The Immutable Law of Progression

NATURE abhors stagnation and has established laws which render it impossible; we must make progress either forward or backward, and it is always more difficult to measure this progress in ourselves than in others. We are prone to criticize our neighbor or competitor as to his progress, but do we often apply the same cold scrutiny to ourselves? In nothing can we better gauge our progress than in critically studying something that we wrote last year or five years ago. Have we traveled away beyond it in straight thinking, in diction and in real knowledge, or are we somewhat startled, not to say alarmed, by the feeling that we are slipping---that we are incapable of keeping up the pace set by ourselves? It is good for us all to check up on our available mental assets from time to time. In this way only are we likely to forestall mental bankruptcy.—Robert Pollock, M.D., (Bulletin, San Diego County Medical Society.)

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

The author of an article appearing in the JOURNAL *is entirely responsible for all statements and conclusions. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the language and method of presenting their subjects. All manuscripts will be carefully read, but editorial privileges will be exercised only to a very limited extent. It is believed that the manner of presentation of any subject by any author determines to no small degree the value of his conclusions. Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented by the author as little disturbed as possible by the editors. However, the right to reduce or reject any article is always reserved.*

ERYTHEMA INDURATUM*

(Report of a case treated with tuberculin and the Kromayer Lamp.)

By H. E. ALDERSON, M. D. and H. C. COE, M. D.
(From the skin clinic, Stanford University Medical School, San Francisco.)

This case of erythema induratum is reported because of the good results obtained in treatment with tuberculin and ultraviolet light.

The patient, an American schoolgirl, referred by P. H. Pierson, complained of ulcers on both legs of two months' duration. The lesions had first appeared as nodules in the skin, which were neither painful nor tender. These nodules gradually broke down, leaving indolent ulcers characteristic of the disease.

The family history disclosed the fact that the father had had similar ulcers on his legs thirty years ago. There was no history of syphilis or tuberculosis in the family. The patient had never been in contact with tuberculosis, as far as she knew. There was nothing in the patient's past history which could influence her present illness.

Physical examination showed a well-developed, very well nourished young woman 16 years of age. The pulse and temperature were normal. The thyroid gland was slightly enlarged, but there were no signs of toxicity. In the right anterior cervical region there was an enlarged lymph gland, about 1 cm. in diameter. It was firm and not adherent to surrounding structures. The tonsillar fossae were clean. Tonsillectomy had been thoroughly done nine years prior to examination. The heart and circulation were normal. There was some harshness to the breath sounds at both hilus regions; otherwise, the lungs were negative and the abdomen and extremities presented nothing abnormal excepting the leg ulcers.

The ulcers were situated on the lower third of both legs. There were four on the left leg (two on the anterior surface, one on the medial aspect, and another on the posterior surface). There was one ulcer on the anterior surface of the right leg. They were irregularly annular in shape, and about 4 cm. in diameter. The ulcers were fairly deep, the edges somewhat raised and crusted, but fairly clean-cut. The bases were covered with a serosanguineous exudate and some necrotic tissue. They were not tender nor acutely inflamed.

Laboratory examinations showed a normal blood count and a negative urine. The Wassermann test was negative in two laboratories. Smears were made from the edges of the ulcers and stained for tubercle bacilli, but none were found.

X-ray plates of the chest showed calcified glands at each hilus and a pleural scar across the apex. This, with the enlarged cervical gland pointed toward past tuberculosis.

The history and appearance of the lesions established the diagnosis of erythema induratum (Bazin). The patient was given a course of tuberculin injections as outlined below by P. H. Pierson, and we administered the Kromayer lamp treatment.

Tuberculin O. T. was given in increasing doses, the dosage being regulated according to local and focal reactions and the patient's temperature. The dosage varied from .001 mgms. to .02 mgms. The smaller doses were given three times a week and the larger ones twice a week.

The Kromayer lamp was applied twice a week without lens, the window of the lamp being held as closely as possible to the ulcer without actual contact. The exposure was for 15 seconds.

About two weeks after beginning treatment a focal reaction was noticed about the ulcers. They became larger and were surrounded by a zone of hyperemia. The patient said the lesions were painful and they were tender to touch. A month later the edges of the ulcers were clean and smooth, healthy granulations covered the bases, and epithelium began to grow in from the edges. In four months the lesions were completely healed. The

* Read before Section on Dermatology at the State meeting, at San Francisco, June 22, 1923.

patient was last seen a few days before reading this paper, four months after the ulcers healed. She has no new lesions and the smooth purplish scars, the remains of the ulcers, are beginning to fade.

A survey of the literature shows that tuberculin has been successfully used by others in the treatment of erythema induratum. In 1909 Clark reported on the therapeutic value of tuberculin in this disease. Fordyce in 1911 reported improvement in a case thus treated, and MacKee in 1913 reported the cure of a case. The Kroymayer lamp as a local application has also given therapeutic results. Recently, Oliver reports cures in five cases of non-ulcerated erythema induratum by the application of the lamp with pressure over the nodules for a one-minute exposure.

SUMMARY

Ulcers on the legs of a young woman were diagnosed as lesions of erythema induratum. The patient was treated with tuberculin and the lesions with ultraviolet light by the means of the Kromayer lamp. Lesions were completely healed in four months. They have remained healed and there have been no new lesions.

240 Stockton St.

DISCUSSION

Edward D. Lovejoy, Brockman Building, Los Angeles—The paper of Alderson and Coe is a valuable contribution, in that they have added to our knowledge of treatment and results of treatment. It is only by collecting such data that we can come to a just evaluation of the methods at our command in the care of dermatological diseases. Far too many reports are wasted because we do not consider a single case or small group of cases of sufficient value to publish, but in the present instance this report added to the previous ones by Clark, Fordyce, Mackee, and Oliver makes an increasing collection from which valuable facts may be later deducted.

Erythema induratum has always been difficult to bring to an ultimate cure, relapses being of frequent occurrence even with the use of tuberculin combined with the local dressings and cleansing of the ulcers which we have previously employed, but the report of Alderson and Coe makes us hopeful that the combination of treatment here employed may serve to destroy the cause and prevent recurrence.

