NEW YORK, November 21, 1913.

To His Honor

The Mayor of the City of New York:

SIR: On behalf of the Board of Health I have the honor to transmit herewith, as required by Section 1168 of the Charter of the City of New York, a report of all the operations of the Department of Health of the City of New York for the year ending December 31, 1912.

Very respectfully,

ERNST J. LEDERLE, PH. D., Commissioner of Health.

GENERAL ADMINISTRATION

A brief summary of some of the more important features of the work of the Department of Health during the year 1912 is given in this section of the report. The work of the various branches of the service is described more in detail in the following sections which embody the reports of the several bureaus and divisions.

REDUCTION OF DEATH RATE.

It is very gratifying to be able to state that the record death rates of 1910 and 1911 were still further reduced in 1912, in which year a new low record was established for New York City. The deaths recorded during 1912 numbered 73,008, which gives a death rate of 14.11 per one thousand. This is the lowest death rate the city has ever experienced, the next lowest being that of the year 1911, when the rate was 15.13 per one thousand. The difference of 1.02 of a point between the two years compared may be interpreted to mean that had the death rate of 1911 prevailed during the year 1912 there would have been 5,276 more deaths than actually occurred. In analyzing the returns a decreased mortality will be found in the case of all the principal diseases which the Department of Health endeavors to control, namely, typhoid fever, measles, scarlet fever, smallpox, diphtheria, tuberculosis of the lungs and diarrhoeal diseases of children. On the other hand, the mortality from organic heart disease and Bright's disease will be found to be considerably increased, homicides slightly increased, while the deaths from cancer have remained stationary.

REDUCTION OF INFANT MORTALITY.

An excellent idea of the sanitary condition of the city may be obtained by studying the mortality of children under one year of age, percentages being based upon each 1,000 births reported. During 1912, the number of births was 135,625. Using these figures as a basis, the rate was 105 deaths for each 1,000 children born. According to the figures published for England and Wales, which include both suburban and urban areas, the rate in 1911 was 130 per 1,000. In Germany in 1910 the rate was 162, and in Berlin 157. It would seem from this that the mortality statistics of infants in New York City compare more than favorably with those of some European countries.

During the summer months the nurses who are regularly on school duty were each placed in charge of 150 babies and required to visit them at home, teaching the mothers how to keep the babies well. In all, 22,417 babies were under the charge of these district nurses, in addition to those registered as under the care of the milk stations. Among this number there were 207 deaths.

During the year 1911 there had been a distinct decrease in the number of deaths under one year of age in New York City. This decrease was due in large part to the active campaign carried on by certain societies interested in the establishment of milk stations. During 1912 the Department of Health conducted the additional stations itself, two of the largest societies hitherto engaged in this work having discontinued their efforts. The total number of stations was not increased, yet, not only did the infant death rate remain at the low figure reached in 1911, but there were fewer deaths of babies under one year of age than there were during 1911. This is the lowest infant death rate recorded in the his-

tory of the city. The decrease in the infant mortality of New York City has been twice as great as the decrease in the remainder of the state.

One of the most gratifying features of this reduction in the number of deaths from preventable causes has been the fact that the excessive infant mortality of summer has been reduced to a most marked degree. In former years there has been an abrupt increase in the number of deaths, which increase, commencing with almost unfailing regularity about the first of July, reached it maximum in midsummer, and then falling very slowly resumed a fairly normal level with the beginning of cold weather.

During the summer of 1911 this usual summer increase was not more than half as great as it had been in previous years, while the number of babies who died each week during the heated term of 1912 was hardly any greater than the weekly average during the year.

SANITARY CONTROL OF THE MILK SUPPLY.

The most important single feature of the department's work in 1912 has been the improvement in the sanitary control of the milk supply. The past year has seen a notable measure of success in the actual application of comprehensive plans which have been under consideration and development for the past three years. Important and far-reaching improvements have been instituted by the grading of the milk supply and the extension of pasteurization.

SYSTEM OF GRADING MILK.

By the adoption of a resolution on January 4, 1912, the Board of Health required all milk brought into the city for sale to be sold under some one of the following grades or designations:

Grade A.—Suitable for Infants and Children.

- (I) Certified Milk.
- (2) Guaranteed Milk.
- (3) Inspected Milk, Raw (from tuberculin-tested cows).
- (4) Selected Milk, Pasteurized.

Grade B.—Milk Suitable for Adults.

- (I) Selected Milk, Raw, from cows which are certified by veterinarians after physical examination.
- (2) Pasteurized Milk.

Grade C.-For Cooking and Manufacturing Purposes Only.

All milk not conforming to the requirements of Grades A and B.

During the past year this grading plan has actually been put in force and compliance with its provisions insisted upon. Much emphasis has been placed upon the requirement of labeling in accordance with these provisions in order that the public might have as full information as possible as to the quality of milk which is purchased. Criminal proceedings have therefore been instituted whenever it was found that milk was improperly labeled.

In order to urge dealers who were selling Grade C milk for cooking, to advance to the Grade B class, a warning sign was placed in all stores in which Grade C milk was sold calling the attention of the public to this fact. All restaurants and hotels were required to obtain permits to sell milk and their permits were restricted to the sale of Grades A and B.

GENERAL ADMINISTRATION.

PASTEURIZATION.

The fundamental object of the grading system is to extend the scope of pasteurization, an expedient which modern knowledge of the transmission of infectious diseases shows to be absolutely necessary in a great city drawing its milk supply from distant points. The effect of the grading system in this direction has been reinforced by specific resolutions of the board, and the resulting extension of pasteurization has been very satisfactory. At the end of 1912 about one hundred pasteurization plants are either in actual operation or soon to be completed, including those in the city and in the country districts, and from one-third to one-half of the milk supply is pasteurized.

OTHER IMPROVEMENTS IN CONTROL OF MILK.

During 1912 rigid inspections were made of stores in which milk is sold and a large number of permits were revoked. Examination of empty containers being returned to the country was continued and a number of prosecutions were commenced for violation of the provision of the Sanitary Code requiring such containers to be cleaned. An important court decision recently rendered has sustained the legality and constitutionality of this provision of the code.

By increasing the severity of the scoring of milk stores, where "loose" or "dipped" milk is sold, an effort has been made to restrict the sale of such milk, but as this method was found not sufficiently successful, the Board of Health adopted a resolution, to take effect June 1, 1913, forbidding the sale of milk dipped from cans, except in special milk stores approved by the department for which a permit has been issued, or in places in which foodstuffs, other than milk products, are sold in original packages only.

INFANTS' MILK STATIONS.

The fifteen municipal infants' milk stations operated in 1911 by the Department of Health, in cooperation with similar stations under the control of private associations proved conclusively the value of such milk depots as centers of activity for the reduction of infant mortality. The city authorities accordingly made financial provision for the continuance of this work on an extended scale in 1912. In accordance with the provisions of the budget schedule for the year, forty additional milk stations were opened during the early spring and late winter months, making a total of fifty-five such stations under the control of this division. These stations are situated throughout the five boroughs and provide places where a mother may obtain pure milk for infant feeding at the lowest market price and in addition may receive such instruction as may be necessary from a physician and nurse to teach her how to keep her baby well and the exact method by which it should be fed.

The experience of the Department of Health in the conduct of these stations was most gratifying. During the year, 41,233 mothers brought their babies to the stations. During the same period a total of only 169 deaths occurred among the babies registered at the stations, a death rate which is phenomenally low, especially when it is remembered that these stations are all situated in those parts of the city where the birth rate and the infant death rate are very high.

SUPERVISION OF FOOD.

During 1912, twenty-one inspectors were employed continuously in the inspection of food. The six abattoirs which are subject to the inspection of this department and over

which the Federal Government exercises no supervision have each been under the care of one inspector during all the working hours. The six inspectors thus detailed have been immediately under the supervision of three veterinarians. The scheme of inspection employed has been one of constant rotation, so that not only have the three veterinarians interchanged posts daily, but each month the six inspectors have been assigned to different abattoirs. It is believed that maximum efficiency and results have been obtained by this method.

The evil of uncovered foodstuffs on push carts and street stands has been fought unceasingly and hundreds of arrests have been made for this violation of the Sanitary Code. While the evil is still prevalent, there is no doubt that it has been much lessened by the continued warfare of the department as evidenced by the many covered stands now to be seen in every section of the city. Retail shops, the proprietors of which were displaying unfit foodstuffs for sale, have received the constant attention of this division and confiscations of such material and arrests of offenders have undoubtedly raised this branch of business to a higher standard than it heretofore possessed. Bakeshops have been systematically inspected and wherever unwholesome eggs and unfit fruits have been discovered active prosecution has followed, with the result that the use of such material has become extremely infrequent. This fact is shown by recent records.

The policy of forbidding the reshipment from the city of unfit canned goods has resulted in the destruction of approximately 2,000,000 pounds of such material during the past year. The leading wholesale grocers have given hearty cooperation to the department in this movement, and this, in a measure, accounts for the splendid results achieved.

The guarding of the waterfront has resulted in the confiscation and destruction of enormous quantities of fruits and vegetables unfit for food which otherwise might have been placed upon the market.

Table waters, now so generally used, have been very extensively analyzed with the result that a number were found absolutely unfit for drinking purposes. Some of these have been withdrawn from the market, while in many other cases the manufacturers have made the changes necessary to eliminate the contamination complained of.

Large numbers of samples of foodstuffs have been collected for examination by the chemist, and in every case in which poisonous ingredients or unadvertised preservatives were found, the prosecution of the offenders has immediately followed. This has resulted in the almost complete discontinuance of the custom, formerly very common, of using preservatives in decaying meats.

The wholesale egg market has received the undivided attention of one inspector, and a marked improvement in the methods formerly employed in this industry has resulted.

With the increased force of inspectors allowed for the coming year, it is intended to follow systematically hitherto impossible lines of investigation. Thus, certain inspectors will be assigned solely to bakeshops, others to restaurants, and still others to make a study of the methods employed in candy factories and prepared food factories. The plans relating to these new channels of effort made possible by the slight increase in force will no doubt produce gratifying results.

MEDICAL INSPECTION OF SCHOOL CHILDREN.

The department has maintained as usual a system of medical inspection and examination of all children in the public schools of the city for the purpose of excluding from school attendance those who show any symptoms of contagious disease, and for the purpose of making a complete physical examination of all the children on an average of once in two years. All children entering school for the first time undergo a physical examination, and another before their graduation, and as nearly as possible one every two years in the interim.

During 1912, 288,469 children received this physical examination. Of this number,

87,361 were found to be suffering from one or more untreated physical defects interfering with their general health, and therefore rendering them less likely to profit by their school training.

In addition, 119,359 children were found to have defective teeth, although otherwise normal.

The character of the defects found was as follows:

| Defective vision | 15,075 |
|---------------------------|---------|
| Defective hearing | 888 |
| Defective teeth | 123,163 |
| Defective nasal breathing | 13,863 |
| Hypertrophied tonsils | 19,549 |
| Malnutrition | 6,106 |
| Cardiac disease | 1,242 |
| Pulmonary disease | 299 |
| Orthopedic disease | 547 |
| Nervous disease | 660 |
| | |

Of the children suffering from the above physical defects, 57,062 received treatment as a result of the efforts of the school nurses who visit the homes of the children and instruct the parents in the methods of hygiene and sanitation, urging the latter to take their children to the family physician for treatment. The cases thereafter are kept under the observation of the nurse until treatment has been received.

During the year the Department established six Children's Medical Clinics, located in those parts of the city where proper facilities for clinical treatment have been lacking. These clinics are designed exclusively for those school children whose parents are totally unable to pay for medical treatment. They are already crowded to their capacity.

The need of facilities for dental treatment has been acute. The budget appropriation for 1913 allowing the appointment of ten dentists makes it possible for the department to make a beginning in establishing dental clinics in connection with the clinics for school children already mentioned.

Typhoid Fever.

An advisory committee on the methods of the department in supervising typhoid fever has been established, consisting of a number of eminent sanitary and medical experts who have volunteered their services. On the recommendation of this committee, numerous improvements have been made in the methods in use in this department and better cooperation with other city departments concerned, particularly the Department of Water Supply, Gas and Electricity, has been secured.

Immunization against typhoid fever, or the inoculation of a healthy person with sterilized typhoid cultures in order to prevent infection with typhoid fever, has passed beyond the experimental stage and has become established as a prophylactic measure of proved efficiency.

Feeling that its wider use, under proper precautions, is called for, the Department of Health of the City of New York provided for the free performance of immunizations on request, under conditions similar to those governing the free administration of diphtheria antitoxin.

For the present all inoculations are made at the homes of applicants by the typhoid inspectors, or at the Central Office of the Department, Centre and Walker Streets, Borough of Manhattan, or the culture is furnished free to physicians for their own use. All requests for immunization by inspectors must be made by, or approved by the attending physician. In all other cases, the applicants are required to come to the Central Office, where the fact that they have no attending physician, and the reasons for and against immunization are very carefully investigated before the same is performed.

Immunization is offered to all other members of every family in which a case of typhoid fever occurs.

HISTORY OF INOCULATION AGAINST TYPHOID FEVER.

The first immunizations against typhoid fever in man were made by Pfeiffer and Kolle, but to Wright is due the credit for the introduction of the systematic practice of immunization on an extended scale, and as before stated, its value is now thoroughly established.

Official committees appointed by the governments of the United States, England, Germany, and France have investigated the matter, and all unite in recommending the employment of immunization as a rational and practical method of diminishing by a sensible proportion, the frequency and gravity of typhoid fever in all individuals whose profession, or whose usual or accidental methods of alimentation, or daily or frequent association with the sick or with typhoid carriers, expose them to direct or indirect contagion by the bacillus of typhoid fever.

The procedure has been widely used, especially in armies, and the conclusions of the present day are based on the results of more than 100,000 immunizations.

The following conclusions are accepted by practically all authorities:

1. The practice confers a notable immunity against typhoid infection.

2. It reduces by three-quarters the case incidence of typhoid fever in groups of individuals submitted to this method of immunization.

3. Under similar conditions, typhoid fever occurring in immunized persons has approximately one-half the fatality of typhoid cases in persons not so protected.

4. Typhoid fever thus is less apt to occur, and when it does occur, runs a milder course among the sick who have been immunized than among those who have not.

Among persons who may be designated as particularly to be benefited by immunization the following may be enumerated:

(a) Physicians, hospital internes, medical students, and orderlies in hospitals.

(b) Members of families among whom typhoid carriers have been proved to exist, or those exposed to the disease or who expect to be brought in contact with it.

(c) Persons who expect to travel or settle in places which are habitual foci of typhoid fever.

(d) Those living in regions where typhoid fever is prevalent.

VENEREAL DISEASES.

By resolution of the Board of Health on February 29, 1912, effective May I, 1912, all hospitals and public institutions were required to report cases of venereal diseases coming under their observation, and all physicians were requested to furnish similar information, concerning private patients under their care except that the name and address of the patient need not be reported. The terms of the resolution provided that all such information and reports should be regarded as absolutely confidential and should not be deemed public records or made accessible to the public. The Department also undertook the free bacteriological examination of specimens for the diagnosis of these diseases and has established a special clinic for diagnosis by means of the Wassermann and other tests. On December 17, 1912, a circular letter was sent to all physicians in New York City reminding them of this action by the Board of Health and again requesting the reporting of all private cases coming under their observation.

Contracts.

In 1912, 110 contracts for supplies were made at a total cost of \$536,467.65; twentyeight contracts for building construction, building materials, and architect's services were made at a cost of \$322,733.33. During the year many items which had previously been purchased on open market orders were included under contract purchase, namely, horseshoeing, guinea pigs and rabbits, green groceries and fruits, textiles, furniture, wagons, etc.

New Buildings.

The following schedule shows the new buildings and permanent improvements to existing plant for which contracts were let during 1912:

| Description and Location. 1912. | Cost. |
|--|--|
| Construction for two concrete pavilions, Riverside Hospital Construction for an Isolation Pavilion, Kingston Ave. Hospital Construction for an extension to Nurses' Home, Riverside Hospital | \$103,317.94 62,625.50 50,496.00 |
| Construction for an Underground Tunnel, Willard Parker Hospital | 13,086.00 15,997.00 |
| Construction for Water Lines at Otisville, New York Construction for Tunnel at Willard Parker Hospital Construction for Pumps at Kingston Avenue Hospital | 26,179.00 17,949.00 2,420.00 |
| Total | \$292,070.44 |

DEPARTMENT OF HEALTH, Comparative Table of Appropriations and Expenditures for 1912.

SECRETARY AND CHIEF CLERK.

LEGAL WORK.

Criminal Actions.

An examination of the accompanying table, under the heading "Criminal Actions, Magistrates' Courts," will disclose the disposition of prosecutions brought during the year. It will be observed that 1,482 defendants were discharged. This does not mean that the Department failed to substantiate the charge brought, but is explained by the fact that 883 actions based upon failure to comply with Board orders or notices were discontinued, the defendant having in each instance fully met the requirements of the Department. The remaining figures contained in the table are self-explanatory.

The table under the caption, "Criminal Actions in Court of Special Sessions," embodies the more important criminal prosecutions. These actions emanate from the Magistrates' Courts, being transferred to the Court of Special Sessions upon a motion made in behalf of the Department in accordance with Section 1265 of the Charter of the City of New York as amended by Section 95 of the Inferior Courts Act. An examination of this table discloses that 1,047 actions were disposed of during the year. Of this number 838 defendants were convicted and 209 discharged. In explanation of the number discharged, it may be stated that only 82 defendants were acquitted after a trial upon the merits of the case, the remaining 127 being dismissed upon motion made at the request of the Department, the defendants having fully met the requirements of the Board of Health. The amount of fines imposed during the year was \$21,675 as compared with \$13,170 imposed by the same court in 1911. Ten defendants received jail sentences, one of whom was both fined and imprisoned. In a number of instances the maximum fine of \$500 was imposed, and, as a whole, the court treated those found guilty of the offense as charged with great severity.

The majority of these prosecutions were directed against individuals, yet a surprising number of corporations were also proceeded against for violating the provisions of the statutes. Criminal prosecutions of corporations are daily increasing. Legal questions involving corporate as distinguished from individual acts are constantly arising and demanding the attention of the courts. During the past year the prosecutions of corporations by the Department of Health were uniformly successful and in many instances the extreme penalty the law provides was imposed.

Brief mention has heretofore been made in regard to the prosecutions of individuals and corporations charged with violating the provisions of Section 181 of the Sanitary Code, in that they caused, suffered or allowed dense smoke to be discharged from buildings, vessels, engines or vehicles within the jurisdiction of the City of New York. Special inspectors were detailed by the Department to this branch of work. Numerous actions were instituted in the courts which resulted in the conviction of a number of defendants, while in other instances the nuisance was abated before trial. The result of these prosecutions is apparent.

Criminal Actions in Magistrates' Courts.

Civil Actions.

