gain, 7 gms. Injection, 5 cc. blood.

May 16: Temperature, 103°; weight, 1,510 gms.; loss, 82 gms. No injection.

May 21: Rabbit chloroformed and blood collected from heart in sterile bottle; allowed to clot in icebox; carbolic acid added; separated serum drawn up into sterile pipet and sealed. Total injection, 25 cc. blood and hydrocele fluid.

RABBIT No. 4.—April 30: Temperature, 100°; weight, 1,195 gms. Injection, 5 cc. blood.

May 2: Temperature, 100.2°; weight, 1,195 gms. Injection, 5 cc. blood.

May 5: Temperature, 100°; weight, 1,170 gms.; loss, 25 gms. Injection, 10 cc. blood.

May 7: Temperature, 101°; weight, 1,160 gms.; loss 10 gms. Injection, 5 cc. blood and 5 cc. hydrocele fluid.

May 9: Temperature, 103°; weight, 1,115 gms.; loss, 45 gms. No injection.

May 14: Temperature, 102°; weight, 1,105 gms.; loss, 10 gms. No injection.

May 16: Temperature, 99.8°; weight, 1,030 gms. No injection.

May 17: Rabbit died suddenly; no cause discoverable.

Total injection, 30 cc.

RABBIT No. 5.—April 30: Temperature, 100°; weight, 1,112 gms. Injection, 5 cc. blood.

May 2: Temperature, 100°; weight, 1,070 gms.; loss, 32 gms. Injection, 5 cc. blood.

May 5: Temperature, 100°; weight, 1,065 gms.; loss, 5 gms. Injection, 5 cc. blood.

May 7: Temperature, 101°; weight, 1,000 gms.; loss, 65 gms. Injection, 5 cc. blood.

May 9: Temperature, 100.2°; weight, 985 gms.; loss, 15 gms. Injection, 5 cc. hydrocele fluid.

May 10: Rabbit died: no cause known.

Total injection, 25 cc.

RABBIT No. 6.—April 30: Temperature, 100°; weight 2,050 gms. Injection, 5 cc. blood.

May 2: Temperature, 101.6°; weight, 2,035 gms.; loss, 15 gms. No injection.

May 5: Temperature, 100°; weight, 2,015 gms.; loss, 20 gms. Injection, 10 cc. blood.

May 7: Temperature, 100.5°; weight, 1,950 gms.; loss, 65 gms. Injection, 10 cc. hydrocele fluid.

May 9: Temperature, 103°; weight, 1,870 gms.; loss, 80 gms. No injection.

May 14: Temperature, 103°; weight, 1,900 gms.; gain, 30 gms. No injection; condition apparently bad.

May 16: Temperature, 101°; weight, 1,900 gms. No injection; condition better.

May 21: Temperature, 100°; weight, 1,880 gms.; loss, 20 gms. Condition good. Rabbit was chloroformed and the blood drawn as before, and the serum sealed up in sterile pipets.

Total injection, 25 cc.

The serum was prepared, as above described, six months ago, viz., in November and December, 1902. Other rabbits have since been immunized in the same way.

#### APPLICATION OF THE TEST.

Five cubic centimeters of the immune serum, prepared as already described, were diluted in a sterile graduate 100 times with sterilized water. A stain of menstrual blood 36 days old was washed out in distilled water, and the resulting reddish liquid repeatedly filtered. To 2 cc. of this solution was added an equal amount of the dilute immune serum in each of four sterile stoppered test-tubes. The tubes were then placed in the incubator at 37° C. for two hours. A faint cloudiness appeared. After 24 hours in the desk at room temperature, the turbidity was marked, especially in the upper part of the tubes. Later a precipitate slowly formed and settled to the bottom of the tubes. No further change occurred. The control tests of normal rabbit serum remained perfectly clear.

A five months' old stain of monkey's blood on filter-paper was tested, as was the human blood in the previous case. After two hours in the incubator at 37° C. there was no change. On standing for several hours in the desk at room temperature the same kind of cloudiness was observed as had been noted in the human blood, although in this instance it was much less marked. No precipitate formed, even after four days. The control test of normal rabbit serum remained perfectly clear.

To 1 cc. of undiluted immune serum were added 2 cc. of a strong solution of menstrual blood. A cloudiness appeared at once at room temperature, and in 20 minutes a heavy flocculent precipitate was formed, which slowly settled to the bottom of the tube.

The following 19 bloods were tested as were the preceding, but with no reaction whatever: Dog, ferret, rabbit, guineapig, cow, red squirrel, gray squirrel, deer, chicken, redbird, chameleon, owl, pig, sheep, mouse, iguana, pigeon, turtle, and parrot. All these tests, as well as the control tests, were unchanged, either in the incubator or at room temperature.

Solutions of human and of monkey blood were diluted so that the red color just faded. These were tested with immune serum previously diluted 500 times. No immediate reaction occurred in any of the tubes. After three hours in the incubator at 37° C. the human blood solution was distinctly turbid and that of the monkey blood perfectly clear. The control tests of normal rabbit serum were also clear.

A solution containing cow, pig, sheep, dog, and human blood was put into one test-tube, and a similar mixture into another, and to the latter was added an equal quantity of the immune serum. The tubes were incubated for three hours. The solution to which had been added the test-serum became turbid, the other remaining clear. No change occurred in the control tests.

Three tubes of a dilute solution of human blood and three tubes of a similarly diluted solution of monkey blood were treated with an equal amount of the immune serum diluted 20,000 times. After the usual incubation the tubes of monkey blood and of the control tests were perfectly clear, while those of the human blood were slightly but distinctly cloudy.

Two tests each of human and of monkey blood were made simultaneously. After three hours in the incubator at 37° C. the tubes of human blood were turbid, and those of the monkey blood clear. The tubes were all incubated for ten hours longer, at the end of which time the tubes of human blood were much more turbid, those of the monkey blood remaining unchanged. The control tests of normal rabbit serum remained unchanged.

The same test was made again, using three tubes each of human and of monkey blood, with the same result.

In the next test 12 tubes were used; five contained human blood treated with test-serum diluted 500 times; three contained normal rabbit serum similarly treated; the other four contained monkey blood treated with the immune serum. After eight hours in the incubator at 37° C. all the tubes containing the human blood were turbid, the control tests were perfectly clear and three of those containing the monkey blood were clear; one of these was cloudy, probably due to the growth of bacteria introduced during the manipulations and developed in the course of this protracted incubation.

Five tubes containing a very dilute solution of human blood, six containing a similarly diluted solution of monkey blood, and an equal number containing normal rabbit serum were treated with the 1-500 solution of immune serum, as before, and incubated four hours. At the end of this time no reaction whatever had occurred in any of the tubes. The test was immediately repeated, the greatest care being observed in all the details. The result was ideal, all the tubes of human blood becoming cloudy and all the rest remaining perfectly clear.

The reason for the failure of the last preceding test is not known.

A human blood solution was diluted 600 times and a single drop of pure immune serum added to 2 cc. of the diluted solution. An immediate cloudiness appeared. The same test applied to monkey blood and to normal rabbit serum gave no result.

The last test was repeated, using 10 tubes each of human and monkey blood and of normal rabbit serum. The same result was obtained.

One tube of human blood, diluted 4,000 times, gave an immediate reaction on adding one drop of the undiluted immune serum.

Human and monkey blood-stains in earth were tested simultaneously, with positive results in the case of the human blood only.

In another test of the same kind, the whole number of tubes, including the control, become turbid, showing the presence of some foreign body, probably one of the mineral salts which cause a cloudiness in albuminous solutions. This test alone is sufficient to demonstrate the value of the control tests in comparative work.

A two-ounce bottle of old, putrid blood of unknown origin was submitted to me for the purpose of determining whether or no it was of human origin. Six tests were made as follow: 1. One tube each of human blood, of normal rabbit serum, and of the unknown specimen were diluted 500 times and three drops of the test serum added. 2. One tube each of the above bloods were diluted ten times and tested as usual, at room temperature. 3. One of each variety of blood was diluted 500 times, and an equal amount of 1-500 test-serum added, all being then incubated for three hours at 37°. The tests of the human blood were positive, while those of the unknown blood and the control serum remained unchanged.

#### METHODS AND RESULTS.

I have followed the Uhlenhuth method, believing that an absolute differentiation of blood-stains is possible by this means, if properly employed, and that a microscopic differentiation is, for the reasons cited, impossible, or, at least, impracticable for medicolegal purposes. Large, strong animals, preferably rabbits, are used, since they have a relatively great resisting power. The animals are injected subcutaneously with 5 cc. to 10 cc. of sterile human blood or serous exudate, the injections being repeated every two to five days, depending upon the condition of the test-animal. The occurrence of a rise of temperature above 101° F., or a decided loss in weight are considered counterindications to further injections until after this reaction has subsided. It is better to give injections of only 5 cc. each, and always with great care as to aseptis, since abscesses often develop at or near the site of the punctures. I lost four of the first six test-animals from septicemia.

The total amount of the injection necessary to produce a potent antiserum varies slightly with different test-animals. Usually 20 to 30 cubic centimeters is a sufficient quantity for an average rabbit, and with due care a specific antiserum can always be produced in three or four weeks.

Human blood, hydrocele fluid or pleural or peritoneal exudate may be injected, and with almost equally good results in the tests; perhaps the hydrocele fluid is a little more powerful than the other exudates mentioned, and is certainly the best to handle, although it spoils readily. All my injections are made subcutaneously with a 5 cc. antitoxin syringe. There is usually a constant loss of weight on the part of the test-animal during the injections.

After a sufficient quantity of blood or of serum has been injected to ensure obtaining an antiserum, the rabbit is chloroformed, the chest cavity opened and the blood drawn from the heart into a sterile receptacle by means of a sterile trocar and cannula. The drawn blood is placed in the ice box for one hour, until well coagulated. Carbolic acid is now added to the serum which has separated, sufficient to make the mixture approximately .5% acid. The serum is then drawn up into sterile pipets and sealed. It will remain potent indefinitely when so prepared, if kept at a low temperature.

The test is made as follows:

A given amount of the test-serum is diluted to the desired extent with sterile water or normal salt solution. To a few cubic centimeters of this diluted solution in a sterile test-tube is added an equal quantity of a similarly diluted solution of the blood to be tested and the tube left at room temperature or

placed for two to three hours in the incubator at 37° C. The reaction, if it occurs, will be more rapid and more marked if the tube is exposed to the higher temperature. If the dilution be sufficient the reaction will not occur at room temperature. If the test-serum is used undiluted and pure human blood is added to it the reaction is immediate. If the dilute solutions are used the time required in the incubator varies from one to several hours. If only the sample of blood to be tested is diluted and the test-serum used pure, the reaction is also immediate. The reaction is marked by a turbidity of the solution, becoming constantly more intense, and in the case of the strong solutions of human blood, going on to the formation of a flocculent precipitate which slowly settles to the bottom of the test-tube.

If an old stain is to be examined by the serum test the material containing it is washed out in sterile water or in sterile normal salt solution, the mixture repeatedly filtered and finally added to some of the test-serum, as in the examination of fresh blood already described.

In making comparative tests it is necessary to use approximately the same dilution of the bloods tested; this may be accomplished by comparison with a hemoglobin scale. It is also necessary constantly to employ control tests of normal rabbit serum, to exclude errors possibly arising from the occurrence of bacterial growth or the presence of the albumin precipitants in the solutions.

When the test-serum is used undiluted and pure blood is tested, human blood can always be differentiated from that of every lower animal, except the monkey. However, when both the human and the monkey blood are made very dilute, and the test-serum also diluted 500 times, the test of the human blood only is positive. Moreover, if only the bloods tested are diluted and the immune serum used pure, the same result is obtained.

There were 35 comparative tests of human and monkey blood made in the manner described, and in 29 the above result was obtained. The six failures all occurred in the one test above described, the reason for which is still unexplained.

Uhlenhuth says<sup>20</sup> that "the reaction, to be positive, must occur immediately." This is true when the test-serum is used undiluted or only slightly so, and allows of a specific test only for most of the lower animals. Without a dilution of the tested blood of at least 1-500 a differentiation between human and monkey blood is impossible. With this dilution the reaction occurs uniformly, and this very essential differentiation is possible. A reaction, positive but not marked, is obtainable in the case of human blood with a dilution of the test-serum of 1-20,000.

From the foregoing experiments it appears better to dilute the blood to be tested 500 or more times and to use the test-serum undiluted because, first, the reaction is immediate; second, it occurs in the cold; third, it excludes monkey blood; and fourth, it excludes turbidity possibly resulting from bacterial growth during the process of incubation.

#### SOURCES OF ERROR.

The most frequent sources of error and the means for their elimination are: 1. Contamination of the specimen tested with monkey blood; excluded by a proper dilution of the specimen, or of both specimen and test-serum; and by control tests. 2. Contamination with albumin precipitants; excluded by control tests. 3. Too long an incubation; excluded by control tests; and by parallel tests in the cold, diluting only the blood tested.

#### CONCLUSIONS.

Judging from these experiments, I believe the following conclusions are justified:

1. The reaction is caused by the development within the blood-serum of the injected animal of an antibody or a property or substance which causes a certain reaction with the serum homologous to the one injected.
2. The reaction does not occur when normal rabbit serum is used.
3. The reaction occurs much more rapidly, especially

when dilute solutions are used, if the test is exposed to a temperature of 37° C., although it will occur at ordinary room temperature.

4. An immediate result in the cold is obtainable by diluting only the blood tested, the test-serum being used pure.

5. The reaction is obtainable when using a dilution of the test-serum of 1-20,000, or of the blood tested of 1-4,000. Hence, only a minute stain and a single drop of the test-serum are required for making the test.

6. The delicacy of the test is not altered by the admixture of other bloods or of other foreign material, except the albumin precipitants.

7. The presence or absence of mineral salts, such as copper sulfate, or of other precipitants of albumin, can be determined by the control tests.

8. The delicacy of the test is not materially altered by the age of the stain.

9. A differentiation from monkey blood is possible, and contamination with monkey blood can be excluded, first, by a great dilution of the blood tested and a dilution of the test-serum of 1-500, with incubation; second, by a great dilution of the blood tested, the test-serum being used pure, and the test made at room temperature.

10. The test is specific, invariable, and therefore applicable to forensic use.

I desire to express my sincere thanks to those who have assisted me in this work. To Dr. Colby, of the Rush Medical College Faculty, for much material for the experiments, as well as for a kindly interest and encouragement at all times; to Professor Schroeder and to Drs. Ferrell, Koehler, and Parker for material furnished; to Dr. Biehn, for his kind assistance in the laboratory work; and especially to Professor Zeit, for his uniformly courteous treatment, his personal interest in the work, and his encouragement and enthusiastic direction of all my efforts.

Since writing this paper I have made six parallel tests with the blood of white and of colored persons to determine whether there is any difference in the reaction of the blood of the two races. In all of the tests the immune serum was used pure; in one-half the tubes the tested blood was diluted 10 times; in the remainder, 500 times. The reaction occurred much more slowly than is usual but at the end of five hours in the incubator at 37° C. all the tubes were equally turbid and the characteristic flocculent precipitate soon formed. The control tests of normal rabbit serum remained unchanged as usual.

**Ptomains in Milk.**—At San Juan, Porto Rico, eighteen people living at a boarding-house were poisoned by milk containing ptomains. Eleven doctors responded to the alarm, and the use of stomach pumps saved the lives of all the sufferers. At the Maternity Hospital the nurses, helpers and some of the patients were similarly poisoned, but were relieved.

## ISOLYSINS IN THE SERUM OF DISEASE.

### A Preliminary Report.

BY

S. PESKIND, M.D.,  
of Cleveland, O.

Recently<sup>1</sup> I had occasion to note the presence in the serum of a leukemic patient of an isolysin—*i. e.*, a substance which caused hemolysis of human blood-corpuscles. This hemolysin may have been a product of the disease, or it may have been derived from the leukocytes,<sup>2</sup> which were present in enormous numbers. The red corpuscles of this leukemic blood appeared to be immune to the hemolysin contained in the serum. Whether the requisite complement was present in the leukemic serum was not investigated. That the leukemic red corpuscles were shielded by an antihemolysin is not likely since this antihemolysin would have protected normal human corpuscles also—which was not the case.

The most probable explanation of the immunity of the leukemic corpuscles to this hemolysin is that they possessed no receptors for the same, and therefore could not fix the hemolysin.<sup>3</sup>

I was led by the foregoing observation to investigate the sera in other diseases to determine if isolysins are present, and, if so, whether such isolysins are specific for these diseases or not.

It is conceivable that an investigation along this line might lead to observations that could be of use in diagnosis. For example, suppose any disease—say cancer—should give rise to the presence of a hemolysin in the serum which, similar to that in the leukemic serum, would not attack the corpuscles of the cancer patient, but would attack normal human corpuscles. Knowing this, if we found that the serum of a patient in whom cancer was suspected would lake normal human corpuscles, but would not lake the corpuscles of a known case of cancer, the inference would be that the suspected patient really suffered from cancer. It was with this idea in mind that I took up this study. So far comparatively few experiments have been made, so that this paper is merely in the nature of a preliminary report.

The technic followed is simple: The blood (obtained by pricking the ear) was drawn up into a small glass tube, one end of which had a capillary opening. After standing several hours in the ice-chest the serum which separated out was pipetted off onto a slide. Then from ten to eighty parts of this serum was measured off by means of a Thoma-Zeiss pipet used in the counting of leukocytes. The measured serum was placed on a slide and then one part of normal human blood taken from the ear, and undefibrinated, was added to the serum and the two quickly mixed with a pointed glass rod. The mixture was then allowed to flow into tubes having capillary openings at both ends. These tubes were made of hard glass, had a diameter of 6 mm., a lumen whose diameter was 2 mm. and a length of about 5 cm. After all this mixture had entered the tube, the latter was in most experiments sealed at both ends with small bits of rubber protective. The tube was then allowed to lie in a horizontal position at a room temperature varying from 16° to 25° C. The blood-corpuscles were in every instance quickly agglutinated by the serum and settled rapidly to the bottom of the serum in the form of a long ribbon. The ends of the tubes were sealed to avoid drying out of the serum.

I. Case of leukemia, blood obtained shortly after autopsy. To one part of a 10% suspension of my own blood in 0.9% saline was added one part of the leukemic serum. A good agglutina-

<sup>1</sup> American Journal of Physiology, Vol. VIII, p. 401.

<sup>2</sup> Considerable evidence has recently been adduced by various hematologists to show that the hemolysis of normal serum originates, at least in part, from the leukocytes.

<sup>3</sup> Compare Ehrlich's and Morgenroth's experiments on formation of autolysins and isolysins. Berl. klin. Woch., 1900, p. 453.

tion and precipitation of the corpuscles occurred. After 20 minutes one-half part of the leukemic serum was added to this mixture. Laking started soon after and in an hour was almost complete.

II. Case of marked anemia, having several of the characteristics of a primary anemia. About 20 parts of serum from this case + 1 part normal blood. (No accurate measurements of serum and blood were made in this case.) No hemolysis after six hours.

III. Case of anemia, blood count gave 2,600,000 reds, 3,200 whites to 1 cmm.; no splenic enlargement. Mixed 40 parts serum + 1 part normal blood. Agglutinated rapidly. No hemolysis at room temperature (16° to 18° C.) at the end of 24 hours. Kept 24 hours longer at a temperature of 20° to 25°, still no hemolysis.