In regard to the case itself, the author leaves us a little in doubt as to whether he considers the focal reaction due to the tuberculin injection or the Kromayer lamp, and also if any change was made in the treatment or frequency of the treatment following the appearance of the reaction.

John C. Yates, Watts Building, San Diego—I wish to acknowledge, in the discussion of paper by Alderson and Coe, of a case of erythema induratum. It is rather difficult to know where to start, as they give us very little to start upon. I appreciate very much the report of one case, as it brings us into more intimate contact with the patient than where the statistics are given of one hundred cases, or perhaps more. I have never been satisfied from my contact with the various writers on this subject, that all are agreed as to its being a tubercular condition, primarily; that is, the patient is usually one having poor circulation in extremities, and the condition existing is a phlebitis, with choking of lumen of vessels by leucocytes, and tuberculosis bacilli are seldom found, although patient usually is suffering with, or has healed lesion of tuberculosis, probably from the predisposing cause, therefore giving one several possible foci of tuberculosis infection.

The laboratory findings in this case showed nothing in particular, outside of some probably healed lesions in apices; however, we will take Alderson's and Coe's diagnosis for granted.

This brings us to treatment administered, which consists of two parts—that of tuberculin internally, and light externally, the description of which is rather vague, in that the authors state the dosage was "regulated according to local and focal reaction, and the patient's temperature," and then apparently "the smaller doses were given, three times a week, and larger ones twice a week."

The treatment of erythema induratum has been conducted for several years by use of tuberculin, together with the usual care of tubercular patients, with more or less fair results; also it must be noted many of these cases tend to spontaneous recovery, at least for the time being; therefore, it comes to the consideration in the treatment of this case of the use of the violet ray as an adjunct, administered through use of the Kromayer lamp, exposure, without lens, for fifteen seconds twice weekly. The author speaks of a focal reaction occurring after two weeks, but does not specify any difference as to this reaction and what might have been from his focal reaction of tuberculin, and although you might get a reaction from Kromayer in ulcerations of any character, and by hyperemia disseminate the leucocytes, I do not feel that the exposures were of long enough duration to do this in an encrusted ulcer with a serosanguineous exudate of any amount, which must have occurred with necrotic tissue. The only question that now remains, can erythema induratum be cleared with ultra violet rays alone, or must we use tuberculin in conjunction?

Philip H. Pierson, 516 Sutter Street, San Francisco—A question was raised in regard to whether this was definitely tuberculous disease and to what has been said in regard to the existing cervical gland, scars at both hiluses and across the apices, the rather destructive type of leg ulcers. I might

add that there was a definite focal reaction in the ulcers, more redness, pain and induration following the injection of one mgr. tuberculin used for diagnostic purposes before the treatment was started.

The question has also been raised as to whether the ultra violet lamp alone would suffice in treating such a tuberculous manifestation, and to this I would say, probably not. And my reason for saying so is that you cannot treat a generalized infection with perhaps only a few superficial manifestations by local treatment only. General regulation of life, habits, diet, rest, etc., is extremely important. Also the effect of the tuberculin on the specific resistance is a great factor in preventing recurrences. I do not deprecate in the least the added help of the lamp in hastening the effect of tuberculin and general hygiene, but I feel that all should be carried out rigidly if we are to be successful both for the present and the future.

Dr. Alderson (closing) — In reply to Lovejoy's discussion we can state that months have elapsed, and the patient who has been reporting at intervals remains perfectly well. She has become a professional dancer, and is quite successful in her work. We expect to keep her under observation for several years before pronouncing her permanently cured. The focal reaction referred to was due to the tuberculin injection which phenomenon offers additional diagnostic evidence asked for by Yates. The tuberculin injections at this stage were temporarily interrupted, but the Kromayer lamp treatments were continued. Pierson has already discussed his part of the treatment. Yates' remarks regarding the sufficiency of the ultraviolet-ray exposure would be justified if the ulcers at the time of treatment were covered with crusts, but the treated surfaces were cleaned, leaving an unobstructed field for the light rays. It is now generally accepted that erythema induratum is due to the tubercle bacillus. In our opinion, a favorable result would have been observed in time from the ultraviolet light alone, but combination with the tuberculin injections brought about involution of the lesions in much less time than otherwise would have been the case.

Harry C. Coe (closing)—I believe that the questions asked by both Lovejoy and Yates have been answered by Pierson and Alderson. I might add that in the paper we referred to E. L. Oliver's recent report of cure by the use of Kromayer lamp alone in case of erythema induratum. This would answer Yates' question on that point.

Professional Pirates—Under this heading, the Financial Times, San Francisco, October 13, 1923, publishes the following editorial: "Next Wednesday (providing there is no golf match on) the State Board of Medical Examiners will summon thirteen physicians to appear and show cause why they should not be deprived of their right to practice medicine in California. Mind you, thirteen in our own State—twelve charged with performing illegal operations, and one for violation of the poison act. Very Pretty! In the mind of the editor, the three greatest professions in the world are law, the church, and medicine. A chief justice should advocate and protect the citizens with law and order. The ecclesiastic is given the rare privilege of teaching the doctrines of Christ and cementing love and tolerance. The physician, honored by degrees, should respect the humanitarian and skillful knowledge he possesses. Bringing children into the world and nursing and treating both young and old alike, when in ill health, are all a part of his duties. These three professions should be a firm foundation for all times. Should be! Now, what do we discover? The foundation is cracked and is leaky. Worms of distrust and selfish gain are eating into the concrete pillars. No penalty is too severe for this ilk. Those noble medicos, who will undoubtedly suffer through this blight brought on their profession by their so-called colleagues, should be vindicated swiftly and surely for all times.

THE TREATMENT OF ACUTE OSTEOMYELITIS*

By A. J. OCHSNER, M. D., Chicago

In discussing this subject it is of the greatest importance to direct attention to the fact that harm comes to patients suffering from acute osteomyelitis as a rule, because of the fact that the diagnosis is not made until great destruction has been done from advancement of the disease, which could have been prevented with the greatest ease had an early diagnosis been made, and to point out the reasons why the diagnosis is not made early, and to supply the remedy for this error.