Civil actions include actions in conversion instituted to compel payment of moneys due the Department of Health for laboratory supplies; actions to compel compliance with sanitary orders, directed principally to non-resident owners of property situated in the City of New York; actions against individuals charged with the duty of reporting births, marriages, deaths, and infectious diseases; actions against persons for issuance of false certificates or reports of births, marriages or deaths; actions against undertakers for the retention of dead bodies of human beings for a longer period than four days, or the removal or burial thereof without a permit; and other actions of a miscellaneous character involving violations of the Sanitary Code and the Charter of the City of New York.

In considering the civil branch of the law applicable to health work, attention is especially called to actions instituted against practising physicians and midwives for failure to report births to the Department of Health, in accordance with the provisions of Sections 1237 and 1239 of the Charter of the City of New York.

This statute requires that physicians and midwives who attend professionally at the birth of a child must report the same to the Department within ten days after the birth. Failure to make such reporting may involve the most serious consequences to the child, affecting its legitimacy, property rights, education and citizenship. The public is also vitally interested from a health and statistical standpoint. It is evident that serious results would occur through the neglect or omission to file the report of birth, whether such neglect be intentional or unintentional, as the injury to the child is the same in either case. The rigid enforcement of this statute is therefore essential to the public welfare in order that the rights of the citizens of the City of New York may be protected.

The requirements of the statute were repeatedly brought to the attention of physicians and midwives by the Department of Health, by personal communications and through the public press. Finding that these efforts were unsuccessful in securing a complete registration, the Commissioner of Health determined to take drastic action, and in the latter part of the year 1910 forwarded all violations of the statute to the Corporation Counsel. Civil actions were thereupon instituted and continued from that time until the early part of the present year. These prosecutions resulted in 310 physicians and midwives paying penalties for their neglect to perform their legal duty. The courts uniformly sustained these actions and held that it was obligatory for physicians and midwives to comply strictly with the terms of the statute. This is another application of the general rule governing health actions, that the welfare and health of the community as a whole are paramount. It is better that a physician or midwife should suffer some slight inconvenience than that the child should be deprived of its legal and equitable rights.

The prosecution of these cases has undoubtedly been of inestimable benefit in causing prompt registration of births.

In a number of other instances, physicians and midwives were prosecuted for filing false reports relative to births and deaths. In such cases the severest penalties were exacted because of the dangerous character of the offense which prima facie called into question the honesty and integrity of the offender. It was, however, found that in nearly all cases the defendants were not actuated by any ulterior motive, but were simply careless and negligent in the performance of their duties. The conclusion reached from this class of cases is that many physicians and midwives neglect to keep a record as required by Section 1237 of the Charter, of the births at which they attend professionally.

As an additional argument for the necessity of the strict enforcement of the laws applicable to the registration of births, we have but to consider the number of applications made to the Commissioner of Health to have placed on file in the Department of Health births which through failure of the physician or midwife in attendance were never filed. The Corporation Counsel received during the year, 1,696 such applications from the Commissioner for examination to determine whether the legal requirements of Section 1241 of the Charter had been fully complied with. Of this number 1,680 were granted and 16 denied. Inasmuch as the majority of persons affected are those in poor or moderate circumstances, the neglect or omission of the physician or midwife is both a legal and a moral wrong.

A number of undertakers and cemetery-keepers were found to be negligent in the performance of their legal duties and obligations. In each instance the defendants were required to pay penalties, which will undoubtedly have the effect of preventing a repetition of the offense.

Civil Actions.

LEGAL WORK

CERTAIN IMPORTANT DECISIONS.

Slaughter-House Odors.

Offensive odors due to careless management and operation of slaughter-houses located in the Borough of Manhattan have long been a source of complaint to the Department of Health. The burden of detecting these odors has heretofore devolved upon the inspectors of the Department, and necessitated almost constant surveillance. The efforts of the Department to prevent the escape of these odors into the outer air had been confined to the issuance of notices of violations of the Sanitary Code to offenders. The Commissioner of Health determined that the burden of preventing odors from escaping should be borne by the slaughter-house proprietors, it being their duty, by virtue of the character of their business, to operate their plants in such a manner as not to violate the strict provisions of the Sanitary Code. He therefore determined to refer all violations discovered by inspectors to the Corporation Counsel for prosecution. Three civil actions to recover penalties were subsequently instituted against the owners of large establishments and resulted in sustaining absolutely the attitude of the Commissioner. In one instance the defendants made a very determined fight to escape from their predicament. The action was tried in the Municipal Court and a judgment obtained against the defendants. An appeal was immediately taken to the Appellate Term of the Supreme Court, which court unanimously sustained the judgment of the lower court. Motion was thereafter made both to the Appellate Term and the Appellate Division for leave to appeal, each of which motions was denied with costs. The determination of the Appellate Term therefore stands as the law governing all future prosecutions of this character.

Stripped of its legal phraseology the decision holds that the escape of offensive odors from slaughter-houses within the City of New York, even though for an inappreciable length of time and in the absence of intent, is a violation of Section 85 of the Sanitary Code. It places the burden upon the proprietors to detect and prevent such odors from escaping into the outer air. The remedying of these conditions in no way affects the question of liability, as the law places an absolute and mandatory obligation upon those who conduct slaughter-houses in the City of New York to so conduct them that no offensive odors shall escape.

Signing of Death Certificate.

The validity of Section 163*a* of the Sanitary Code prescribing that a certificate of death must be signed by a physician upon whom was conferred the degree of Doctor of Medicine, as a condition to issuing a burial permit, was upheld by the Court of Appeals. The legality of this Section had been attacked by Charles F. Bandell, an osteopathic physician, acting in behalf of himself and other osteopathic physicians of the city. This decision establishes the right of the Department of Health to require all death certificates to be signed by physicians upon whom has been conferred the degree of Doctor of Medicine.

Cleaning of Milk Receptacles.

A very important decision was rendered by the Court of Special Sessions, First Division, in the cases People vs. Roth, People vs. Frudenberg, and People vs. Meyers, the defendants being employees of a large milk concern doing an extensive retail business in the City of New York. The defendants were charged with having received and having in their possession unclean milk receptacles which, in violation of Section 183 of the Sanitary Code, had not been washed after holding milk. The defendants demured in each instance to the information upon the grounds that the facts stated in said information do not constitute a crime, and that the latter portion of the said section which provides: "*** nor shall any person receive or have in his possession any such receptacle which had not been washed after holding milk or cream or which is unclean in any way," is void because the said ordinance conflicts with the Agricultural Law of the State, and, furthermore, that the said ordinance conflicts with the Constitutions of the State of New York and the United States, respectively, because it deprives or tends to deprive the defendants of their property without due process of law.

Hon. Isaac F. Russell, Chief Justice of the Court of Special Sessions, wrote an exhaustive opinion in these cases sustaining the contention set up in behalf of the Department of Health, that the said section was a reasonable and valid exercise of police power and in no way conflicted with the constitutional rights of the defendants, nor was it in conflict with the Agricultural Law.

One of these cases subsequently came on for trial in the Court of Special Sessions for the purpose of testing the validity of the ordinance in question in the higher courts. The court found the defendant guilty. The defendants immediately appealed to the Appellate Division, in which court at the date of this report the cases were pending awaiting final determination.

Rotten Eggs.

A criminal prosecution was on April 28, 1911, instituted against the F. E. Rosebrock Company, a corporation, charging the said company with having violated the provisions of Section 42 of the Sanitary Code, in that the said defendant on the 15th day of April, 1911, unlawfully did bring into the City of New York and hold and offer for sale a certain quantity of eggs which were not then healthy, fresh, sound, wholesome and safe for human food. The said defendant is a domestic corporation engaged in the sale of butter, eggs and bakers' supplies, at 325-327 Greenwich Street, Borough of Manhattan, City of New York. The case came on for trial in the Court of Special Sessions on the 18th day of December, 1911, and the defendant was found guilty and the maximum penalty of \$500, was imposed by the court. The defendant immediately appealed to the Appellate Division, which unanimously sustained the judgment of the Court of Special Sessions.

Unwholesome Meat.

One, Isidor Adler, was convicted in the Court of Special Sessions on the 19th day of October, 1911, of having violated Section 42 of the Sanitary Code, in that he did bring into the City of New York, a "quantity of meat, and hold and offer for sale, keep and store therein, although the said meat was then and there not healthy, fresh, sound, wholesome and safe for human food." In passing sentence on the defendant the court stated, "This is one of the most vicious cases we have had before the court. The defendant is sentenced to the penitentiary for the term of three months." From such judgment of conviction the defendant appealed to the Appellate Division and the court unanimously affirmed the said judgment of conviction, no opinion being written. The defendant thereupon made a motion for a new trial to the Court of Special Sessions on the ground of newly discovered evidence. The said court granted the motion. Upon the retrial, the defendant was again found guilty, but the court modified their former judgment and fined the defendant \$200, which he paid.

Examination of Records.

In the matter of the application of William H. Allen to examine certain records on file in the Department of Health, the Court of Appeals affirmed, without opinion, the judgment of the Appellate Division, which court denied the application of the said Allen and refused to allow such examination, sustaining the right of the Department to determine what safeguards and regulations should protect the privacy of its records. The opinion of the Appellate Division, written by Mr. Justice Scott, published in the yearly report of 1911, is, therefore, by the affirmance of the Court of Appeals, the final determination of the Courts upon the question.

LEGAL WORK.

Court Procedure in Health Cases.

One, Morris Cohen, arrested pursuant to a warrant issued on an information filed by an inspector of the Department of Health, charging him with violating the provisions of Section 68 of the Sanitary Code, obtained a writ of habeas corpus for the purpose of testing the right of the Department to have the case transferred to the Court of Special Sessions in accordance with the provisions of Section 95 of the Inferior Courts Act, thereby excluding his right to an examination of the witness upon whose depositions the warrant had been issued. The writ of habeas corpus came on for argument before a Special Term of the Supreme Court, First Department, which Court dismissed the said writ and remanded the defendant for trial in the Court of Special Sessions. The defendant thereupon appealed to the Appellate Division, which court unanimously sustained the judgment of the Special Term. The questions involved in the decision are of vital importance to the Department of Health, and the decision will prove of inestimable value, because it sets at rest for all time a question of law which has troubled the lower Courts for many years, and absolutely sustains the validity of the section involved, as well as holding that the defendant's constitutional rights were not invaded.

SANITARY BUREAU.

YEAR ENDING DECEMBER 31, 1912.

DIVISION OF INSPECTIONS.

As the result of the action of the Board of Health during the month of May, a number of changes were made in regard to the inspection and supervision of places in which foodstuffs are handled, prepared, stored or offered for sale, and the supervision of all permits required by these places was assigned to the Division of Food Inspection. In consequence of this, six inspectors of the Division of Inspections were temporarily assigned to duty elsewhere, thus reducing the force of sanitary inspectors from 30 to 24 in the Borough of Manhattan.

About the usual number of citizens' complaints were received and investigated by the inspectors and patrolmen assigned to this division, and these complaints in a large city like New York embrace all manner and kinds of subjects, both within and without the province or jurisdiction of this department. In addition to the investigation of citizens' complaints, the inspectors are required to make reinspections on notices or orders that have been previously issued.

STABLES.

The usual attention was paid to buildings occupied for stable purposes with the result that not as many complaints were received as would be expected from a business of this nature conducted in a congested city. Routine inspections are constantly made for the purpose of enforcing cleanliness in this character of premises. The Sanitary Code requires a permit to be obtained when horses are to be stabled in a cellar. It having been established that flies are disseminators of disease, the Sanitary Code has been amended so as to require that in any stable where manure is not removed daily it shall be adequately screened or otherwise protected so as to prevent the access of flies.

LODGING HOUSES.

Lodging houses are operated under permits issued by the Board of Health, and before such permits are issued it must be shown that the proposed lodging house complies with the requirements of the Sanitary Code, which, among other things, insist that 400 cubic feet of air space shall be allotted to each lodger. One inspector was assigned during the year to the duty of supervising lodging houses. The law requires that two inspections of each lodging house shall be made each year. During 1912 the number of inspections made averaged twenty-two for each house.

Lodging-House Inspection.

GENERAL SANITARY INSPECTION.

SMOKE NUISANCE.

During 1912, the smoke nuisance has been the subject of much concern and activity upon the part of the department, and during the early part of the year the situation appeared to be well in hand. About the beginning of May, however, it was noticed that more than the usual amount of dense smoke was being discharged from a number of business houses throughout the Borough of Manhattan. Upon investigation, it was alleged that the cause lay in the fact that the coal-producing sections were unable to furnish a sufficient amount of anthracite coal to meet the commercial demand, with the result that a large amount of bituminous coal had been placed upon the market. While there is no law prohibiting the use of the latter fuel, its character is such that if used without proper care upon the part of firemen and engineers large quantities of dense smoke will be discharged. All notices or orders relative to the discharge of dense smoke were marked for reinspection within twentyfour hours and, if their requirements were not finally complied with, summons were issued requiring the appearance of the offender in one of the Magistrates' courts. At this point the defendant usually requested an adjournment for one or two weeks and in many cases this was granted by the Magistrate, or the defendant was placed under bond and his case referred to the Court of Special Sessions. As a result of this activity, many notices were complied with before a summons was issued. When such a case is referred from the Magistrates' Court to the Court of Special Sessions, two, three, and sometimes four or five weeks will elapse before the case is called, and in almost every instance during the past year the defendant then applied for an adjournment of from two weeks to a month which was usually granted, and in many instances two or three such adjournments would be obtained. It is but rarely in cases of this kind that the defendant complies with the order of the Board of Health until the court decision is rendered.

Permits.

In October, 1912, the Board of Health adopted the policy of issuing yearly permits only and directed that all permits then in force and having an indefinite period to run should be revoked, and that persons holding such permits should make application for permits which would expire one year from date of issue.

TRANSPORTATION OF REFUSE MATERIAL.

The problem of the collection, transportation and removal of refuse material in a large and congested city like New York is one that deserves special attention. The Department of Street Cleaning has charge of the removal of ashes and garbage. All other refuse material, together with a considerable amount of ashes and garbage, is removed in vehicles operated by private individuals under permits issued by this department. During the year 1912, the Board of Health adopted new and more stringent rules and regulations in relation to the transportation of refuse material, including the issuance of a metal enamel permit, five inches wide and fourteen inches long, to be displayed upon the vehicle in such a situation as would be readily observed.

MOSQUITO EXTERMINATION AND PREVENTION.

This work is in charge of a sanitary engineer who, during the latter half of 1912, was assisted by a sanitary inspector. Nine laborers and one foreman were employed continuously throughout the year. On August 5th twenty extra laborers were employed at \$2.00 per day and two assistant foremen at \$2.50 a day. These extra men worked seventyeight days, when their services were dispensed with. The entire laboring force, both permanent and temporary, was employed exclusively in the Borough of Richmond.

The following tables show the location and the amount of work performed during the year:

WORK PERFORMED BY THE POLICE SQUAD DETAILED TO THE DEPARTMENT.

During 1912, the force, consisting of fifty men, under the charge of a lieutenant of police, was distributed as follows:

| Manhattan | 24 |
|-----------|----|
| Brooklyn | 12 |
| Bronx | 10 |
| Queens. | ્ર |
| Dishmond | 5 |
| Řichmond | 3 |

The officers cover sections laid out in the different boroughs and known as sanitary districts, within which they confine themselves to the enforcement of all sections of the Sanitary Code and perform such other work as the department assigns to them. They enforce quarantine, when necessary, and assist by their presence in enforcing vaccination of the occupants of premises in which smallpox is discovered. They also assist in enforcing the removal, when necessary, of patients to the hospitals. They destroy all glandered horses condemned by the department, also all rabid dogs and, at certain periods of the year, all stray dogs, if so ordered by the Board. They enforce the vacation of premises declared insanitary and uninhabitable by the Department of Health. They investigate citizens' complaints of violations of the Sanitary Code, inspect daily all manure, ash and garbage dumps, enforcing those sections of the Sanitary Code relating thereto, and, in fact, enforce compliance with all sections of the Sanitary Code so far as is possible by a police officer.

During the first quarter of the year, the records of the work performed by the patrolmen of the Health Squad formed part of those of the Division of Inspections. During the last nine months, such records were forwarded directly to the Board by the lieutenant in command.

DIVISION OF FOOD INSPECTION

During the year 1912, the inspection of food supplies and their supervision were conducted under one administrative head, although the budgetary allowance for milk and food inspection was divided into two schedules. The single administration proved most satisfactory as there were many instances where the two lines of work interlocked and their being under the same control made greatly for efficiency. The most radical move, and one which has been a great step in advance, was the assignment to this division of one supervising and sixteen sanitary inspectors on May 26, 1912. These men inspect all places where foodstuffs are prepared, stored or sold, and examine the sanitary surroundings of the food. This has been productive of two great results: it has permitted the food inspectors to devote all their time and energy to the examination of food and has placed in trained hands the important duty of maintaining proper sanitary conditions in the various premises concerned. When it is remembered that there are 28,510 establishments of this character, the force seems altogether too small for the work demanded. Revolutionary and progressive rules and regulations for the control of the manufacture of sausages and the preserving of meats were adopted by the Board of Health, on February 20, 1912. The enforcement of these rules has occupied a large amount of the time of the sanitary inspectors. On January 4, 1912, amendments made to the Sanitary Code reorganized completely the management of the milk supply. These amendments established three grades of milk and defined clearly the different kinds of milk which were henceforth to compose each grade. At the same time the rules and regulations for the care and sale of milk were altered so as to conform to the new amendments. Practically all the time of the milk inspectors has been devoted to the examinations necessary to the enforcement of the amendments.

FOOD CONDEMNED IN 1912

During 1912, the food section condemned and destroyed a total of 23,950,321 pounds of foodstuffs or 11,975 tons. The heaviest individual seizure was of approximately 4,561,-164 pounds of spoiled potatoes which were imported from Scotland during the months of April and May. The loss of this enormous quantity of potatoes has been charged to carelessness in transportation. One of the principal losers declared that his tubers were of first quality when he saw them loaded in Scotland, but were unrecognizable when unloaded in New York. He charged that the change was brought about by dampness of the ship's hold, caused possibly by the wetting of the containing bags by a severe rainfall during the period of embarkation. Whatever the contributing cause, the condition and quantity of these several shiploads of potatoes, presented a difficult problem to the officers of the food division, inasmuch as it became their duty to identify, classify and dispose of the mass, which had been collected on two adjoining piers. The stench was well-nigh unbearable and resulted in several gangs of laborers refusing to continue the work of transferring the potatoes to scows for removal to their point of final destruction. No useful purpose could be discovered for these spoiled potatoes and it became necessary to dump them into the sea. Then arose a new problem. The potatoes must be dumped beyond the tidal limit and the owners of flat scows did not care to risk their boats so far from land, nor were the sea-going, self-dumping scows practicable because, when opened, such buoyant contents as potatoes would not empty from them and remained floating within the opened boat. A solution was finally arrived at by half-filling the self-dumping scows with potatoes, and then placing on top of these dirt and other heavy material of sufficient weight to

submerge the potatoes temporarily and thus to permit the closing of the emptied scows. The magnitude and immediate need of this condemnation rendered necessary the employment of a force of five inspectors working twelve hours a day for almost a week. Four of these inspectors were drawn from other districts and their transfer crippled in a measure the work of the division during its busiest month.