IV. Case of pneumonia, temperature had been normal for three days, but the affected lung was still markedly consolidated. Blood contained large proportion of fibrin. Mixed 17 parts of the serum + 1 part normal blood; mixed 10 parts of the serum + 1 part normal blood. Agglutination was marked and immediate. After 5 hours no laking in either tube. After 16 hours slight trace of laking in both tubes.

V. Case of pneumonia, temperature 104° F. Mixed 40 parts serum + 1 part normal blood. Average room temperature 22° C. No hemolysis after 48 hours.

VI. Case of cancer of the stomach, patient very anemic and cachectic. Mixed 70 parts serum + 1 part normal blood. Agglutinated well. Showed considerable laking in two hours at room temperature of 22° C. Laking not complete at end of 48 hours.

VII. Case of cancer of the breast (of one year's standing). No ulceration; patient not cachectic. Mixed 60 parts serum + 1 part normal blood (tube closed at both ends); mixed 30 parts serum + 1 part normal blood (tube closed at both ends); mixed 30 parts serum + 1 part normal blood (tube left open at both ends). Agglutination took place in all the tubes. No hemolysis after four days in any of the three tubes—room temperature, 20° to 22° C.

VIII. Case of cancer of the stomach; patient very anemic. Mixed 30 parts serum + 1 part of blood obtained postmortem from a case of cancer of the liver. No hemolysis after 12 hours.

IX. Case of typhoid in the fourth week; temperature, 104° F. Mixed 30 parts serum + 1 part normal blood. Gave powerful and immediate agglutination. No hemolysis after three days, even though drying out had taken place (tube left open at ends).

X. Case of typhoid; beginning of third week; temperature, 102° F. Mixed 25 parts serum + 1 of normal blood. Good agglutination. Absolutely no hemolysis at room temperature at end of three days, even though some drying out had taken place.

XI. Patient suffering from uremic coma; had been bled and transfused a short time previous to the test. Mixed 30 parts serum + 1 part normal blood. Good agglutination. No hemolysis after three days, even though some drying out had taken place.

a. Mixed 1 part serum from Case IX (typhoid) with 1/2 part of blood (obtained from clot) from Case X (typhoid). Powerful agglutination. Tube kept open and kept at room temperature. Considerable laking after 12 hours, showing itself principally where slight drying out had occurred, *i. e.*, at the ends of the tube. After two or three days, very much laking.

b. Mixed 1 part serum from Case X (typhoid) + 1 part blood (obtained from clot) from Case IX (typhoid). Good agglutination. Tube left open. After 12 hours, considerable laking, especially marked where slight drying out had occurred (at end of tubes).

c. Mixed 1 part serum from Case IX (typhoid) + 1 part blood (obtained from clot) from Case XI (uremia). Tube left open. Strong agglutination. After 12 hours, considerable laking, beginning at ends of tube where slight drying had occurred. Very marked hemolysis after two or three days.

d. Mixed 1 part serum from Case XI (uremia) + 1 part blood (obtained from clot) from Case IX (typhoid). Good agglutination. Tube left open. Good laking after 12 hours; considerable after two or three days. Laking began at ends of tube.

The sera from the two cases of typhoid and the case of uremia caused absolutely no laking of normal human blood-corpuscles after two or three days, even though drying out had occurred at the ends of the tube. But the sera in all these cases produced rapid laking of each other's blood-corpuscles, the laking beginning at the ends of the tubes where slight drying out had occurred.

This laking in all probability is due to the lowered resistance of the blood-corpuscles in these diseases to hyperisotonic solutions.

Dr. Guthrie<sup>1</sup> has shown that normal blood-corpuscles after drying are readily laked by the addition of serum

or normal saline solution. In none of the tubes in my experiments in which normal blood was used was any laking observed for several days, probably because no mixing of the serum and dried corpuscles had occurred. In the case of the diseases under consideration, it is possible that the envelopes of the corpuscles deteriorate and become more permeable, so that the latter are more readily laked during the drying out process than is normally the case.

It is my intention to examine the blood in various diseased conditions along the lines already mentioned, although it is quite likely that the final results will have no practical value other than that which attaches to any work of a statistic nature.

MODIFICATION OF MILK FOR INFANT FEEDING.<sup>1</sup>

BY  
EDWIN E. GRAHAM, M.D.,  
of Philadelphia.

Clinical Professor of Diseases of Children in Jefferson Medical College, Philadelphia.

By the modification of milk for infant feeding we mean in a broad way adapting cow's milk to the digestive powers of the infant. This means that cow's milk must be so changed as to contain the proper ingredients in the proper proportions and quantity to nourish a child properly. This is a matter that always requires considerable care for a well infant, and often presents very serious difficulties when we come to treat a sick child. The difference in the composition of human and cow's milk is very decided, and as the cow is the only animal upon which we can depend, its milk is now looked upon as the only kind to be used for this purpose. The breed of cow is also of some importance, and while the scope of this paper does not permit of an extended consideration of this part of the subject, we will take it for granted that the high grade Jersey or Guernsey must not be selected, but the commoner breeds—the cows that show a distinct ability to raise their young, freedom from much inbreeding, and that yield milk of an average of 4% fat. The Holstein is unquestionably one of the best cows for infant feeding.

The following table (No. 1) shows the composition of both human and cow's milk. The reaction of woman's milk is amphoteric, while that of cow's milk is slightly acid. The percentage of water is practically the same. Cow's milk contains a higher percentage of mineral matter, and a slightly greater amount of solid material;

TABLE I.

	Woman's milk directly from the breast.	Cow's milk, as ordinarily received, about 24 hours old.
Reaction .....	Amphoteric. (More alkaline than acid.)	Slightly acid.
Water.....	87% to 88%.	86% to 87%.
Mineral matter.....	0.20%.	0.70%.
Total solids.....	13% to 12%.	14% to 13%.
Fats.....	4%. (Relatively poor in fatty acid.)	4%.
Milk-sugar.....	7%.	4.50%.
Proteids .....	1.50%.	4%.
Caseinogen (König).....	0.59%.	2.88%.
Lactalbumin (König).....	1.23%.	0.53%.
Coagulable proteids.....	Small proportionally.	Large proportionally.

the percentage of fats is the same in both. Human milk is sweeter than cow's milk, and the proteid of human milk is 1.5% compared with the proteid of 4% of cow's milk. The proteid of cow's milk is coagulated into larger, firmer masses than the proteid of human milk, and these masses are more difficult to break up in the stomach and to digest.

The first problem presented to us is, therefore, to

<sup>1</sup> Read April 22, 1903, before the Philadelphia County Medical Society.

<sup>1</sup> Am. Journal of Phys., Vol. viii, p. 441.

modify the percentages of cow's milk to resemble those of mother's milk, and upon the success of this modification depends very often the saving of human life, and if not the life, the future strength and vigor of the individual. Proper feeding usually means the absence of malnutrition, rickets, scurvy, possibly tuberculosis, and in the end, the perfect type of infant and child, compared with the frail and delicate.

In the modification of cow's milk, it must be remembered that the proteids are much more difficult to digest than the proteids of mother's milk, and the object of modification is to select the correct percentage of fat, sugar, and proteids for the digestion of healthy and sick infants. When indigestion is present, the proportion of fat or proteids, or of both, may be at fault. Cow's milk should be free from all foreign matter, and should never contain more than 10,000 bacteria to the cc., and no microorganisms such as streptococci or staphylococci. All persons brought in contact with the milk should be absolutely free from all contamination with any disease, such as scarlet fever, typhoid fever, diphtheria, etc. The cow should be healthy and free from tuberculosis. It should be fed and groomed most carefully, have an abundance of fresh, pure drinking water, and the stables should be constructed so that each animal receives plenty of fresh air, free from dust. As the milk of a herd is less likely to vary, it is to be preferred to that of a single cow. In the consideration of the modification of milk, everything depends on carrying out the minutest details of all the instructions given, as the neglect of any one of these means often a complete failure.

The cow proteid, by reason of its amount, 4%, its indigestibility by infants, and its difference in chemical composition from human proteid, makes its consideration of the first importance. The proteids replace the waste of nitrogenous material ever going on in the body, and have much to do with the production of animal heat. The proteids easiest of digestion are those of mother's milk, and the substitution of cow proteids is the greatest difficulty encountered in infant feeding. During the first few months of life, the amount of proteid should not be greater than 1%. Children who do not receive sufficient proteid are apt to become anemic, to have blueness and coldness of the hands and feet, and their flesh is, as a rule, soft and flabby.

The two most important ingredients of proteids are caseinogen and lactalbumin; the least important is lactoglobulin. Chemists do not agree as to the exact proportion of the different proteids present. The small amount of proteid given in early infancy has probably much to do with the small, hard, dry stools so commonly seen in the first few months. During this early period, colic and curds in the stools usually mean too high proteid percentages or the inability of the child to digest the proteid given.

By what is usually called the "split proteid," it is possible to give a child, and especially a young infant, a proteid in which the caseinogen is only one-fourth, and the lactalbumin three-fourths of the total proteid. This is, however, only possible when 1% or less of proteid is required. The following prescription illustrates this. In this prescription the amount of fat and sugar can be increased or decreased at will:

TABLE II.

Fat.....	3.50%	Number of feedings.....	8
Sugar.....	6.50%	Amount at each feeding...	3 oz.
Proteids (total).....	1.00%	Infant's age.....	9 wks.
(a) Lactalbumin (whey proteid).....	0.75%	Infant's weight.....	9 1/2 lbs.
(b) Caseinogen.....	0.25%	Alkalinity.....	5%.
		Heat at.....	155° F.

By the use of whey, the infant's food can be so prepared that the proportion of lactalbumin to caseinogen can be made during the earlier months of life to approximate closely to the proportion found in normal mother's milk. This ability to split up the proteid is one of the most important in infant feeding, often being of great

assistance in carrying the infant through the first few months of life, because as the infant increases in age its power to digest cow's proteid also increases. The great advantage of the whey proteid in early infancy and in cases of proteid indigestion in infants of 9 to 12 months can really only be appreciated by those who have used it and seen the results.

The following conclusion seems to me only a fair and just one: By the use of whey cream mixtures we can render cow's milk much easier of digestion to the infant. Whey mixtures should not be exposed to a temperature above 69.3° C., else the whey proteid is coagulated. The following table gives the possible percentages of fat and proteid with creams of 20%, 16%, and 12%, combined with whey, fat 0.32:

TABLE III.

Possible percentages of fat and proteid with creams of 20%, 16%, and 12%. Fat and whey containing fat 0.32.

Cream, 20%.	Whey, q. s.	Fat, 1%.	Proteid, 0.94.
0.70 oz. ....	" " 20 "	" 2%.	" 1.06.
1.71 oz. ....	" " 20 "	" 3%.	" 1.18.
2.72 oz. ....	" " 20 "	" 4%.	" 1.30.
3.74 oz. ....	" " 20 "	" 4%.	" 1.30.
Cream, 16%.	Whey, q. s.	Fat, 1%.	Proteid, 0.98.
0.87 oz. ....	" " 20 "	" 2%.	" 1.15.
2.14 oz. ....	" " 20 "	" 3%.	" 1.32.
3.42 oz. ....	" " 20 "	" 4%.	" 1.50.
4.69 oz. ....	" " 20 "	" 4%.	" 1.50.
Cream, 12%.	Whey, q. s.	Fat, 1%.	Proteid, 1.03.
1.16 oz. ....	" " 20 "	" 2%.	" 1.28.
2.88 oz. ....	" " 20 "	" 3%.	" 1.53.
4.59 oz. ....	" " 20 "	" 4%.	" 1.79.
6.30 oz. ....	" " 20 "	" 4%.	" 1.79.

The fat in the food prevents nitrogenous waste, and is a great source of animal heat. The fats probably play an active part in the growth of bone and nerve-tissue. Fat is required in infants in greater proportion than at any later period of life. Lack of fat in the food usually means a rachitic child. The fat of woman's milk consists of palmitin, stearin, and olein; the amount of fatty acids is small, less than in cow's milk. In the modification of cow's milk, too high percentages of fat often produce vomiting of thick, sour milk, or diarrhea, the stools being thin, green; and sour-smelling.

*Sugar.*—The digestion by the infant and young child of milk-sugar is usually attended with little or no difficulty. The carbohydrates should not be given to the infant of a few months in the form of starch, owing to the poor starch digestive power previous to the seventh or eighth month of life. An excess of sugar often leads to a rapid gain in weight, the flesh acquired being, however, in such cases usually soft and flabby, and the child frequently becomes anemic. The sugar has much to do with the production of animal heat. The sugar in both human and cow's milk is the same, lactose.

*Cereals in Infant Feeding.*—Mother's milk does not contain starch, and it seems, therefore, plain that in the earlier months of life, especially in view of the poorly developed amylolytic function of the infant, that our modified milk should not during these earlier months contain starch. The addition of a small proportion of oat-jelly, wheat or barley-water after the eighth month, in my experience, has certainly seemed of benefit. In laboratory feeding the ability to prescribe the exact amount of cereal required and desired by the infant has much to commend it.

The question has been much discussed lately as to the benefit to be derived from the addition of gruels to the milk of infants who are unable to digest more than a very low percentage of proteid. The general belief at present is, that the addition of a small amount, about 1%, of cereal often makes it possible to increase the amount of proteid given.

It is important when diluents other than water are used to observe the quantity of starch the diluents give to the milk modification, a starch diluent of 1% giving, according to White (quoted by Rotch), a fine flocculent

coagulum, while a diluent with .3% starch gave a much coarser coagulum.

**Heating of Milk.**—The large number of bacteria always found in milk naturally suggested the use of heat as a means of destroying or at least checking their growth. Sterilization was formerly the rule, the temperature of the milk being raised to 212° F. This temperature, if continued for 45 minutes, destroys practically all fully-developed bacteria, but not the spores, and these may rapidly cause changes in the milk. Milk so treated is changed in taste, is apt to constipate, the fat is affected, and the casein is not so quickly coagulated by rennet, and most important of all, infants fed upon sterilized milk have been occasionally known to develop scurvy.

Pasteurization, or the heating of milk to 140° F. to 155° F. for 20 to 30 minutes, has practically replaced sterilization. This temperature destroys the typhoid, diphtheria and tubercle bacilli, and all of the bacteria in milk, except, perhaps, 2%. The changes in milk produced by sterilization are not noted in pasteurization. The spores, of course, are not destroyed. Milk should always be rapidly cooled after pasteurization.

The question is occasionally asked, "Why heat milk at all?" In my opinion, the future of infant feeding will show very little milk heated, simply because the necessity for heat in any form will be unnecessary. When children can secure pure milk, containing no more than 2,500 bacteria to the cc., free from all foreign matter, and free from all pathogenic bacteria, when this milk is properly transported and *always* kept cold, we will see aseptic milk and unheated milk just as we now see aseptic surgery, rather than antiseptic surgery.

**Peptonized Milk.**—Pancreas .32 gram (5 grains) and of sodium bicarbonate 1 gram (15 grains) are dissolved in 118 cc. (4 ounces) of cold water and added to 355 cc. (12 ounces) of fresh whole milk. This is placed in a

itself is not fresh, clean as regards dirt and bacteria, and of known chemical composition. At the milk laboratory, the separator by its centrifugal force removes from the milk and cream a large part of any foreign material as dirt, which is always present, although perhaps in small amount.

Centrifugal or gravity cream, whole milk, fat free milk, sugar solution, cane or milk-sugar, whey, lime-water, sodium bicarbonate, soda and sterile water, the exact composition of each being known, together with gruel of oats, wheat and barley of known composition, constitute the pharmacopeia of the milk clerk. Each set of bottles is placed in a separate basket, labeled with the patient's name and address and delivered so soon as possible. The bottles and basket when returned are immediately sterilized, and the bottles washed in boiling, sterile soda solution.

The question of heating is of some importance. Milk from a laboratory farm, if served in cool weather to patients at short distances from the farm, requires no heating; if the weather is hot, pasteurization is safer. Milk transported long distances, or if two or three days' supply is needed, should be sterilized. Unheated, modified laboratory milk has been kept fresh and pure for days, as on ocean voyages. An important factor in this connection is in keeping the bottles *always* on ice.

In the earlier use of milk laboratories the great mistake was made of supposing that all that was necessary was to give a child of a certain age a milk that contained certain known percentages corresponding to those of mother's milk, but further study showed conclusively that the milk of each mother varied in its composition from time to time and that different mothers at the same period of nursing often showed a marked difference in the analyses of their milk, and yet this was compatible with a child having a good digestion and showing a steady gain in weight. (Table IV, Rotch.) This

TABLE IV.—Human Breast Milk Analyses. Mothers healthy and infants all digesting well and gaining in weight.

water-bath at a temperature of 110° F. for 10 minutes, then removed and kept on ice, or raised quickly to the boiling point, the rapid cooling or raising to the boiling point being required in order to check further peptonization. If it is desired to peptonize the milk completely, the temperature of 110° F. must be continued for about two hours instead of 10 minutes, as mentioned above.

Peptonization is a valuable aid to infants and children whose proteid digestion is weak; it is of benefit in both acute and chronic cases, and of especial benefit in infants. Care must be taken not to continue its use too long, as it is never wise to remove from any organ for too long a time the performance of its proper function, it being rarely necessary to peptonize for a longer period than four to six weeks. Modified milk mixtures may be peptonized in bulk, or by adding the proper portion of a peptonizing tube to each bottle, and heating just before feeding. My preference is for this latter method.

**Laboratory Feeding.**—A milk laboratory is a milk store where prescriptions calling for certain percentages of fat, sugar, proteid, alkalinity, heating, number of feedings and amount of each feeding are handed to a clerk, and the filled prescription sent to the patient's house. Milk modification will almost invariably fail if the milk

knowledge clearly showed the necessity of considering the child as an individual, and of adapting our milk to two great considerations—its digestion and its gain in weight.

The object of the milk laboratory is, then, to enable physicians to vary within certain wide ranges the milk modification necessary for the feeding of well and sick infants. The laboratory never prescribes milk for children; it simply provides for the physician an up-to-date plant, where everything is done to ensure accuracy, cleanliness and the prompt fulfilment of the physician's milk modifications. Its work is done by trained, skilled clerks, and I most heartily recommend it.

**Home Modification of Milk.**—The first requisite for home modification is to obtain cream and milk of known percentages. If possible, these should be secured from a milk laboratory, or a milk obtained similar to that recommended by the milk commission of the Philadelphia Pediatric Society. All bottles and nipples should be immediately cleansed after using with very hot water and a brush, and the nipples kept in cool, sterile water, to which has been added a small portion of sodium bicarbonate. The bottles are kept filled with this same soda solution. The bottles should be boiled for 10 minutes just before the day's milk supply is prepared.

Before beginning the preparation of the day's milk, the one to do the modifying, be it mother or nurse, should thoroughly cleanse her hands and forearms. She will need for her modifications the following :

- Cream of known chemical composition for certain modifications.
- Milk of known chemical composition.
- Milk-sugar in a clean jar, with tight cover.
- Limewater.
- Milk-sugar measure, holding 14 grams (3/8 drams).
- Eight ounce graduate.
- Milk dipper or siphon.
- Large spoon, sterilized.
- Sterile water.

The first and most important point to consider in home modification is the composition of the milk and cream used. The best milk, as has been mentioned earlier in this paper, is one obtained from the commoner and hardier breed of cows, containing 4% fat, sugar 4%, and proteid 3.5%. This milk should always be from a herd, and not from a single cow, and can always be obtained from a laboratory, or in Philadelphia from those dairies recommended by the Milk Commission. Gravity cream obtained from this milk is quite stable in its composition, as is shown by the following table (Holt):

TABLE V.