In order to clearly understand the history and progress of the disease one must bear in mind the structures involved in this infection, which enters the bone through the nutrient artery and progresses through the peculiar circulatory system present in the bone. Taking as an example one of the long bones, we have in the center the medulary cavity, which is especially rich in blood vessels through which the infection can progress readily if no outlet is provided to the external surface of the extremity involved. From this cavity the vessels extend into the hard portion of the bone through the Haversian canals, which communicate in turn through the tiny canaliculi with the lacunae, and ultimately with the periosteum. The latter structure is thick and hard and difficult to perforate, consequently the infection is confined within this dense covering and backs up into adjoining portions of the marrow until ultimately the entire shaft may be involved.

On the other hand, if an exit is provided by an incision down to the bone through the periosteum, the lymph stream immediately begins to carry the infectious material away from the original location. The pressure is relieved at once, and the pain subsides immediately and the infection ceases to progress, so that there is no danger of further involvement of bone which had previously remained free from infection.

Occasionally, the primary point of infection is located immediately underneath the periosteum; especially is this true in cases in which there has been a contusion of the periosteum. In these cases an incision through the periosteum down to the bone will result in complete, permanent relief without any involvement of the bone proper. On the other hand, if this treatment is not instituted early the infection may destroy a portion of the bone before relief comes from perforation of the periosteum by pressure necroses and evacuation of the pus through an abscess in the soft tissues overlying the periosteum.

In reviewing the histories of the cases which have come under my personal observation, I have found that an early diagnosis has been made only in those cases in which a careful physical examination had been made. The delayed diagnoses were due to the fact that the trouble was looked upon by the parents, or the family physician, or both, as a case of rheumatism or growing pains, the diagnosis having been based entirely upon the fact that

* Read at the Utah Medical Association's annual meeting, Salt Lake, June, 1923.

the child complained severely from pain in one of the extremities.

A careful review of the case invariably brought out the fact that the child had suffered previously from some localized form of infection. In many cases this was present in the form of tonsillitis, fernuculosis, otitis media, sinus infection, infected dental roots, acne or some form of intestinal infection. The bacteria present varied, staphylococcus being the most common, but pneumococcus, streptococcus, colon bacillus, Klebs Loeffler bacillus and typhoid bacillus and others were present in some of the cases.

In many of the cases that come later for treatment, there are two or more varieties of microorganisms present. The cases which came under our observation early with a diagnosis had all been examined physically with great care by the family physician, with the result that it was possible to prevent the spread of the infection and that the cases recovered with the destruction of only a small amount of bone or none at all. The attack may be mild if the infection is not virulent amounting to slight pain usually near the end of one of the long bones, but occurring at times in any bone of the entire skeleton.

In other cases the attack may be extremely violent so that the patient may suffer extreme pain within a few hours after the beginning of the attack. The temperature may rise rapidly to exceed 103 degrees F., and there may be a high leucocyte count, although it is dangerous and foolish to postpone operation in any case because of a low leucocyte count.

The symptom, however, which is of supreme importance, is the pain upon pressure over the portion of the bone involved. It is difficult to overlook an acute osteomyelitis, if one carefully goes over the bone with pressure. The area which is painful upon pressure may be absolutely circumscribed in very early cases, while later on it will extend over a larger area and may extend over the entire bone, but whenever pain is present upon pressure immediate surgical interference is indicated, and the less time is wasted the better.

One form of preliminary examination should be condemned in the most vigorous terms in cases in which a diagnosis of acute osteomyelitis has been made upon physical examination. I refer to the X-ray examination. Many cases are not operated early because an X-ray examination fails to show an abnormal condition. In these cases usually repeated X-ray examinations are made until one shows the presence of a sequestrum or until external swelling indicates the presence of the underlying infection. By that time the amount of destruction is much greater than it was when the patient was first examined, and when by the simple physical examination a positive diagnosis could have been made. Unfortunately, the fact that the X-ray is most valuable in determining the extent of necrosis in cases of chronic osteomyelitis has given the impression that it is also valuable in acute cases, and has caused this foolish practice to be employed to the great harm of many patients. It should never be employed in any case in which drainage has not already been provided by the splitting of the periosteum over the entire area over which the bone is tender upon pressure and at least 2 or 3 cm. beyond, above and below.

This is the treatment that should be instituted at once upon making a diagnosis of acute osteomyelitis, and the diagnosis should be made at once upon finding tenderness over the bone upon pressure, and every case should at once be examined by making pressure upon the bone from end to end as soon as a patient complains of pain in one of the extremities.

Under no condition should time be wasted in obtaining X-ray plates, and if for any reason an X-ray plate is made because it is demanded by the family or by some stupid consultant, a negative result should never prevent an immediate operation, which should never go beyond splitting all the overlying tissues through the periosteum down to the bone. The incision should always be very free, so that there can be free escape of lymph which will carry with it the infectious material. This can be materially increased by the application of a large dressing saturated with a saturated solution of boric acid in hot water covered with oiled silk or some other impermeable dressing. Additional solution should be added every three to twelve hours. Within half an hour after the application of these dressings of saturated solution of boric acid, the boric acid can be demonstrated in the patient's urine. Whether this fact is of any importance in the treatment has not been definitely proven, but it is an interesting fact.

As a rule, the operation for acute osteomyelitis should go no further than the free splitting of the periosteum because this will stop the progress of the disease, and many times a portion of bone which appears to be in a hopeless condition will recover entirely or in part if left in place. Moreover, these patients are often extremely ill at the time of operation, and many deaths have occurred from the shock caused by an extensive operation which could have been avoided had the patient not been exposed to the unnecessary trauma.

Moreover, even in cases in which a large portion of a bone is in a hopeless condition at the primary operation, if left in place it will serve as a splint for the development of an involucrum, which will in turn replace the bone and leave the extremity in a very much better condition than it would be if the dead bone had been removed at the original operation. Occasionally, but very rarely, an exception may be made in a case in which there is only a very small circumscribed point of severe tenderness. In such a case there may be a small circumscribed abscess surrounding an infarct, which may have been discovered very early. In these rare cases one may properly use a very sharp gauge after incising and reflecting the periosteum and then, without traumatizing the bone, one may cut out the overlying bone and carefully evacuate the small abscess with a sharp curette. The number of cases in which this form of treatment is indicated is, however, extremely small.