CONDEMNATION OF CANNED GOODS.

The second largest condemnation of the year consisted of 1,724,893 pounds of unfit canned goods. A quite recent policy of the department in refusing to allow the reshipment to the manufacturers of spoiled canned foodstuffs for the ostensible purpose "of identifying the goods" has received the co-operation of the leading wholesale receivers and has resulted in the condemnation and destruction of millions of pounds of such material during the past few years. The seizure of foreign fruits, when found to be in an unwholesome state upon their arrival at the piers, has continued actively. The consignees of such fruits are willing aids to the inspectors because without a "condemnation certificate" from the Department of Health they are unable to recover their rebate of duties on such useless material from the custom authorities. With the limited number of inspectors on the waterfront, this necessity of the consignees has proved to be a most welcome aid, without which there is a possibility that some consignments of damaged fruits on obscure piers might never be discovered.

OPIUM AND COCAINE.

The work which in former years was performed by this department in the detection of the sale of opium and cocaine without a physician's prescription has in practically all instances been referred to the Police Department. The reasons for this are that the food division has not sufficient men to cope with this evil in a proper manner and, as the offense is now classed as a felony, it comes more properly under the supervision of the Police.

WOOD ALCOHOL.

In the early part of 1912, several cases of blindness and one of death occurring in a Southern laboring camp were brought to the attention of this department by the Italian Consul. It was believed that these results had been brought about by a certain brand of liquor shipped to the camp from New York City. Investigation led to the discovery that these liquors originated from a factory situated in a basement in Leroy Street. Inspectors in this division took possession of the basement and its contents and chemical examination of numerous samples of liquor found therein disclosed the fact that about 95 per cent. of the stock was adulterated with wood alcohol. More than a thousand bottles were seized and destroyed, and the owner of this material was sent to the penitentiary for a term of eight months upon pleading guilty to a violation of the interstate law. From record books found in his office a number of local receivers of this material were traced, and prosecuted and punished and the liquor destroyed. More recently, investigation has revealed that some unscrupulous druggists have been using wood alcohol in mixtures of paregoric and spirits of lavender, and prosecutions of the offenders are under way. A number of cases of complete or partial blindness reported from the lower eastern section of the city were traced to the consumption of so-called "Weisser Schnapps" containing wood alcohol, and in several instances in which the offenders could be reached, prosecution and punishment followed. The use of wood alcohol as an adulterant of cheap liquors is due partly to ignorance on the part of the manufacturer, and partly to his cupidity, in an attempt to avoid the heavy Federal tax imposed upon grain alcohol. Evidence in cases of this character is most difficult to obtain for the dealers in this material are very wary of strangers

and their victims belong to an ignorant foreign class unable to suspect the source of their symptoms, and who, therefore, do not report them promptly to the authorities.

TABLE WATERS.

Bacteriological examination of the many table and spring waters now so extensively used revealed the fact that many of them were polluted. The owners of such contaminated waters were compelled by the Department of Health either to render their products safe or to withdraw them from the market.

BAKERIES.

Bakeshops have been frequently inspected for the purpose of examining the materials employed, and in order to check the use of unfit eggs and spoiled fruits, which practice has been greatly diminished by the prosecutions and punishments which resulted. Several fines of \$250 were imposed and in two instances the offenders were imprisoned.

EGGS.

The wholesale egg market has required the entire attention of one inspector. Large quantities of unfit eggs have been destroyed and one offender was fined \$750. The handling of eggs and egg products has been restricted by the enforcement of strict ordinances governing this industry, and it is believed that as a result this business has been put on a more legitimate basis than it has ever before occupied. Unsound eggs, of course, enter the market in large quantities in the original package. This is an unpreventable occurrence for. under stress of weather or on account of the length of time en route, some eggs in each package are almost certain to deteriorate. All egg merchants employ "candlers" and the examination by the latter is capable of disclosing with great accuracy the presence of unfit eggs. The problem is to prevent such eggs from entering the market as food. While the honest merchant requires no supervision in this matter, those less scrupulous require to be watched constantly, and the records of this division show that vigilance in this direction has been productive of good results. Rotten eggs are used legitimately by leather manufacturers in the form of the so-called "tanners' yolk," and there is no desire on the part of this department to interfere with such use of these eggs. Their use in this manner is rather to be encouraged for, by offering this method of employing unfit eggs, the desire to dispose of them in an illegitimate manner is diminished.

OYSTERS.

During the spring of 1912, a thorough investigation of Jamaica Bay, L. I., and its estuaries was made, and samples of water from various parts of the bay during different tidal variations were taken for purposes of bacteriological analysis. As a result, "floating," "drinking," or "storing" of shellfish in the waters of Jamaica Bay was prohibited. As a result of a similar investigation, no oysters which are "drunk" in Chesquake Creek, N. J., are permitted to be sold in this city. All permits "To Keep Oysters For Sale" which were in force prior to November 1, 1912, were revoked and dealers were required to obtain new permits. In issuing such permits to the wholesale dealers, the department requires that the exact location of all beds must be given, together with a statement as to whether oysters are "floated," "drunk," or "washed," and the location of the "drinks" and "floats," the location of storehouses must also be stated, and the purity of the water flowing over the oyster beds and of the water in which oysters are "floated" or "drunk" must be proven to the satisfaction of the department.

The sale of oysters at retail within the City of New York is also conducted under permits from this department. At the present time, however, only those retail dealers who procure their oysters from wholesale dealers located outside the City of New York or from those who do not operate under a permit from this department are required to procure permits.

Food Inspection-Criminal Actions.

ANNUAL REPORT OF THE DEPARTMENT OF HEALTH.

SANITARY BRANCH OF THE DIVISION OF FOOD INSPECTION.

The sanitary branch of the Division of Food Inspection was established for the purpose of relieving the Milk and Food Inspectors of the necessity of making sanitary inspections in connection with their examination of foodstuffs. This work is at present performed by twenty (20) inspectors and one Supervisor. The city is divided into districts and the inspectors are held responsible for the conditions within their districts. The greater part of the work originates through complaints from citizens, references from other Bureaus and Departments, and requests for permits to conduct certain forms of business. The Inspectors are required to devote their time to original investigations when not engaged in complying with direct orders or investigating complaints.

For the purpose of this report, all premises where foodstuffs are manufactured, stored or sold, will be classed under two headings:

First: Retail Stores, which comprise

| Restaurants | Delicatessen Stores |
|-------------|----------------------|
| Markets | Grocery Stores |
| Hotels | Confectionery Stores |
| Bakeries | Butcher Stores |

Second: Factories, which comprise the following forms of business:

- a. Breaking out egg yolk for food or other purposes.
- b. Manufacturing confectionery, mineral and carbonated waters.
- c. Preserving and canning fruits and vegetables.
- d. Preparing and preserving meats and fish, manufacturing sausages and maintaining smoke houses.
- e. Rendering fat for food and other purposes, utilization of slaughter-house waste and manufacturing of fertilizer.
- f. Slaughter houses for poultry, cattle, calves, sheep, lambs, hogs and horses.

The most important class of business from the viewpoint of this division is the food factory, because the greater part of the output of the factories is consumed by the inhabitants of the City of New York.

When making inspections of retail stores, the inspectors are chiefly concerned with the sanitary conditions. They do not make examinations of foodstuffs, but, in all cases where milk is sold without a permit or when foodstuffs are apparently unwholesome or of a suspicious character, a reference is made to the proper Inspector of Foods.

Factories.

As previously stated, the factories are considered to be of the greatest importance and, for this reason, each class of factory will be treated separately.

a. Breaking out egg yolk for food and other purposes.—This class of factory, as a rule, uses the yolk of eggs, which for various reasons, is considered unfit for human consumption in its raw state. Some of the raw material is invariably offensive to the smell and is of such a nature as to create extremely insanitary conditions.

b. The manufacture of confectionery, mineral and carbonated waters.—This class of factory is one that requires constant supervision on the part of the Department. The manufacturing of confectionery, as is well known, tends to create extremely insanitary conditions, which are dangerous from the standpoint of health. The finished product is

not packed air-tight, is often allowed to remain exposed to flies and may form a culture ground for the bacteria of diseases which are transmitted by the fly. The manufacture of ice cream necessitates the use of large quantities of ice, and it is therefore necessary to provide proper drainage for the waste water. In the manufacture of mineral and carbonated waters adequate facilities for filtering the water used must be installed. Proper appliances for thoroughly cleansing bottles must also be provided.

c. *Preserving and canning fruits and vegetables.*—The work of the Department in this class of factory may be fully covered by the statement that it insists upon perfect sanitary arrangements within the premises, with proper receptacles and adequate arrangements for the disposal of waste material.

d. Preparing and preserving meats and fish, manufacturing sausages and maintaining smoke houses.—This class of factory is one that requires constant and careful supervision, chiefly because the business is conducted upon a small scale by a class of persons who do not seem to realize the necessity of cleanliness and that the use of the smoke house is liable to create a nuisance in the adjoining neighborhood.

e. Fat rendering for food and other purposes, utilization of slaughter-house waste and manufacture of fertilizers.—This class of business is most frequently carried on in conjunction with cattle, calves, sheep, lamb and hog slaughter houses, but in some instances this is not the case. The interior arrangements must be such as to permit of thorough and easy cleansing at all portions of the premises. The fats which are rendered for food purposes must be kept entirely separate from other fats and the rendering must be done in separate portions of the building.

Chicken Slaughter Houses.

These slaughter houses are required to be located in buildings which are not used for dwelling purposes and in a section which is not thickly populated. The character of the neighborhood is also taken into consideration, and in those sections where the religious beliefs of the people do not make it necessary to have fowl killed in any particular manner, the requirements as to location are more severe. Also in those sections, if there are a sufficient number of slaughter houses to serve the population within the area, the conditions are again made more stringent. This difference of procedure is explained by the fact that even under the most favorable conditions these slaughter houses are the cause of many complaints due to the character of the animals handled, and as this business is conducted on a small scale with a few irresponsible employees who do not seem to realize the importance of scrupulous cleanliness, offensive odors escape unless the greatest care is exercised at all times.

The sanitary inspectors are instructed to visit all poultry slaughter houses within their districts at least once a week.

Cattle, Calves, Sheep, Lambs and Hog Slaughter Houses.

These slaughter houses are of necessity kept under supervision both by the Food and Sanitary Inspectors, for they are liable at any time to become a nuisance to the neighborhood in which they are located. The possibility of a nuisance arising is not so much due to the methods of slaughtering or to the lack of precautions taken to maintain the premises in a cleanly condition, as to the reduction and utilization of slaughter-house waste, which is carried on in conjunction with the business of slaughtering animals. For this reason one Inspector who is thoroughly conversant with all the methods now employed, is permanently detailed to slaughter houses to the exclusion of all other work. The following is a list of the various forms of business for which a permit is required by this Department and which are inspected by the Sanitary Inspectors of this Division.

To keep cows.

To keep and sell live poultry in crate lots only at wholesale.

To eart fat and bones (out of town).

To use well water.

To keep oysters for sale at retail.

To keep oysters grown outside the City of New York for sale at wholesale within the City of New York.

To manufacture artificial mineral and carbonated waters.

To prepare and preserve meats and fish, manufacture sausages and maintain smoke-houses.

To render fat for food and other purposes; utilize slaughter-house waste and manufacture fertilizer.

To break out eggs for food and other purposes.

To conduct slaughter houses for poultry, cattle, calves, sheep, lambs, hogs, horses.

51

MILK INSPECTION IN THE CITY.

Twenty-five inspectors were employed in seeing that the milk entering the city was properly handled and safeguarded until it reached the consumer. The magnitude of this problem may be realized when it is considered that approximately two million (2,000,000) quarts of milk are received daily, that the milk enters at 15 different terminals, is inspected as delivered in 6,000 wagons, and is dispensed at 14,000 stores and 15,000 restaurants, hotels and clubs.

Of the inspectors assigned to city milk inspection, one was detailed for six months to the Division of Laboratories, two for six months to the Division of Communicable Diseases, and another to food inspection other than milk. These left practically only twenty-two inspectors of foods assigned solely to city milk inspection for the year.

Enforcement of Grading System.

On January 4, 1912, the Board of Health adopted certain amendments to the Sanitary Code, and subsequently revised the rules and regulations in order to make effective the new classification of milk sold in New York City.

The first step taken in the enforcement of these rules was to notify the dealers in making application for permits, to state which grade or grades they intended to sell. These applications were investigated by the Country Division which then recommended that permits be granted, according to the grade or subdivision the dairy producing the milk came under. After the dealers had received permits they were immediately notified to label their milk in accordance with the requirements of their permits.

It was felt that the success of the plan of grading the milk depended largely upon the enforcement of proper labeling, and by September 1, 1912, practically all the milk sold was labeled with the proper grade or designation.

In view of the fact that it was found that a large percentage of milk received in New York City was of the Grade C class, and that to exclude this milk from sale would have created a milk famine, the Board of Health amended its regulations for this grade and permitted its sale in stores, provided it was properly labeled. Immediately after this amendment was put into effect the following signs were posted in stores where Grade C milk was sold:

WARNING.

The milk sold in this Store is fit for cooking Purposes only.

GRADE C

Displayed by Order of the Board of Health.

These signs were printed in English German, Italian and Yiddish. After these signs had been posted by the inspectors, a number of storekeepers immediately notified their dealers that they would not sell Grade C milk, and demanded Grade B, and as a result, the dealers redoubled their efforts to get their milk into the Grade B class.

At the close of 1912, it is estimated that the daily milk supply of New York City may be classified as follows:

| GRADE A. I. Certified. Guaranteed. 2. Inspected Milk (Raw). 3. Selected Milk (Pastcurized). | ••• | 2,000 |
|---|-----|--------------------|
| GRADE B. | | |
| Selected Milk (Raw). Pasteurized Milk. | ••• | 700,000 725,000 |
| Grade C. | | |
| For Cooking | • • | 244,000 |
| Total | I | ,700,000 |

NOTE: The amount of milk sold in the winter months is materially less than that sold in summer.

It is also estimated that within three months the Grade B Pasteurized milk will be increased by 200,000 quarts, and in view of the number of requests for reinspections made by dealers who desire to get into the Grade B Selected Milk (Raw) class, a material increase will also be shown in its figures.

Control of Stores.

One of the most difficult problems in the handling of the milk supply and one to which a great deal of attention was given in 1912, was the sale of clean milk in clean stores.

The control of stores has been maintained by means of the permit system. Prior to October, 1910, permits were issued for an indefinite period and were good until revoked. Since that date all permits expired one year from date of issue. This rule, however, applied only to new permits and as no steps had been taken to rescind permits issued prior to October, 1910, one of the first steps to be undertaken in 1912 was the rescinding of all these old permits and the issuing of yearly permits.

The system of scoring stores was also changed, and the requirements were made more stringent. The extent to which this work was conducted may be seen from the following figures:

17,994 permits recommended granted

11,640 permits recommended revoked

862 prosecutions made for selling milk without a permit

\$1,746.50 fines collected.

This work in most instances has shown good results, as it has driven out of business a number of very dirty stores, has increased materially the amount of bottled milk sold daily and has resulted in the establishment of a number of stores solely for the sale of milk.

Milk Containers.

Another important feature of milk control, to which considerable attention was given, was the question of clean empty containers. The responsibility for unclean containers rests as much with the consumer as with the storekeeper and dealer, but up to the present time no action has been taken by the Department against the consumer. A large percentage of the consumers, however, are cleaning their bottles, but in some sections of the city dealers have found it almost impossible to secure the return of clean containers and rather than lose their customers accept the unclean empty containers and have erected depots for their cleansing. One company alone spends \$25,000 annually for this purpose.

The district inspectors have insisted that all storekeepers clean the empty containers. If unclean containers are found, the storekeeper is warned and if the containers are subsequently found unclean, prosecution follows.

During the summer months inspectors were detailed to night duty, and devoted most of their time to the inspection of empty containers which were being returned to the country. As a result, a number of dealers have employed special men, to inspect empty containers as they are unloaded from milk wagons to the railroad platform, and if any unclean containers are found they are returned to the depot for cleaning.

As in former years, a number of samples of milk, cream and condensed milk were collected for chemical analysis, and whenever the milk was found to be below standard, criminal proceedings were instituted. Wherever a high bacterial count was found, the dealer from whom the samples were taken was notified that immediate steps must be taken to remove the conditions causing it. If after repeated warnings the bacterial count continued to be excessive, the revocation of the permit was recommended. When milk was found to have a temperature exceeding 50 degrees Fahrenheit, it was destroyed.

During the summer months complaints were received that the milk offered for sale in restaurants was very poor. The Commissioner therefore directed that the established ruling that milk sold in hotels, restaurants and clubs, was part of a meal and was not sold as milk, should be disregarded and that all restaurants be required to have permits limiting them to the sale of Grade A and Grade B milk.

† Samples taken and analyzed.

[‡] The technical definition of adulteration is found in section 53 of the Sanitary Code, the chief items being "containing less than 11.50 per centum of milk solids" and "containing less than 3 per centum of fats." In enforcement a distinction is made between samples whose milk solids are found between 11.50 per cent. and 11.4 per cent.: the former are made occasions for warning only, the latter for prosecution.

Milk Inspection Within New York

MILK INSPECTION IN THE COUNTRY DISTRICTS.

The year 1912 opened with 33 inspectors detailed to this work. Early in September in order to enforce more properly the rules and regulations in regard to labeling, it became necessary to somewhat reduce this force and transfer the men to the city. Reductions were made from time to time until there were but 16 inspectors left for country work.

At the beginning of the year, routine systematic inspection was made of dairies irrespective of their class or character. Creameries were visited one after another. The dairies patronizing the respective creameries were inspected, and if conditions did not indicate that the milk produced or handled was fairly safe and wholesome, steps were taken to prevent either dairy or creamery from making shipments to this city. The standard required for shipments was based upon the score card now in use, and entailed a minimum score of 33 per cent. on methods. Reinspections were undertaken to ascertain whether improvements had been made after warnings had been given, and if little or no improvement had taken place, the dairy's products were excluded. Investigations at creameries were continuous in order to insure the exclusion of such dairies. On January 29, 1912, the exclusion of dairies and creameries was discontinued and up to this date two creameries and more than two hundred dairies had been excluded.

The procuring of samples of milk in the country for bacteriological analysis was conducted by a squad of five men under the charge of a supervisor. Exclusion was enforced whenever bacteria counts and dairy scores were found to indicate an improper milk supply. This work was practically discontinued on January 15, 1912, although since that date samples have been taken from time to time, by district inspectors.

A change in country milk inspection came with the enforcement of the classification system. The decisive step to enforce the present system as outlined in Section 56 and 56-a of the Sanitary Code and in the rules and regulations amended by the Board of Health on January 4, 1912, took place on January 8, 1912, when all milk dealers were notified to submit to the Department within ten days a statement showing what grade of milk each intended to sell.