Amount and percentage of gravity cream in 4% fat milk after standing 8 hours.

Removing 16 oz., or the upper half, we secure approximately 7% fat.					
" 11 " " " " third, " " 10% "					
" 8 " " " " fourth, " " 12% "					
" 6 " " " " fifth, " " 16% "					

Separator cream from the laboratory can be obtained of 10%, 12%, 16%, or 20% fat. Gravity cream contains more bacteria than separator cream; in fact, the major portion of the bacteria in milk are found in the upper cream layers. On the other hand, it is claimed that the centrifuge injures the emulsion in centrifugal cream. From a very large experience in the use of both creams, I can say very positively that I have found both to be equally useful.

What is required in a home modification is simplicity; all directions should be written out in ounces of cream, milk, water and limewater, and measures of sugar of milk.

The physician, in his laboratory and home modification, must learn to think in percentages. In prescribing a milk for a well child, he must first decide upon the percentages to be given and by reference to his pocket memoranda translate this into ounces and milk-sugar measures. For an ill child, he must note the percentages being taken, decide, if indigestion, which ingredient of the milk, fat or proteid, or both, is at fault, make his changes accordingly, and if home modification, translate the changed percentages into a new formula of ounces capable of being understood by the mother or nurse.

Home modification, in its easiest form and yet capable of giving the usually prescribed percentages is as follows: After allowing the milk to stand eight hours, remove the top eight ounces from a quart jar of 4% fat milk by means of a dipper and count this as 12% fat cream. Count the lowest eight ounces of the quart fat free milk. From these the following formula may be obtained, covering fairly well the different percentages required for the different periods of life. With a quart of milk home modification can, as a rule, be carried on until the child is about three months old; an extra pint is then ordered. Surely this should stop the cry of expense.

TABLE VI.

FIRST WEEK.			
Fat.....	2.00	12% cream.	Fat-free milk.
Sugar.....	5.00	Cream .....	3 1/2 oz.
Proteids.....	.075	Milk .....	1 1/2 oz.
		Milk sugar .....	2 meas.

SECOND WEEK.			
Fat.....	2.50	Cream .....	4 1/2 oz.
Sugar.....	6.00	Milk .....	1 1/2 oz.
Proteids.....	1.00	Milk-sugar .....	2 1/2 meas.

THIRD WEEK.			
Fat.....	3.00	Cream .....	5 oz.
Sugar.....	6.00	Milk .....	1 oz.
Proteids .....	1.00	Milk-sugar .....	2 1/4 meas.

FOUR TO SIX WEEKS.			
Fat.....	3.50	Cream .....	5 3/4 oz.
Sugar.....	6.50	Milk .....	0 oz.
Proteids .....	1.00	Milk-sugar .....	2 1/2 meas.

SIX TO EIGHT WEEKS.			
Fat.....	3.50	Cream .....	5 3/4 oz.
Sugar.....	6.50	Milk .....	0 oz.
Proteids .....	1.50	Milk-sugar .....	2 1/4 meas.

TWO TO FOUR MONTHS.			
Fat.....	4.00	Cream .....	6 3/4 oz.
Sugar.....	7.00	Milk .....	2 1/4 oz.
Proteids .....	1.50	Milk-sugar .....	2 1/2 meas.

FOUR TO EIGHT MONTHS.			
Fat.....	4.00	Cream .....	6 3/4 oz.
Sugar.....	7.00	Milk .....	4 3/4 oz.
Proteids .....	2.00	Milk-sugar .....	2 1/4 meas.

EIGHT TO NINE MONTHS.			
Fat.....	4.00	Cream .....	6 3/4 oz.
Sugar.....	7.00	Milk .....	7 1/2 oz.
Proteids .....	2.50	Milk-sugar .....	2 meas.

NINE TO TEN MONTHS.			
Fat.....	4.00	Cream .....	6 3/4 oz.
Sugar.....	7.00	Milk .....	10 1/2 oz.
Proteids .....	3.00	Milk-sugar .....	1 1/2 meas.

TEN TO TWELVE MONTHS.			
Fat.....	4.00	Cream .....	6 3/4 oz.
Sugar.....	5.00	Milk .....	11 3/4 oz.
Proteids .....	3.50	Milk-sugar .....	1 1/2 meas.

AFTER TWELVE MONTHS.  
Unmodified cow's milk.

The great difficulty, however, is that this method of home modification does not enable us to change our percentages except within certain limits. For instance, using in home modification a 10% cream the lowest possible proteid with 2% fat is 0.75; with a 12% fat cream the lowest possible proteid with 2% fat is 0.63. It is necessary, then, to have creams of 16% and 20% fat.

In order to place home modification on as near a level as possible with laboratory feeding it is necessary to have at command creams of 10%, 12%, 16%, and 20% fat. The following table, arranged by Dr. Maynard Ladd, makes the calculation of any desired percent only a matter of a few seconds.

TABLE VII.

No.	20-oz. mixtures. Percentage of				Ounces of cream.				Ounces fat-free milk used with creams of				Ounces limewater.	Milk-sugar, meas.
	Fat.	Sugar.	Prot'd.	Alk.	10%	12%	16%	20%	10%	12%	16%	20%

## THE INEFFICIENCY TO RESTORE PELVIC SUPPORT OF IMMEDIATE SUTURE OF LACERATIONS SUSTAINED DURING LABOR.<sup>1</sup>

BY

WILLIAM E. GROUND, M.D.,

of Superior, Wis.

Chief Surgeon Great Northern Railway (E. Div.).

During recent years we are coming to realize more and more the importance of careful and painstaking attention to women during pregnancy, labor, and the puerperium.

I will not attempt to add anything new except my own legitimate experience, from which I draw my conclusions, and these are to the effect that women are neglected in the majority of instances during this, the most important period of their lives. I might be more emphatic and say maltreated, because there are instances in which wanton meddlesomeness and thoughtlessness at this time have been responsible for a woman's misery the rest of her life. Labor may be a physiologic process and as such should be left to nature; at least until such a time that surgical interference is demanded, and when assistance is called for it should be rendered in the most careful manner at the proper time. But the woman should not be abandoned as soon as the immediate effects of labor are passed, but kept under observation and any after consequences noted and corrected.

It is practically impossible as conditions now exist for a woman to be delivered of a child at full term without more or less injury to the pelvic floor, vagina, or perineum. When we remember that the outlet of the birth canal, with a diameter of from 1 to 1½ inches, is suddenly dilated until a ring of 10 to 12 inches in circumference is produced, it is not hard to understand why injury is inflicted. These injuries do not take place as a rule where they are plainly visible, but subcutaneously. The line of laceration follows the direction of least resistance or at the point of greatest pressure. The tear may go through the skin in the median line, but as the force strikes the muscular and fascial structures underneath, whose weakest point is in an entirely different direction along the sides of the vagina and rectum, an irregular or zigzag tear is produced instead of a straight up and down wound through the same plane of structures.

The tears in the vaginal mucous membrane and perineum may not be, and in fact usually are not at the same point. Lacerations of the pelvic floor (levator ani muscle and fascia) may occur immediately under the tear in the vaginal mucous membrane, or it may be submucous at another point, or the musculature of the pelvic floor may be extensively lacerated and the skin and mucosa remain intact. Under such circumstances, suturing the superficial rents in the skin and mucous membrane, passing through a promiscuous mass of structure beneath, will not restore the pelvic floor nor prevent vaginal prolapse. Who would attempt to cure hernia by simply suturing together the skin over the abdominal ring, and pelvic herniation is practically what happens when the musculature and fascial structures of the pelvic diaphragm are impaired?

The consequences of lacerations occurring during labor depends entirely upon the structures injured. If confined to the skin and external muscles, the perineum, no harm will follow so far as support is concerned, but if the deeper tissues, the levator ani muscles, are involved there will occur loss of the perineal flexure of the rectum and vagina, with recession of the vagina and anus from the pubic arch and rectocele, cystocele, prolapsus uteri and uterine retrodeviation, subinvolution of the uterus and vagina, and splanchnoptosis, followed by dynamic disturbances of the influence of intraabdominal pressure,

supervention of reflex phenomena and a state of ill-health will be instituted.

Notwithstanding the fact that for several years I have given special attention to the immediate repair of all lacerations of the vulva, vagina, and perineum, and frequently the cervix, I observed that this repair work did not leave the woman in anything like the condition she was before labor. I therefore began to study the condition of the pelvic floor of my obstetric patients before and after delivery at different periods and found almost invariably a condition of relaxation. I do not mean to infer that immediate repair work is useless. Quite the contrary. Lacerations of the perineum are fruitful sources of infection, inasmuch as they are constantly exposed to microbic invasion. Lacerations of the cervix, however, occupy a sterile region of the vagina and are therefore much less frequently the source of infection. In some cases it may be possible to unite essential structures, but as a rule suturing is limited to the skin and superficial tissues. A careful search is very rarely made for deep and damaging lacerations. The tissues at this time are often so swollen, edematous, and distorted that it is very difficult or impossible to place the sutures properly. Certainly repair work attempted on a bed without proper assistance, retractors, and a good light is little more than a farce so far as restoring the function of the pelvic floor is concerned. At best such operating simply restores the symmetry of the pudendal aperture unless the sphincter ani is torn, when immediate suture is imperative to prevent fecal incontinence.

In the first place I wish to eliminate the perineum from discussions on the pelvic floor. Anatomists have repeatedly called attention to the dissociation of these two structures. One great trouble with the medical profession today is their eagerness to discover new things, thereby failing to utilize fully information at hand. The pelvic floor proper and the perineal structures have entirely different functions. The pelvic floor is for the support of the superimposed viscera and is for this purpose alone. The perineum is simply a common meeting point for muscular and aponeurotic structures entirely below and external to the pelvic floor and has to do with the mechanism of the closure of the clefts of the visceral outlets, the sphincters.

It is safe to say that the human species is composite, the result of evolutionary processes. The requirements of higher life have necessarily modified anatomic structures to meet the demand thrown upon them. The pelvic floor of the human female is a marked example of this. The upright position has made necessary the entire reconstruction of the plane of muscles closing the pelvic outlet. This plane of muscles and fascia contains clefts, the exit of the alimentary and genitourinary canals. In those animals which habitually assume the horizontal position all the muscular mechanism that is necessary is to prevent the escape of the contents of these canals, except at voluntary intervals. To accomplish this certain muscular bands are thrown around the respective termini, called sphincters; the support of the abdominal viscera being maintained by the ventral abdominal wall. In the human subject it becomes necessary to modify especially the muscular mechanism of the pelvic outlet, so that in addition to the sphincters muscles of support must be supplied. So that we then have in the highly differentiated pelvic floor of the human female two distinct muscular layers, functionally and morphologically different.

Those muscles having to do with sphincteric action are developed from the primitive sphincter cloaca; while those forming the pelvic diaphragm were originally the muscles of the caudal end of the vertebral column, and are developed from the primitive flexors and adductors of the caudal vertebra. In tailed animals it was the business of these muscles to move that appendage. When the upright position was assumed and

<sup>1</sup>Read before the Western Surgical and Gynecological Association, at St. Joseph, Mo., December 30, 1902.

tails were no longer necessary, these muscular structures were utilized to furnish support for the superimposed pelvic and abdominal viscera. Hence the levator ani and the pelvic floor.

In considering the myology of the pelvic floor, only those muscles that are actively engaged will be considered. The superficial muscles, the sphincter ani, the constrictor vagina and transversus perinei have nothing to do with pelvic support, and will therefore not be investigated in this discussion.

The pelvic diaphragm is formed by a thin muscular sheet, called as a whole the levator ani. It is composed of four paired muscles—the ischiococcygeus, the iliococcygeus, the pubococcygeus, and the puborectalis. This series of muscles take their origin, roughly speaking, from around the brim of the true pelvis, and are inserted into the sacrum, coccyx, and median tendinous raphe. The pubococcygeus and the puborectalis form the most important constituent element of pelvic support. The pubococcygeus arises from the back of the body of the pubic bone along an oblique line which extends from the lowest limit of the symphysis outward toward the obturator canal, and to a limited extent from the obturator fascia. From this origin the fibers pass back by the urethra, vagina, and rectum, and are inserted by a tendinous expansion to the ventral surface of the lower part of the sacrum and coccyx. The puborectalis, or sphincter recti of Holl, "arises from the back of the lowest part of the symphysis, under cover of the pubococcygeus, from the upper layer of the triangular ligament, and from the pubis immediately below the symphysis. From this origin the fibers pass around the lower rectum, meeting with the fibers from the opposite side, to form a loop or girdle which slings the rectum and vagina up under the pubic bone."

I wish to call particular attention to the fact that fibers of this muscle pass not only around the rectum, but between the vagina and rectum. This is the muscle that receives the major part of the injury sustained during delivery. The process of evolution has radically changed this muscle, even more than its associates. While its influence upon the caudal vertebra has diminished, its influence upon the rectum and vagina has increased. So much so has this been the case that Holl considers that the puborectalis is the best developed of the muscles of the pelvic floor, whereas in the lower animals it is hardly discernible. This muscle keeps the rectum and vagina pulled forward under the pubic bone, so that the anus occupies a position on a line from one tuber ischii to the other, and midway between the tip of the coccyx and the symphysis pubis. This is the position when the puborectalis is intact, but when it is lacerated or has lost its tone, it allows the perineal body to recede and the perineal flexure of the rectum and vagina is lost. The puborectalis forms a complete sling around the rectum and vagina, and by direct continuation of its fibers produces an angulation of these canals about an inch from the skin surface.

If the practice is made of investigating the tonicity of the puborectalis in all vaginal examinations, both before and after parturition, the difference can be readily determined. In women who have not borne children, this muscular band can be felt tense and firm, as it passes along by the side of the vagina just within the introitus. In the majority of cases after delivery there is a condition of relaxation, of flaccidity and loss of tonicity, often with little or no resistance to backward or lateral pressure with the finger until the ligaments and pelvic bones are reached. Breaks in the musculature of the pelvic floor can frequently be felt distinctly. I have observed the physical condition of the muscle and fascia before and after delivery in the same woman, and noted the difference. These observations were systematically made not only immediately, but months after labor and they rarely recover their tone, even in those cases in which I have done the most painstaking immediate repair, with

the woman on the table, in a good light, with anesthesia and ample assistance. This led me to believe that immediate work was not sufficient to restore the pelvic floor to its normal condition. These observations were made not only with the woman lying quietly in bed or on a table, but standing. In fact most of these inquiries were made while the woman was standing unsupported. The erect position brings out the contractile power of the levator ani and the integrity of its fascia, and with the finger within the vagina this muscular band can be studied and any interruptions in its continuity noted. This can be graphically demonstrated by placing a wax phallus in the vagina and asking the woman to contract the pelvic floor and noting the indenture.

My conclusions are: That almost every woman suffers injuries during confinement from which she does not recover, unless she is subjected to a secondary operation for the repair of lacerations of the pelvic floor.

That immediate suture of apparent lacerations does not restore pelvic support in the vast majority of instances.

That from one to two months after labor the woman should be subjected to a thorough examination with reference to the integrity of the pelvic floor. Should indications of unrepaired lacerations exist, as evidenced by vaginal relaxation and prolapse, uterine displacement, etc., an operation for immediate repair should be made before the woman's health has been impaired.

## AN INTERESTING CASE OF ENDOCARDITIS WITH FATAL TERMINATION.

BY

FREDERICK G. CANNEY, M.D.,

of San Francisco, Cal.

Dr. R. H. C., aged 32, a promising physician of San Francisco, about 17 years ago while fencing with a friend was accidentally thrust through, the foil entering about the third intercostal space two inches to the left of the sternum, and taking its exit at the back about one inch from the spine, about six inches of the foil showing posteriorly. It was considered that the heart was thrust through, and six or eight physicians of San Francisco took an unusual interest in the case. The exact details are not now to be obtained. There was no alarming hemorrhage following the thrust. The temperature ran very high, 105°-107° F., for several weeks during a subsequent attack of septic poisoning. The patient finally recovered. Immediately after the thrust occurred, a very loud roaring systolic cardiac bruit appeared that absolutely disguised all normal sounds. This bruit persisted for the remaining 17 years of his life. During this time he had excellent health and appeared robust and ruddy, weighing of late years about 190 pounds.

During the summer months he usually went hunting in the northern part of California, and after hunting all day would carry a deer on his shoulder into camp. He was also an enthusiast at rowing, and frequently, once or twice a week, would go to Bellvedere in the early morning and row a heavy boat for two or three hours. He often allowed his medical conferees to listen to his heart, and seemed to enjoy the utter surprise depicted upon their faces on hearing the loud roaring systolic bruit in such a robust subject.

About a year ago he became aware that he had a fever and was also losing flesh, in spite of which he continued to feel well and had a good appetite. He placed himself under the care of an able physician for treatment. His fever varied between 102°-104° F., and at the beginning of last summer he had lost about 40 pounds. He concluded to go on a vacation, and went into the north of the State on a camping expedition, which was cut short by a persistent continuation of previous symptoms. He returned home and went to bed. During all this time he was under the care of a prominent physician, besides being carefully examined at various times by six or eight others.

The blood examination showed a normal count and hemoglobin percentage. The urine was normal. The physical examination showed normal organs, with the exception of the heart, but as this bruit was unchanged it was not considered that it was at fault. Several of his near relatives had died of tuberculosis, and after excluding, as was thought, all other diseases, it was pretty much the consensus of opinion that some tuberculous lesion must be the diagnosis. He had no cough, and there were no tubercle bacilli in his sputum or urine. He had a slight enlargement of his liver and spleen late in the disease. One of the best specialists in heart and lungs in San Francisco examined him and thought he detected some consolidation in the apex of one lung. As the loss of flesh persisted and the

fever was practically unabated, it was again decided to try change of climate. Even at this time he felt well and had an excellent appetite.

He was taken to Arizona, and in a few weeks it was reported that, as a result of spending much of his time in the saddle, he was gaining considerable flesh and had otherwise improved. Within a week or 10 days, however, he returned to his home in San Francisco, and died in less than a week.

The autopsy was made by a confrere, and all the important organs were sent to me for microscopic examination. I made sections of the lungs, liver, kidneys, and heart. There were no evidences of tuberculosis in any of them. The kidneys showed degenerative lesions, but only such as would result from the heart lesion presently to be described. The liver showed similar changes. There were no indications to show where the thrust occurred in the heart 17 years ago. The heart as a whole was slightly hypertrophied. The cusps of the pulmonary valves were the seat of very extensive vegetations, being very much contracted and thickened. They must have offered considerable obstruction to the passage of blood into the pulmonary artery, besides allowing regurgitation. There were also smaller vegetations on the mitral, aortic, and tricuspid valves. At the site of the foramen ovale was a very extensive vegetation, presenting an umbilicated appearance, the center of which was necrotic and patulous. A probe could easily pass through, so some exchange of blood undoubtedly took place between the auricles.

I cut out the umbilicated area and made transverse sections through it. The section showed a ragged necrotic center, around which were areas of inflammatory infiltration of small, round cells. Around this were seen the fibers of the heart muscle, the cross striations of which were very much obliterated, as well as the muscle nuclei. There were no cultures taken from the valves, because I did not get the heart until contamination with extraneous germs was probable. The sections of the cusps of the pulmonary semilunar valves showed superficial necrosis, the deeper tissue showing very intense round cell infiltration; in places actual abscess formation was present.

The question that naturally presents itself is, What had the foil thrust to do in producing the loud systolic bruit that persisted for 17 years and the malignant endocarditis that caused death?