After the patient has recovered from the operation for acute osteomyelitis, one should invariably try to determine the primary location of the infec-

tion. We have met many cases in which recurrent osteomyelitis was apparently due to the fact that the patient had infected tonsils, which had been overlooked, or infected roots of teeth or sinus infection, but most commonly the infection seemed to be located in the tonsils; sometimes these were small and buried, but contained abscesses which could not be demonstrated until the tonsils were removed. For a number of years we have made it a routine practice to remove the tonsils in all cases of acute or chronic osteomyelitis. Many of these cases suffer from chronic furunculosis or chronic acne.

Among these cases who suffer from furunculosis there are many who eat great quantities of sugar, which seems to predispose to the formation of superficial infection which in turn may supply the infectious material which is carried by the circulation into the bones causing osteomyelitis. These patients should give up the use of sugar in every form.

CONCLUSIONS

My experience, which covers a series of more than 200 histories, 151 of which I have analyzed, will justify the following conclusions:

1. In every patient suffering from pain in any bone, the latter should be carefully palpated at once.

2. Pain upon pressure over a bone indicates the presence of osteomyelitis or periostitis.

3. The earlier this is demonstrated the less destruction will occur if operated immediately.

4. The operation should consist in splitting the overlying tissues down to the bone through the periosteum.

5. The incision should extend beyond the painful area above and below.

6. The periosteum should be loosened to 1 or 2 cm. on each side of the incision.

7. As a rule, this should be the extent of the primary operation.

8. In rare cases of very circumscribed infection, the infectious area may be very carefully excised, care being taken not to spread the infection by rough handling of gauge, which should be very sharp.

9. Hot, moist dressings with electric light treatment hastens recovery.

10. The shaft of long bones should never be removed until involucrum has been formed.

11. The primary focus of infection should always be determined if possible.

12. As soon as the patient has recovered from the acute operation, the primary focus of infection should be removed if possible.

2106 Sedgwick Street.

For Rent—Something New. Just what you have been looking for. Studio offices complete, with apt. conveniences. . . . They are suitable for chiropractor, musical, dramatic or academic instructor, osteopaths, hairdresser or **similar** professional lines.

A CASE OF SIMULATED PREGNANCY AND DELIVERY

By A. D. ELLSWORTH, Fresno

Cases are not rare in which a woman, for any one of a variety of motives or for none at all, deceives herself or attempts to deceive others in the belief that she is pregnant. It is much more unusual to meet with cases in which the pretense is made that delivery has taken place.

The motive in such cases is usually apparent, such as to obtain damages, to compel marriage, or to gain admission to a charitable institution and, as a rule, the claim is made that delivery was more or less remote, or at least not very recent. There seem to be no cases reported in which the affair has been staged in quite as elaborate a manner as in the present case, which is all the more surprising when we consider that the chief actress in the drama was an ignorant Mexican woman who had never had children.

A word of explanation as to her motive. It is almost unheard of for a Mexican woman of this type to seek or to produce an abortion; their desire is to have large families of children, who are to them a sort of insurance against want in old age. Women who have had as many as seven children will come to the doctor to find out what is the trouble that they do not have more. When a woman of this class is married, if she does not soon begin to produce this form of insurance, there is very apt to be trouble in the family.

In this case the young woman, after being married a few months, had evidently announced that she was pregnant. Later, when she found she was mistaken, she sought for some means by which she could find the "easiest way out."

The history given, which was, of course, partly fictitious, was as follows:

M. F., age 25, had never had any children. She had been married eleven months. Her last period had been in April or May (she was not sure which), which would make her at this time five or six months pregnant. She said that the day before she had been standing on a box reaching for something on a shelf, when she fell, striking the floor in a sitting position. This was at 4 o'clock in the afternoon, and nothing further had happened until 3 o'clock the next morning, at which time she said she had had a severe, prolonged pain and had passed a mass of tissue, which was shown me for examination.

In the poor light which was available, this might easily have been mistaken for an afterbirth. One feature, however, demanded inquiry, and that was how there could be so well developed an umbilical cord, but no foetus. She had not been to an old-fashioned toilet, and there seemed no other way of accounting for the absence of the foetus.

Although it is better, I believe, not to make any vaginal examination in such cases, at least in the midst of such unsanitary surroundings, yet here was a case in which it seemed to be imperative. Accordingly, a vaginal examination was made with a sterile glove. There was no softening or relaxation of the perineum, the cervix was hard and undilated, and the fundus was in the normal non-pregnant position.

The mass of tissue was taken away for further examination, and, in order that there might be no question, was sectioned and examined under the microscope.

Here is what this ignorant Mexican woman had done. She had taken a pig's liver, and on the undersurface of this she had punched a couple of holes. Through these she had passed a piece of pig's intestine, one end of which was then split; through the opening thus made she had passed the other end of the piece of intestine, and the loop thus formed had been drawn up tight, so that this "cord," which was about eight inches in length, appeared to come directly from the liver substance without any knot being apparent. Along with this work of art she had included a couple of collapsed lungs, evidently also from the pig, which served in the role of blood-clots.

As there seemed nothing to gain by undeceiving her family, they are still under the impression that a most unfortunate miscarriage has taken place.

A FEW NOTES ON HALLE'S CLINIC, WITH ESPECIAL REFERENCE TO HIS ENDONASAL SURGERY*

By ROBERT D. COHN, M. D., San Francisco

On my leaving Berlin this summer, after having spent a couple of months at Halle's clinic, it appeared to me a matter of regret that Halle's varied and important contributions to rhino-laryngology, especially operative, during the past ten to fifteen years had thus far not appeared in book-form and were accessible only in scattered journal articles and society reports, as well as to some extent in recent text-books. Halle stated that such a book is in preparation, but that owing to conditions in Germany its publication in the immediate future seemed far from assured. He had the kindness to place at my disposal his numerous reprints. These and my own observations and jottings are the basis of these notes.

Turbinectomy—Halle does no turbinectomies. Conchotomes and turbinectomy scissors are under the ban in his clinic. With its menace of subsequent rhinitis atrophica and pharyngitis sicca, he considers turbinectomy "unphysiological mutilation." He cuts off hypertrophied tips, but never sacrifies the structure proper. In operating in the upper and posterior parts of the nasal chamber he does not amputate the middle turbinate, but secures through its temporary subluxation the necessary space in which to operate.