The work from February 1, 1912, consisted, for the greater part, in the inspection and reinspection of dairies for the purpose of enrolling the name under the various designations. By August 1, 1912, every dealer had been provided with proper permits, in accordance with the new rules and regulations. In many instances seven or eight reinspections were made during the past year, whereas the number of inspections per dairy had previously averaged about one in eight months. During the year, 41,292 dairy inspections were made, and about 5,100 of Grade B (Raw) dairies were enrolled.

Generally speaking, great progress had been made by dealers, in inducing farmers to produce Grade B Selected Milk (Raw), which had been augmented by the offer by dealers, of a premium for the production of this grade of milk. The paying of a premium has also tended to secure a better supply for pasteurization, since numerous dealers are compelled to pay this premium for milk produced on dairies sufficiently high for Grade B Selected Milk (Raw), even though the milk is pasteurized and sold as Grade B (pasteurized) for which no score requirement is set.

On the other hand, it was found that since the exclusion system had been dropped, conditions upon a large number of dairies had again become very unsatisfactory. The careless dairyman felt that he could ship his product, if the dealer whom he patronized was in a position to transform into Grade B (pasteurized) Milk, or if the dealer could find ready sale for the product as Grade C. It was deemed necessary to exercise some restriction on the more insanitary dairies, and a modified exclusion system was again resorted to, a low limit exclusion point of 40 per cent. total on the score card being fixed.

As the endeavors of the past year have been devoted principally to such dairies as supply dealers desirous of selling Grade B Selected Milk (Raw) in this city, this modified exclusion system has acted as a check on only a small part of the total number of dairies producing the milk sold in this city. Conditions under which Grade C Milk is produced, are to a large degree satisfactory, because the bulk of such milk consists of the product of dairies that have fallen somewhat short of producing Grade B Selected Milk (Raw).

To enforce properly the present rules and regulations for the sale of milk makes it necessary to establish a method of checking at creameries. It has been found in some instances, where permits have been granted for the sale of Grade B Selected Milk (Raw), including only a part of the dairies patronizing a creamery, that the entire supply received has been shipped as Grade B Selected Milk (Raw). Detection of improper labeling in such cases is impossible in the city, for there is no way of telling whether the milk has been produced upon a dairy entitled to produce the grade of milk mentioned upon the label. It is for this reason that checking in the country becomes imperative. There are few creameries which cannot obtain and ship a certain amount of Grade B Selected Milk (Raw) and the issuance of a permit for a small amount of such milk provides a subterfuge for the labeling of the greater quantity of the milk as Grade B. Owing to the small force of men available, constant checking is at present impossible. The visit of the inspector to the creamery in his routine inspections must, with the exception of isolated cases, be depended upon as the only means at the command of the Department at the present time to prevent this practice.

Milk Inspection Outside of the City of New York.

PASTEURIZATION OF MILK.

During the past year the practice of pasteurizing milk for sale in the City of New York, increased very greatly and the work of its supervision and control called for increased effort.

The resolution of the Board of Health which went into effect on January 1, 1912, and by which the milk sold in New York was regarded and classified as "Grade A-B-C" produced two striking results.

First, those dealers who believed that the sale of raw milk was preferred to the sale of pasteurized milk, made greater efforts to induce the farmers to place their farms in such a satisfactory condition that they would be scored on the Department score card sufficiently high to permit them to come within the class of farms allowed to produce "Grade B Selected Milk (Raw)."

Secondly, those dealers who favored the sale of pasteurized milk were induced to equip more plants for this purpose and to increase their output. Those dealers also who after

making considerable effort found that they were not able to produce "Grade B Raw Milk," and who also found that the demand for "Grade C Milk" was small and growing smaller, were induced to equip plants with pasteurizing apparatus in order that the milk for which they found no sale, could, by pasteurization, be converted into "Grade B Milk."

At the beginning of the year, permits for the pasteurization of milk had been granted only to plants located within the city or its immediate surroundings. There were probably six or eight plants outside the city equipped with milk heating and holding apparatus, but none of them was in condition to comply fully with the requirements of the Department. At that time there were eighteen pasteurizing plants within the city, at which about 270,000 quarts of milk were pasteurized daily, most of which was sold in bottles and very little in bulk. At the end of the year, six new pasteurizing plants, at which about 95,000 quarts of milk were pasteurized daily, had been equipped within the city, and the plants previously equipped had increased their daily output by at least 25,000 quarts. During the year, permits to pasteurize milk outside the city were granted to thirty-four plants and applications were made for permits by 20 additional plants which had been equipped to pasteurize milk. By the end of the year 336,000 quarts of milk were being pasteurized daily, outside the city. About 40 per cent. of the entire milk supply is at present pasteurized.

The heating and the holding of the milk must comply with the regulations of the Department of Health as indicated by the following table:

No less than 158 degrees for at least 3 minutes. No less than 155 degrees for at least 5 minutes. No less than 152 degrees for at least 10 minutes. No less than 148 degrees for at least 15 minutes. No less than 145 degrees for at least 18 minutes. No less than 140 degrees for at least 20 minutes.

It has been recommended that the milk be heated to a temperature somewhat higher, and held for a period of time somewhat longer than indicated in this table in order to provide a sufficient margin of safety, and allow for possible variations in the temperature, and in the time for which the milk is held.

Over 400 inspections of pasteurizing plants nearly equally divided between the city and the country districts, were made during the year and 20 permits for pasteurizing plants in the city and 34 permits in the country were granted.

FOOD AND MILK INSPECTION.

DIVISION OF CONTAGIOUS DISEASES.

During 1912 a new form of postal card, on which appeared a list of the diseases to be reported, was issued to physicians for the reporting of contagious diseases, and every report was acknowledged by an official postal. In previous years it had been customary to acknowledge only reports of diphtheria, scarlet fever and measles, and these acknowledgments were formerly conveyed by means of a circular which contained the rules of the department relating to these diseases. On January 1, 1912, 23 district medical inspectors were dropped from the Division of Contagious Diseases, leaving 22 on the roll, and 30 registered nurses were appointed who were required, under the direction of district medical inspectors, to make the necessary revisits to cases of contagious disease. This change in the method of isolating and inspecting cases of contagious disease at their homes has not been entirely satisfactory. During those months of the year in which large numbers of cases of contagious disease were reported, there was considerable delay in their termination and it frequently became necessary to obtain assistance from the Division of Child Hygiene and to invoke the aid of the diagnosticians.

On December 5th an automobile ambulance was placed in commission at the Department stable, foot of East Sixteenth Street, Borough of Manhattan, and is used to convey cases of contagious disease from the outlying portions of all the boroughs to the Willard Parker Hospital in Manhattan and the Kingston Avenue Hospital in Brooklyn. It has proved to be a valuable addition to the hospital service and, especially on long hauls, shortens the period of conveyance very materially. An electric ambulance has also been ordered and will probably be placed in commission during the early part of 1913.

DISINFECTION.

During the year a change was made in the method of terminating cases of diphtheria and measles, and new regulations have been put in force. Experience has shown that diphtheria bacilli, as a rule, die out in a short time after drying and exposure to light, and that when a person suffering from diphtheria has completely convalesced and the throat is free from diphtheria bacilli there is little likelihood of any infection from the sickroom. Conditions, however, are quite different when the patient is removed from the sickroom at the height of the illness, or when death occurs at this time. Under these conditions, it is probable that fresh discharges are present, and that these contain living diphtheria bacilli. The action of the department, therefore, depends upon the circumstances attending the termination of the case and the period at which this takes place.

(I) If the patient completely convalesced in the sickroom, the department does not perform disinfection, but insists that the apartment be thoroughly cleaned and aired. After recovery of the patient at home, the woodwork of the room in which the patient has been isolated must be thoroughly scrubbed with hot soda solution (one-half pound to three gallons) and the room thoroughly aired for at least twenty-four hours before being again occupied. Goods will be removed to the Department of Health Disinfection Station for sterilization and will then be returned.

(2) If the patient is removed from the sickroom during the height of the illness or dies at this period, the room with its contents will be disinfected, and all goods exposed to the contagion will be removed to the Department of Health Disinfection Station and returned after disinfection by steam. Bedding or other infected goods from such infected rooms must not be taken from the house or thrown into the street by the owner. After the goods have been removed and the premises reinspected, if conditions are found satisfactory, the inspector will issue the necessary school permits. Children in the family are not allowed to attend school until they have received a certificate from the Department of Health.

Experience has shown that there is little likelihood of any infection from the sickroom or when the person suffering from measles has completely convalesced. The main danger, as already stated, is from fresh discharges. So far as disinfection is concerned, therefore, the action of the department depends upon the manner and period of termination.

The regulations are the same as those for diphtheria with the exception that, in the case of measles, the department does not remove goods for sterilization.

This method has proved very satisfactory and the wisdom of the change has been shown by the appreciation of the public and the absence of secondary cases.

DIVISION OF COMMUNICABLE DISEASES

During 1912 three new bureaus were established in the Division of Communicable Diseases. The first was charged with the supervision of typhoid fever, cerebrospinal meningitis, and acute poliomyelitis, and the second, with the control of venereal diseases, while the third was a bureau of supplies, requisitions and accounts.

Moving picture exhibits were given in the city parks throughout the summer, with the assistance of the Committee for the Prevention of Tuberculosis of the Charity Organization Society. An exhibit was prepared for the International Congress on Hygiene and Demography which took place in Washington, D. C., during September. An exhibit was also provided for the Association of Tuberculosis Clinics.

The following new publications were issued during the year:

Monograph No. 1.—The Registration and Sanitary Supervision of Pulmonary Tuberculosis in New York City. Monograph No. 2.—The Tuberculosis Clinics and Day Camps of the Depart-

ment of Health.

New circulars of instruction and information:

- I. Cerebrospinal Meningitis.
- 2. Circular of Information Regarding Acute Poliomyelitis (Infantile Paraly-
- sis) (information for the public). 3. Circular of Information Regarding Acute Poliomyelitis (Infantile Paraly-
- sis) (information for physicians).

 Circular of Information Regarding Venereal Diseases.
 Circular of Information Regarding Immunization Against Typhoid Fever. New editions of the Handbook of Division of Communicable Diseases and of the Handbook of Help for Consumptives.

A series of weekly lectures for the instruction of nurses of the sanitary bureau was organized and delivered. These were given with the assistance of the School of Philanthropy, Teachers' College, The Nurses' Settlement and the Charity Organization Society

| | 1910 | 1911 | 1912 |
|--|---|--|---|
| Inspectors on duty. Days on duty. Nurses on duty. Days on duty. Total inspections. Total cases communicable diseases reported. Total number employees. | 6,593 130 23,803 204,023 28,151 | 28 6,571 114 22,776 195,622 23,091 359 | 27 6,190 91 18,542 178,824 24,398 362 |

The reduction in the number of district nurses is due to the fact that a number of nurses were detailed to duty in the branch registration offices. There is a corresponding diminution in the number of inspections by nurses. It will be noticed that the total number of cases of communicable diseases reported was slightly greater than in 1911.

Tuberculosis.

The system of branch registration offices, which was introduced in the latter part of 1911, was extended throughout the entire city and new branch offices were established at Centre and Walker streets, 80th street and Broadway, 22 Vandam street, and at 229

East 57th street, all in the Borough of Manhattan. The office at 22 Vandam street. serves also as a clinic. All the tuberculosis clinics of the department were consolidated, and each was placed in direct relation with its branch office, with a physician in charge to direct all tuberculosis work in the district. A simplified and more complete system of recording cases of tuberculosis was introduced. While the number of cases of tuberculosis in the register increased from 27,000 in 1911 to 32,000 in 1912, 1,500 fewer new cases were reported. The number of deaths was slightly greater than in 1911. Careful studies in regard to the number of tuberculous children in New York City were undertaken during the year and the results will be published later. Although the staff of district purses was decreased from 114 to 91, 3,000 more visits were paid to new cases in 1912. The visiting of very ill, delinquent, and undiagnosed cases at their homes is now done by the attending physicians of the tuberculosis clinics, and the increased number of visits during 1012 illustrates the advantage of this new system. A decrease in the number of cases under observation from 7,413 on October 1, 1911, to 2,159 on October 1, 1912, was due to the distinction now made between cases under close sanitary supervision and those under periodical observation only. Almost as many visits were made by the physicians of the clinics as by the former staff of inspectors. During 1912 the staff of tuberculosis inspectors was abolished and their places taken by the physicians of the clinics. A new clinic was opened on May 6th at 22 Vandam street, Manhattan, replacing the Morgagni clinic. The clinics in Brooklyn and Queens joined the Association of Tuberculosis Clinics. The clinics at 81 Second street and 307 West 33rd street were renovated throughout.

A number of entertainments were given on public holidays for the children in the clinics.

Day Camps.

During 1912 the old ferryboat "Rutherford," which is used as a day camp for tuberculosis, was renovated throughout and new plumbing, shelters, etc., were installed. The "Rutherford" was removed permanently to a more satisfactory dock at the foot of Fulton street, Brooklyn. A number of entertainments were given for children and patients at the camps.

| | 1910 | 1911 | 1912 |
|--|------------|-------------------------|--------------------------|
| Cases in attendance Jan. 1st. New cases received. Cases discharged. Cases in attendance Oct. 1st. | 499 446 | 153 293 366 80 | 146 405 387 164 |

Four hundred and five new cases were received during 1912 as compared with 293 cases in 1911.

Clinic Relief Committees.

Clinic relief committees composed of the physician in charge and representatives of the auxiliary and of various charitable organizations were organized at the larger clinics. A Woman's Auxiliary of the Manhattan Tuberculosis Clinics took over the Chelsea Day Nursery at 346 West 37th street. A clinic physician and a department nurse were detailed to assist in the work.

Hospital Admission Bureau.

The two buildings used for this purpose were renovated throughout and electricity was installed in the one situated at 424 First avenue. The physician in charge was appointed an official examiner for the preventorium for children and for the New York Hospital for Incipient Tuberculosis at Ray Brook, N. Y. Two physicians were detailed to the Department of Charities to assist in the work.

COMMUNICABLE DISEASES.

| | 1911 | 1912 |
|--|-------|-------|
| Cotal number of cases admitted to hospitals | 8,663 | 9,326 |
| Cotal number of cases discharged from hospitals | 6,035 | 6,539 |
| otal number of cases admitted to Otisville Sanatorium | 680 | 783 |
| otal number of cases discharged from Sanatoria | 525 | 683 |
| otal number of cases forcibly removed to Riverside Sanatorium. | 43 | 63 |
| otal number of applicants for hospital care | 6,959 | 7,053 |
| otal number of persons refusing hospital care | 506 | 436 |

Typhoid Fever.

An advisory committee of expert sanitarians was appointed during 1912, and has been of the greatest assistance in connection with the sanitary supervision of typhoid fever. Among the changes in procedure recommended by this committee and which have been put into effect are as follows: I. The Sanitary Code has been amended so as to require superintendents of hospitals to report all cases of typhoid fever. 2. All inspections of sources of milk supply in the city and the country in connection with typhoid fever are now made by the Division of Communicable Diseases. 3. All physicians are required to furnish reasons for delayed reports. About 400 fewer cases of typhoid fever were reported in 1912 than in 1911, notwithstanding a sharp outbreak in the Borough of Brooklyn, especially in the Bay Ridge section, during the late summer which was probably caused There was also a well-marked outbreak in the Woodhaven section by infected milk. of the Borough of Queens which was probably due in part to an infection of the water supply. The milk supply responsible in Bay Ridge was very likely also responsible for some of the Queens Borough cases. The morbidity of typhoid fever in the Boroughs of Manhattan and The Bronx was lower than it has been for years.

Cerebrospinal Meningitis.

All cases of this disease except those reported from hospitals are visited by a physician from the Research Laboratory and lumbar puncture and serum treatment are performed with the approval of the attending physician. A new circular of information was prepared and issued.

Acute Poliomyelitis.

A new circular of information was prepared and issued. In 1911, 128 cases of this disease were reported and in 1912, 344. This apparent increase was probably due to the increased attention paid to the disease by the medical profession. Its incidence in 1912 probably did not actually exceed that of 1911. Cases are kept in quarantine by inspectors of the Division of Communicable Diseases for a period of six weeks.

Venereal Diseases.

By resolution of the Board of Health, February 20, 1912, all public institutions were required to report all cases of venereal diseases coming under their observation after May 1st. The Wassermann or diagnostic clinic was transferred from the Research Laboratory to much larger quarters at Centre and Walker streets on December 2, 1912, where clinics are held to obtain material for the Complement Fixation Tests for syphilis, gonorrhœa and glanders, daily, from 9 to 10 a. m.

| | Syphilis. | Chancroid. | Gonorrhœa. |
|--|-----------|------------|------------|
| Number of cases reported from May I to | | | |
| Dec. 31, 1912 | 2,124 | 288 | 2,418 |

Diphtheria Antitoxin.

More work was performed by the individual antitoxin inspectors during 1912 than during 1911 for the reason that it was found necessary to reduce the staff by detailing permanently two inspectors to duty in the typhoid bureau. The work was, nevertheless, well done, and the case fatality of diphtheria which was 9.5% in 1911 sank to 8.3% in 1912.

Diagnosis Laboratory.

The microscopical agglutination test for glanders proving unsatisfactory, this work was transferred to the Research Laboratory where tests for this disease are now made by the Complement Fixation method. The work will be retransferred to the Diagnosis Laboratory during 1913. During the year the antiformin method of sputum examination was at last introduced. The number of examinations of sputum during 1912 exceeded that of 1911 by about 10,000, and the number of examinations of blood and urine for typhoid fever exceeded those of the previous year by about 6,000. The number of diagnostic outfits prepared during 1912 more than doubled those of 1911, and the number of supply stations for diagnostic outfits was increased from 483 to 512.

Staff.

SUPERVISION OF MIDWIVES.

During the year 1912, 1,524 women applied for permits to practice midwifery. Of this number 1,325 permits were granted, three were denied and the remainder were under consideration at the end of the year. As these permits are in force for one year from their date of issue, the number of permits granted represents the number of women licensed to practice midwifery. Out of 135,655 births reported to the department during the year, 82,390 were reported by physicians and 53,265 by midwives.

Previous to 1912 there was no specific appropriation for the supervision of midwives and it was necessary for the Division of Child Hygiene to employ its medical school inspectors for investigation of the women and their equipment before recommending the granting of the permit, as well as for subsequent inspections to ascertain whether the rules governing the practice of midwives had been complied with. At the beginning of 1912 a special force of five medical inspectors and ten nurses was assigned to the duty of supervising midwives and foundlings boarded in private homes. By this means the character of the supervision has been greatly improved. The inspectors and nurses of this special staff have been able to familiarize themselves with the women and their medical work. The inspectors make the preliminary investigations before the application for a permit is forwarded to the Board of Health. The nurses make subsequent inspections and instruct the midwives in regard to asepsis, the technique of nursing and the care and feeding of infants.