As I have said before, the sound of the bruit was apparently no more angry during the febrile period than formerly. Throughout the whole attack up to the last two or three weeks of his life he felt well and had a good appetite. In the "American Textbook of Pathology" it states that in congenital cases of stenosis of the pulmonary orifice defects of the septum are common.

**Infant Yearly Deathrate in Chicago Falling.**—From the Bulletin of the Chicago Health Department we quote the following: "During the six years of the present administration of the Health Department there have been only 51,046 such deaths. According to the United States census the under 5 years population increased about 30% between 1890 and 1900; so that instead of 51,046 under 5 years deaths in the second period there would—had the earlier deathrate continued—have been 85,083 deaths, or 34,757 more than actually occurred. If this reduced infant and child mortality is to be maintained the quality of the milk-supply must also be maintained. Those who tamper with it by business rules or regulations assume a fearful responsibility, and the public should know where to locate it."

**Surgery Versus the Pulpit.**—It appears that the surgeon of the future is likely to replace the minister and all the elements of moral suasion for the reform of the wayward. A New York exchange contains the following news from London: One of the patients was a boy of good family who had developed brutal instincts which seemed to be beyond control. He gave his time to the invention of malicious mischief, delighted in killing or wounding, was the terror of the neighborhood in which he lived, and promised to grow up a desperado and criminal. A clever surgeon took him in hand, examined his head with care, located what he considered the seat of the trouble, removed a portion of the skull, and thus relieved the deforming pressure. The change was immediate. The lad forgot his previous tastes and habits and was restored to his parents a normal and lovable boy, the complete antithesis of his former self. The other was a soldier who was injured in a skirmish, and after his discharge for disability became a thief and burglar. His previous character had been unexceptionable, his military record was the best, and the change was naturally attributed to the injury to his head, caused by a blow from the butt of a musket. When he was taken in hand by the surgeons he had about come to the end of a career of crime, being paralyzed on one side and unable to get about except on crutches. A depression in the skull sufficient to bring an abnormal local pressure upon the brain was found and an operation was decided upon, which restored his physical powers as well as his mental and moral faculties. His discharge was secured and he has since lived an industrious and honest life, with no evidence of a disposition to go wrong.

## THE WORLD'S LATEST LITERATURE

Journal of the American Medical Association.

5. The Treatment of Empyema by Continuous Aspiration. WELLER VAN HOOK.
6. Unilateral Disease of the Kidney Simulating Stone. JOSEPH RANSOHOFF.
7. Acute Suppurative Cervical Adenitis of Infancy. THOMAS S. SOUTHWORTH.
8. The Estimation of Urea by Mercuric Nitrate. J. H. LONG.

**1.—Medical Discoveries by the Nonmedical.**—G. M. Gould calls attention to the therapeutic practices of the lower animals and epitomizes the discoveries of medical facts and anticipations of modern methods by the ancients and by the nonmedical among both the savage and civilized of recent times. We have not yet learned all that the ancients and barbarians and common people about us have to teach. They incite us to keener observation. It is only by the systematizing of modern science, however, that the scattered discoveries of the world become of use to all. [H.M.]

**2, 3.**—See *American Medicine*, Vol. V, No. 20, p. 774.

**4.**—See *American Medicine*, Vol. V, No. 22, p. 864.

**5.—Treatment of Empyema by Continuous Aspiration.**

—W. Van Hook notes the disastrous results sometimes following drainage. The proper material to fill the cavity left is lung, and correct procedure lies in inducing the lung at once to meet the parietal pleura so that the surfaces may quickly heal by granulation. All the methods described are defective as compared with Perthes' plan, which consists in maintaining a pressure less than that of the atmosphere in the pleural cavity so that the lung may be made to more rapidly approach the chest wall. Perthes has devised a special apparatus costing about \$15.00. Van Hook describes an extemporized arrangement provided for less than \$5.00, requiring a Bunsen pump, a garden hose, a three-necked Wolf bottle, a manometer, and tubing to connect the exhaust of the pump with the collecting vessel and the chest cavity. The dressing applied to the chest wall is of heavy rubber dam, bicycle cement being used to seal the tube to the opening in it, and to seal the dam to the chest wall to prevent wrinkling. The edges are fastened with adhesive plaster. The apparatus should be applied soon after draining the chest cavity. [H.M.]

**6.—Unilateral Disease of the Kidney Simulating Stone.**—J. Ransohoff reports a case of atypical chronic inflammation simulating stone. Detection by sounding is altogether fortuitous. Aside from positive presentment by radiography the signs most relied on are pain, paroxysmal or continuous, and certain changes in the urine. The pain may be simulated by tuberculosis, tumor, hydronephrosis, or by microscopic changes affecting either the secreting, circulatory, or supporting framework. Every one associates hematuria with stone, but in 20 of the author's cases it has been marked by sparse-ness. That in certain cases of chronic nephritis albumin and casts are often absent for months, and both pain and hematuria present, and that it often manifests itself as a unilateral disease, makes it evident that differential diagnosis may be insurmountably difficult. Capsule splitting and section of the kidney will doubtless relieve many cases which simulate stone and which because of the impossibility of making a positive diagnosis are not now subjected to exploratory incision. [H.M.]

**7.**—See *American Medicine*, Vol. V, No. 20, p. 777.

**8.—Estimation of Urea by Mercuric Nitrate.**—J. H. Long gives a table calculated by himself in which the amounts of urea corresponding to different volumes of the mercury solution used are stated. The volume of mercury solution to be employed in the calculation is that which remains after subtracting the amounts used by the chlorids, uric acid, ammonia, and creatin. A study of the literature reveals that in the methods in use corrections are still necessary, and that they are not suitable when a rapid and accurate process is required. [H.M.]

## Boston Medical and Surgical Journal.

May 23, 1903. [Vol. CXLVIII, No. 22.]

1. The Relation of Chronic Enlargement of the Spleen to Anemia in Infancy. JOHN LOVETT MORSE.
2. The Report of Three Cases in Which Embryos of the Strongyloides Intestinalis Were Found in the Stool: Autopsy of One Case. PHILIP KING BROWN.
3. A Case of Gunshot Wound of the Stomach; Operation; Recovery. HUGH WILLIAMS.

1.—See *American Medicine* report of Congress of American Physicians and Surgeons, Washington, D. C., May 13, 1903.

2.—**Strongyloides Intestinalis.**—P. K. Brown reports three cases, one coming to autopsy. Interest in these cases has been aroused by the reports of Strong and Thayer. One of the patients was an American, the other two were natives of Porto Rico, where this parasite is exceedingly common. The author says that it is not at all certain that these parasites, which bury their heads deep in the mucous membrane of the intestine, are as harmless as we have been led to believe. It is probable that they are true parasites of the host, and not a class that subsist upon the contents of the bowel. Two of the cases were complicated with uncinariasis, and the anemia was exceedingly severe. One of the patients was a laborer, aged 18; another a laborer aged 30; and the other, a man of 65, was an American, pastry cook. Detailed history reports are given of all of the cases. In the case coming to autopsy, neither eggs nor worms were found in the muscularis mucosa, but both were found in considerable numbers in the crypts of Lieberkuhn. The adult parasites that were found were all of exactly the same type, and represented what was taken to be the parthenogenetic mother worm. No adult male worms were found. [A.B.C.]

3.—**Gunshot Wound of the Stomach.**—Hugh Williams reports the case. The patient, a youth of 16, was accidentally shot with a 32-caliber revolver. The ball entered the abdomen 1 inch to the right of the umbilicus and  $\frac{1}{2}$  inch below. The patient was taken by ambulance four miles to a hospital. There was no vomiting; shock was not severe. He had to be catheterized for retention of urine, which was normal. Operation was done four hours after the injury was received. The abdomen was practically normal in appearance, without distention, but the lineæ transversæ and semilunares were exaggerated. The ball had passed from right to left, inflicting a wound on the anterior surface of the stomach, which organ it supposedly entered after passing at an angle through its anterior wall. Free gas was in the peritoneal cavity. No fluid, intestinal or gastric content, or blood, was found in the peritoneal cavity. The accident having occurred immediately after a full meal, it appeared that digestion had been arrested, and the stomach was still markedly distended with food. It was feared that this would lead to vomiting, which would seriously interfere with the progress of the case. The wound of the stomach was enlarged to a three-inch incision, the stomach contents evacuated, the wound closed by Lembert sutures, the peritoneal cavity flushed out, and the abdominal wound closed with drainage after the lesser peritoneal cavity had been explored and found normal. The patient made an uneventful recovery. The author is of opinion that the emptying of the stomach at the time of the operation, although it contributed an element of danger, was most probably the important factor in the subsequent favorable progress of the case. [A.D.C.]

## Medical Record.

May 30, 1903. [Vol. 63, No. 22.]

1. Primary and Recurrent Mammary Carcinoma Treated by the X-ray. WILLIAM JONES MORTON.
2. The Treatment of Purulent Conjunctivitis. EDGAR S. THOMPSON.
3. Notes on Cases Treated by Venesection. GEORGE PIERCE ANDREWS.
4. On the Active Principle of *Rhus Diversiloba* (Poison Oak). CARL SCHWALBE.
5. Reflex Symptom from Biliary Calculus. G. W. SQUIRES.

1.—**Mammary Cancer Treated by Röntgen Rays.**—William J. Morton says he will soon report a complete list of all his cases treated by the Röntgen rays, favorable and unfavorable. In the present paper he reports some 20 cases in which the growths have disappeared or in which there has at least been much improvement. The more superficial the growth the greater are the chances of cure, and the more recent the

newgrowth the more favorable is the prognosis under Röntgen ray treatment. But the more preponderant the fibrous or scirrhous character the slower the action of the rays. An open ulcer with much secondary septic infection is almost sure to progress unfavorably. In some instances of scirrhous cancer it appears that this method of treatment causes an increased growth of the fibrous tissue, with decrease or degeneration of cancerous infiltration. The author holds that it is justifiable to subject suspected early mammary cancer to Röntgen ray treatment, hoping for a cure, rather than resort to surgical intervention in the first instance. Much investigation and experimentation yet remains to be done before we shall be able to ascribe to the Röntgen rays their proper place in the treatment of cancer. [A.B.C.]

2.—**Purulent Conjunctivitis.**—E. S. Thompson points out the importance of a microscopic examination of the pus as a first step in the treatment, as stronger germicides are indicated in gonorrhœal than other infections, and these should be used at once before the gonococci have penetrated the conjunctiva, since later the eye will probably be lost. The disease varies somewhat, but in the majority of cases is more severe than the worst cases caused by other infections. A 2% solution of silver nitrate should be used on an applicator if the case is seen early, or a 3% or 4% solution two days after infection. When this irritates, causing increased discharge of serum and a tendency to bleed, a 6% solution of protargol may be used. The latter is also indicated when the discharge is caused by the pneumococcus, Koch-Weeks' bacillus, or other pus organisms. This applied once daily will limit an attack of pink eye to a few days. Argyrol, 25%, or silver vitellin, fulfils the same indications as protargol, and is absolutely nonirritating. It is less effective than the nitrate when an astringent as well as germicide is required. Cleansing should be done often enough to keep the eye clean, even if that is every 10 minutes. Ice cloths tend to inhibit growth of organisms. Scarification does good when chemosis is severe. Cauterization of the cornea helps to combat ulceration. When the latter appears hot applications should be used. [H.M.]

3.—**Value of Venesection.**—G. P. Andrews details ten cases in which venesection was done with prompt relief in all but one. They were in the order given: Eclampsia in a young primipara; catarrhal pneumonia in an old man of 70, with degenerated bloodvessels and heart; eclampsia in a woman of 32; asthma in a frail man of 60; epileptiform seizures in a plethoric man of 62, repeatedly relieved by this means; dyspneic attacks occurring every three or four weeks in an old man of 70, who had sought and found relief in this way periodically since 25 years of age; pulmonary hemorrhage in a robust seaman of 32; severe migraine at menstrual period at each menstrual epoch; eclampsia in a primipara of 23 (fatal); eclampsia in a woman of 23 at second labor. In all the above cases except one relief followed the flow of blood promptly; in several of them when other means had failed. In each case bleeding was curative, in the sense that it tided over an emergency. Its action is first upon the volume of the circulation; second, upon the nerve centers, and is in the nature of shock; third, in certain instances, when the patient is conscious, the effect of expectancy upon the imagination is marked and benign, as in Cases IV, VI, and VIII. No notable ill effect or depression dependent on the loss of blood was noticed at any time. [A.B.C.]

4.—**Active Principle of *Rhus Diversiloba*.**—C. Schwalbe reviews reported cases of rhus poisoning whose histories show that it must be a solid particle, and not gaseous matter which causes the lesion. There are lactiferous vessels which contain the poisonous matter, and upon these vessels grow hairs loaded with the poisonous oil. These are carried by the wind and penetrate into the openings of the sudoriferous and sebaceous glands. They are found on the plant even in winter. Persons perspiring easily are more liable to the affection. Carbonate of potash, concentrated lye in 0.1% to 0.5% solution several times daily is sufficient to protect exposed persons from bad effects. [H.M.]

5.—**Reflex Symptom from Biliary Calculus.**—G. W. Squires reports a case in which occurred stiffness, tenderness, and then pain in the heels directly over the tendo-Achillis,

affecting the gait, and in the morning making it difficult to move around. A herpetic rash appeared over the affected area, causing paroxysms of pain of distressing intensity. This lasted for 18 months until a calculus the size of a pigeon's egg with four sharp prongs was passed, when the pain and eruption subsided almost immediately, and an indigestion of 15 years' duration disappeared. [H.M.]

### New York Medical Journal.

May 23, 1903. [Vol. LXXVII, No. 21.]

1. In the Hemisphere of X-ray Activity. J. RUDIS JICINSKY.
2. The Ureteral Pelvis. BYRON ROBINSON.
3. Eclampsia: Its Prevention and Treatment. EDWARD A. AYERS.
4. Atony of the Duodenum Diagnosticated and Corroborated by Operation. MARK I. KNAPP.
5. A Few Differential Diagnoses in Connection with the Exanthemas. WILLIAM L. SOMERSET.

**2.—The Ureteral Pelvis.**—Byron Robinson describes in detail the minute anatomy, forms and relations of the ureteral pelvis. Bilateral pelvic symmetry arises rarely. The first, prime, and most frequent form is that which consists of a triangular voluminous pouch lying partly internally and partly externally to the hilum renale, and divides mainly into a larger distal major calix and a smaller proximal major calix. A second form of the ureteral pelvis is where the ureter divides dichotomously and practically no ureteral pelvis exists or only a small one. A third form of ureteral pelvis might be considered as a half pelvis. It may happen that only the distal major calix of a dichotomously divided ureter enters into the formation of a half ureteral pelvis. In such a case the proximal major calix passes directly into the ureter, and the pole of the kidney contributing to form the half pelvis is the larger. [C.A.O.]

**3.—Eclampsia.**—E. A. Ayers maintains that the great majority of the cases of eclampsia can be prevented. The bowels must be kept properly emptied. This not only sustains the eliminative function, but permits the uterus gradually to occupy abdominal space with less interference to the daily work of the kidneys, ureters, and heart. Cascara, either alone as the fluid extract, or in tablet with aloin and podophyllin, is very satisfactory; and this should be varied with the use of calomel once a week, more surely to keep the liver in proper condition. The rule for every pregnant woman should be, to be regular in meal hours, moderate in the use of meats, exclusion of the more indigestible vegetables, and of all wines, and avoidance of excessive quantity at any time. Whenever the amount of urine secreted or excreted, or of urea excreted, falls below normal, or albumin or casts are present, the patient should be treated by diet, laxative and diuretic, to restore to normal the urinary function. In the treatment of cases of eclampsia each case must be a law unto itself. Whenever feasible, Ayers aims to secure such degree of elimination of toxins promptly as will put a temporary check upon the convulsions, and then to test whether he can remove the evidence of insufficient elimination by usual methods, and so, if successful, permit the pregnancy to go to term. If the effect which the convulsions have had is not marked, the mind being clear, the pulse under 100, and the convulsions not occurring oftener than every hour or two, he favors giving a saline cathartic by the mouth and a high saline solution in the bowel. Hot packs, water-bags, wet blankets and sheets must be used with reserve. If the case presents the highly nervous type, restlessness, tossing, and mental activity, he favors the administration of 20 to 30 grains of chloral per rectum, seeking not narcosis, but removal of nerve tension; nitroglycerin,  $\frac{1}{10}$  of a grain, should be given at the start, and repeated as needed. Oxygen and injection of saline infusion into the subcutaneous tissue are indicated. It is useless to try to select a particular anticonvulsive and use it, for there is no disease that calls more for special selection than eclampsia. If labor is going to continue whether we can check the convulsions or not it is best to hasten delivery. [C.A.O.]

**4.—Atony of the Duodenum.**—The case reported by M. I. Knapp is that of a woman of 43, whose illness began three years previously with attacks of severe abdominal pain, cramp-like, often severe and cutting in character and more severe on the left side. At first there was an interval of several weeks between the attacks, but later they became of almost daily

occurrence. She often vomited during the attacks, which were more apt to occur after eating. She was troubled with constipation, had lost weight, and there was increased abdominal distention. Below and to the left of the umbilicus an indistinct mass could be felt. A malignant growth was suspected. Upon opening the abdomen a constricting infiltration of the jejunum was found just distal to a much distended coil. Fifteen inches of the intestine was removed and recovery followed. There was entire absence of cancerous lesions in the growth. [C.A.O.]

**5.—Differential Diagnosis of Exanthemas.**—W. L. Somerset reports some cases in each of which there existed, at some time in its history, a justifiable difference of opinion concerning the diagnosis. The first was that of malignant variola, which might easily have been mistaken for malignant scarlet fever. The second case reported is that of erythema scarlatini-forme, in which scarlet fever had been suspected. The appearance of the face of a third patient with measles was unpleasantly similar to variola. In another case the diagnosis of rubeola was made first, later the child was thought to have scarlatina, but it soon developed into a confluent case of rubella. In the fifth case an atypical variola might easily have been mistaken for varicella. The sixth case was thought to be either one of quinin poisoning or ptomain poisoning. [C.A.O.]

### Medical News.

May 30, 1903. [Vol. 82, No. 22.]

1. Professional Discretion: The Medical Secret. PRINCE A. MORROW.
2. A Report Upon the Physics and Therapeutic Value of Cathode and Ultraviolet Rays; with Reference to the Electromagnetic Theory of Light: An Attempt to More Clearly Define the General Character of These Recently Introduced Agents in the Treatment of Cancer. ROSWELL PARK.
3. The Cure of Anal Fissure Without Operation: Report of Eight Cases. S. LEWIS.
4. The Therapeutic Use of Suprarenal Gland in Certain Diseases of the Skin. MARTIN F. ENGMAN and WM. P. LOEH.
5. On Simplicity in the Operation for Laceration of the Cervix Uteri. LOUIS KOLLIPINSKI.
6. Tuberculosis of the Larynx and Aspiration Tuberculosis of the Lungs Following Dermatitis Blastomycetes. ORTO T. FREER.