Submucous Septum Resection—This is the most frequent of all the operations done. There is first of all the usual indication of impaired nasal respiration *per se*. In addition to that, Halle, as early as 1900 (Zur Behandlung des Empyems der Highmoreshoehle, Berl. Klin. Woch. 1900, No. 35), advanced the theory that normal nasal respiration is the main essential for the cure of acute and chronic empyemas, especially of the antrum and sphenoid, respiratory air being necessary for the mucous membranes not only of the nose itself, but likewise of the sinuses. He believes that the normal respiratory air current, both inspiratory and expiratory, by negative pressure draws the sinus fluids from the sinuses; that this air moreover is antiseptic and, acting by suction, tends to dry out the cavities. Hence, many empyemas, especially antral, are cured spontaneously as soon as normal nasal respiratory conditions are restored. As, furthermore, almost all intranasal operations performed require a maximum of operative space, a septum correction almost invariably precedes the various operative procedures described below.

The septum correction in adults is always done under local anesthesia and its technique except in one point is that practiced by American rhinologists. The incision is a slight modification of that of Killian. The cartilage is removed with a straight Ballenger swivel knife, is then pared down somewhat and thereupon reimplanted, the septum flap being sutured with Halle's own crook-shaped needle. Infection and septum abscess are not feared.

As to the operation in children, Halle believes that it should be done only exceptionally before the twelfth year. However, he has frequently operated upon children of 8 and some as young as 4. In the last-named cases the operation was under general anesthesia; in children from 8 upward he operates, as a rule, under local anesthesia.

Operation for Closing of Septum Perforation—This was first reported, with demonstration of cases, to the Berlin Laryngological Society in 1919 and published in the "Monatsschrift fuer Ohrenheilkunde" in 1921. Up to that time Halle had done the operation in 60 cases, with reported complete success in 56 and incomplete in 4. The operation is a modification of the Yankauer plastic and consists in the formation of two or three small flaps along the lower edge of the perforation, which are turned into it and partially close it. A large semi-circular flap is then outlined above the perforation and, after being displaced downward so as completely to cover the perforation and the smaller lower flaps, is carefully sutured in place. Tampons in the opposite side serve to press the smaller flaps against it until union ensues. The crescent-shaped defect resulting in the septum above heals promptly by epithelization. A good description of the operation is to be found in Passow and Claus's "Operationen am Gehoergang, an den Tonsillen und in der Nase," Leipzig, 1923.

The operation is easy in the reading and difficult in the performing. In the one case that I witnessed the operation was done on a man of 30 for a traumatic perforation, the result of an earlier septum correction. Although local anesthesia was perfect and the patient exceptionally tractable, the operation even in Halle's hands was difficult, tedious and troublesome.

Endonasal Frontal Sinus Operation—This is Halle's chef d'oeuvre, his main contribution to rhinological surgery. It is based upon the earlier operation of Fletcher Ingals, and was developed in the years just before 1910. Halle's technique is very briefly as follows: After the usual cocaine-novocaine anesthetization the middle turbinate is subluxated toward the septum. A large muco-periosteal flap corresponding to the entire region in

* Read before the San Francisco County Medical Society, November 27, 1923.

front of the middle turbinate is then made by means of three incisions: the first from the head of the middle turbinate upward to the roof of the nose, the second extending thence along the roof of the nose to the piriform aperture, the third thence along the free edge of the aperture to the head of the inferior turbinate. The flap thus made is turned down over the inferior turbinate. The agger narium is now chiseled away, whereupon the anterior ethmoid cells and the opening into the frontal sinus come into view. With Halle's blunt-headed pear-shaped electric burrs this opening is now enlarged with ease and, above all, with safety. The frontal sinus is then curetted, the muco-periosteal flap thereupon replaced, and the nose packed. The usual simple post-operative treatment follows. A broad permanent communication between the frontal sinus and the nose results, normal natural drainage is restored, and ideal conditions are created for whatever subsequent irrigations and the like may be necessary.

Halle has never claimed that his intranasal method could or would supplant all external operations. As a matter of fact, in 1910, when he reported his first series of nineteen cases (Berl. Laryngol. Gesellschaft, November, 1910), he merely modestly hoped that in certain cases the external operation would thereby be rendered unnecessary and that within its limitations his procedure would not be without benefit. Since then his series has grown from 19 to over 850, and in the light of his experience in the past twelve years he now believes that in chronic frontal sinusitis no external operation whatever is at any time necessary in almost 95 per cent of all cases. He states that the Killian operation, which for over twenty years alone dominated the field and was the undisputed operation of choice, now no longer holds that position. Due to the uncertainty of its final results and the hazards of its outcome cosmetically, it shares, in common with all other similar external frontal sinus operations, ever-increasing disfavor.

Ethmoid Operation — Halle's present ethmoid technique, which he first reported in 1914, is as follows: The middle turbinate is subluxated and pressed tightly against the septum, whereby an unobstructed view of the middle meatus is obtained. With a long, narrow knife two sagittal incisions are made, one just under and along the lateral surface of the middle turbinate, the other along the medial surface of the lamina papyracea, both meeting at the head of the middle turbinate. The ethmoid cells within the area thus defined can now be removed with safety with punch forceps and curette, provided the operator remains within the lines of the two incisions, the middle turbinate acting as a safety-wall against injury to the cribiform plate.

This method suffices for the opening and exenteration of the middle and posterior ethmoid, not for the anterior, however. Halle exposes and obtains access to this latter, including the infundibular cells, by means of the muco-periosteal flap described above. He therefore, as a rule, clears out the anterior ethmoid cells in the course of his frontal sinus operation.

Sphenoid Operation—Halle refers to the relative rarity of sphenoid disease. He states that in some years he does not see a single chronic sphenoid empyema and that up to 1922 he had operated only thirty-four cases. While he finds that in general a more or less extensive removal of the anterior wall suffices, in some cases of long standing with pronounced degeneration of the mucosa, the opening, however large, tends to close. In these cases he makes two flaps in the shape of an H, the lower flap as large as possible. After the anterior and a large part of the inferior wall have been removed (the latter by means of his pear-shaped burr) the two flaps are turned into the cavity, where they are kept in place with small tampons.