Midwives who practice medicine illegally are liable to prosecution by the County Medical Society and those who perform criminal operations come under the jurisdiction of the District Attorney. The Division of Child Hygiene investigates all cases coming under either classification whether the complaint originates with an inspector or nurse or is sent to the department by a citizen, and when any evidence is discovered that might be made the basis for further investigation or legal action the matter is referred to the proper authorities. Permits to practice midwifery are revoked by the Board of Health upon the legal

CHILD HYGIENE.

conviction of the midwife or upon evidence that the rules and regulations of the department have been disobeyed. In case of a simple infraction of the rules, the midwife is warned against a repetition of the offense and the second infraction is followed by the recommendation that her permit be revoked. During 1912, 71 permits were revoked for various reasons. including failure to use the one per cent. solution of nitrate of silver as a preventive of ophthalmia neonatorum, the occurrence of puerperal sepsis, improper equipment, negligence, and illegal practice. Midwives are supplied with a special form of postal card, upon which they are required to report all cases of sore eyes occurring in the new-born. This rule has been well observed. Each case reported is visited by an ophthalmologist for the purpose of making a definite diagnosis. During 1912, midwives reported 91 cases of sore eyes, of which 44 proved to be ophthalmia neonatorum. Physicians reported 12 such cases, nine of which were ophthalmia neonatorum, institutions reported 61 cases, and the nurses nine, the positive diagnosis of ophthalmia neonatorum being made in 60 and three cases respectively. With the present force it has been possible to refer these cases to proper agencies for treatment, and, by repeated visits, to determine that the proper treatment has been received. In no instance has the department obtained evidence that blindness has resulted, although persistent efforts have been made to follow the course of all cases reported. All deaths from puerperal septicæmia are investigated and when a midwife has at any period attended such a case it is charged against her record. During 1912, a total of 203 deaths from this cause were reported. One hundred and forty of these women were wholly under the care of physicians at the time of confinement, while 44 were confined by midwives. In the remaining 19 cases no information in regard to the attendant could be obtained owing to the fact that the deceased left no near relative or friends or on account of removal of the family and the impossibility of locating them. While the character and the methods of practice of midwives have greatly improved during the past year, it has been evident that many of them are unfitted for their profession and do not maintain either the ethical or technical standards that are essential. The habitual delinquents are, generally speaking, the older midwives who have practiced for many years unsupervised and unrestrained. The younger women and those recently entering the profession are more amenable to instruction and are of a better type. The need of proper preliminary training and education is increasingly evident. The superior character and ability of the graduates of foreign schools, as well as of those graduated from the Bellevue Hospital School for Midwives in this city, are strikingly evident. Training of a similar nature should be made available and compulsory for all future applicants, and it is essential that facilities for this purpose should be available in the near future.

FOUNDLINGS BOARDED IN PRIVATE HOMES.

A special staff of five inspectors and ten nurses available during 1912 for the supervision of midwives and of foundlings boarded in private homes has resulted in increased efficiency in this direction. By limiting the duration of permits to one year it has been possible to maintain a more effective supervision of the holder of the permit and to limit more definitely the issuing of permits to women who are well able to give proper care to babies in their homes. The primary reason for boarding out in private homes infants who would be committed to the care of institutions is the reduction of the high infant mortality in this class of cases. While institutions provide such modern methods for the care of infants as are prescribed by their medical staff, and while their equipment is in most instances modern, the appallingly high infant death rate in foundling institutions still remains the most serious problem in the consideration of this subject, and fully justifies an extension of the system of boarding foundlings in private homes. In the hospitals, for instance, and foundling asylums, 4.522 deaths from all causes of infants under one year occurred during 1912 as contrasted with 9.693 similar deaths occurring in dwellings. The following tables show the gravity of the situation in the Borough of Manhattan, where the largest institutions of this kind are located:

| | Institutions. | Dwellings. | Total. |
|--|---------------------------|--|---|
| New York City Borough of Manhattan Borough of The Bronx Borough of Brooklyn Borough of Queens Borough of Richmond | 3,358 208 814 68 | 9,693 4,275 900 3,629 713 176 | 14,215 7,633 1,108 4,443 781 250 |

Deaths from All Causes Under One Year of Age-1912.

Deaths from Diarrhæal Diseases Under One Year of Age-1912.

| | Institutions. | Dwellings. | Total. |
|--|------------------------|---|---|
| New York City Borough of Manhattan Borough of The Bronx Borough of Brooklyn Borough of Queens Borough of Richmond | 703 26 306 18 | 2,303 867 206 951 215 64 | 3,379 1,570 232 1,257 233 87 |

That this institutional mortality can be greatly reduced by boarding infants in private homes has been demonstrated beyond the possibility of doubt. In order, however, that such a practice should be productive of the greatest good, continued and persistent supervision of the women and their homes is essential, and in addition the women should receive instruction in infant hygiene and in the proper methods of feeding. During the past year, there has been increasing evidence of the desire of these women to be instructed and to give the best possible care to the infants under their charge. With the largely increased number of infants' milk stations under the control of the Department of Health, it has been possible to refer these foster mothers to the stations nearest their homes and thus to insure their

CHILD HYGIENE.

supervision and control by the station doctor and nurse. The death rate among these infants could be still further reduced if the institutions would rescind their rule requiring that a baby shall be returned to the institution upon the first evidence of illness. The enforcement of this rule means in many cases that infants breast fed by the foster mothers are returned to the institution and fed artificially at a time which is least favorable for weaning. Proper medical care, with a continuance of breast feeding, would undoubtedly save a majority of their lives.

Supervision of Foundling Babies Boarded Out in Private Homes.

REDUCTION OF INFANT MORTALITY.

Probably the most effective work of the Division of Child Hygiene during 1912 is shown by the marked reduction in the death rate among infants under one year of age. During 1912, deaths from all causes under one year numbered 14,289 as contrasted with 15,053 during 1911, the latter year showing a decided reduction as compared with 1910. In the past ten years, the infant death rate has decreased from 181 per 1,000 births in 1902 to 105 in 1912. The interesting feature of this decline is that it has been most marked in that class of cases which are grouped under the term "diarrhœal diseases," and that for the past two years the greatest decrease has been noted during the summer months. For the first time in its history, the Department of Health during 1912 was able to conduct its campaign for the reduction of infant mortality throughout the entire year. The campaign has been largely educational and the results obtained have demonstrated the value of the methods employed.

Infants' Milk Stations.

Forty new stations were opened during the year which, added to the fifteen established in 1911, make a total of fifty-five municipal stations. Twenty-seven were placed in the Borough of Manhattan, twenty-four in the Borough of Brooklyn, two in the Borough of The Bronx and one each in the Boroughs of Queens and Richmond. Extensive studies were made of localities and of infant birth and death rates throughout the city and the stations were located in those districts in which the need was greatest. The sixteen infants' milk stations formerly conducted by the Brooklyn Children's Aid Society and the thirty-two conducted by the New York Milk Committee were discontinued in the fall of 1911, so that the additional stations maintained by the department provided a total of only two more

than were formerly in operation. The number of infants' milk stations at present existing in the city, with the agencies controlling them, are as follows:

Through a cooperative plan, under the organization of the Babies' Welfare Association, the City has been districted with reference to the milk stations. Uniform methods in the keeping of records and in reporting to a central office have been established, and the former duplication of work, overlapping of territory, and waste of effort have been eliminated. The stations of the department have been operated by a staff consisting of two supervising medical inspectors, one supervising nurse, 18 medical inspectors, 56 nurses, 55 nurses' assistants, and 18 cleaners. The methods of dispensing milk have been those instituted in 1911. The New York Dairy Demonstration Company, under an agreement with the Board of Health, has stationed an employee at each station to sell the milk to mothers. The milk is sold in quart bottles, its pasteurization and quality being guaranteed by the Board of Health, under a system of supervision and inspection rigidly maintained. The method has been followed of dispensing whole milk with an individual formula for its modification prescribed in each case by the medical inspector, with instructions as to methods of modification given by the nurse at the station and at the home. This method has been entirely satisfactory and few mothers are found too ignorant or negligent to follow the instructions. At the stations, and during home visits, the mothers are instructed in the methods of infant hygiene and care. In order to induce the mothers of young infants to visit the stations, the following methods of publicity have been followed:

1. The press of the city has published articles explaining the object and giving the locations of the stations, expatiating on the importance of prophylaxis in the care of infants and advising mothers to avail themselves of the advantages offered by the stations.

2. "To the mothers of all children born since January I, 1912, and living within a radius of four blocks of each station, a letter was sent signed by the Commissioner of Health stating the object of the stations and giving their locations.

stating the object of the stations and giving their locations. 3. Principals of public schools have requested their pupils to inform their mothers of the location and object of the stations.

4. The members of Little Mothers' Leagues have been instructed in the object of the stations and informed of their location.

5. Inspectors and nurses, when visiting homes, have advised all mothers of young infants to avail themselves of the stations' services.

6. Placards were hung in stores situated within a certain radius of the stations, giving the address of the nearest station and its object. These placards were also displayed on recreation piers and in school playgrounds and other places where women and children congregate.

7. Pocket cards, giving location of the stations, were distributed to the police force, station houses, settlements, social service agencies, hospitals, and various other organizations.

8. Weekly bulletins of information regarding the number of infant deaths were sent to all the newspapers, and were not only published by them but were made the subject of many special articles. The publicity obtained was widespread and productive of much good.

CHILD HYGIENE.

The importance of breast feeding has been kept constantly in mind and every effort has been made to impress mothers with its desirability. Where bottle feeding has been rendered necessary on account of poor quality or insufficiency of breast milk, every effort has been made to minimize its disadvantages. Mothers have been instructed in regard to proper diet, exercise, and general hygiene, and when necessary, appeal has been made to charitable organizations for material relief. A study was made of 3,592 consecutive cases in order to ascertain the causes determining the choice of method of feeding. The results obtained are sufficiently interesting to be noted and are shown in the following table:

| | Number | Breast- | Bottle- | Breast and |
|--|-----------------------|---------------------------------|---------------------------------|--|
| | Investigated. | Fed. | Fed. | Bottle-Fed. |
| All nationalities. Russian Jews. American Italian Bohemian | I,506 330 I,532 | 49% 53% 51% 48% 22% | 32% 24% 34% 32% 73% | $\begin{array}{c} 19^{C'_{0}}\\ 23^{C'_{0}}\\ 15^{C'_{0}}\\ 20^{C'_{0}}\\ 20^{C'_{0}}\\ 5^{C'_{0}}\end{array}$ |

Further investigation of the Italian cases shows the difference in the percentage of breast feeding among those mothers who were employed in work other than that of their household and among those who were not.

| | Number | Breast- | Bottle- | Breast and |
|-------------|---------------|---------|---------|-------------|
| | Investigated. | Fed. | Fed. | Bottle-Fed. |
| Working | 642 | 44% | 41% | 15% |
| Not Working | 890 | 51% | 26% | 23% |

The case of the Bohemians deserves special attention. These mothers were nearly all employed, many for the entire day, in cigar factories and could not nurse their children at all, while others, working at home, were so poorly nourished and anæmic that nursing was impossible. The poor physical condition of these mothers is doubtless largely due to the character of the material on which they worked.

During the year 37,935 women and their babies were registered at the stations. Thirtyone thousand nine hundred and thirty-nine of these women were in attendance for only short periods of time on account of their continual change of residence. In a certain proportion of cases attendance ceased on account of failure on the part of the women to comply with the rules, some were discharged because their infants had passed the age at which nursing is essential, and some ceased attending because they were fully instructed in the proper care of the infant and preferred to buy the milk nearer their homes. A decrease in attendance is characteristic of the winter months. The mothers are generally fully aware of the need of additional care of their babies during the summer, but in winter it is difficult to convince them that special attention is necessary, and there is a well-rooted aversion to bringing infants to the stations in cold weather. One of the most essential and, at the same time, most difficult features of our educational work consists in combating this theory. In order to determine the number of deaths occurring in babies who had been in attendance at the stations, home visits are made for two weeks after attendance has ceased. Illness resulting in death, or death occurring during this period, is charged against the station. All babies referred to hospitals or to other agencies for treatment are kept on the records and every death noted. Every effort is made by investigation of death records and by

coöperation with institutions to ascertain all deaths that may legitimately be charged against the station. In this connection it is important to note that the proportion of sick babies brought to these stations is exceedingly high, about 60% of the infants exhibiting some ailment at the time of their first registration. The true value of the stations consists in their prophylactic efforts, but it is not yet possible to eliminate the prevalent idea that the stations are dispensaries, and in many instances mothers do not bring their babies to the stations so long as they are well. During the year 169 deaths occurred among babies registered at the stations, 83 from diarrhoeal diseases and 86 from other causes, amounting in all to .5 of 1% of the total registration, or 1.8% based on the number of babies registered at the end of the year, and is indicative of the great value of infants' milk stations in the reduction of infant mortality.

District Visiting.

The inspectors and nurses assigned to school duty during the school year were employed during the summer months in caring for babies not under the jurisdiction of the stations. This work is also carried on in part during the school year, when the nurses at every opportunity afforded them by their home visits instruct mothers in the principles of infant hygiene and care. Also throughout the year medical inspectors respond to emergency calls in the case of sick babies where the families are unable to employ a private physician. Following the plan instituted with such marked success in 1911, the efforts of the staff have been especially directed to those districts showing the highest rate of infant mortality. Commencing July 1st a definite district was assigned to each school nurse not engaged in other duties and she was required to locate one hundred and fifty babies under one year of age and to visit each at least once in ten days. Those who were sick or delicate were visited as often as necessary, and mothers were instructed in detail in the value of breast feeding and the hygiene of infancy. Each day the nurses and inspectors conferred in regard to sick or delicate babies, the inspectors visiting those cases in which the parents were unable to pay for medical attendance. When possible, sick babies were referred to hospitals or dispensaries for further treatment, the full force of the department's campaign being thus exerted in keeping the baby well. By cooperation with the infants' milk stations duplication of effort was eliminated. Systematic home visiting, for the purpose of instructing mothers in infant hygiene, has proved to be most effective, and the limiting of this preventive work to homes in those districts of the city where the need was the greatest has caused it to develop a practical value much greater than in former years when the force was distributed over the entire city, allowing but one or at most two calls on each mother. The infant mortality figures are much lower and the number of requests for medical attention is far less than under the old plan. From June 15th to September 15th, 18,605 babies were kept under constant supervision, 113,540 visits to mothers were made by the nurses, and 2,029 visits to sick or delicate babies were made by the medical inspectors. Two hundred and seven deaths occurred among babies under care, 86 from diarrhoeal diseases and 121 from other causes, a mortality of about 1.1%.

COOPERATION.

Forty-two conferences for mothers, with a total attendance of 2,293, were held at the offices of the charity organizations and other agencies. Seven medical inspectors and three nurses were assigned to regular duty at the infants' milk stations of the New York Diet Kitchen Association during the summer months, and the assignment was continued on Saturdays during the remainder of the year. Inspectors examined all children taking advantage of the daily boat outings of St. John's Guild. Two nurses were assigned to the recreation playground on the roof of the Educational Alliance building. Social service agencies of the city, including the Charity Organization Society, the Association for Improving the Condition of the Poor, the United Hebrew Charities, the Brooklyn Bureau of

CHILD HYGIENE.

Charities, and the Children's Aid Society of Brooklyn, have supplied free milk for indigent mothers and babies, in addition to furnishing many other forms of material relief. Through the coöperation of the *Herald* Free Ice Fund and the president of one of the large ice companies, 317,700 pounds of ice were distributed to indigent families in order that milk intended for babies might be kept in proper condition. Outing societies, settlements, and many other organizations interested in infant welfare work have coöperated with the department in a manner most helpful. This coöperation has been placed on a most satisfactory and systematic basis by the formation of the Babies' Welfare Association, which is the outgrowth of the Association of Infants' Milk Stations instituted in 1911. The association is a federation of all the agencies interested in infant welfare and was inaugurated at the suggestion of the Department of Health in order that the work might be more comprehensibly and systematically conducted. The first year's work of this federation has proved conclusively that coöperation in efforts of this nature is essential and that its beneficial results are immediately apparent.

Infant Mortality-Infants' Milk Stations.

Little Mothers' Leagues.

One hundred and ninety-three of these leagues were formed during the spring of 1912, which was the third year of this work, the value of which has been each year increasingly evident. During 1912 a regular course of one lesson each week for twelve weeks was instituted, the same lesson being given in each league each week. The increase in the number of infants' milk stations made it possible to hold many of the meetings in the stations, obviating to a great extent the difficulty experienced in former years of securing proper meeting places, and also rendering available a complete equipment for teaching. Seventeen thousand seven hundred and eighty-four members were enrolled, and 1,164 meetings were held, with an attendance of 85,355. The enthusiasm of the members has been marked, and the leagues have been of definite aid to the department in referring mothers to the milk stations and securing better care for the babies under their charge. It is to be hoped that the Board of Education will institute a course in infant hygiene for girls in the public schools. It can hardly be doubted that such action would have a definite effect in lessening infant mortality.

SUPERVISION OF DAY NURSERIES AND INSTITUTIONS FOR DEPENDENT CHILDREN.

The day nurseries of this city continue to be maintained under satisfactory conditions, few violations of the rules and regulations of the department being found. During the year 36 applications for permits to conduct day nurseries were granted and four were denied.

CHILD HYGIENE.

There are now 87 permits in force. Each nursery is regularly inspected once a month, and two inspectors are assigned especially to this work. Institutions for dependent children have also been inspected once a month in accordance with the State law. While the authorities of these institutions show readiness and intent to comply with the law governing their management, it is evident that the physical condition of the children would be benefited by a more complete system of control of each child. Such a system should be modeled on that of the medical inspection and examination of school children, with the necessary modifications to make it of the greatest value in conserving the health of children committed to institutions.

Supervision of Institutions and Day Nurseries.

MEDICAL INSPECTION AND EXAMINATION OF SCHOOL CHILDREN.