**2.—Physics and Therapeutic Value of Cathode and Ultraviolet Rays.**—Roswell Park, in the space of a magazine article, gives the most exhaustive and philosophic discussion on the origin, nature, and therapeutic value of cathode and ultraviolet rays which has come within our observation. The paper should be read in full by all those interested in the subject. As to the therapeutic value he says that is as yet undetermined; it is yet too early to report cases. This much, however, has been determined with reference to the rays in question: 1. They afford methods of treatment for extremely newgrowths of limited area and superficial character which, while not exactly certain, are extremely promising. 2. They not only cause no pain, but tend to relieve pain, both superficial and deep, in a most pleasing and satisfactory way. 3. They are adapted to cases which can hardly be submitted to any other method of treatment, and they afford more hope in delayed or inoperable cases than does any other method of treatment. 4. It will be found that the odor of putrefaction may often be suppressed by their use and the putrefying process itself checked. 5. Burns and intense dermatitis, so frequently noted when the treatment first came into vogue, may now be almost certainly avoided. 6. More than this, they afford a supplementary method of treatment after operation, by which the benefits of the same may be enhanced and enlarged. 7. It is not necessary to intermit such work as the patient may be engaged in, in order to carry out the x-ray or phototherapeutic method of treatment. [A.B.C.]

**3.—Cure Anal Fissure Without Operation.**—S. Lewis reports eight cases, four of which were chronic, and all suffering from agonizing pain after stool. Treatment consisted in applying to the fissure and surrounding area a saturated solution of potassium permanganate, and using a suppository containing sulphathyolate of bismuth. Cocainization for 10 to 15 minutes with a 6% solution applied on a pledget of cotton is often necessary before examination and application of the permanganate can be made. Smarting pain lasting two or three minutes usually follows the application. Severe pain and tenesmus he has not observed following the use of suppositories in these cases. The suppository used is sold under the

name of anusol. Aside from its astringent and soothing effect it secures a pultaceous stool daily. It should be applied night and morning. The second treatment is as the first, except the cocain is omitted. After the third treatment the suppositories are reduced to one daily. The author is highly gratified at the results secured, and holds that this treatment should replace many operations. [A.B.C.]

**4.—Suprarenal Gland in Skin Diseases.**—M. F. Engman and W. P. Loth have found published reports of the use of the gland only in two articles, it having been used in acne rosacea and pruritus vulvæ. The diseases in which it is effective are those produced probably by some toxic disturbance, exhibited by a derangement of the vessels or the nerves controlling them. They have used it with success in general pruritus, chronic urticaria, lichen urticatus, and morphea. They use the dried extract in powdered form. Between 4 and 12 years 1 grain is the initial dose gradually increased to 3 grains three times daily. In adults 2 grains increased to 6 grains may be used. It should not be taken on an empty stomach. After long-continued doses in certain individuals tremor of the extremities occur showing a cumulative effect on the nervous system, disappearing when the drug is stopped. [H.M.]

**5.—Laceration of the cervix uteri,** according to L. Koli-pinski, is the most common cause of postpartum hemorrhage, abortion, miscarriage, and cancer. Admitting the necessity of its repair, the writer emphasizes the simplicity of the operation even for old cervical tears. The normal sensibility of the cervix uteri is probably not greater than that of the gums, and anesthesia, either general or local, is unnecessary. The operation consists in denudation, apposition and retention of approximated surfaces. The torn lips are denuded on both sides with scissors, cutting away but little tissue. The prepared surfaces should be raw and bleeding. From two to three silkwormgut sutures are inserted on each side, and the wound having been irrigated and dusted with iodoform are securely tied and cut short. An antiseptic tampon is placed against the neck of the uterus. This is removed in a day or two and voluminous boric acid douches are practised until the removal of the sutures in three weeks. In a week at the latest the patient is allowed to rise daily. The writer has followed this method in more than a dozen cases with satisfactory results, and he wishes to give the proper subjects of this operation a rational idea of its importance, its freedom from danger and from pain, and its simplicity, such that it can be done at home without anesthesia and with little expense or loss of time. [w.k.]

**6.—Tuberculosis Following Dermatitis Blastomyces.**—O. T. Freer finds that this has occurred so infrequently that the sequence may be merely a coincidence. He reports a case in which the side of the larynx affected corresponded to the side of the face attacked by blastomycetic ulceration, the tubercle bacilli having probably effected entrance here by means of the lymphatics. The blastomycetic organism was not found in the tissues of the larynx or other affected parts of the body. [H.M.]

#### Philadelphia Medical Journal.

May 30, 1903. [Vol. XI, No. 22.]

1. The Treatment of Fracture of the Neck of the Femur at Bellevue, St. Vincent's, and New York Hospitals. JOSEPH B. BISSELL.
2. A Case of Ulcerative Endocarditis Involving the Pulmonary Valve and Causing Perforation of the Ventricular Septum, Gangrene of the Nose and Ears, Multiple Infarcts in the Kidneys, etc. HENRY M. FISHER.
3. A Report of a Case of Malignant Gonorrhœal Endocarditis, with Specimens. C. J. HABHEGGER.
4. Preliminary Report of an Operation for Abdominal Pregnancy of Twenty-one Months' Duration. CHARLES P. NOBLE.
5. Uterine Fibroma Near the Menopause. GEORGE ERETY SHOEMAKER.

**1.—Treatment of Fracture of the Neck of the Femur.**—J. B. Bissell details the results of the treatment of a series of 316 cases of fracture of the neck of the femur in the Bellevue, St. Vincent's, and New York Hospitals. In none of these cases was an operation performed, either to unite the fractured surfaces, to remove a detached head, or to carry on or assist in any manner the treatment. It seems that in all three of the hospitals the patients were kept in bed either longer than was necessary or not long enough. If the broken neck would not unite at the end of six weeks under treatment while confined

to bed it is hard to be convinced of the possibility of its uniting at the end of eight or nine weeks, especially as "splints" do not, in most cases, prevent motion between the fragments and do not secure perfect coaptation, neglecting in this way the two essentials—immobilization and firm coaptation—without which a "splint" is not only useless, but of positive harm. The experience of the writer has led him to a much more optimistic view than is usually held, and he would suggest that the best treatment for this injury would be an open operation, with the pegging or wiring of the fragments, or the application of whatever other method or means may be necessary to retain them in a correct position until bony repair takes place. [F.C.H.]

**2.—Ulcerative Endocarditis.**—Henry M. Fisher reports the case of an Italian barber of 20 who suffered from an ulcerative endocarditis involving the pulmonary valve and causing perforation of the ventricular septum, gangrene of the nose and ears, and multiple infarcts in the kidneys, etc. The patient had a severe and distressing cough, probably due to pressure of the vegetations on some of the cardiac filaments of the pneumogastric nerve, as no evidence of disease of the lungs could be detected. At no time did the patient have any fever. Considering the gravity of the obstruction, the maintenance of a fairly slow, regular pulse of moderately good volume during the whole course of his illness appears to be very curious. [F.C.H.]

**3.—Malignant Gonorrhœal Endocarditis.**—C. J. Habegger reports the case of a painter of 27 suffering from an endocarditis, supposed to be gonorrhœal in origin, although this had not been proved by cultures, but assumed for the following reasons: The disease occurred during the fourth or fifth week of a typical gonorrhœa and at a time when the gonococci had migrated to the posterior urethra, as shown by the complicating epididymitis. Cultures from the various organs on ordinary media remained sterile. The diagnosis of septic endocarditis was practically made at the first examination of the patient. In the differential diagnosis malaria with an old endocarditis was excluded by the blood examination and the exhibition of quinin. One interesting feature which was of considerable moment in the diagnosis, showing as it did an acute process involving the heart, was the rapid changes that took place in the size of the heart, the character of the murmur, sounds, pulsation, and pulse. These changes could almost be made out from day to day and depended upon the damage done the heart valve by the vegetations and ulceration. [F.C.H.]

**4.—Preliminary Report of an Operation for Abdominal Pregnancy of Twenty-one Months' Duration.**—C. P. Noble reports the operation on a case of abdominal pregnancy in a nullipara of 30. The most interesting point in connection with the operation was the method adopted to avoid hemorrhage; this was accomplished by ligating the ovarian and uterine vessels; then the fetus and sac were elevated out of the pelvis, and the lower end of the mass turned upward, in order to gain access to the mesenteric vessels from below and behind. The patient made a good convalescence. The fetus was in an excellent state of preservation. [F.C.H.]

**5.—Uterine Fibroma Near the Menopause.**—G. E. Shoemaker believes that among the medical heresies which are fast fading away is the idea once popular that fibromas of the uterus are likely to diminish in size or to cease to bleed and to grow about the time of the menopause. He details three cases illustrative of the onset of severe symptoms after the age of 44. [F.C.H.]

#### CLINICAL MEDICINE

DAVID RIESMAN                      A. O. J. KELLY

#### EDITORIAL COMMENT

**The Unsolved Problem of Cancer.**—Modern medical research, though continually winning brilliant victories in the domain of etiology and prevention of disease, must still acknowledge defeat in the campaign against cancer. New theories regarding its origin are advanced only to be proved untenable or to remain, at best, as theories only. The most hopeful thing about the whole matter is the persistence with which investigations, and theorizing also, are being prosecuted.

Persistence eventually wins. Among the more recent contributions to the subject is that of Jonas on cancer and immunity in which he inclines strongly to the view that cancer has a chemic basis. The *Practitioner* for May, which comes in the form of a special number devoted to "Malignant Diseases of the Mouth," is replete with suggestive statements regarding the origin and treatment of cancer. The editorial pages are devoted entirely to an excellent review of the subject. It is there stated that the apparently established facts regarding cancer may be brought into line by supposing that the necessary basis of tumor formation is the separation, in some manner, of certain cells of the body from their normal connection with neighboring cells. This separation may be the result of maldevelopment, momentary trauma, or inflammatory changes. Cells thus cut off from their organic connection may develop in an entirely irregular manner, seemingly because of their lack of a controlling force. The possibility that the influence of the nervous system is this absent factor is suggested by clinical evidence. The strong probability of cancer houses and cancer villages is set forth by one of the contributors to the above mentioned journal. Another calls attention to the increase of cancer in Ireland which in 1891 had a cancer deathrate of 4.6 per 10,000 of population. In 1897 the rate was 5.8 and this steadily increased to 6.5 in 1901. An increase is also noted in other countries.

Passing from this rather gloomy consideration of the etiology and increase of cancer what is there new in treatment? Barring the x-ray, which has a distinct but not as yet definitely determined therapeutic value in certain cases, the surgeon holds out but one hope of lowered mortality—earlier diagnosis and operation. This is the battle-cry when discussing cancer of the breast, the tongue, the stomach, the rectum, the uterus, in fact cancer of any part of the body that can be reached by modern surgery. Adherence to this principal means more exploratory operations in doubtful cases, but in the light of our present knowledge of cancer they are justified, we had almost said demanded. This sentiment was voiced recently at a notable meeting of the Philadelphia Academy of Surgery when early exploratory operation in supposed but doubtful cases of gastric carcinoma was strongly urged by authoritative men. One writer in the *Practitioner* speaks of operation during the precancerous stage of leukoplakia of the tongue. Another mentions the responsibility of dentists as regards the early recognition of malignant disease of the mouth. A recent article elsewhere calls attention to the probability of cystic involution being a precancerous condition of the mammary gland. This, then, is the present trend of surgery, to operate upon incipient cancer, to even anticipate it by removing conditions that have been known in other persons to undergo cancerous transformation. And in his effort to grapple early with this dread disease the surgeon should be aided loyally by the physician. The difference between early and late diagnosis means to the patient the difference between life and death.

#### REVIEW OF LITERATURE

**Diagnosis of Catarrhal Pyelitis.**—The diagnosis of this affection has been and still continues to be very difficult, owing to certain anatomic, physiologic, and clinical peculiarities. However, a diagnosis is possible, according to A. P. Fawitzky and W. F. Orloffsky,<sup>1</sup> the contrary opinion of numerous authorities notwithstanding. The cardinal symptoms or signs are: Pain in the region of the affected kidney, spontaneous and elicited by means of bimanual palpation and by percussion; the occurrence of temporary exacerbations which often run a typical course; presence of abundant mucus in the urine, its low specific gravity, and polyuria. Occasionally blood or pus may be present in the urine, but this is not a sufficiently frequent finding to be of negative diagnostic importance. The

exacerbations just mentioned are characterized by fever, depression, nausea or vomiting, intestinal derangements, and other symptoms which may closely simulate typhoid fever. The differential diagnosis of catarrhal pyelitis requires the exclusion of numerous conditions, such as lumbago, localized peritonitis, gastralgia, intestinal catarrh, nephritis, paranephritis, malignant tumors of the kidney, and certain gynecologic inflammations. The authors illustrated all these points on a series of 14 cases selected from an immense clinical material. [L.J.]

**Asphyxia Due to Lumbricoid Worms Obstructing the Larynx.**—Wagner<sup>1</sup> reports the case of a boy of 8, who during convalescence from scarlet fever was suddenly taken with violent abdominal colic and slight abdominal distention, but no other threatening symptoms were present. Opium quieted the pain and laxatives brought to light a number of ascarides. He passed 26 more during the next two weeks; another was taken from right nostril after producing an inflammation of nose and conjunctiva. A week later two were found in his vomitus and the same day he was found in a state of partial asphyxiation, from which he did not recover. The autopsy showed the cause of death to be impaction of lumbricoids in the upper part of esophagus, shutting off the larynx. The lower part of esophagus and stomach literally swarmed with worms. [E.L.]

**Illuminating Gas Poisoning.**—A very practical and valuable contribution to this subject is furnished by P. M. Pilcher,<sup>2</sup> who reports 25 cases with a thorough analysis of types and a discussion of treatment. The deaths in New York City from this cause show a rather remarkable increase, being 90 in 1898, 102 in 1899, 136 in 1900, 156 in 1901. The condition is considered from its clinical aspect entirely. Cases belong to one of three types: (1) Mild cases; (2) profound cases; (3) cases in which edema of the lungs has already developed. The following points are to be noted in the profound cases: Changes in the blood, exhaustion of nerve centers, loss of muscular tone, general vascular paresis, marked tendency to develop edema of the lungs, development of pneumonia, inability of the patient to take food. Treatment must be directed against these factors. Among the points emphasized is that oxygen, to be of value, must be administered pure, through a cone or similar appliance and not simply by means of a nozzle thrust into a nostril or the mouth of the patient. A copious infusion of salt solution should be given. This should be reinforced in severe cases by a direct blood transfusion. In one case detailed, the salt solution gave only temporary benefit, while the effect of a direct blood transfusion was very marked and lasting. This procedure is not dangerous if carefully practised by one experienced in the technic of intravenous infusion. [A.G.E.]

MARTIN B. TINKER

A. B. CRAIG

C. A. ORR

#### REVIEW OF LITERATURE

**Operative Treatment of Cirrhosis of the Liver.**—Talma's operation, the suturing of the omentum to the anterior abdominal wall, has been tried by Lanz,<sup>3</sup> who has been able to collect about 60 cases with 24 cures. He reports two cases of his own. The first concerned a woman of 54, who had marked ascites, which required frequent tapping, reaccumulating more and more quickly in every instance. At the operation 15 liters of fluid were evacuated. The liver was found hard, irregular, its surface granular. A tumor of the ovary, which was found on microscopic examination to be a strumous growth, was removed. The parietal peritoneum was rubbed dry; omentum and peritoneum were sewn to rectus muscle. Three months later there was no ascites, the patient feeling perfectly well. The second patient, a man of 35, had had ascites for four years, which gradually became very marked. Under local anesthesia a small incision was made, the peritoneum punctured, and 20 liters of fluid removed. The peritoneum was opened and the omentum sutured to the peritoneum with two sets of sutures. The result of this case is not known as yet, as

<sup>1</sup> Deutsche medicinische Wochenschrift, December 4, 1902.

<sup>3</sup> Correspondenzblatt für Schweizer Aerzte, 1902, September 15.

<sup>1</sup> Russki Vrach, February 22 and March 1, 1903.

but two weeks have passed since the operation, Lanz thinks so well of the operation that he expresses his preference to performing epiploxy at an early stage of the disease, instead of waiting, as has been the custom, until it is the last refuge. [E.L.]

**Narcotile, a New Anesthetic.**—I. Plasencia<sup>1</sup> reports on this anesthetic, which is an ethyl compound; was first prepared by Zenqué in Paris. It was introduced into London in 1901, and was employed in various hospitals and at the dental school. It is administered by means of a mask, such as that of Hirschler, which is bell-shaped, made of celluloid, and fits over nose and mouth. The anesthetic is administered through valves in the smaller end. Patients are anesthetized in from three to four minutes. It is employed only for brief narcosis. If it is used first and then followed by ether or chloroform, narcosis is more rapid, and less chloroform is necessary. The author has used it in five cases, and has had no accidents, but has obtained rapid anesthesia; the period of excitation is reduced and a smaller quantity of chloroform than usual is required. [G.C.D.]

**Idiopathic Dilation of the Esophagus.**—R. Sievers<sup>2</sup> reports the case of a man who had a peculiar difficulty in swallowing, dating back to earliest childhood. The food would evidently accumulate in the esophagus, causing an oppressively painful sensation in the chest. This could only be relieved by pressing the food into the stomach, to accomplish which extraordinary efforts were necessary. Various methods of examination showed that the dilation was situated at the lower end of the esophagus, and had a capacity of 1 liter (2 pints). It was not a diverticulum, but was a spindle-formed enlargement. The sac had no digestive powers. The stomach was normal. There was no indication of tumor or aneurysm causing the obstruction. Spasm of the cardia was excluded by the non-intermittent character of the condition, and the total absence of any evidences of nervous disorder to account for the spasm. The only possible explanation seems to be that of congenital malformation. [B.K.]

**Acquired Diaphragmatic Hernia.**—F. Luksch<sup>3</sup> reports a case of acquired diaphragmatic hernia in a 75-year-old woman, who for some time had suffered from an umbilical hernia. The latter became incarcerated and was relieved by operation. Several days later the patient died suddenly. Autopsy showed the presence of a hernia in the right half of the diaphragm. The latter had bulged upward and formed a sac about twice the size of a fist. It was lined with peritoneum and contained the ascending colon. Luksch considers this a rare condition and one that occurs in very old people. The author recognizes two varieties of diaphragmatic hernia. In one there is a congenital defect of the musculature of the diaphragm, and in the other the structure of the diaphragm is not injured, the hernia being caused by intraabdominal pressure. [W.E.R.]

**Cancer of the Lips.**—In a large experience Sir Thornley Stoker<sup>4</sup> has not found evidence to show that epithelioma of the lips is due to an inherited disposition, but he states positively that the use of the pipe is the exciting cause of lip cancer in almost every case. Irritation by faulty teeth is a factor to be considered, but it is doubtful if syphilis is of importance. In over 350 cases only 3 were females and they were assiduous smokers. In the diagnosis of cancer of the lip only two conditions can be confounded with it—sarcoma and a syphilitic sore. Surgical treatment is much the same as during the past few decades. One great lesson has been learned, the propriety of the disuse of caustics and pastes of all kinds. Early operation is simple and successful and rarely followed by recurrence. If accompanying disease of the jaw and its soft coverings be extensive operation is best left undone. Lymphatic involvement alone should not prevent operation. As to the method of operating Stoker strongly advises that all intricate cutting and elaborate movement of flaps should as far as possible be avoided and the operation, however extensive, made as simple as may be. The more elaborately cosmetic the operation the more likelihood there is of recurrence. [A.G.E.]