Radical Antrum Operation—In conformity with his principle of performing all nasal operations as far as possible intranasally, Halle confines himself almost entirely to the Canfield-Sturmann method. This method obviates the necessity of an oral incision with the possibility of a subsequent fistula, the post-operative reaction is minimal, the patient can eat and drink immediately after the operation, and after-treatment through the mouth is avoided.

Blindness Following Injections into Orbit—Halle warns insistently against all pre-operative injections into the orbit. After having reported two cases of his own in which, following such injections, immediate total blindness resulted, in March, 1923, he reported four further such tragic cases in the practice of others, but coming to his notice. He believes the condition due to an acute edema in the region of the optic foramen. Precisely such a case came under my observation while at Halle's clinic: In a young girl of 18, an injection of 2 or 3 ccm. of ½ per cent novocaine had been made into the left cheek just below the lower orbital ridge preliminary to a left antral operation. By a mischance the needle probably entered the inferior orbital canal. A few moments later there followed extreme swelling of the lids and total amaurosis of the left eye with enlarged immobile pupil. Halle immediately made a number of broad and deep incisions into the orbit above and below, including a broad opening of the orbital periosteum. Great haste was necessary, he stated, as a few hours' delay would undoubtedly result in permanent blindness. On the removal of the bandage on the following morning the patient, to the relief of everyone, could count fingers, and in a few days the eye condition cleared up entirely.

Ozaena Operation—As is well known, it was Lautenschlaeger who first conceived the brilliant idea of curing ozaena by an operative narrowing of the abnormally patent nasal chambers. Whatever may be the ultimate fate of Lautenschlaeger's theories as to the etiology of ozaena, there can be no question as to the striking results of the operation he devised for this purpose. The aim of the operation is to bring the medial wall of the antrum, that is, the lateral wall of the nose, up against the septum and to keep it pressed in that position until more or less extensive union results between the turbinates and the septum.

Halle was quick to recognize both the great merits of the operation and the difficulties of its technique and promptly applied himself to the task of its simplification. Instead of the oral he chose,

as usual, the nasal route and by 1917 had perfected a method which, in its relative simplicity, is a decided advance upon the original Lautenschlaeger method. Halle's technique is briefly as follows: An L-shaped incision is made in the nasal mucosa beginning in front of the head of the middle turbinate and extending downward to the head of the inferior turbinate, thence continuing horizontally across the floor of the nose to the septum. Through this horizontal incision the mucoperiosteum lining the floor of the nose is elevated and the lower anterior portion of the nasal wall of the antrum brought into view. The entire lower border of this antral wall is now chiseled from the nasal floor, whereupon the anterior vertical border of the antral wall is chiseled through. The result is a broad opening from the nose into the antrum, which if diseased may now be readily curetted. Hereupon the entire inner (medial) antral wall is carefully pushed over to the septum, against which it is held tightly by gauze-packing in the antrum, the turbinates and septum having previously been refreshened in order to promote the formation of adhesions. These adhesions can easily be separated later in case a too pronounced narrowing of the nasal chambers follows the operation. Halle states that thus far he has not found this necessary.

In the four years from 1917 to 1921 Halle's operated cases totaled 131; of these he was able to follow up 76 longer than one year. His conclusions are: 1. Lautenschlaeger's expectations have been brilliantly realized. There is no case of genuine ozaena that cannot be at least strikingly and lastingly improved. 2. In many cases the ozaena as such is no longer recognizable; the mucosa is red, fresh, often even hypertrophic. 3. Crust formation ceases partly or entirely. 4. The foetor is so much improved in all cases that in most it disappears entirely, even in the absence of all irrigations. Only in a small minority a faint foetor persists unless irrigations are continued. 5. Some patients even report a return of the lost sense of smell, due, Halle believes, to the fact that the inspiratory air current in consequence of the narrowing of the nasal chambers is now better directed toward the nerve-ends of the olfactory nerve.

Endonasal Lacrymal Sac Operation — Halle's technique is a modification of the original West technique of 1910. In that year West reported his first series of seven cases to the Berlin Laryngological Society. From that time to this a dispute as to priority has raged between West and Halle with reference to one essential part of the operation, the point at issue being the muco-periosteal flap which, while not a part of the original procedure, is now an element of the technique of both West and Halle. Halle claims (Zeitschrift fuer Laryngol., Rhinol., etc., Leipzig, 1922) that he, Halle, was present when West presented his first report; that he recognized the shortcomings of West's operation and that he thereupon devised the flap in question, which West adopted without acknowledgment. This claim West rejects in its entirety. No more need be said here than that the controversy is a regrettable one.

A few general observations may, however, be made. Both West and Halle operate only endonasally. Neither does the Toti nor any form of combined Toti-endonasal operation. Their technique is essentially the same except that Halle cuts out a small window-shaped quadrangle from the flap before bringing it down over the lower turbinate, and counts on replacing the flap so accurately at the conclusion of the operation that its window corresponds with the bony window in the lateral nasal wall facing the sac. West considers that good on paper but not in practice and neither necessary nor advisable. Instead, he amputates the posterior end of the flap in those cases in which on its replacement at the conclusion of the operation it tends to close the bony window. There is this further difference that, while Halle excises only the medial half of the sac, West in recent years has excised it *in toto* in over one hundred cases and is now inclining more and more to the total extirpation as his usual routine.

Whatever may be the points of difference between West and Halle as to the operation, they are in entire agreement on one point, namely, that it is the most difficult of all intranasal operations. That is far more important than all else. When all is said, the ultimate fate of the operation as a generally adopted procedure will depend very much upon the facility with which its technique can be generally acquired. Mosher reports (Annals of Otology, Rhinology, etc., March, 1923) that after a series of seven cases, having found it "more difficult, indirect and to a great extent blind," he abandoned it for the combined intranasal and external operation, finding this latter "easier, direct, done by sight, with less danger of opening the orbit." After having studied the endonasal operation with both Halle and West, and having done a series of six operations under West, I am not prepared at the present time to take issue with Mosher. On the contrary I find Mosher's attitude reasonable, consider the question an open one and believe that it remains for the future to fix upon a generally accepted operation of choice.