The beginning of the year marked an important change in the method of conducting the work of school inspection. Preliminary studies had been made during the spring of 1911 in cooperation with a special committee of the Board of Estimate and Apportionment, in order to determine if a more economical method than was then in force could be devised without sacrificing efficiency. The practice then in vogue of having both a medical inspector and a nurse visit each school daily doubled the time consumed in transit between the schools visited, and it was the purpose of this study to ascertain whether this waste could be eliminated. The success of any plan having for its object the eradication of infectious diseases from schools depends wholly upon the exclusion of infected children before and not after symptoms of contagious disease have developed. When a contagious disease has sufficiently developed to make diagnosis possible, it is evident that the harm has been already done in so far as the danger of contagion is concerned, and it was believed that it would be far better to exclude from school all sick or ailing children, with the possibility that some of the exclusions might later be found to be unnecessary, than to risk allowing them to remain in school until the true nature of their illness manifested itself. These studies showed that if a nurse alone visited each school daily she might refer to the principal for exclusion all children found with symptoms of illness and attend to her other duties of health instruction and attention to minor ailments as well. This plan permitted of a reduction in the number of medical inspectors employed and an increase in the number of nurses, the inspectors devoting their entire time to the physical examination of the children and exercising a controlling oversight over the work of the nurses, and, while in

many ways it has been successful, modifications will probably be necessary in the future in order to insure the best results. The possibility of overlooking cases of contagious disease has been guarded against as follows: The school inspectors and nurses are divided into groups and each group is under the charge of a supervising inspector, who receives daily on separate index cards the name and address of all cases of contagious disease occurring among school children in his district with data as to the school attended and date of last attendance at school previous to illness. He is required to keep this information in such order that he may know at once when more than one case of contagious disease has occurred in any classroom. He then visits the classroom, examines each child, instructs the teacher as to the necessity of noting symptoms of illness, and makes repeated inspections until all danger of further infection has passed. When two or more cases of diphtheria occur in one classroom, trial cultures are taken from the throats of all the children and immunization is offered. Children excluded from school by the principal at the suggestion of the nurse are visited at their homes by a medical inspector for the purpose of diagnosis, and when contagious disease is found to exist exclusion is continued. This method has proved satisfactory in controlling contagious diseases in the schools. It is open to some criticism. In the first place, it increases the duties of the nurses to such an extent that the time formerly devoted to visits in order to induce parents to seek treatment for physical defects in the children has been greatly curtailed, and secondly, the principals and teachers generally are not satisfied with a plan which causes the school doctor to visit the schools at infrequent intervals. Both of these criticisms are worthy of consideration and should be met by a modification of the present system which, however, would depend upon readjustment of the budget appropriation. Each nurse now has about 4,000 children under her supervision, and each inspector about 9,000. A nurse cannot properly care for more than 3,000 children and it is really questionable whether the best results can be obtained if her quota exceed 2,000. The present number of medical inspectors permits of the physical examination of approximately 280,000 children each year. Every child entering school for the first time is examined, all children are examined before graduation, and the remainder are examined grade by grade in regular order. All cases with marked physical defects, or those which apparently need immediate attention, are examined as soon as noted. Difficulty is often experienced in securing treatment for children. Nurses exhaust every effort to induce parents to take their children to physicians or to dispensaries and hundreds of instances are on record where parents have consented to have their children treated only after a year or more of persistent work on the part of the nurse. Ten, or even twenty, home visits paid by the nurse to a single case are recorded in a large number of instances.

Contagious Diseases.

During the year, 4,949 children were excluded from school on account of contagious diseases, and 3,929 unreported cases of contagious disease were found in the course of home visits made by the inspectors and nurses. With the present attention to the possibility of infection while the child is in attendance at school, the ratio between the number of cases found in the school and the unreported cases found in the homes, is of deep significance. When it is realized that one unreported and therefore unisolated case in a tenement house is a focus of infection for all the families in the house and more remotely for the neighborhood, it is evident that the probability of a child contracting a contagious disease is now greater in its home than in the school. While Io6 cases of scarlet fever were excluded from school, 185 unreported cases were found ill at their homes. The contrast is even more striking in the case of measles. Seven hundred and forty-two children were excluded from school because of early evidence of this disease, while 1,570 unreported and uncared for cases were found in their homes.

The cases of contagious eye and skin disease occurring in school children continue to show a gratifying decrease. This is particularly true of ringworm, scabies and impetigo contagiosa. There are 519 public schools under medical inspection. On an average, eight

CHILD HYGIENE.

cases of ringworm were found in each school, five cases of scabies and twenty cases of impetigo. Pediculosis is still unduly prevalent, constant reinfection taking place at home from other members of the family. On an average, eight inspections of each school child were made during the year.

Physical Defects.

The number of cases of physical defects discovered is shown in the subjoined tables. It was impossible to obtain treatment for but a very small number of those presenting defective teeth on account of the lack of facilities for free dental treatment. These facilities will be considerably increased during the ensuing year through the free dental clinics to be established by the department. A definite decrease has been noted in the occurrence of all physical defects and the total decrease in the past four years since systematic efforts have been made to induce the parents of these children to place them under treatment is evidence of the efficacy of this work.

Clinics for School Children.

The budget appropriation for 1912 rendered possible the establishment of six dispensaries for the free treatment of school children. In these dispensaries no child is treated whose parents are able to pay for the services of a physician. The clinics have been placed in those locations lacking dispensary facilities and services are maintained for the estimation of refraction in cases presenting defective vision, for the treatment of contagious eye diseases, and for medical and operative treatment of the nose and throat. They were opened as early in the year as proper buildings could be rented and equipped, but owing to the restrictions of the building and fire laws, provision for hospital service could not be instituted until late in the year. In all cases operated upon, whether for trachoma or for the removal of adenoids and hypertrophied tonsils, the child is kept in the hospital during the

CHILD HYGIENE.

night preceding and following the operation, and all operations are performed under general anæsthesia. Six clinics have been established, two in the Borough of Manhattan, three in the Borough of Brooklyn, and one in the Borough of The Bronx. During the year operations were performed at only one clinic. Each dispensary is in a separate building, equipped with clinical facilities and hospital accommodations for operative cases. For the work performed at these institutions the subjoined tables should be consulted. The need of these clinics has been thoroughly demonstrated, and it is not possible for them to care for more than a fraction of the children referred by the school inspectors. Hospital facilities will be provided in each clinic early in 1913 and this will furnish the more extensive opportunities for operations upon the tonsils and adenoids which are so greatly needed.

Issuing of Employment Certificates.

During the early part of 1912, each child applying for an employment certificate was examined at the school attended, and the application was denied if the physical health of the child did not reach the required standard. On October 1st, an amendment to the Child Labor Law became effective and required that the results of these physical examinations should be recorded on a special form provided by the State Department of Labor. In order that the examinations might be carried on more systematically, a special corps of physicians and nurses was assigned and an examination room was provided in each borough office. The physical condition of a child upon leaving school and beginning to work exercises an important bearing upon his future welfare. When a physical defect is discovered, or ill health not immediately amenable to treatment is present, the application for an employment certificate is denied. When it is probable that proper medical attention will result in recovery, the case is referred to a school nurse, and the application is withheld pending a reëxamination of the child's physical condition.

The law requires that a child must have attended school for a definite period previous to his fourteenth birthday or to the date of his application for an employment certificate. Unfamiliarity with this law causes the issuance by teachers of unacceptable records of attendance, but the number of applications which are denied for this reason is steadily decreasing as the law's requirements are becoming better known.

Issuance of Employment Certificates—Mercantile Statistics.

97

The number of applications denied on account of insufficient education is slowly decreasing. It may be debatable whether certain children who have not succeeded in acquiring even the rudiments of an education at fourteen years of age should be required to remain in school, still their dismissal from school attendance is not in accord with the law. The physiological activity of children of this age demands expression and most school curricula seem to provide no outlet for their physical unrest. Vocational training must eventually fill this need and its provision will undoubtedly lessen the number of applicants for employment certificates not only among those who are unable to progress further in the subjects taught in the schools, but also among those who, having passed the grade required by law, leave school and go to work, not from economic necessity but because the school course no longer provides for their physiological need of physical expression. The number of applications denied on account of insufficient education during 1912 showed a slight decrease as compared with 1911.

The cases in which applications were denied on account of physical incapacity were, so far as possible, kept under extended observation and referred to physicians or dispensaries for proper treatment and care.

DIVISION OF HOSPITALS.

The highest census of the year was reached during April, when there were 1,214 cases in the hospitals of the Department of Health, distributed as follows:

| Willard Parker Hospital | 476 |
|--------------------------|-----|
| Kingston Avenue Hospital | |
| Riverside Hospital | 387 |

The highest census in any one hospital occurred during May, when there were 501 cases at the Willard Parker Hospital. During 1912, the death rate, speaking generally, has been reduced about one per cent. in scarlet fever and measles, and about three per cent. in diphtheria. During the year, two new cement tuberculosis pavilions, with a capacity of 160 beds, were erected at Riverside Hospital on North Brother Island. These buildings will be ready for occupancy about March I, 1913. During the year, cement pavilion No. 4 was opened to patients, thereby adding 80 beds to the capacity of the hospital. A heating plant, entirely new, consisting of a boiler house, with four new boilers, with a capacity of 360 additional horse-power, and a pipe gallery containing the high pressure steam, hot water and return lines to every building on the island, have recently been constructed. In February, the two Croton water mains coming from the mainland were frozen for seven weeks, and during this period the only water obtained was conveyed to the island by the department's boats. This experience showed the necessity of immediately replacing the old and worn-out water mains with new. The Department of Water Supply, Gas and Electricity furnished the pipe and pipe fitters, and the Commissioner of Corrections supplied laborers from among the convicts from the Riker's Island penitentiary. A complete water system, with eight-inch mains, was installed, and it should be noted that the installation, which, under contract, would have cost many thousands of dollars, was accomplished with a minimum cost to the city.

The steamboats of the department have been overhauled and repaired. A new measles pavilion, with a capacity of 320 beds, is in process of erection at the Willard Parker Hospital. At Willard Parker Hospital there is also in course of construction an underground pipe gallery which will contain the high pressure steam, hot water and return lines connecting the boiler house with all the buildings of the plant. In September, the interior of the Drug Laboratory was destroyed by fire, but this building has been repaired, entirely by departmental labor, and is now in as good condition as it was before the fire.

At the Kingston Avenue Hospital, a new isolation building, with a capacity of 80 beds, is now in course of construction, and a new sewer plant, by means of which the sewage, which up to this time has been collected in a settling tank and pumped therefrom to the Clarkson street sewer, will be conveyed to a septic tank on the department's property at the northeast corner of Albany avenue and Hawthorne street whence the effluent will be pumped to the sewer on Clarkson street.

Kingston Avenue Hospital.—1912.

HOSPITALS.

OTISVILLE SANATORIUM.

The year 1912 was marked by considerable activity in the building of new pavilions and by the alteration of existing buildings in order to accommodate additional patients. The new pavilions were commenced at the female unit and will soon be ready for occupancy. The excavations for another building are well under way and will probably be ready to receive patients early in the summer of 1913. The upper floor will be used for a maternity ward, the lower floor for children. These buildings, when completed, will increase the census of this unit by 120 beds. The porches of four male pavilions and one female pavilion were equipped with partitions five and a half feet high, dividing them into cubicles of sufficient size to hold two beds each. The large tent of the female unit which accommodates 16 children was converted into a permanent structure during the summer. An incinerator is in process of installation at the male unit and will serve the purposes of the tent colony.

An active effort is being made to increase the output of the chicken farm. Facilities are at hand at present to care for one thousand hens. Three houses, each of which will accommodate 700 chickens, are in process of construction, and will be ready for the spring hatching. They can be used to house laying hens after the brooding season is over. All the labor of excavating, the cement work of the sides and floors, and a part of the carpenter work of these buildings will be performed by patients.

During the fall of 1911, the former laundry, a frame structure, was burned. A modern fire-proof building to replace it is nearing completion. The large dining hall at the female unit was completed during 1912. Plans for perfecting the water supply were matured during the year and a tunnel, piercing the high hill at the rear of the plant and connecting the forty-acre reservoir on the top with the lines to the buildings, is well under way. This reservoir, which is thoroughly protected from any source of contamination, is to be dredged in the near future. Fire hydrants are being placed at various points about the grounds and weekly fire drills are held. An up-to-date fire alarm system was installed during the winter of 1911–1912.

For the purposes of treatment, the patients are divided into groups, each of which comprises fifty-five to seventy-five members, with a specially trained medical man in charge. This arrangement assures to the patients all the personal attention possible in any but the very smallest institutions.

A new laboratory for research work in tuberculosis is to be established in the antitoxin department. With the abundance of clinical material at hand some very valuable results should be obtained.

DIVISION OF LABORATORIES

The Division of Laboratories is divided into two subdivisions, the Bacteriological and Chemical Laboratories. In the bacteriological laboratories a considerable portion of the time is devoted to research work concerning problems of a practical nature applicable to the prevention or treatment of disease. In addition, an enormous amount of routine work is performed.

Because of the small force of chemists, the Chemical Laboratory necessarily devotes most of its work to the routine chemical examinations made for the Department of Health and for the Police Department. Whenever possible, some research work is undertaken.

WORK PERFORMED AT THE BACTERIOLOGICAL LABORATORIES.

Bacteriological examinations of some forty thousand samples of milk have been made in order to detect the conditions under which milk is produced, transported and sold. A special investigation of the pasteurization of milk and of the effectiveness of the forms of apparatus employed has been conducted. Examinations of water have also been made daily in order to determine the wholesomeness of wells and of the many other supplies which come under the jurisdiction of the Department of Health. This has included the examination of water supplies at farms furnishing the city with milk and of the water covering oyster beds. So great is the importance of the typhoid carrier on milk farms that wherever any suggestion of peril is found, stools of the men employed at the farms are examined as soon as possible for typhoid bacilli.

The Research Laboratory has produced for free distribution, as in past years, all the products used by the city in the work of preventive medicine, such as diphtheria antitoxin, tetanus antitoxin, antimeningitis serum, antistreptococcus serum, pasteur vaccine, vaccine for smallpox and the bacterial vaccines. The laboratories supplied most of the serum employed in the epidemic of cerebrospinal meningitis in Texas and the Southwest.

During August and September the city was threatened with bubonic plague through possible importation of the infected rats from Porto Rico. In order to insure that any infection that might have taken place should be eradicated, some 3,000 rats were caught on the wharves and carefully examined. Fortunately, no infection was found in them.

The two important new fields of activity undertaken during the year have embraced the investigation of trachoma and infectious eye diseases, and have made available the application of the Wassermann reaction in all cases in New York City in which a suspicion of syphilis or latent gonorrhœa exists.

TRACHOMA STUDIES.

These studies concerning the specific cause and prevention of trachoma have given such evidence as to make the outlook most encouraging for a speedy solution of this problem. It has been demonstrated that:

1. Practically all cases of so-called trachoma (granular and papillary conjunctivitis) in the public schools of New York City have been apparently cured within a year when cases have been seen at or near beginning of disease.

2. With careful treatment of all cases of acute conjunctivitis in homes, clinics and schools, the cases of papillary and granular conjunctivitis have become markedly fewer in number.

3. Prophylactic and curative treatment of these eye conditions has been greatly

LABORATORIES.

helped by providing special classes in schools for these cases, where they may be under direct and continuous control.

The chief practical point made emphatic in these studies is that all acute cases should have greater care, i. e., they should have more frequent home visiting; there should be frequent examination for infection of other members of the family and continued inspection of the home after the cases are cured. An ophthalmia school has been started.

ESTABLISHMENT OF SERODIAGNOSTIC LABORATORY.

In compliance with sections 4, 5 and 6 of the resolutions regarding venereal diseases adopted by the New York Board of Health on February 29, 1912, a serodiagnostic laboratory for making the Wassermann test for syphilis and the complement fixation test for gonorrhœa was officially established at the Research Laboratory on May I, 1912. This was done for a double purpose; first, to gain information of the prevalence of these diseases, and secondly, to help the individual case by giving information which would aid in diagnosis and treatment. This test is so difficult and costly that the poor are not able to avail themselves of it unaided. The amount of this work has exceeded all expectations.

A diagnostic clinic for collecting blood specimens in cases in which physicians do not care to collect the blood themselves was held every Monday and Thursday from 9 a. m. to I p. m.

During 1912 the average attendance at the clinic was fifteen daily.

Outfits for the use of physicians desiring to collect blood specimens in their offices and at the patients' homes, were prepared and distributed to the Department Supply Stations.

In October, 1912, after a large number of preliminary tests had been successfully performed, the complement fixation test for glanders was added to the work of the serological laboratory. From May 1, 1912, to January 1, 1913, 3,988 sera were tested for syphilis and 384 for gonorrhœa. Diagnostic examinations of smears for gonococci were continued in all cases of suspected vaginitis.

During the months of October, November and December, 1912, 552 specimens of horse sera were tested for glanders.

The Division of Preventive Medicine, which was added to the laboratory two years ago, has responded to all calls from physicians requesting that experts be sent to administer the laboratory products in the homes of the sick. This feature has been of great service to both the physicians and their patients, especially in cases of suspected meningitis. The laboratory bacteriologists and diagnosticians have been able to differentiate certain forms of meningitis from poliomyelitis and so have been able to aid in the diagnosis and treatment of these conditions. It is interesting to note that the general employment of diphtheria antitoxin prepared in the laboratory of the Department of Health has reduced the death rate in diphtheria to the lowest in the history of the city.

EXPERIMENTAL WORK.

A number of important experimental researches have been inaugurated, the results of which will be utilized during 1913.

Extensive studies have been instituted in regard to the most efficient procedure concerning the point (intravenous, intraperitoneal, subcutaneous) of injection of cells in animals in order to produce specific immunity and the results obtained promise a solution of the question. Also studies have been made upon the rate and degree of absorption of antitoxin of different protein concentrations when given subcutaneously. These have shown that the department's preparation of antitoxin could with safety be even more concentrated than at present. Studies have been continued upon the chemical character of diphtheria antitoxin, etc.

A series of cases of pneumonia has been treated with a serum produced in the laboratory. The results have encouraged us to employ it more extensively during 1913. The

methods of the transmission of scarlet fever, typhus fever and of hydrophobia have been carefully studied during the year. The knowledge that the virus of rabies will pass through stone filters is one of the important results of these studies.

A final report of our investigations on the relation of bovine infection to human tuberculosis was made. This has attracted a great deal of attention and aided very much in establishing the relation of tuberculosis in cattle to that of man. Other subjects taken under investigation were Vincent's Angina and Noma. The routine work is briefly summed up in the tables.

VACCINE LABORATORY.

The method of obtaining seed for vaccinating calves which was devised early in 1911, and was used extensively during the last eight months of that year, was employed during the entire year of 1912 with eminently satisfactory results. There were no failures, the yield of virus per calf was increased by 37% over 1911, and 51% over 1910, and the life of the virus was almost uniformly long so that practically none of it was wasted. It was thus possible to reduce the number of calves vaccinated from 124 in 1910, and 89 in 1911, to 48 in 1912. A further reduction in the number of calves vaccinated and a corresponding increase in output per calf is expected during 1913. During the latter part of the year a new style of package for the capillary tubes of vaccine virus was devised, the improved package to be substituted for the old style early in 1913.

CHEMICAL LABORATORY.

The court work for the Police Department is constantly increasing and takes up much valuable time. The following table shows the number of half days of attendance at court required by the health department and police department respectively during the years 1911 and 1912.

BUREAU OF RECORDS

VITAL STATISTICS OF NEW YORK CITY FOR THE YEAR Ending December 31, 1912

-

POPULATION.

The population of the City of New York, according to the State Census of 1905, was 4,014,304 and to the Federal Census of 1910 was 4,766,883, an increase of 752,579. Assuming that the geometric rate of increase prevailing in the quinquennium 1905–1910 has been maintained since 1910, the estimated population of the City of New York on July 1, 1912 was 5,173,064, divided among the five boroughs as follows:

| Manhattan | |
|-----------|---------|
| The Bronx | |
| Brooklyn. | |
| Queens | 334,297 |
| Richmond | 92,669 |

The table on next page shows the population of the City of New York in 1900 and 1910 according to the Federal Censuses, arranged by age groups.