## GYNECOLOGY AND OBSTETRICS

WILMER KRUSEN

FRANK C. HAMMOND

### EDITORIAL COMMENT

**Nitroglycerin in Dysmenorrhea.**—The presence of painful menstruation indicates the necessity for careful physical examination to ascertain its cause. These causes are varied. Any malposition of the uterus or its appendages, a stenosis of its canal, or any inflammatory condition along the genital tract, may be the causative factor of dysmenorrhea. The position of the pain and its relation to the flow of blood afford material aid in diagnosis; but very frequently the gynecologist finds that severe dysmenorrhea occurs without any demonstrable pathologic lesion in any part of the genital apparatus, and often this so-called neuralgia or spasmodic dysmenorrhea is most difficult to treat. As a rule it is unwise and irrational to mask the symptoms by giving opiates, although it may be necessary during a severe paroxysm; but the satisfactory results which we have obtained by the use of nitroglycerin lead us to emphasize its value for the relief of this condition. By detailing a typical case its range of usefulness may be indicated. The patient is usually a nulliparous woman, of sedentary occupation, often anemic, who just a few hours prior to the establishment of the flow has marked vasomotor constriction as shown by facial pallor, blueness of the lip, coldness of extremities and a sense of pelvic engorgement. By the administration of  $\frac{1}{100}$  grain of nitroglycerin every three or four hours until the flow is satisfactorily established, the physician may often relieve his patient in a thoroughly rational manner without resorting to opiates or other anodynes. Be it understood that it is only when clear indications exist for vasomotor dilation that this remedy will alleviate. Other cases in which cervical angulation or stenosis is present are best treated by rapid dilation under anesthesia; or if due to malposition or diseased appendages, appropriate surgical procedure must be employed.

### REVIEW OF LITERATURE

**Laryngeal Tuberculosis During Pregnancy.**—Loehner<sup>1</sup> has observed 5 cases of pregnancy complicated by laryngeal tuberculosis. He believes the condition to be more common than is usually supposed, believing in fact that pregnancy in a tuberculous woman predisposes her to laryngeal tuberculosis, and even in healthy pregnant women the larynx is more likely to be the starting point of the disease than any other organ. The slightest hoarseness during pregnancy should be followed by a most careful examination of the larynx, and if a diagnosis cannot be made, this should be repeated. On account of the very fatal prognosis to mother and child which is accorded the disease by all observers the author recommends the prevention of marriage of tuberculous people, the prevention of conception after marriage, the proper diagnosis of laryngeal disturbances during pregnancy, the removal to the most favorable surroundings if tuberculous laryngitis is diagnosed. Of his patients the first was delivered prematurely; mother and child died about the fourteenth day. The second patient died 1½ months after delivery, the child being apparently in the best of health. Both these patients were apparently very well prior to pregnancy, the larynx was the seat of primary infection, followed shortly after by the lungs. The other three patients had pulmonary tuberculosis and developed laryngeal disease during pregnancy; of these three the mothers and two of the children died. [E.L.]

**Hematosalpinx Due to Tubal Pregnancy Complicated by Twisted Pedicle.**—T. J. McCann<sup>2</sup> quotes the only case of this kind found in literature reported by Martin, and then adds a second from his own practice. In 1898 a woman, aged 34, was cured for purulent uterine discharge, which ceased with great improvement in health. In 1900 she was seized with pain in the kidney region, which was relieved by hot application.

<sup>1</sup> Münchener medicinische Wochenschrift, February 24, 1903.

<sup>2</sup> Lancet, May 9, 1903.

<sup>1</sup> Revista Medica Cubana, November 15, 1902.

<sup>2</sup> Zeitschrift für klin. Med., Bd. xlix, p. 45.

<sup>3</sup> Prager medicinische Wochenschrift.

<sup>4</sup> The Practitioner, May, 1903.

There occurred in 1901 a similar attack and a third early in 1902, at which time she sought medical advice and the trouble, which was supposed to be renal colic, soon subsided. The final attack, a month later, was accompanied by a rise in temperature, and other symptoms of local peritonitis. McCann was called in by the attending physician and the examination under ether showed a smooth, round swelling in the right posterior quarter of the pelvis. The abdomen was opened, adhesions broken up, revealing a tumor of the tube with a pedicle twisted three times. A ligature was applied below the twist and the tumor removed. The convalescence was rapid and uneventful and the patient has been absolutely well ever since. The dilated tube contained blood clots and dark fluid blood. A section of the tubal wall showed chorionic villi infiltrated with blood. The tube was closed at the fimbriated extremity. [w.k.]

**Management of Brow-presentations.**—Having observed the tendency of brow-presentations to become face-presentations in nearly one-fifth of all cases, G. A. Solowjew<sup>1</sup> recommends a method of imitating nature in this respect. No time should be lost waiting for the brow-presentation to change, but the head should be extended further by means of a finger introduced into the child's mouth. This extension must be maintained until the uterine contractions are able to do the work of the finger. Three cases were thus managed by the author with success, only one requiring the additional aid of forceps. [L.J.]

**Complete Nephroureterectomy.**—J. Wesley Bovée<sup>2</sup> defines this term as the complete removal of kidney and ureter at one attempt. It may be called an American operation, since the first four were performed by American surgeons, Kelly probably doing the first in December, 1895. Of the 17 cases on record, only 2 were done outside the United States. But 4 of these were males and only 2 ended fatally. Tuberculosis of kidney and ureter was the indication in 14 of these cases. Complete nephroureterectomy may be done by the extraperitoneal and the transperitoneal routes. Bovée seems to prefer the loin extraperitoneal with a vaginal incision to remove the lower part of the ureter, and thinks it best to begin with the vaginal incision. He gives a full history of his second case, with the technic of the operation and its results. In tuberculosis of the kidney and ureter the strictest care to prevent contamination of normal structures is necessary. That virulent organisms other than the bacillus of tuberculosis may be in the pus should be remembered. It is well to remove the kidney and ureter *en masse* when possible, liberating the kidney first, care being taken that leakage from the cut end of the ureter does not occur. In favorable cases, if thought advisable, the ureter may be divided between clamps at any point where distention is not marked. Whether pus be present or not drainage should be employed, as not to do so is to invite at least the accumulation of a large amount of serum in the extraperitoneal space made in the operation. [w.k.]

**TREATMENT**

SOLOMON SOLIS COHEN

H. C. WOOD, JR.

L. F. APPLEMAN

**REVIEW OF LITERATURE**

**Old Methods of Treatment Which Are Not Obsolete.**—Syers<sup>3</sup> deprecates the displacement by some of the so-called modern treatments of older and better modes of combating disease. An example is found in the antiseptic treatment of typhoid fever and the use of antipyretics in this disease. The extremely vigorous efforts sometimes made to reduce the temperature in typhoid fever, as a rule, do more harm than good. In insomnia, which is so frequent a symptom of this disease, antipyretic measures may be very harmful. He believes one of the most useful drugs in enteric fever is opium, especially in those cases in which there is a low muttering tendency to delirium. He believes that the systematic use of opium by quieting the nervous system is most beneficial. The prejudice against opium in pneumonia is unjustified. In asthenic pneumonia

with muttering delirium and insomnia, the drug is capable of great good. Syers also places faith in the old-fashioned treatment of appendicitis, reserving surgical intervention only for very violent cases. He avoids purgatives, restricts the diet, and gives opium freely. He does not find opium counterindicated as is usually believed in cases of chronic nephritis. In the latter stages of chronic kidney lesions, when insomnia becomes a marked symptom, he recommends the early employment of morphin as one of the best hypnotics in this condition. [H.C.W.]

**Urosin.**—Lang<sup>1</sup> says that Weiss has shown that the value of fruit in gouty conditions depends upon the chinic acid which they contain. This by uniting with glycochol to form hippuric acid prevents the formation of uric acid. Chinic acid itself is but slightly soluble and strongly acid. To overcome these objections Weiss recommends the soluble lithium salt of this acid, which is sold under the name urosin. Urosin has been found useful in both typical and atypical gout, also in the chronic gout of lead-poisoning. In the typical gout it has been useful for the purpose of shortening the attacks and of preventing them. It may be administered in the form of tablets in dose of 3 to 5 drams (45 to 75 grains) per day; an effervescent preparation of the salt is also obtainable. [H.C.W.]

**The Climatotherapy of Functional Neuroses.**—Heilighenthal<sup>2</sup> says that while there is no doubt that a mere change is often beneficial in neurasthenia and similar functional disorders, it is necessary in advising the change to consider where the patient is likely to improve most rapidly. The first point in determining this is the patient's personal likes; to some the sea is restful, to others it is wearying. Neither mountains nor seashore exercise any specific influence. If a mountain resort is decided on it must not be too high, on account of the severe disturbances, especially sleeplessness, occurring during the acclimatization; the limit may be put at about 1,000 meters (3,000 feet). Moderate altitudes, Heilighenthal believes, conduce to sleep. To the uses of baths, as at health resorts, Heilighenthal does not ascribe a great deal of importance. Indifferent warm baths are sometimes useful as sedatives, while CO<sub>2</sub> baths and brine baths are stimulating, the brine being preferable. In those who are strong-enough to stand it ocean baths exercise frequently a valuable tonic action. This effect depends on a combination of the low temperature, the salt contents, and the mechanic influence of the waves. [H.C.W.]

**The Effect of Mud-baths on the Blood-pressure.**—Loebel<sup>3</sup> has made some studies with Gärtner's tonometer on the changes in blood-pressure brought about by mud-baths. He finds that there is during the bath an almost uniform tendency to fall of pressure, but this fall is only moderate in baths below 42° C. In baths 38° C. to 39° C. there was as an after effect a cumulative fall. Temperatures below were without any constant secondary action, while after higher temperatures there was usually a rise. The pulse-rate was lessened by 20-minute baths if the temperature was below 39°; higher temperatures were irregular in their action on pulse-rate. [H.C.W.]

**Icthalbin as an Intestinal Antiseptic.**—Marcuse<sup>4</sup> recommends the use of ictthalbin as an intestinal antiseptic not only in enteritis, but also in scrofula and tuberculosis. The compound, unacted upon by the gastric juices, is broken up in the intestines, liberating icthyol. It has been shown by Rolly and Saam to lessen the destruction of nitrogen. Under the use of ictthalbin there is an increase in appetite, with a gain in weight. Marcuse has employed it as a substitute for cod-liver oil. Dose for adult, 0.5 gm. to 1 gm. (8 to 15 grains) three times a day. [H.C.W.]

**FORMULAS, ORIGINAL AND SELECTED.**

Little<sup>5</sup> recommends the following as a pleasant mode of prescribing Epsom salts, especially for children:

Magnesium sulfate . . . . . 15 grams (4 drams)  
Syrup of raspberry . . . . . 62 cc. (2 ounces)  
One tablespoonful. [H.C.W.]

**Palatable Castor-oil.**—The taste of castor-oil often seriously interferes with its use. Among the many substances

<sup>1</sup> Journal Akusherstwa, etc., May, 1902.  
<sup>2</sup> American Gynecology, April, 1903.  
<sup>3</sup> Treatment, February, 1903, Vol. 6, p. 881.

<sup>1</sup> Klin. therapeutische Wochenschrift, 1903, Vol. 10, p. 247.  
<sup>2</sup> Balneol. Centralzeitung, April 6, 1903.  
<sup>3</sup> Klin. ther. Wochenschr., 1903, x, 346.  
<sup>4</sup> Merck's Arch., 1903, v, 119.  
<sup>5</sup> Brooklyn Med. Journ., xvii, No. 1.

recommended to conceal the unpleasant taste glycerin deserves the first rank. Either of the following will be found efficient:

- Castor-oil . . . . . 30 cc. (1 ounce)
- Glycerin . . . . . 30 cc. (1 ounce)
- Oil of wintergreen (or cloves) . . . . . 0.6 cc. (10 minims)
- Mucilage of acacia, a sufficient quantity.
- Water sufficient to make . . . . . 125 cc. (4 ounces)

Make an emulsion.

Each tablespoonful represents a teaspoonful of the oil, or, for those who can swallow it:

- Castor-oil } of each . . . . . 8 cc. (2 drams)
- Glycerin }
- Oil of peppermint . . . . . 0.2 cc. (4 minims)

Mix, place in an ice-cold spoon until it solidifies, and swallow at once. [H.C.W.]

## THE PUBLIC SERVICE

**Health Reports.**—The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended May 29, 1903:

### SMALLPOX—UNITED STATES.

**Changes in the Medical Corps of the U. S. Army for the week ended May 30, 1903:**

- SHAFFER, JOS. J., contract surgeon, leave granted April 10 is extended one month.
- GORGAS, Colonel WILLIAM C., assistant surgeon-general, now on leave in New York City, will report on June 1 to the commanding general, department of the East, for temporary duty as chief surgeon of that department during the absence on leave of Colonel Henry Lippincott, assistant surgeon-general.
- JONES, GEO. H., contract surgeon, now on leave at Toledo, Ohio, is relieved from further duty in the division of the Philippines and will proceed to Fort Fremont for duty, to relieve Contract Surgeon J. Randolph Harner, who will proceed to Fort Totten for duty.
- GREGORY, WM. G., contract surgeon, is granted leave for one month, upon surgeon's certificate, with permission to leave the limits of the department of California and to apply for an extension of one month.
- MCCULLOCH, Captain CHAMPE C., JR., and GODFREY, Captain GUY C. M., assistant surgeons, are relieved from further duty in the division of the Philippines and will proceed to San Francisco, Cal., and report by telegraph to the adjutant-general of the Army for further orders.
- FARR, First Lieutenant CHAS. W., assistant surgeon, leave granted January 28 is extended two months, and is charged to sick leave for two months from April 26.
- ASHBURN, JAMES K., contract surgeon, leave granted is extended ten days.
- FANNING, GEO. F., contract surgeon, leave granted April 22 is extended one month.
- HOWELL, First Lieutenant PARK, assistant surgeon, leave granted May 12 is extended fourteen days.

**Changes in the Public Health and Marine-Hospital Service for the week ended May 28, 1903:**

- WHITE, J. H., assistant surgeon-general, relieved from duty in Washington, D. C., to take effect June 6, 1903, and directed to proceed to Mobile, Alabama, and assume command of the service, relieving Surgeon W. P. McIntosh—May 28, 1903.
- GEDDINGS, H. D., assistant surgeon-general, detailed to represent the service at South Carolina Sanitary Association at Columbia, S. C., May 28—May 26, 1903.
- GLENNAN, A. H., surgeon, relieved from command of the Plague Laboratory, San Francisco, Cal., and directed to proceed to Washington, D. C., for duty—May 26, 1903.
- BROOKS, S. D., surgeon, upon being relieved at Portland, Me., by surgeon W. P. McIntosh, to proceed to Savannah, Ga., and assume command of the service, relieving Acting Assistant Surgeon E. S. Osborne—May 28, 1903.
- MCINTOSH, W. P., surgeon, upon being relieved at Mobile, Ala., by Surgeon J. H. White, to proceed to Portland, Me., and assume command of the service, relieving Surgeon S. D. Brooks—May 28, 1903.
- GUITERAS, G. M., surgeon, relieved from duty at Philadelphia, to take effect June 5, 1903, and directed to proceed to Cairo, Ill., and assume command of the service, relieving Passed Assistant Surgeon J. H. Oakley—May 28, 1903.
- PERRY, J. C., passed assistant surgeon, detailed for temporary duty at Washington, D. C.—May 25, 1903.
- NYDEGGER, J. A., passed assistant surgeon, relieved from duty at Baltimore, Md., and directed to proceed to Cincinnati, Ohio, and assume command of the service, relieving Assistant Surgeon J. W. Kerr—May 28, 1903.
- GARDNER, C. H., passed assistant surgeon, upon being relieved at Port Townsend, Wash., by Passed Assistant Surgeon M. H. Foster, to proceed to New York, N. Y., and report to Surgeon G. W. Stoner, immigration depot, for duty—May 28, 1903.
- BLUE, R., passed assistant surgeon, to assume command of the plague laboratory, San Francisco, Cal., relieving Surgeon A. H. Glennan—May 26, 1903.
- OAKLEY, J. H., passed assistant surgeon, upon being relieved at Cairo, Ill., by Surgeon G. M. Guiteras, to proceed to Port Townsend quarantine, Wash., and assume command of the service, relieving Passed Assistant Surgeon M. H. Foster—May 28, 1903.
- FOSTER, M. H., passed assistant surgeon, upon being relieved by Passed Assistant Surgeon J. H. Oakley, at Port Townsend quarantine, Wash., to proceed to Port Townsend, Wash., and assume command of the service, relieving Passed Assistant Surgeon C. H. Gardner—May 28, 1903.
- LUMSDEN, L. L., passed assistant surgeon, to proceed to San Juan, Porto Rico, and assume temporary command of the service—May 26, 1903.
- DECKER, C. E., assistant surgeon, granted extension of leave of absence, on account of sickness, for thirty days from May 8—May 26, 1903.
- KERR, J. W., assistant surgeon, upon being relieved at Cincinnati, Ohio, by Passed Assistant Surgeon J. A. Nydegger, to proceed to New York, N. Y., and report to Surgeon G. W. Stoner, immigration depot, for duty—May 28, 1903.
- RICHARDSON, T. F., assistant surgeon, granted leave of absence for three days from June 17—May 25, 1903.
- TROTTER, K. E., assistant surgeon, granted leave of absence for ten days from June 15—May 28, 1903.
- DUFFY, F., acting assistant surgeon, granted leave of absence for four days from June 1—May 28, 1903.
- HICKS, W. R., acting assistant surgeon, granted leave of absence for five days from June 2—May 28, 1903.
- RODMAN, J. C., acting assistant surgeon, granted leave of absence for four days from June 1—May 27, 1903.
- TOWNSEND, F., acting assistant surgeon, granted leave of absence for one week—May 24, 1903.

PUBLISHED WEEKLY AT 1321 WALNUT STREET PHILADELPHIA BY THE AMERICAN-MEDICINE PUBLISHING COMPANY

VOL. V, No. 24.

JUNE 13, 1903.

\$5.00 YEARLY.

The prejudice against night-air ventilation turns out to be in part at least the result of the experience of the peoples of malarial countries. The word malaria itself suggests the reason for the prejudice. Unless the bad air were shut out the bad mosquito was not shut out. Those who shut both out escape one of the world's greatest scourges, and even in the present year the Baedeker guidebooks of Italy contain the advice, "windows should be closed at night." Somebody should send the guidebook publishing company some mosquito netting. It is claimed that the descendants of the window-closers so well learned their lesson that those who did not obey the beatitude, "blessed are they who do not ventilate their sleeping-rooms," have been cut off from perpetuating the race by the pitiless laws of Darwinism. In this way the race escaped malaria, but found a worse evil in tuberculosis and pneumonia. Now that it is known that it is not malaria, but malmosquito that brings the evil, the crusade against malventilation and the prejudice against night-air may be undertaken with greater certainty of success, and the ravages of tuberculosis may be checked.

**The Antimalarial Prejudice Not the Chief Cause of Bad Ventilation.**—The theory that the necessity of excluding from houses the injurious night air is the cause the world over of the practice of poor ventilation will not hold. It is at least not the sole nor the chief reason of the prejudice against fresh air. Manifestly it does not obtain for countries in which there is no mosquito, and these form a relatively small part of the world inhabited by civilized peoples. In cold climates, and especially in the winter season, the theory has no applicability, and another explanation must be found. This is, we believe, the necessity that exists, especially among the vast majority of the poor, to economize warmth. A large portion of the peasants of France today secure this economy by keeping their domestic animals at night in the combined house and stable. In Arctic climates and in winter even in temperate zones, and especially in previous centuries, the securing of sufficient clothing and saving the loss of warmth has doubtless been a chief cause of the universal fear of ventilation. In this way today in some countries medical college lecture-rooms get on without the expense of fuel

by utilizing the foul but warm exhalations of the bodies of hundreds of students, who in anger cry out against a door ajar or a crack in a window. The greatest and best remedial agent in tuberculosis and many other devitalizing diseases is fresh air, by night or by day, ever fresh air! Now that the mosquito is "barred," and that civilization can provide the poorest with good houses and fuel, there should be a speedy lessening of the deathrate by perfect ventilation.