SUMMARY

The swing is definitely away from the radical external nasal surgery of the past twenty years.

As far as possible all nasal operations should be done intranasally, and not by an external or an oral route.

Establishment of normal nasal respiration is in many cases all that is necessary for the cure of chronic nasal empyemas, especially antral and sphenoidal.

Ozaena, hitherto incurable, is now a curable condition. That is the outstanding achievement of recent rhinological surgery.

The problem of chronic lachrymal disease, long the despair of oculists, has been virtually solved. The key to the solution is the restoration of drainage from the conjunctival sac into the nose. The only question remaining concerns the surgical technique best suited to that end.

PRESENT-DAY X-RAY AND RADIUM THERAPY*

By CLAUDE E. PIERSALL, Reno

Since the discovery of the X-ray in 1895 and of radium in 1898, the world has been attentively watching the gradually accumulating evidence of their increasing usefulness in the diagnosis and treatment of disease.

It is now generally agreed that X-ray and radium have established an important place in the treatment, among other diseases, of both benign and malignant neoplasms.

In considering briefly the effects of radiation upon both the normal and pathological cells, the law of Bergonie and Tribandeau is quoted:

"Immature cells and cells in an active state of division are more sensitive to the X-ray than are cells which have already acquired their fixed adult, morphological or physiological characters."

This law has been repeatedly verified by many American pathologists. It applies equally to the application of radium. It has been proved, both experimentally and clinically, that insufficient doses of radium tend to render animal tissues hyperemic and only stimulate growth rather than produce cellular degeneration. This phenomenon was perhaps largely responsible for the difference of views among some of the earlier workers with radium. It is because the abnormal cells are more susceptible to the rays than are normal cells that radiation can be successfully used. The more highly differentiated the normal cells the more resistant they are to rays. Brain cells withstand heavier doses than any other tissue.

It was early discovered that radium emits three classes of rays of different degrees of penetration and clinical activity, and which produce different effect upon cellular life. This explains the need of various metal and rubber filters to eliminate the effects of one or more groups of these rays, and to give the highest degree of radiation upon the particular depth or tissue we desire to effect. The development of this knowledge, and the manufacture of radium needles and emanation tubes, which can be inserted directly into the tumor mass, has materially improved the percentage of cures in cancer of the deeper and more remote structures of the body. Likewise the improved X-ray machinery and advanced knowledge of its uses assist the radiologist.

Radiation therapy has been tried for almost all human ills. Its most conspicuous successes have been attained in that class of disease manifested by hyperplasia of soft tissue or lawless cellular proliferation.

The difference in the X-rays and the radium rays and their uses are briefly these: They are very similar, but the radium is the stronger potentiality. It requires no machinery to use it. It is small in size and is more applicable in lesions of the orifices, in crevices of skin, in open wounds or to be buried in neoplasms, while the X-rays require heavy machinery for deep therapy, are not applied at so close a range, and by reason of their wider radiation are preferable in covering large areas. The two thousand volt deep therapy apparatus is at least a time saver, and it can now be used to advantage in some cases where radium is yet applicable and formerly was preferable.

This age finds radium and X-rays to be the agents of first choice in the treatment of four groups of cases. This classification is not essentially different from that of Lain:

First Group—Angiomas, birthmarks, leucoplakia, keloids, moles, warts, uterine fibroids, or other non-malignant uterine hemorrhages.

Second Group—In inoperable and post-operative cancer and in such diseases as Hodgkin's disease, lymphatic leukemias or lymphosarcomas, radiation is used to give comfort, prolong life, and give hope for an occasional cure.

Third Group—All pre-cancerous lesions such as papillomas, pigmented moles, senile keratomas and leucoplakias, also non-suppurative tubercular adenitis, all premetastatic cancers, especially about the face, and cancer limited to the cervix uteri.

Fourth Group — In this last group might be placed leucorrhea, subacute and chronic, the enlarged thymus glands in children, toxic goiters, chronic and hypertrophied tonsils, soft nasal polypi after surgical removal, cancer of the bladder, cancer of the rectum, and cancer of the esophagus.

Many other conditions are improved or cured by radiation. Some of these are chronic eczema, psoriasis, lichen planus, lupus vulgaris, rodent ulcer, sarcoma, sycosis, acne, favus, actinomycosis, blastomycosis, and hyperidrosis.

Fortunately, however, we have the ultraviolet or actinic rays, which are more effective in many such conditions or are used as an adjuvant to the X-rays or radium, and other well-known remedies. Incidentally, these quartz lamps which give the ultraviolet light are an aid in preventing or healing X-ray burns.

As to dosage for treatment of the diseases named above, there is no set amount of radiation required, because each case may vary as to the degree of the disease, location of the lesion, and also susceptibility of the patient to radiation. Yet we do recognize that certain types of diseases require within certain limits a lethal dose for their particular pathological cell structure. A few examples follow:

An ordinary wart requires about 50 mg.-hrs.—that is, 50 mg. of radium for one hour, or its equivalent of 25 mg. for two hours.

Keloids and birthmarks vary according to the age of both the growth and the patient, as well as the size and nature of the growth. Some keloids require a destructive effect, and others absorption doses. Fibroids and myopathic lesions of the uterus require from 200 mg.-hrs. to 1500 mg.-hrs., depending upon the age of the patient, size of the uterus, amount of bleeding, and other factors.

Cancer of the cervix uteri or the fundus requires from 3500 to 6000 mg.-hrs. within six days' time, followed with heavy crossfire X-ray treatments, given after several weeks interval through several portals of entry.

Contra-indications for radiation therapy are:

Pedunculated fibroids; fibroids causing acute

* Read before the twentieth annual meeting of the Nevada State Medical Association, Reno, September 28th and 29th.

pressure symptoms; those very soft, or over 12 cm. in diameter; any acute inflammatory process, particularly in the tubes or ovaries, and infections, except when in or near some malignant growth.

In melanoepitheloma and melanosarcoma, and carcinoma of the esophagus, only palliation may be expected. There is no satisfactory method as yet for treating malignancy in the gastro-intestinal tract.