It is to be noted that the percentage under one year is less in 1910 than in 1900. This is due probably to an incomplete census return for infants under one year in 1910. In this year there were 129,080 births reported. Assuming 98 per cent. of births were reported, 130,382 births occurred. There were 16,215 deaths under one year during 1910, leaving a probable population of 114,167 under one year as against census figures, 110,524. In estimating this number the question of emigration and immigration of those under one year was not considered as figures were not obtainable.

The percentage of children under five years of age is stated as 10.6, the lowest reported in at least two generations, that of 1865 having been 13.1, that of 1875, 12.3, the censuses following showing a percentage varying between 11.5 and 11.6: between the ages 5 to 19 the percentage is given as 27.5 as against 27.9 in 1900; between 20 to 64 the percentage is 58.4, one-tenth of one per cent. less than in 1900, and at age grouping 65 and over the percentage rose from 2.79 in 1900 to 2.83 in 1910.

The following table shows the excess of males or females for different age periods in year 1910 in New York City.

| | Excess of Males. | Excess of Females. |
|--|---------------------|-----------------------|
| Under I year. I to 4 years | 2,828 | |
| 5 to 9 years. 10 to 14 years. 15 to 19 years. 20 to 24 years. | | I,235 25,474 |

ANNUAL REPORT OF THE DEPARTMENT OF HEALTH.

The excess of males up to five years is due probably to the natural excess of male births over female births. Then, as the more venturesome male loses his life more often than the less exposed female, an excess of females begins to appear and continues to increase up to the twenty-fifth year. It is likely, however, that a good deal of the apparent excess of females from 15 to 24 is due to the placing of their ages in this period by females who are older than 25, and in a slight degree to the lessened female mortality at this age group. After 25, the immigration of males causes an excess in the male population up to 55. Then again, the more exposed life of the males and their greater mortality reduce their number so that after 55 the females are again in excess. On the whole, the excess $(2\frac{1}{2})$ of females amounts in absolute numbers to 1,919, or one-fiftieth of one per cent.

BIRTHS.

There were reported during 1912, in the City of New York, 135,655 births, giving a rate of 26.22 per 1,000 of population. The births and rates by boroughs are as follows:

| | Births. | Rate per 1,000 |
|-------------------|------------------|----------------|
| Manhattan | 66,249 | 27.17 |
| The BronxBrooklyn | 13,676 45,454 | 25.74 25.58 |
| Queens | 8,002 | 23.93 |
| Richmond | 2,274 | 24.54 |

The birth rates for the City of New York for the preceding ten years are as follows:

| 1903 | 25.06 |
|------|-------|
| 1904 | 25.52 |
| 1905 | 25.80 |
| 1906 | 26.83 |
| 1907 | 27.98 |
| 1908 | 28.39 |
| 1909 | 26.54 |
| 1910 | 26.87 |
| 1911 | 27.00 |
| 1912 | 26,22 |

It must be borne in mind that the City of New York has never had a complete registration of all the births occurring within its limits and that it is only within the past seven years that the percentage of registration has reached 95 to 98. The decrease in the birth rate is due chiefly to the avoidance of motherhood by many of the married females, especially those of native birth, and if it were not for the presence of the foreign mother, the birth rate would approximate the death rate. The following crude birth rates per 1,000, of the nationalities mentioned emphasize this view strongly: the rate per 1,000 of entire native population in the year just passed was 17, of the Italian population 88, Russian and Polish 53, Irish 31, Swedish 27. Compared by a more accurate standard, that is, the rate per 1,000 females between the ages 15 to 45, to the native mother is credited a birth rate of 29 against 112 to the foreign mother, almost in proportion of I to 4: other factors in the decreasing birth rate are the postponement of marriage to a later age, and the degree of financial prosperity among the community in general.

| Foreign Cities. | Rate per 1,000. | American Cities. | Rate per 1,000. |
|-----------------|--------------------|-------------------|-----------------|
| Amsterdam | 23.06 | Baltimore | 20.01 |
| Berlin | 20.26 | Boston | 25.32 |
| Birmingham | 26.05 | Buffalo | 26.05 |
| Edinburgh | 20.86 | Detroit | 29.20 |
| Genoa | 20.07 | Cincinnati | 20.57 |
| Liverpool | 29.56 | Cleveland | 21.86 |
| London | 24.67 | Pittsburgh | 26.00 |
| Milan | 22.88 | San Francisco | 14.93 |
| Paris | 16.81 | St. Louis | 20.79 |
| Stockholm | 20.86 | Washington, D. C. | 19.85 |

The birth rates for 1912 of some large cities of the world are as follows:

It is evident from the above table that the birth rate of the city compares more than favorably with that of the large cities of the world, and only one of the foreign cities given in the table possesses a rate higher than that of New York; it must be admitted that several of the American cities given in the table do not possess even approximately complete registration of births.

In 1912, the number of children recorded as born of native mothers was 43,685; of foreign mothers 91,970; or 32.2% of the births were of native mothers and 67.8 of foreign. Of the 91,970 births of foreign mothers, 30,044 or 32.7% were of Italian mothers, 25,714 or 28.0% Russian-Polish, 14,221 or 15.5% Austrian, 7,842 or 8.5% Irish, 4,160 or 4.5% German, and 9,989 or 10.8% of other foreign mothers.

As usual, there were more males born than females, the males numbering 69,425, the females 66,230. There were reported 2,416 births of colored children, 24 births of Chinese children, 2,017 births of apparently illegitimate children, 1,330 pairs of twins and 9 sets of triplets; 82,912 births were attended by physicians and 52,743 by midwives.

STILL-BIRTHS.

During 1912, there were reported 6,619 still-births, or a rate of 1.28 per 1,000. These occurred during the different months of uterogestation, as follows:

| | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | Not Stated. |
|-------------------------|-----|-----|-----|-----|------|------|------|-------|-----|----------------|
| Number of still-births. | 32 | 132 | 289 | 590 | 781 | 927 | 756 | 2,808 | 255 | 48 |
| Per cent | .48 | 2.0 | 4•4 | 8.9 | 11.8 | 14.0 | 11.4 | 42.4 | 3.9 | 0.7 |

MARRIAGES.

The number of marriages reported during 1912 was 51,703, during 1911, 48,765, making an increase for 1912 of 2,938. The marriage rate per 1,000 of population in 1912 was 9.99 against 9.79 in 1911, an increase of .20 of a point.

Of males married there were 47,446 single, 3,826 widowed, and 431 divorced. Of females, 47,768 were single, 3,346 widowed and 589 divorced. There were married 67 bachelors out of every 1,000 above fifteen years of age, as compared with 77 spinsters, that is, 11 out of every 1,000 spinsters married either widowers or divorced men, the number of bachelors marrying widows or divorcees not being of sufficient number to affect the conclusion just stated. Out of every 1,000 widowers 61 remarried, while only 18 widows did likewise; the marriage rates of divorced men (140 out of every 1,000) and of

divorced women (113 out of every 1,000) are rather high and are in measure dependent upon the misstatements made to the census enumerators by divorcees, who prefer to be numbered among the single or widowed; 20 white females married negroes and 5 white females married Chinamen.

Of 51,703 couples married, 10,436 males and 11,672 females were native born, and 21,344 males and 20,108 females were foreign born; 8,269 marriages were performed by Catholic clergymen, 6,915 by Protestant, 8,920 by Jewish, and 23 by the leader of the Society of Ethical Culture; 7,611 couples were married by aldermen and 42 by judges.

DEATHS.

There were 73,008 deaths reported in the City during 1912, equivalent to a death rate of 14.11 per 1,000 of the population, against a rate of 15.13 in 1911, a decrease of 1.02 points. The rates of the various boroughs in 1912, based upon the number of deaths reported therein were: Manhattan 14.99, The Bronx 13.07, Brooklyn 13.50, Queens 11.90, and Richmond 16.64. The rates based upon the correction of the deaths for borough of residence were: Manhattan 14.91, The Bronx 12.01, Brooklyn 13.79, Queens 12.78, and Richmond 15.33, this last high rate being due to two factors, first the presence of a large number of residents at advanced ages among whom high death rates prevail and the presence of two large institutions, the inmates of which come from towns and cities outside New York, and whose deaths cannot be distributed at present to the cities whence the decedents came.

The number of deaths that actually occurred in the city in 1912 was 73,100, an increase of 92 over the number reported, the death rate for the former mortality being 14.13, an increase of .02 of a point from all causes of death: the rate from specific diseases, such as tuberculosis, cancer and pneumonia, etc., being affected only in the fourth integer. The chief reason for the adoption of the reported and not the actual mortality is the saving of time in the issuance of the monthly, quarterly and annual reports. The table on next page shows the difference between the reported and actual number of deaths from all causes and from certain prominent diseases in the various boroughs and city.

As the age groupings of the population of the city have remained fairly constant since the organization of the Board of Health in 1866, it is fair to make comparison of the rates of the present with those of the past years. The rate per 1,000 of the population in the area covered by the present city in the decennium 1868-77 was 27.17, in the following decennia 25.27, 23.62 and 19.17 respectively; in the quinquennium, 1908 to 1912, the rate fell to 15.51 and if compared with the rates of the foregoing decennia in the order given, a reduction of 43 per cent., 39 per cent., 34 per cent., and 19 per cent. will be found.

The table on page 19 shows the increased or decreased mortality at various age groups of the year 1912, compared with that of the three years 1909 to 1911. The greatest gain is to be found at the age group under five years and is in harmony with the greatly decreased mortality at this age during the past forty years; the number of lives gained at other individual age groupings is insignificant in comparison; at the ages 70 to 75 years among males and 80 to 85 years among females there was a slight loss of life.

Complete Life Table for City.

On pages 176–177 will be found a complete life table based upon the mortality of the years 1909–1911 and the population returns of the Federal Census of 1910; on page 178 will be found a copy of the American Experience Table of Mortality upon which are based in a measure the rates charged in insuring lives, the latter table representing the probabilities of living of individuals, chiefly males, who have been insured after medical examination, and usually termed selected lives.

A comparison of the male table based upon the experience of the individuals living in the City of New York with that of the American Table based upon medical examination, shows that at all ages up to 78 years the selected lives can look forward to an increased

Comparative Mortality of City of New York, During the Three Years, 1900 to 1911, and Year 1912, With Gain or Loss in Number of Lives and Years of Life.

VITAL STATISTICS.

after lifetime of several years. After 78 years of age the difference is slightly in favor of the unselected lives.

The table on page 160 gives the population, deaths and death rates for the Greater City since its formation in 1898.

DEATH RATE.

The death rate from all causes reached the lowest level on record, 14.11 per 1,000, a decrease of 1.02 points compared with that of 1912 and of 3.90 points compared with the average rate of the preceding fourteen years, this latter fall in the rate being equivalent to a saving of 20,174 lives during the year 1912.

MORTALITY UNDER FIVE YEARS OF AGE.

In 1912 the rate was 38.3 per 1,000 children living at these ages, a decrease of 3.8 points compared with that of 1911 and a decrease of 17.1 points compared with the average rate for the preceding fourteen years, in this latter comparison a reduction of 33 per cent. The death rate of children under five years of age is considered by demographers as a most trustworthy index of the sanitary conditions prevalent in a community, and this excellent showing is due in great measure to the steps taken by the sanitary officials to minimize the mortality among children, especially from the infectious diseases of childhood, to wit, measles, scarlet fever, diphtheria and croup and diarrhead diseases.

Typhoid Fever.

The lowest mortality ever recorded in the city from this cause took place in 1912, the rate being 10 per 100,000 as against 11 in 1911 and 16 for the average preceding four-teen years.

MALARIAL FEVERS.

Twenty deaths were reported from malarial fevers in 1912 as compared with 38 in 1911 and 250 in 1898. This decrease is due in great measure to the more accurate certification of causes of death on the part of physicians, who are aided in their diagnoses by the free examination of blood by the department in all suspected cases of malarial and typhoid fever.

SMALLPOX.

Two deaths were reported from smallpox during the year against three reported in 1911. During the past ten years 49 deaths have occurred in the city from this cause, a yearly average of almost five.

MEASLES.

There were 671 deaths and a rate of 13 per 100,000 of the population reported in 1912 against 659 deaths and the same rate in 1911. The average rate for the preceding fourteen years was 18.5, that of 1912 showing a decrease of 5.5 points. Out of 671 deaths in the city, 631 or 94 per cent. were at ages below five years, the greatest mortality occurring at one year of age. The Borough of The Bronx showed a mortality of 9, Brooklyn 11, Queens 12, Richmond 13, and Manhattan 15, per 100,000 of the population.

SCARLET FEVER.

There were 615 deaths and a rate of 12 per 100,000 recorded in 1912, as against 741 deaths and a rate of 15 in 1911, a decrease of 126 deaths and 3 points in the rate; the average rate for the preceding fourteen years was 20, the rate for 1912 showing a decrease of 8 points per 100,000 of population, a saving of 413 lives from this cause. This is one of the lowest rates on record, and is the same as that occurring in 1905 and 1906. Out of 615 deaths from this cause, 550 or almost 90 per cent. were below the age of 10 years, the greatest mortality occurring between the ages of five and ten years. The three larger boroughs, Manhattan, Brooklyn and The Bronx, had each the same mortality, 12 per 100,000; that of Queens and Richmond showed the much lower mortality of 7 per 100,000.

DIPHTHERIA AND CROUP.

There were 1,125 deaths and a rate of 22 per 100,000 reported during the year, against 1,281 deaths and a rate of 26 per 100,000 in 1911, a decrease of 4 points: the average rate for the preceding fourteen years was 47, the rate for 1912 thus showing a decrease of 53 per cent. in the mortality. At the ages under 10 years, 1,071 deaths were reported out of a total of 1,125 at all ages, constituting 95 per cent. of all deaths, the greatest mortality, as in measles, occurring at one year of age.

WHOOPING COUGH.

The deaths and death rates from whooping cough were 287 and 5 per 100,000 respectively, in the year 1912, against 384 deaths and a rate of 8 in 1911, a decrease of 97 deaths and 3 points; the rate from 1898 to 1911 inclusive was 10.6 per 100,000, the rate for 1912 showing a decrease of 53 per cent. Out of the total of 287 deaths, 132 were of male and 155 of female children, whooping cough being one of the few causes of death in which the mortality is greater among females than among males. Ninety-five per cent. of all deaths occurred during the first five years of life; 55 per cent. occurred before arrival at the first year of life.

PULMONARY TUBERCULOSIS.

There were 8,591 deaths and a rate of 166 per 100,000 of the population as against 8,790 deaths and a rate of 176 during 1911, a decrease of 199 deaths and 10 points. The average rate for the preceding 14 years was 211, the rate in 1912 showing a decrease of 45 points, or a saving of 2,328 lives. By reason of the presence of large institutions in the Boroughs of The Bronx and Richmond, a majority of whose inmates are afflicted with tuberculosis and who are residents of other boroughs, the death rates uncorrected for the borough of residence are misleading. The uncorrected rate for the Borough of Manhattan was 169, the corrected 189 per 100,000; the Borough of The Bronx had an uncorrected rate of 297 and a corrected rate of 146; Brooklyn's uncorrected rate was increased from 137 to 148; Queens' from 107 to 133, while that of Richmond was lowered from 148 to 137 per 100,000. Out of 8,591 deaths, the males numbered 5,673, the females, 2,918; the number of deaths under 5 years for both sexes was 144 or less than 2 per cent. of the total; among the males the greatest mortality took place at 35 to 40 years of age, 909 deaths or 16 per cent. of all males' deaths; between the ages of 20 and 50 the male deaths numbered 4,221 or 75 per cent, of the male deaths at all ages; among the females the greatest mortality was found at the age groups 20 to 25 years and 25 to 30 years, the number of deaths reported at each of these age groups being exactly the same, namely, 444 deaths; between the ages of 20 to 50 years the female deaths numbered 2,118 or 73 per cent. of the female deaths at all ages. There were 297 deaths of colored males and 199 of colored females reported, the rate for the colored males based on population figures of Census of 1910, being 705, and colored females 401 per 100,000, that of both sexes being 540 per 100,000. These rates contrast strongly with those of the white males and females based upon the population figures of the Census of 1910, the white males giving a rate of 230 and white females a rate of 125 per 100,000 of each sex, that of both sexes being 178 per 100,000.

EFFECTS OF MARRIAGE UPON TUBERCULOSIS MORTALITY.

At ages 15 to 24 years the rate was 146 among the single males and 121 among the married males, the widowers at this age being so few that rates would be misleading; at this same age group the rate among single females was 106, married females 174 and widowed 353, this last rate being rather questionable. The rate of total mortality at this age group was 144 for males and 122 for females. At ages 25 to 44 the rates among the single, married and widowed males were 545, 233 and 1,148 respectively, and among single, married and widowed females, 172, 163 and 358. The rate of total mortality at this age group was 344 for males and 176 for females. At ages 45 years and over the rates among

single, married and widowed males were 1,196, 249 and 637 respectively, and among single, married and widowed females, 175, 109 and 1,556 respectively. The rate of total mortality at this age group was 403 for the males and 133 for the females. At all ages over 15 years the total mortality according to civil condition was represented by a death rate of 348 among bachelors, 233 among married men, 750 among widowers, 130 among spinsters, 151 among married women and 344 among widows.

The death rate of males, irrespective of marriage at ages above 15 years was 301 per 100,000 against a rate of 149 among females. It is evident that the death rates of single males at each age group are greatly in excess of the married males, being almost two and a half times as great at the ages 25 to 44 years and five times as great at ages 45 years and over. On the other hand, the mortality among widowers at 25 to 44 years is slightly more than double that of the bachelors and five times that of the benedicts, and at ages 45 years and over is one-half that of the bachelors and two and a half times that of benedicts.

Among females no such decided contrasts in the mortality rates appear as among males. The single female presents a lower mortality at ages 15 to 24 years than her married sister, at ages 25 to 44, a slightly increased mortality, and at 45 years and over a considerably increased mortality. Widows present a mortality treble that of the single and double that of the married at ages 15 to 24, double that of single and of married at ages 25 to 44, and a slightly decreased mortality compared with single and a considerably increased mortality compared with married at ages 45 years and over.

ACUTE RESPIRATORY DISEASES.

There were 10,711 deaths reported and a rate of 207 per 100,000 during 1912 from bronchitis and pneumonia combined, as compared with 10,932 and a rate of 220 per 100,000 in 1911, a decrease of 221 deaths and 13 points. The average rate from these combined causes for the fourteen years 1898–1911 inclusive, was 290, the rate of 1912 being 83 points lower, equivalent to a saving of 4,293 lives.

DIARRHŒAL DISEASES UNDER FIVE YEARS OF AGE.

There were 4,149 deaths and a rate of 760 per 100,000 children living at those ages in the year 1912, as compared with 4,696 deaths and a rate of 890 in 1911, a decrease of 547 deaths and 130 points in the rate. The average rate for the fourteen years 1898–1911 was 1302 per 100,000 children, the rate for 1912 showing a decrease of 542 points.

CANCER.