**Compulsory vaccination is declared constitutional by the Supreme Court of Massachusetts,** says our valued contemporary, the *St. Paul Medical Journal*, and all persons over 21 may be convicted for refusing. "If a person should deem it important," says the Court, "that vaccination should not be performed in his case, and the authorities should think otherwise, it is not in their power to vaccinate him by force, and the worst that could happen to him under the statute would be the payment of the penalty of five dollars. The defendants' contention that the statute works unequally in making an exception of minors and persons under guardianship is not well founded. It only limits the liability to a penalty for neglect of the requirement to persons who have a right to control their own conduct." The best part of the decision lies in the opinion expressed by the Court that the only competent evidence in the matter is the testimony of experts. This is a square placing of the bar against the ignoramuses and ranters who have not any knowledge of medicine or of the subject whereon to base an opinion. It would seem axiomatic that men who had never studied law, or electric engineering should decide as to legal matters or dynamos. It is an amazing fact that legislators and governors often think the judgment of medical experts to be scorned in public health concerns, and those who have never studied medicine are to be their official guides. Medical societies, local, state and national, should set about their common duty to secure the passage of laws making vaccination compulsory. All physicians and all intelligent laymen have no doubt of the wisdom and beneficence of such laws. The majority rules, or should rule, in our form of government, and the small minority of silly cranks should no longer be allowed to kill thousands of their fellow-citizens each year.

**One Governor's Splendid Veto.**—What a disgrace to Minnesota it is that her Legislature has given to those who choose to call themselves osteopaths all the rights and privileges of practitioners of medicine. The high-minded *St. Paul Medical Journal* says of this vicious legislation that the result of the bill is that the osteos may now treat all diseases and sue for their bills, but that *they cannot be sued for malpractice*. Their creature who lobbied the bill through seems to have been Senator Heiler H. Horton, and the first official act of the osteopathic board was to elect this man as their attorney. The bitterness of the respectable citizens of Minnesota is doubled by the synchronous action of the Governor of Utah, who in an intellectual and honorable veto stamped the nonsense of an osteopathic bill as follows:

The saving of human life, whether by means of looking to the prevention of disease or by means calculated to cure disease already established, will be admitted without question to be the proper climax of professional ambition as well as the highest humanitarian desire of legislative enactment. In both these directions the State of Utah, by vigorous sanitary laws and by strict requirements as to the quality of medical practitioners, stands well in the forefront of enlightened and progressive commonwealths.

Only through conviction should we venture to weaken in any degree these safeguards which experience and observation have proved to be beneficent and satisfactory.

Whatever the term or nature of the tenets of the particular school which this bill aims to recognize, its practice must, it seems to me, be considered a branch of the science of medicine. After all, the physician, of whatever school or designation, has to deal with the same physiology, the same conditions, the same laws of cause and effect in health and disease. All practitioners may not have the same knowledge and the same skill, yet our statutes have wisely provided as a matter of public policy and protection that a certain amount of skilled knowledge all of them must have.

It requires considerable honesty in any practitioner to admit that a case in hand is beyond his powers. His training may be limited, his pretensions modest; but the consequences of his weakness in refusing to concede it are equally dangerous. The natural treatment of any physical disorder is necessarily determined by a diagnosis of a case—a preliminary of first and absolute importance. To do the wrong thing by performing dangerous manipulations, or to do nothing at all—either of which courses is easily open to the unskilled—may be equally fatal. The peril is not lessened if the physician, perhaps by happy accident or coincidence, has discovered the true condition. He may be manly enough to confess inability to suggest proper remedies, or reckless enough to attempt treatment of his own altogether without reason or applicability, or indifferent enough, as already suggested, to do nothing at all. In either case the patient suffers the risk. Is not human life too precious to be thus trifled with?

The foregoing suggests that the treatment of disease should not be permitted to be a matter of mere experiment; and inasmuch as the authority to practise presupposed an acquaintance with the science as recognized by all the regular schools, any knowledge short of that should be deemed insufficient. I consider it unfair and dangerous, therefore, to allow the adherents of osteopathy or of any other school to practise without undergoing the ordinary tests to which other practitioners have to submit. The specialist may go so far as his talents and inclination may carry him, and the public be benefited by his advancement, but the fundamental and essential knowledge which every physician ought to have can not safely be waived or ignored. Science is progressive; advancement can not be stayed, in the art of healing least of all; and the dogmatism of disputants, whether in medicine or anything else, must soon yield to the light of truth and reason. Whatever merit osteopathy may have will assuredly find recognition. The present

contention is that in the bill before me the necessary requirements and safeguards with which the law surrounds the physically afflicted are thrown down and swept away. To this I am unwilling to consent. No practitioner of this school who possesses the qualifications required of the practitioners of other schools needs such a law. I deem it unwise to enact it for the benefit of those who have not those qualifications. Whenever all who seek to engage in the healing art shall be equally recognized as competent under the regulations now generally established, one medical law will be sufficient. This condition complied with it would give me sincere pleasure to name as a member of our State Board of Medical Examiners an adherent of the very school in whose behalf this piece of legislation is proposed.

HEBER M. WELLS, Governor.

**The cost of forest fires in an average year is as follows:**

Real property destroyed . . . . .	\$25,000,000
Young forest growth destroyed . . . . .	\$75,000,000
Acres of timber land burned . . . . .	10,274,089
Lives lost . . . . .	60

A competent authority states that whenever earth has been denuded of its forests, except in very humid regions, desolation has come. The greater the summer heat the more complete the desolation. This is true of the fairest portions of Asia, the birthplaces of letters, law, art, religion, civilization. Persia, Asia Minor, northern Africa, and the Mediterranean States of Europe lost their primacy, in so far as natural causes are concerned, mainly through the destruction of their forests, whereby the soil was rendered unable to support the needs of a progressive people. The number of lives lost can be roughly estimated, but the sickness and suffering are utterly incalculable. Perhaps no other physical cause produces such an indirect, but no less real, crop of want and deprivation, and so reduces the general stock of vital energy. Every State should have more stringent fire laws, and should see that they are administered with more thoroughness. The terrible expense may be prevented when the duty is recognized. The future health and prosperity of the continent largely depend upon scientific forestry.

**Three hundred and fifteen new cases of typhoid in Philadelphia last week** is a record which could be paralleled in many American cities, and with it should be considered the fact set forth in the following excerpt from an indignant newspaper editor:

Councils appropriate \$25,000 for the abatement of nuisances. After deducting salaries, the sum actually available is less than \$19,000. That is a beggarly amount with which to prevent the spread of disease. Year after year Councils are informed of the situation; that the money does not begin to meet requirements, and that in the summer months work must practically come to a standstill, but year after year the same policy is maintained. When the appropriations were made up at the beginning of the present year, the Department of Public Safety did its best to obtain \$50,000, but Councils in their wisdom refused the demand in spite of its importance, and as usual the health authorities will labor under great disadvantage this summer.

And the alert and public-spirited *City and State* adds:

There has been a woful lot of politics, wasteful of public money and health, in the operation and conduct of the sanitary affairs in Philadelphia of late years. As a single, significant example he might look into the subject of disinfectants used by the Health Bureau. Formerly a plant established in the basement of the city hall turned out what competent authorities

declared to be a thoroughly effective disinfectant at a cost of a few cents per gallon. During the last three or four years there was substituted for public use an article to which the name of "La Relse" was given by reversing the maker's name, and which has been bought in large quantities at prices incredibly extravagant as compared with the city's product—bought not directly from the producer, but of a man who seems to have had a most extraordinary "pull" with the late administration.

The nuisances that Dr. Martin would be apt to encounter in a search of this kind will be found to center in the political germ that has been so prolific at the city hall and which in a large part remains as yet unabated.

**The Red Cross** may have a useful function to perform in the future, but unless it is completely reorganized it will hardly have the virtue, the means, or the permission of the American people to do it. Dr. Anita Newcomb McGee, of Washington, has published a brief history and statement of the general condition of the society, from which we learn that the American Society is erroneously confused with the Geneva or Red Cross Treaty, which last is a mere treaty between governments without reference to any "Society." The International Red Cross Committee again is "a small body which exercises a slight supervision over and calls conferences of the officially recognized war relief societies of the countries which adhere to the Geneva treaty." Several incorporations have preceded the present organization to which a national charter was granted by Congress, 56 persons being named as members of the American National Red Cross. Up to this time the president, Miss Barton, had apparently accounted only to herself for moneys received and paid out. Dissatisfaction with the financial conduct of the present organization became public in December, 1902. By means of proxies the "slight changes" to be made in the by-laws became an entirely new set of by-laws, the result of which was to place in the hands of the president, now elected "for life," the policy of the organization and the administration of its finances. Protests arose, and appeals to the President of the United States and his cabinet (the "board of consultation"). The President at once disavowed authority for the use of the names of himself and cabinet and disclaimed responsibility for any of the proceedings of the organization. Some gentlemen wished to retire the Red Cross president on an annuity of \$2,500, but she did not accept the proposition. On April 6 the Executive Committee of the Red Cross suspended from membership all of the 22 persons who had signed the memorial to Congress. "So the matter now stands."

#### Gastrotomy for "Vague Gastric Symptoms."

—In an editorial note entitled "Surgery Gone Clean Daft" (p. 807, May 23), we took exception to the astounding dictum given editorially by the *Medical News* that the general practitioner should advise patients having "vague gastric symptoms which do not respond to rational internal treatment" to "submit to a harmless exploratory investigation." We are informed that Dr. Mayo disclaims having made the statements attributed to him by the *News*, and from which that journal drew its most amazing "corollary." Whether the alleged quotation from Dr. Mayo was correct is, however, extraneous to the principle involved. Our comment is

in no way a reflection upon that eminent surgeon or upon legitimate surgical intervention, but is directed entirely against the pseudoscience of surgical extremism. We would ask the *Medical News* how long it may be until exploration of the brain will be considered proper in "vague" headaches, and would also with due humility offer as a corollary to its corollary that after such "exploratory investigations" as it advocates the incision be closed with buttons and buttonholes instead of catgut, in order to facilitate further inspection should other "vague symptoms" arise!

**The Christian Hospital** scheme, to which we made allusion some weeks since, has attracted the attention of the medicolegal committee of the Chicago Medical Society, which is gathering evidence wherewith to bring the swindle to an end. Our mail of late has been loaded with the literature of this continuation of the extinct St. Luke's Hospital fraud carried on by the same men. The indignant letters we have received have been too numerous to answer. The last batch of circulars received contained a noteworthy enclosure squinting toward a descent into the exploitation of erotic curiosity. Drs. Granville and Probert appear to be old offenders, one having served a term in the Wisconsin Penitentiary, and the other was arrested in 1899 for bigamy, specifying five wives. The rage for "certificates" on the part of some medical men is a fact as unaccountable as the ease with which they are gulled. The medicolegal committee have letters from at least six physicians who have bought certificates because of the unwarranted use of Dr. J. B. Murphy's name by the Christian Hospital literature, and Dr. Murphy has postponed his determination to ask for an injunction in order to help the committee to secure evidence for a more thoroughgoing exposure and prosecution. The cooperation of the profession is desired by the committee.

#### Science-quackery and Fashionable Materialism.

—Last year *American Medicine* commented upon the pseudoscience of a certain plebifier of Professor Loeb. So avid are the popular magazines for this sort of nonsensical unscience that even the best of them have accepted his articles as if they had any value or warrant. At last the editor of the *Popular Science Monthly* has felt compelled to stop the folly and in answer to a correspondent he says:

Mr. Snyder appears not to have had a scientific training; his articles are sensational and inaccurate. This somewhat sweeping condemnation is easily justified. Let us consider the last article by Mr. Snyder that has come to our attention, "The Mechanism of the Brain," in *Harper's Monthly* for May. It is a potpourri of truth, half-truth and falsehood concerning chemistry, physics, anatomy, physiology and psychology. Thus we are told:

"Or, supposing that this special colloid can not be fixed upon as the seat of the highest powers of man, they might be thrown upon that extraordinary and rather hypothetical ether, of which physicists talk so much and know so little."

Within half a column Mr. Snyder passes easily from ether to electricity:

"As there is no nerve action without the evident presence of electricity, it seems probable that nerve action, thought and consciousness, and what in our present ignorance we call electricity, are one and the same."

Physicists may not know all that they would like to know about the ether and electricity, but they know enough not to write nonsense about them.

**Teaching the Filipinos the Vices of Civilization.**

—Is the *New Voice* correct in saying that there were 1,990 liquor shops licensed in Manila in the year 1902? It repeats that according to the report of the Philippine Commission there were 19,398 arrests made in the city during the year, classified as follows:

Natives . . . . .	13,386
Chinese . . . . .	2,355
Americans . . . . .	2,014
Europeans . . . . .	149
Japanese . . . . .	71
Spaniards . . . . .	67

The report gives the population of Manila on February 1, 1902, at 302,154, showing the tribes to be divided as follows:

Filipinos . . . . .	223,900
Chinese . . . . .	60,680
Americans (including garrison) . . . . .	9,722
Foreigners . . . . .	7,852

Reducing the arrests by nationalities, according to the population officially reported by the commission, we are confronted with the astounding fact that out of every 1,000 Americans in Manila 212 were arrested during the year. In other words, a little over one-fourth of the American population in the islands were law-breakers. The official figures of all nationalities per thousand are as follow:

Nationality.	Arrests.
Americans . . . . .	212
Natives . . . . .	60
Chinese . . . . .	38
Foreigners . . . . .	36

Is it true that we are three and one-half times as criminal as the Filipino himself? What an example to set!

**Smallpox Among Infants.**—From the Bulletin of the Chicago Health Department we quote the following: Chief Medical Inspector Herman Spalding says: "To the shame and reproach of parents the helpless unvaccinated baby continues to fall a victim to smallpox. Three of the seven cases this week were children under 3 years of age. Since January 1, 1903, 52 children under school age have fallen victims to smallpox because the parents had neglected to have the little ones vaccinated. The Department Bulletin has persistently pointed out this neglect of children under the school age."

**Antityphoid Serum.**—Dr. Chantemesse, of France, has prepared a series of comparative statistics, which he claims show the favorable action of antityphoid serum. His figures show that in the Paris hospitals the mortality from typhoid fever over a period of 20 months was 19%. In the same period the mortality at the Chantemesse Hospital was only 3.7%. Dr. Chantemesse's inoculatory methods have also been tried at the Naval Hospital at Toulon. Of 171 typhoid cases in which the Chantemesse serum was used 13 succumbed. This result is less favorable than that obtained under the personal supervision of Dr. Chantemesse—though it is better than that achieved by the ordinary methods of the Paris hospitals—but the smaller degree of success is explained as being due to less intimate knowledge of the proper doses to give in individual cases.

The sixth annual meeting of the Association of Medical Librarians was held Saturday, May 16, 1903, at Brooklyn, N. Y. The scientific sessions was held in the afternoon at the New York Academy of Medicine. Papers and discussions were contributed by C. P. Fisher, T. C. Lee, G. W. Myers, E. H. Brigham, J. S. Brownne, W. S. Dennet, A. T. Huntington, et al. The officers elected for the ensuing year are: President, William Osler; vice-president, Abraham Jacobi; secretary, Albert T. Huntington; treasurer, George D. Hersey. Executive Committee: John S. Brownne, Charles P. Fisher, James M. Winfield. Manager of Exchange: Marcia C. Noyes. The meeting adjourned to meet June, 1904, at Atlantic City. A full report of the proceedings of the Association will be published in the *Medical Library and Historical Journal* for July, 1903.

**BOOK REVIEWS**

**A System of Physiologic Therapeutics: A Practical Exposition of the Methods Other than Drug-giving Useful in the Prevention of Disease and in the Treatment of the Sick.**—Edited by SOLOMON SOLIS COHEN, A.M., M.D. Vol. V. Prophylaxis, Personal Hygiene, Civic Hygiene, and the Care of the Sick. By JOSEPH MCFARLAND, M.D.; HENRY LEFFMAN, M.D.; ALBERT ABRAMS, A.M., M.D., and W. WAYNE BABCOCK, M.D. Illustrated. Philadelphia: P. Blakiston's Son & Co., 1903. Eleven volumes.

This, Volume V of a System of Physiologic Therapeutics, which the editor assures us in the preface has been a source of special pleasure to him, is in many respects the most important of the series—comprising as it does prophylaxis, personal hygiene, civic hygiene, and the care of the sick. Although the chief aim of the physician is the cure of disease, he has still a higher aspiration—the prevention of disease. This, together with the conviction on the part of the editor that the subjects of prophylaxis and of treatment should not be divorced in teaching, study, or thought, has induced him to include in a system of therapeutics a book on the preservation of health and the prevention of disease. The wisdom of this course must be apparent to all that read the book. In Part I, which deals with the origin and prevention of disease, Drs. McFarland and Babcock discuss in an attractive and lucid manner the intrinsic and extrinsic factors of disease, the methods whereby diseases are spread, and the natural and artificial means of defense against disease. In the discussion of the etiology of disease, bacteria are naturally accorded especial attention, although rightly precedence in the discussion is given to the not less important but frequently overlooked intrinsic factors of disease, such as age, sex, heredity, auto-intoxication, etc. In these days of the omnipresent (and one may well believe almost omnipotent) bacterium, it is a treat to read such an altogether admirable presentation of the importance of nonbacterial causes in the etiology of disease, and this too, from the pen of a distinguished bacteriologist. In the discussion of the diffusion of disease, we read of the diffusion of disease through air, water, and soil; of the methods of transmission of disease by animals, of the conveyance of disease by foods, of social intercourse as a factor in the transmission of disease, of the modes of parasitic invasion, and of the action and the elimination of bacteria. In the discussion of the prevention of disease there is a satisfactory account of natural and acquired immunity, of artificial defenses, asepsis, antiseptics, and disinfection, of the prevention of the transmission of disease by animals, and of the prophylaxis of special infections of the different systems of the body. In Part II, Dr. Leffman discusses the important subject of civic hygiene, writing in an entertaining and authoritative manner on the city—its site and plan, street cleaning, nuisances, offensive trades, etc.; municipal health organization—comprising hospitals, quarantine, notification of infectious diseases, control of venereal diseases, etc.; of the food-supply and the water-supply, and of the disposal of waste and of the dead. Unfortunately, of many physicians it may be said that their knowledge of civic hygiene is in inverse ratio to the importance of the subject; but whether well informed or not, all of us will be much benefited by a careful reading of Dr. Leffman's contribution to the subject. In Part II, Dr. Abrams writes of domestic and personal hygiene, and of nursing and care of the sick. His discussion of these subjects constitutes a fitting close to a book that is a real addition to medical literature, comprising as it does a discussion of the hygiene of dwellings, of the school, and of travel; of personal hygiene, and of hygiene of special periods (infancy, childhood, puberty, old age, etc.), and of the diatheses (tuberculosis, rachitis, gout, etc.); a discussion of the sick-room and its appurtenances, of the care of the patient, and of nursing in special diseased conditions. We fear that many young women would be appalled at the mere mention of the 38 qualities demanded of a nurse by Dr. Abrams, but the matter of his entire contribution is of excellent quality, and well repays the reading. In reviewing previously issued volumes of the System of Physiologic Therapeutics we have taken occasion to commend both the editor and the publishers for the scope and the plan of the

work, and as each volume has appeared we have become convinced that the scheme was masterly conceived and skilfully executed. That every physician should possess a set of the books need not be reiterated.

**Transactions of the Luzerne County Medical Society.**—It is a gratifying sign of the times to see a county medical society in an interior section of the State, far removed from the teaching centers, issuing a formal report of its transactions. The volume before us consists of 162 pages and contains a large number of valuable articles. The ambition and energy of the Luzerne County Medical Society may well serve as an example to medical societies in other counties of this and other States.

#### BOOKS RECEIVED.

[Prompt acknowledgment of books received will be made in this column, and from time to time critical reviews will be made of those of interest to our readers.]

**Gynecological Diagnosis: The Diagnosis of Diseases of Women A Treatise for Students and Practitioners.**—By PALMER FINDLEY, M.D., Instructor in Obstetrics and Gynecology in Rush Medical College, in affiliation with the University of Chicago. In one octavo volume of 494 pages, richly illustrated with 210 engravings and 45 full-page plates in colors and monochrome. Cloth, \$4.50 net; leather, \$5.50 net. Lea Brothers & Co., publishers, Philadelphia and New York.

**Diseases of the Eye: For Students and General Practitioners.**—By CLARENCE A. VEASEY, A.M., M.D., Demonstrator of Ophthalmology in Jefferson Medical College, Philadelphia. 12mo. 410 pages, with 194 engravings and 10 full-page colored plates. Cloth, \$2.00 net. Lea Brothers & Co., publishers, Philadelphia and New York.

**Bacteriology: A Manual of Bacteriology for Students and Physicians.**—By FRED. C. ZAPFFE, M.D., Professor of Histology in the College of Physicians and Surgeons, and Professor of Pathology, Bacteriology and Hygiene in the Illinois Medical College, Chicago. In one 12mo volume of 350 pages, with 150 engravings and 7 full-page colored plates. Cloth, \$1.50 net; flexible leather, \$2.00 net. Lea's Series of Pocket Textbooks, edited by BERN B. GALLAUDET, M.D.

**How to Keep Well: An Explanation of Modern Methods of Preventing Disease.** By FLOYD M. CRANDALL, M.D. Doubleday, Page & Co., New York, 1903.

**Medical and Surgical Uses of Electricity: Including the X-ray, Flourescent Light, Vibratory Therapeutics and High Frequency Currents.**—By A. D. ROCKWELL, A.M., M.D., formerly Professor of Electrotherapeutics in the New York Postgraduate Medical School and Hospital, etc. With 252 illustrations. New edition. E. B. Treat & Co., New York, 1903. Price, \$5.00.

**International Clinics: Vol. I, Thirteenth Series.** A Quarterly of Illustrated Clinical Lectures and especially prepared original articles on Treatment, Medicine, Surgery, Neurology, Pediatrics, Obstetrics, Gynecology, Orthopedics, Pathology, Dermatology, Ophthalmology, Otolaryngology, Rhinology, Laryngology, Hygiene, and other topics of interest to students and practitioners.—By leading members of the medical profession throughout the world. Edited by A. O. J. KELLY, M.D., of Philadelphia. J. B. Lippincott Company, Philadelphia, 1903.

**Postmortem Pathology: A Manual of Postmortem Examinations and the Interpretations to be drawn therefrom. A Practical Treatise for Students and Practitioners.**—By HENRY W. CATTELL, A.M., M.D., Pathologist to the Philadelphia Hospital and the West Philadelphia Hospital for Women, and sometime Director of the Josephine M. Ayer Clinical Laboratory of the Pennsylvania Hospital, etc. With 162 illustrations. J. B. Lippincott Company, Philadelphia and London, 1903.

**The Röntgen Rays in Medicine and Surgery: Designed for the use of Practitioners and Students.**—By FRANCIS H. WILLIAMS, M.D. (Harv.), Graduate of the Massachusetts Institute of Technology, Visiting Physician at the Boston City Hospital, etc. With 428 illustrations. Third edition, with enlarged appendix. The Macmillan Company, New York, 1903. Price, \$6.00.

**Ambulance Work and Nursing: A Handbook on First Aid to the Injured, with a section on nursing, etc.** Profusely illustrated. W. T. Keener & Co., Chicago. Price, cloth, net, \$3.50.

**State Board of Health of New Jersey: Twenty-sixth report, 1902.** J. L. Murphy Publishing Company, Trenton, 1903.

**Pathology of the Skin: An Introduction to the Histology, Pathology and Bacteriology of the Skin, with special reference to technic.**—By J. M. H. MACLEOD, M.A., M.D., M.R.C.P., Assistant in the Dermatological Department, Charing Cross Hospital; Physician to the Skin Department, Victoria Hospital for Children. With 8 colored and 32 black and white plates. P. Blakiston's Son & Co., Philadelphia, 1903. Price, \$5.00 net.

**Suter on Refraction: A Manual of Refraction and Motility. For students and practitioners of medicine.**—By WILLIAM NORWOOD SUTER, M.D., Assistant Surgeon to the Episcopal Eye, Ear, and Throat Hospital, Washington, D. C. 12mo, 382 pages, with 101 engravings and 4 colored plates. Cloth, \$2.00 net. Lea Brothers & Co., Philadelphia and New York.

**Surgical Treatment of Gastric and Duodenal Ulcers.**—By B. G. A. MOYNIHAN, M. S. (Lond.), F.R.C.S. (Eng.), Senior Assistant Surgeon Leeds General Infirmary; Consulting Surgeon to the Skipton Hospital and to the Mirfield Memorial Hospital, etc. Illustrated. Price, cloth, \$2.50 net. W. B. Saunders & Co., Philadelphia and New York, 1903.

**System of Physiologic Therapeutics: A Practical Exposition of the Methods Other Than Drug-giving, useful for the prevention of disease and in the treatment of the sick.**—Edited by SOLOMON SOLIS COHEN, A.M., M.D., Senior Assistant Professor of Clinical Medicine in Jefferson Medical College, etc. Vol. X: Pneumotherapy. Inhalation.—By DR. PAUL LOUIS TISSIER, one time interne in the Paris Hospitals, Assistant Consulting Physician to Lennec and Lariboisiere Hospitals, etc. Illustrated. P. Blakiston's Son & Co., Philadelphia, 1903.

**The Utero-ovarian Artery.**—By BYRON ROBINSON, B.S., M.D., Chicago, Ill. E. H. Colegrove, Chicago, Ill., 1903. Price, \$1.00.

## AMERICAN NEWS AND NOTES.

### GENERAL.

**Smallpox in the United States** as officially reported from December 27 to June 5 amounts to 22,522 cases, with 593 deaths, as against 35,480 cases with 1,132 deaths during the corresponding period in the previous year.

**Miscellaneous.**—NEW YORK CITY: Dr. James R. McLane has resigned as dean of the College of Physicians and Surgeons of Columbia University. Dr. Clarence A. McWilliams and Dr. Forbes Hawkes have been appointed instructors in surgery at this institution. BALTIMORE, Md.: Dr. Norman M. Harris, associate professor of bacteriology at the Johns Hopkins Medical School, has accepted a call to the University of Chicago.

**Sale of Opium in Manila.**—From an exchange we quote the following: Mail advices from Manila announce that the bill now pending and which comes before the commission in June for passage, providing for the regulation of traffic in opium provides among other things that no opium shall be sold to a Filipino, and that it shall be sold to a Chinaman who has attained his majority only. Protection is afforded to druggists who handle opium for medicinal purposes, and machinery is provided the police for keeping track of its importation. The revenue derived under the operations of the act is to be used to defray the expenses of educating young Filipinos in American schools, that they may become school teachers.

**How We Go to Sleep.**—From an exchange we take the following: This subject has been investigated during several years past, in an experimental study of the psychophysiology of sleep and dreams by Messrs. Vachide and Vurpas. According to a report in the *Revue Scientifique* they have established the following facts: "Sleep begins, in its first phase, by a state of distraction which brings on states of absent-mindedness accompanied always by numerous and separate hallucinations, closely connected with the length of the absent-minded states. Immediately afterward, in a second phase, these states of distraction pass into a very delicate motor disturbance, due to the absence of parallelism in the axes of the eyes or by the deviation of their conjugate movements. Finally, in a third and final phase, which indicates the very near approach of actual sleep, the vasomotor system seems to conform to laws very different from those that regulate its mechanism during waking hours."

**Opium Traffic in the Philippines.**—It appears that the Philippine Commission propose putting up for competitive bid monopoly of the opium business and privileges to the highest bidder. This was done under Spanish rule, and the revenue from opium farming in the Philippines amounted to \$650,000 a year, which appears to have been applied to general expense account. The Commission purpose applying the revenue derived from the monopoly to sending young Filipinos to this country to be educated, to building additional schoolhouses in the islands, and to increasing the pay of the local teachers. The opium farmer will be required to furnish a heavy bond. Every ounce of opium which comes in will be recorded, and every ounce he sells must be recorded also, with the date, name, and address of purchaser, etc. The idea is thus to keep a tally on all the opium in sight and where it goes. The sale, except to full-blooded Chinese, will be prohibited. The Commission thinks that this system will have the effect of reducing the gross volume of consumption, and will make the official farmer a detective for the government in preventing the smuggling or illicit traffic of others, so that there will be practically only one man to watch.

### EASTERN STATES.

**Deathrate in Boston.**—It is two years and six months since the mortality of Boston was as low as it was during the last week in May. Only 168 deaths occurred during the week as against 202 during the corresponding week last year, according to the report from the Board of Health, and this shows a death-rate of only 14.94. For the summer season that is unusually low.

### NEW YORK.

**Craig Colony.**—Dr. B. Onuf has been appointed resident pathologist at the Craig Colony for Epileptics. It appears that the doctor has had considerable experience in this line of work, and in selecting a pathologist the authorities deemed it wise to utilize the unusual opportunities given at the Colony for studying the causes of epilepsy.

**Tents for Consumptives.**—*Charities* gives a general description of the tents and tent-life for the treatment of tuberculosis in connection with the Metropolitan Hospital, Blackwell's Island. A general description of the tents is given, and of the feeling manifested by the patients toward occupying the tents it says: The patients were rather reluctant at the outset to use the tents for sleeping purposes, believing that they would be draughty and uncomfortable. They were persuaded with some difficulty to try it, and without exception, after a few nights all were so much impressed by the tent-life that it is with

the greatest difficulty that any of them are persuaded to return to the buildings if for any reason this becomes necessary. The first tent was occupied in April, the weather being still quite cold, and although the temperature one morning was near the freezing point, the occupants neither asked for nor desired artificial heat.

**Rochester and Hope Hospital.**—The special committee of the Rochester Academy of Medicine has made a public report of the careful investigation in the management of the epidemics of smallpox in that city and of the management of the Hope Hospital in particular. It appears that there had been adverse criticism from several sources against the health department and Dr. Goler in particular concerning the management of affairs coming within their authority. Among other things the report says: In spite of what some persons considered imperfect quarantine, both epidemics were stamped out quickly; Dr. Goler was thoroughly fitted for the position of health officer by reason of his long experience, extensive study, and personal energy and integrity; nearly all of the horrors of the epidemic were caused by unnecessary and unwarranted interference and blockade of the health department by those who were notoriously ignorant of the subject which they aspired to control; the charter should be amended so that the health officer may become the actual head of the department with the power to conduct its affairs without political interference; the methods adopted by certain members of the committee of public safety of the common council have been a disgrace to the city of Rochester.

#### PHILADELPHIA, PENNSYLVANIA, ETC.

**New Hospital.**—The new Frankford Hospital, which was incorporated March 26, 1903, is now open for inspection and for the reception of patients.

**Doctors for Board of Education.**—Dr. Chas. S. Turnbull and Dr. Thos. J. Buchanan have been appointed by the board of judges members of the Board of Education respectively to succeed Dr. Thos. G. Morton from the Ninth section, and Max Bruemann, resigned, from the Thirteenth section.

**Eastern Hospital for Epilepsy.**—The Governor has appointed Dr. Thos. C. Fitzsimmons, Wilkes Barre; Alexander Knight, Ambler, and Francis Von A. Cabeen, of 1725 Pine street, Philadelphia, members of the commission to select a site and erect the Eastern Pennsylvania State Institution for the Feeble-minded and Epileptic. Four members of the Legislature will act in conjunction with the Governor's appointees as members of the commission.

**University of Pennsylvania.**—A series of clinics will be given on Alumni Day, June 16. Dr. Barton Cooke Hirst will give an obstetric clinic in the new Scott Memorial Amphitheater of the Maternity to members of the class of 1883. All alumni of the medical department will be welcome. The entrance to the amphitheater is on Thirty-sixth street below Spruce. Dr. Clark will give a gynecologic clinic; Professor James Tyson a medical clinic; and Professor J. William White a surgical clinic.

**Tuberculosis.**—Hereafter Director Martin, of the Department of Health and Charities, intends to classify tuberculosis as a contagious disease. He will join forces with Dr. Lawrence Flick, of the Phipps Institute, in combating the disease in Philadelphia. It is stated that another feature of his work will be a surveillance of the milk supply in various portions of the city. Chicago's experience in this particular has caused an awakening of public sentiment throughout the larger cities of the country, and it is hoped that in Philadelphia and elsewhere the experience of the western city will have its fruit in a more thorough inspection of the milk-supply during the hot months of the summer in larger cities of the country.

#### SOUTHERN STATES.

**Report of the Health Department for Baltimore** for the month of May shows that there were 753 deaths as compared with 781 for the same period in 1900, 754 in 1901, and 804 in 1902, comprising 285 white males, 272 white females, 100 colored males and 96 colored females. There were 172 deaths of children under 5 years of age, or 22.84% of the whole number of deaths. A total of 678 births were reported during the month, comprising 259 white males, 260 white females, 79 colored males and 80 colored females.

**Pharmacy Laws to be Discussed.**—The annual convention of the Maryland Pharmaceutical Association will be held at Ocean City from July 14 to 17. Two important matters to come before the convention are the poison law and the State pharmacy law. The poison law is claimed to be unfair. It provides that every seller of poison shall be a registered pharmacist, and druggists shall make a record of all poisons sold, together with the name of the purchaser and the amount of poison sold. It is claimed that in all parts of the State the law is being violated by the sale of Paris green and other deadly poisons necessary to farmers by country stores. The pharmacy law will be taken up by reason of a recent suit by one of the members of the State Pharmacy Board against the other members regarding the interpretation of the law.

#### WESTERN STATES.

**New Hospital.**—At Macomb, Ill., the new St. Francis Hospital has lately been opened. This is the only hospital in the United States conducted by the Sisters of St. Francis, a Catholic order, which has for its object the teaching of nurses, the care of the sick, and of orphans. The order is distinctly American and is patterned after the American International Organization, which has its headquarters in Europe.

**Smallpox in Chicago.**—The Chicago Bulletin of the Health Department for the week ended May 31 says: "During the month 45 cases of smallpox were discovered and removed to the Isolation Hospital. Of these 39 never had been vaccinated; 6 had old, imperfect marks, said to be from vaccination in childhood. Fifteen were unvaccinated children under 6 years of age. There were 7 deaths and 35 cases remain in the hospital at the close of the month, as against 47, May 31, 1902, during which month there were 57 cases removed to the hospital; 45 in May, 1903."

**Warning to Children and Parents.**—The health authorities in Chicago deemed it wise to call attention of children and negligent parents to the danger from scarlet fever, diphtheria, rabies, and other infectious diseases which may be conveyed by dogs and cats. Accordingly the following notice has been posted in all of the schools: "Hydrophobia is increasing throughout the city, and many of the dogs running at large are affected with it. Dogs and cats frequently come from rooms where scarlet fever, diphtheria, and other contagious diseases exist, and can transmit germs to children who fondle them."

**Free Baths in Chicago.**—From *Charities* we quote the following: "Five hundred and fifty-three thousand four hundred and one baths are tabulated for the year 1902 in the last quarterly issue of statistics published by the Chicago Municipal Library and Bureau of Statistics. This number was served by the four public baths and two pumping stations. Statistical cleanliness in Chicago is at low ebb in February—30,064 bathers for the month. The increase which sets in with the warm weather more than doubles this total for August—72,618. In addition, 208,539 persons bathed in 1902 at the three free beaches."

## FOREIGN NEWS AND NOTES

#### GENERAL.

**Plague in India.**—The deaths from the plague in the Punjab from January 1 to May 2 numbered 141,879, according to a statement made by Lord George Hamilton, the Indian Secretary, in the House of Commons.

**Mission to Lepers.**—The society known as the Mission to the Lepers has for its object not only the medical treatment of the leper colonies in the Orient, but likewise seeks to raise the moral standard of these people. The twenty-eighth annual report has recently been made. It shows that the work is being carried on in 54 stations in India, Burma, and Ceylon; in 11 in China, Japan, and Sumatra. Nearly half of these hospitals or asylums are maintained wholly by this mission. The inmates of the society's institutions and of those aided by it number 6,425, including 570 untainted children and 270 leper children.

**Molasses to Cure Cancer.**—Dr. Henzell, the medical officer of the Maikay Hospital at Queensland, Australia, declares that cancer can be cured by the use of molasses, and he has cabled details of the treatment to Europe. He says the molasses must be taken on an empty stomach four times daily, mixed in milk or water. The dose should begin with one dram and be gradually increased to two ounces. The patient must abstain from alcoholic drink. The molasses to be given must be pure sugar-cane and not refined. It is stated that the Middlesex and Brompton Cancer Hospitals in London are to try the new cure at once.

#### OBITUARIES.

**George P. Andrews,** in Honolulu, H. I., May 9, aged 65. He was graduated from the New York College of Physicians and Surgeons in 1862. He was one of the founders of the Detroit Medical College, Detroit Academy of Medicine, and the Michigan State Medical Society. Up to 1881 he was professor of theory and practice of medicine in the Detroit Medical College.

**Thomas McCann,** in Pittsburg, Pa., May 9, aged 40. He was graduated from the Bellevue Hospital Medical College, New York, in 1886. He was surgeon of Pennsylvania and Allegheny Valley Railroads. He was professor of practical surgery Western Pennsylvania Medical College, and consulting surgeon to St. John's Hospital, Allegheny.

**John Perrier,** in Cleveland, Ohio, May 10, aged 60. He was graduated from McGill University, Montreal, in 1868. He was professor of theory and practice of medicine in the Cleveland College of Physicians and Surgeons, and a member of the American Medical Association.

**William C. Eichelberger**, of Terre Haute, Ind., died in Jackson, Tenn., May 18, aged 62. He was graduated from the Rush Medical College, Chicago, in 1870. He was a member of the American Medical Association, and of the Vigo County (Ind.) Medical Society.

**James C. Channell**, in Wrightsville, Pa., May 19, aged 50. He was graduated from the University of Pennsylvania, Philadelphia, in 1871. He was a member of the American Medical Association, and of the York County (Pa.) Medical Society.

**George P. Cassidy**, in Shawneetown, Ill., May 15, aged 43. He was graduated from the Miami Medical College, Cincinnati, Ohio, in 1855. He was a member of the Illinois State Medical Society, and of the American Medical Association.

**W. C. Marden**, of Pittsfield, Me., at Prescott, Ariz., May 1, aged 36. He was graduated from the Medical School of Maine, Bowdoin College, Brunswick, in 1896, and was a member of the American Medical Association.

**Edgar D. Smith**, of Chicago, Ill., June 1, aged 40. He was graduated from the Rush Medical College in 1891. He was at one time surgeon at the Cook County Hospital and later a professor at the Polyclinic.