There were 4,071 deaths and a rate of 79 per 100,000 reported during the year, as compared with 3,873 deaths and a rate of 78 during 1911, an increase of 198 deaths and of 1 point in the rate. The average rate for the fourteen years 1898–1911 was 70 per 100,000, the rate for 1912 showing an increase of 9 points. The question is often asked, "Is this increase an actual one, or is it due to the more accurate and complete diagnoses of the disease as ^B result of advanced technique and greater knowledge of the cause of cancer?"

The following table shows the deaths and death rates at ages over 35 years from cancer of various organs and parts of the body for the years 1901 and 1912:

| |] | 901. | 1 | 912. |
|-------------------------------------|-----------|-----------------------------|---------|-----------------------------|
| | Deaths. | Death Rates Per 100,000. | Deaths. | Death Rates Per 100,000. |
| Cancer of mouth, tongue, lips, etc | 104 | 7 | 146 | 7 |
| Cancer of stomach and liver | 987 | 70 | 1,589 | 77 |
| Cancer of intestines and peritoneum | 324 56 | 24 | 575 | 28 |
| Cancer of skin | 56 | 4 | 66 | 3 |
| *Cancer of uterus | 379 | 54 | 564 | 56 |
| *Cancer of breast | 206 | 30 | 337 | 33 |
| Cancer of other organs | 349 | 25 | 639 | 31 |
| *Non-cancerous tumors of uterus and | | | | |
| ovaries | 158 | 22 | 115 | II |

* Rate per 100,000 females.

122

A perusal of the above table will show that of all the visible and accessible cancers, the only variety showing a slight increase in the rate in the past eleven years is that of eancer of the breast, the other accessible cancers (as cancer of the mouth, tongue and skin) show a rate the same as that of eleven years ago. Cancer of the uterus, which might be termed an accessible form, shows an increase of 2 points per 100,000, but if the non-cancerous tumors of the female genital organs be grouped with the cancerous the result will be a decrease in the rate of 9 points per 100,000: undoubtedly, some of the non-cancerous tumors of the womb have been by reason of more accurate diagnosis transferred of recent years to the cancerous variety. On the other hand, cancers of the inaccessible variety such as those of the stomach, liver, intestines, spleen, bladder and kidney, show an increased death rate leading us to conclude that the increase in all cancer is due in great measure to more careful and accurate diagnoses and certification on the part of the physicians.

INFLUENCE OF MARRIAGE UPON CANCER.

Cancer being a disease of advanced life, that is, over forty-five years of age, a few words as to influence of civil condition. The single males at ages over 45 years show a mortality of 326 per 100,000 living at those ages as compared with a rate of 280 among married men and 575 among widowers, so that the married man at middle and advanced age is less liable to death from cancer. The single females at ages over 45 years have a rate of 449 per 100,000 living at those ages, as against 347 among the married females and 571 among widows, the rate among married females indicating less liability to death from cancer than among spinsters and widows.

ORGANIC HEART AND KIDNEY DISEASE.

These two diseases by reason of the frequency with which they are given conjointly as causes of death, and the lack of uniformity of procedure as to assignment of one or the other as the chief or determining cause, should be combined in discussion of mortality from each.

In 1912 there were reported 14,614 deaths and a rate of 285 per 100,000, as compared with 13,072 deaths and a rate of 262 in 1911. The average rate for the fourteen years 1898–1911 inclusive was 274 per 100,000, the rate for 1912 showing an increase of 11 points.

In the decennium 1878–1887 the rate from these combined causes was 195 per 100,000, in the next decennium it rose to 244, in that of 1898–1907 it reached 278, and in the quinquennium 1908–1912 it retrograded to 269.

INFANT MORTALITY.

This is expressed as a ratio to every one thousand births reported in cities and countries where the registration of births is fairly complete; in this city the number of births received is estimated at 98 per cent. of the total occurring. The number of infants under one year of age dying in the year 1912 was 14,289 with a death rate of 105 per 1,000 births, against 15,053 deaths and a rate of 112 in 1911. This is the lowest infant death rate ever recorded in the city. On a previous page is given the excellent showing of the city as to infant mortality compared with that of various large foreign and domestic cities.

The following table shows the infant mortality in the city at subdivisions of this age for fifty-two weeks of 1912, from all causes and diarrhœal diseases:

| Ages. | All Causes. | Diarrhœal Diseases. |
|------------------------------|----------------|---------------------|
| Under I month | 5,165 | 281 |
| I month and under 2 months | 1,430 | 378 |
| 2 months and under 3 months | I,I44 | 42 I |
| 3 months and under 6 months | 2,539 | 1,030 762 |
| 6 months and under 9 months | 2,132 1,801 | 762 |
| 9 months and under 12 months | 1,801 | 507 |
| Total under I year | 14,211 | 3,379 |

Out of every one thousand deaths under one year of age in 1912 from all causes, 363 died before the completion of the first month of life, 544 before the age of three months was reached, and 723 before attaining six months of life.

The following table gives the causes of death under one year of age and the percentages of all deaths occurring at this age in the city for 1909:

| Causes. | Number of Deaths. | Per Cent. of Total. |
|--|---|--|
| All causes. Congenital. Diarrhœal. Acute respiratory. Contagious. Tuberculosis. Convulsions. Syphilis. Erysipelas. Violence. Meningitis. Other causes. | 5,477 3,392 3,226 506 291 221 217 154 130 92 | 100.0 38.3 23.7 22.6 3.5 2.0 1.5 1.5 1.5 1.1 0.9 0.6 4.1 |

In 1912 almost 2 out of every 5 children that died under one year of age were doomed to death by reason of congenital defects, either from malformations of the heart, brain, spine or other organs, from prematurity, from inherited weakness, difficulty in delivery, etc.; the probability of living among these defectives was zero.

Over 46 per cent. of the total mortality was due to diarrhœal and acute respiratory diseases. Eighteen male and thirteen female infants under one year of age were victims of homicide.

The table on page 198 gives the mortality per 1,000 infants living in the former City of New York, present Boroughs of Manhattan and The Bronx, for a series of years, and shows considerable reductions in the death rate from the various causes specified therein with the exception of syphilis, which shows a material increase.

SEARCHES AND TRANSCRIPTS.

Since 1904 the work of making searches and issuing transcripts of the records has increased tremendously. Previous to 1904 the only searches made without cost was in the event of application for employment certificates between the ages of 14 and 16 years, but the rule of the Superintendent of the Department of Education, compelling every child entering school to obtain a certificate of birth from the Department of Health had the effect of increasing the searches from 36,074 in 1903 to 68,824 in 1904.

In 1912 over 110,000 free searches of the records of birth were made, 63,000 of which were for school and the remainder for employment purposes. In addition, the paid searches increased from 27,340 in 1902 to 62,784 in 1912; the number of paid transcripts issued in 1912 was 58,541. Of these over 45,000 were copies of certificates of death, over 8,000 of certificates of birth, and almost 5,000 certificates of marriage.

U. S. Department of Agriculture Weather Bureau.

NEW YORK, N. Y.

ANNUAL METEOROLOGICAL SUMMARY 1912

With Comparative Data.

ANNUAL SUMMARY.

January and February, with a total of 17 hours with temperatures of zero or lower were unusually cold. In the last 18 years this record has been exceeded only by 1904 with 18 hours in January, and by 1899 with 22 hours in February. Temperature departures were small from March to September, but October, November and December were sufficiently warm to compensate for January and February, so that at the close of the year there was a slight accumulated excess in temperature. The annual range was 96°, from -3°, January 13, to 93°, July 8. There were no long periods of extremely hot weather such as occurred in the summer of 1911.

Precipitation was deficient, except in March, April, May, October and December. The total, 38.50 inches is 6.26 below normal. This is the fifth consecutive year with deficient precipitation, the accumulated deficiency for this period being 22.75 inches. Rainy days, totaling 119 are 9 less than normal, but days with one inch or more of rain, totaling 11, are exactly normal. There were three periods of 15 days each without measurable precipitation.

The average hourly wind movement, 17.7 miles, seems extraordinary when compared with the normal, 11.5, but this difference is probably almost entirely due to a change in the elevation and exposure of the anemometer on May 1, 1911, from 350 feet at 100 Broadway to 454 feet at 17 Battery Place.

Records were broken, February 22 for highest wind velocity at this station, April 23 for highest wind velocity in April, and September 30 for lowest temperature in September.

WEATHER BY MONTHS.

January—Extreme temperature fluctuations and cold weather were features of the month in striking contrast with the unusually mild December preceding. The first cold wave, 5th—6th was moderate. The second, from a temperature of 46° at midnight of the 8th, reached a minimum of -3° at 6:30 a. m. of the 13th, the first zero weather since January 24, 1907. In the third cold wave the temperature fell from 38° at 2 p. m. of the 15th to 1° at 9 a. m. of the 16th; and in the fourth, from 52° at 10 a. m. of the 19th to 15° at 7 a. m. next day. The mean temperature, 23.5° is 6.7° below normal and is the lowest January mean since 1893. The period, 5th—17th with a mean of 16.6° is the coldest 13-day period in the last 42 years, except January 10th—22nd, 1893 with a mean of 14.5° . By the 13th the Hudson River was frozen over solid at Yonkers—said to be the first time since 1893. Precipitation occurred on 15 days, three more than the average, but the total, 1.86 inches, is less than half the normal amount. There was snow on the ground during 19 days, the heaviest fall, 3.0 inches, occurring on the 12th.

February—Was continuously and at times severely cold from the 3rd to 14th. In the only well defined cold wave, the temperature fell from 25° at 1 p. m. of the 9th to -2° at 7 a. m. of the 10th. The period, 16th—26th was generally warm for the season. The mean 28.4° is 2.3° below normal. Precipitation was deficient. The 15 days, 5th—19th, were without measurable amount. The only measurable snowfall was 1.8 inches on the 4th. The ground was practically bare of snow after the 7th. An unprecedented windstorm occurred on the 21st—23rd. On the 22nd the average hourly movement was 58 miles. For 5 minutes ending 1:13 a. m. of the 22nd, the average was 96 miles per hour, the highest of record, and two miles were recorded at the rate of 120 miles per hour. The damage from this storm to shipping in the harbor was considerable.

March—Opened cold with temperatures constantly below freezing till the 7th. The periods, 12th—20th and 27th—31st were notably warm. Between was a well defined cold wave, the temperature falling from 54° at 9 a. m. of the 20th to 22° at midnight of the 21st. The monthly mean, 36.8° is 0.7° below normal. Measurable percipitation occurred on 16 days, the total, 5.68 inches, being 1.58 above normal. The 20th–25th, 6 days, is the longest period during the year with precipitation on consecutive days. Heavy rains on the 12th, 13th, 24th and 29th, on frozen ground, resulted in unusually heavy run-off, filling storage reservoirs and causing considerable damage from surface erosion. Snow fell on the 5th, 6th and 12th, and snow and sleet on the 21st and 23rd. The ground was snow covered only on the 5th, 6th and 21st. Windstorms of importance occurred on the 12th—13th, 15th—16th and 29th. The highest velocity was 78 miles from the southwest on the 15th.

A pril—Showery weather was the rule—16 days, five more than normal, being "rainy," but the total precipitation, 3.61 inches, is only 0.31 above normal. Much of this rain occurred at night. Thunderstorms occurred on the 2nd, 18th, 19th, 23rd and 27th. A warm wave, 5th—7th, reached its high point, 74° at 4 p. m. of the 6th. It was followed by a drop from 70° at 1 p. m. of the 7th, to 30° on the morning of the 8th. Another warm spell, 15th—16th, was followed by much colder on the 17th. The month closed cold. The mean, 49.0° is 0.9° above normal. Important windstorms occurred on the 3rd, 7th—9th, 23rd—24th and 27th—28th. That of the 23rd was severe. The maximum velocity in this storm and for the month was 84 miles from the northwest at 9:25 a. in., the highest of record for April.

May—Mild temperatures with ample and well distributed showers occurring mainly at night, made May nearly an ideal month. The mean temperature, 60.7° is 1.4° above normal. A warm period, 19th—21st, culminated in a temperature of 84°, the highest of the month, at 3 p. m. on the 21st. The total precipitation, 3.94 inches, is 0.76 above normal. During the rainy period, 5th—9th, 1.86 inches fell in 24 hours on the 7th—8th.

June—Precipitation was deficient, the total for the month, I.17 inches, being practically one-third of the normal. Excepting a shower of 0.16 on the 25th there was no measurable rainfall after the 17th. By the close of the month, vegetation was suffering and short pastures resulted in a great decrease in the milk supply for the city. Warm periods are shown, Ist—4th and 2Ist—26th, with a single hot day—the 29th on which the temperature reached 93°, the highest of the month. The periods, 5th—Ioth and I4th—I5th were cool. The mean temperature was nearly normal. Sunshine was much above normal, there being nine days with Ioo per cent.

July—The first 10 days were without measurable precipitation. Frequent showers during the next 10 days and a heavy rain, 1.91 inches, on the 21st, relieved the drought considerably. Of this rain on the 21st, 1.85 inches fell in two hours. This is one of the most intense rainfalls on record for this station. (See table, page 12.) The 3rd—12th and 14th—17th were generally warm with temperatures above 90° on the 8th, 9th, 10th and

16th. The rest of the month was cool. The mean, 74.0° is only 0.5° above normal. The per cent. of sunshine was 76, there being 8 days with 100 per cent.

August—Cool weather prevailed the first 10 days; then moderately warm, 11th— 15th; cool 16th—17th; warm 18th—22nd and 25th—26th; and cool 27th—31st. The mean, 70.7° is 1.5° below normal. Showers were well distributed and more frequent than normal, but generally light; the total amount, 2.77 inches, being but 61 per cent. of the normal. Heavy showers on the 19th totaled 1.17 inches. Thunderstorms occurred on 8 days, three more than the normal for August.

September—Opened cool but the temperature rose gradually to the maximum for the month, 88° on the 11th. The weather turned much cooler on the 12th, but returned to normal on the 14th. After the 20th it was continuously cool, and the minimum, 39° on the 30th, established a new low record for September. The mean, 65.9° is 0.6° below normal. The 17 cloudy days equal the record for cloudy days in September. Sunshine was correspondingly deficient. Precipitation was well distributed, and practically normal in frequency and amount.

October—From September 26th to October 10th, 15 days, no measurable rainfall occurred. Moderate rain on the 11th was followed by another period of 10 days without measurable precipitation. On the 23rd—24th, 3.77 inches occurred within 24 hours, 2.26 of which fell in two hours. (See table, page 12.) The total for the month, 4.32, is 0.61 above normal. The month was generally warm, averaging 58.5° —2.9° above normal, with cool periods, 1st—3rd, 8th—9th, 15th—17th, and 24th—25th. The highest, 79° on the 7th, and lowest, 40° on the 16th, are well within the extremes for October. Sunshine, 70 per cent. of the possible, is 12 per cent. above normal; 12 days show 100 per cent. sunshine. The maximum wind velocity of 60 miles from the northwest occurred on the 15th.

November—Warm waves on the 6th—7th, 11th—13th and 21st—22nd, with moderately cool periods between, were features of the month. The mean, 46.6° is 2.6° above normal. Precipitation was deficient in both frequency and amount. A moderately heavy rain, 1.09 inches, occurred on the 7th. The first appreciable snowfall of autumn, 0.8 inch, occurred on Thanksgiving day, the 28th, and disappeared the following day. The 24th— 25th were windy with a maximum of 60 miles, the highest of the month, on the 25th. Total possible sunshine occurred on 9 days.

December—Excepting the periods, 8th—9th, 11th—13th and 23rd—25th, mild temperatures prevailed. The mean, 38.5°, has been exceeded but four times in 42 years. The lowest, 17° on the 9th, is a high minimum for December. The mean humidity, 67 per cent., is the lowest of record. The only measurable snow occurred on the 24th. From 2 a. m. to 11 a. m. the rate of fall was more than an inch per hour. The total, 11.8 inches, is exceeded in December only by the 14-inch fall of 26th—27th, 1890. It melted rapidly and disappeared with a heavy, warm rain on the 30th. The period, 7th—16th was without appreciable precipitation. A severe windstorm occurred 27th—28th,—highest velocity 72 miles northwest.

MISCELLANEOUS DATA FOR 1912.

Barometric Pressure (reduced to sea-level)—Mean, 30.02 inches; highest, 30.65 inches, March 3rd; lowest, 29.23 inches, April 2nd.

Temperature—Greatest daily range, 36 degrees, January 9th; least daily range 5 degrees, May 7th.

Greatest monthly range, 60 degrees, February; least monthly range, 35 degrees, July. Highest mean temperature of three consecutive days, 83 degrees, July 8th to 10th; lowest mean temperature of three consecutive days, 10² degrees, February 10th to 12th.

Precipitation—Longest period without a measurable amount of precipitation (.01 in. or more), 15 days, February 5th to 19th, June 26th to July 10th and September 26th to October 10th, inclusive.

Greatest number of consecutive days with precipitation (.oI in. or more) 6 days, March 20th to 25th, inclusive.

Snow—Greatest snowfall in 24 hours, 11.5 inches, December 24th.

Greatest depth of snow on the ground, measured at 8 p. m., 11.0 inches, December 24th. Last snow in spring occurred on April 29th; first snow in autumn occurred on November 24th.

Frost—In Spring: last killing frost occurred on April 9th. No frost recorded subsequent to last killing.

In Autumn: first killing frost occurred on November 3rd, and no frost occurred before first killing.

Thunderstorms-First, February 26th; last, November 24th.

Hail-May 9th.

VITAL STATISTICS.

187

SUMMARIES FOR THE YEARS 1790 TO 1912, INCLUSIVE.

The following tables have been compiled from the records of the Health Departments of New York and Brooklyn before consolidation into the present City of New York. The New York tables, therefore, present the statistics of the present boroughs of Manhattan and The Bronx, and the Brooklyn tables those of the present Borough of Brooklyn. It has been found impossible to prepare similar tables for the boroughs of Queens and Richmond:

Former New York (Boroughs of Manhattan and the Bronx).

Estimated Population, Deaths, Births and Marriages, from 1790 to 1912, Inclusive.

* Previous to 1880 most of the deaths caused by illuminating gas were supposed to be intentional and were classed with suicides. Since that year the deaths believed to be accidental have been separated from the others.

Deaths from Small-pox, Cholera, Yellow Fever and Hydrophobia, in New York City, from 1804 to 1912, inclusive.

Deaths from Small-pox, Cholera, Yellow Fever and Hydrophobia, in New York City, from 1804 to 1912, inclusive.—(Continued.)

* The number of deaths from Yellow Fever in the year 1798, as reported to Mayor Varick, was 714.

† In 1874 there was a death reported as due to Hyssophobia in addition to the 5 deaths from Hydrophobia. ‡ Vaccinating Corps organized September 27, 1874, under act of Legislature passed June 15, 1874.

Note.—These diseases have been selected from the confessedly imperfect records of the years preceding the organization of the Health Department as being diseases of such bold characteristics and exciting so great public interest as to make it probable that the record of them is complete.

Marriages Reported by Months, Former New York City, since 1866.