In treating any malignancy, that part or organ affected should not be allowed to function, in order to give physiological rest, or, in other words, to stop all irritation. If it is a cancerous uterus, coition is not to be allowed. If in the rectum, a colostomy should be done. In case of breast cancers, for example, pre-operative radiation makes some inoperable cases operable by closing the lymphatics, by producing destruction of the surrounding malignant cells, by producing immunizing substances, and by preventing the grafting of cancer cells with the knife. Such radiation often stops the cancer pain within a few hours. Post-operative radiation to all surrounding lymphatics prevents or retards recurrences of the growth, but is not necessary if pre-operative radiation was sufficiently lethal. In carcinoma of the prostate and bladder, radium tubes or needles are buried at the time of operation. Some favorable reports, however, have been made on the use of radium packs or deep X-ray treatment without operation or implantation of radium. Cancer of the fundus uteri, if known to be localized, is a surgical case after radiation, provided the patient is able to stand a radical removal. Cancer of the cervix is always a radium case.

Sarcoma of the post-nasal space or the tonsil is best treated with radium; in other localities, we advise radiation and surgery.

For osteosarcomas, surgery, X-ray and radium or deep X-ray therapy are advisable. For lymphosarcoma, radiation alone is sufficient. The reason for the high mortality rate of malignant cases is that they are not treated for malignancy until a definite diagnosis is made. A small chronic lump in the breast, a chronic sore or fissure or induration should be treated early as a cancer without a biopsy.

In conclusion it may be said that the leading internists and surgeons realize that radiation therapy is progressively filling a long-needed gap in medicine of both benign and malignant diseases.

Board of Education Assigns Physicians' Work to Technicians—When all physicians are employed and directed by laymen news items like the following (Journal A. M. A., September 22, 1923) will not be interesting:

"The three physicians who for a number of years have been retained by the Board of Education of Belleville regularly to 'inspect' the physical condition of school children, will not be reappointed. Their former duties in this regard have been taken over by a school nurse employed at $160 a month, which means a saving to the board of $900 a year. Abandonment of the school physician system, it is said, was due largely to a controversy that arose last year in which the physicians objected to the school nurse making diagnoses. Those who will not be reappointed are Drs. Adolph E. Hansing, Henry Reis Jr., and Charles R. Huggins.

ROENTGEN-RAY THERAPY IN THYROTOXICOSIS; ITS EFFECT AS MEASURED BY THE BASAL METABOLIC RATE *

By J MARION READ, M. D., San Francisco

The feature possessed in common by all of the cases herein reported was a definite increase in the basal metabolic rate, together with other variable signs and symptoms indicating abnormal thyroid function. Many presented the typical Graves syndrome, a few had adenomata with toxic manifestations and some were atypical, or "formes frustes" types. From a therapeutic viewpoint, definite classification is desirable, but in some cases it is difficult. Roentgen irradiation is a therapeutic measure, which seems to have a beneficial effect on a great majority of patients suffering from thyrotoxic signs and symptoms. By distinguishing between the Graves' syndrome and toxic adenoma, considerable progress has been made and more satisfactory results obtained. Most observers agree that the treatment of choice in patients presenting toxic adenomata is surgical intervention. Considering the neoplastic nature of adenomata, excision is the logical procedure, and the results obtained have justified its employment. The situation, in respect to Graves' disease, is not so satisfactory, and there is much controversy over the proper therapeutic course to follow in caring for sufferers with this disease. Some of the factors contributing to this state of uncertainty will be suggested in the course of this discussion, and illustrative cases will be cited.

Since September, 1920, most of the patients receiving Roentgen-ray treatment for thyrotoxicosis at St. Luke's Hospital have had one or more determinations of the basal metabolic rate. During the greater part of this time, an estimation of the rate has been prerequisite to the institution of therapy, and the test has been repeated monthly during the period of irradiation. During the past three years, over fifty patients have received Roentgen-ray exposures to the thyroid, and their cases constitute the basis of this report. Only a few were clinic cases, the greater number being referred by private physicians.

Through the kindness and interest of these physicians, it has been possible to obtain follow-up reports on many of the patients, but absence of basal metabolic rate determinations at the conclusion of treatment in many instances is to be deplored.

The cases have been divided into two classes, namely, Graves' disease and toxic adenoma. Not infrequently, however, a patient presented a clinical picture, together with a history and physical examination, which made classification difficult. This applied particularly to those patients with slight, if any, thyroid enlargement, who complained of nervousness, small loss of weight, and some heart hurry, but who lacked all the classical eye-signs of exophthalmic goiter. The basal metabolic rate in these cases was rarely above plus 45 per

* Presented to the Section on Radiology at the Fifty-second Annual Session of the California Medical Association, San Francisco, June, 1923.

cent, and they responded particularly well to Roentgen irradiation. This type has been referred to sometimes as "simple hyperthyroidism," but the term is objectionable, as it is probably neither "simple" nor "hyperthyroidism."

Standard technique, carried out under the direction of Dr. J. M. Rehfisch, roentgenologist of St. Luke's Hospital, has been followed in all cases. In the earlier cases exposures to different portions of the gland were made at weekly intervals, but more recently treatment to the whole thyroid has been administered once a month. This is the technique successfully followed at the Massachusetts General Hospital by Holmes.

The longest period of observation was three years, though reliable histories and hospital records for the past twelve years were available in some cases. Some of the patients are still under observation and receiving treatment, and a future report will be made on the further progress of this work. A more careful study will then be possible, since the X-ray department will not irradiate any thyroids without a preliminary estimation of the basal metabolic rate and redeterminations of the rate at regular intervals. Past experience, both here and elsewhere, has shown this to be the only safe policy to pursue.

It is now almost universally conceded that the basal metabolic rate is the most reliable single test in thyrotoxic cases, and its fluctuations are accompanied by subjective and other objective changes in the patient's condition. The regularity with which the pulse rate, for example, may follow changes in the metabolic rate is illustrated in Figure 4. For these reasons the basal metabolic rate has been used as a criterion of change or cure, though the patient's own statement or that of the attending physician as to condition has been accepted where no determination of the rate was obtained at the conclusion of treatment. A few patients ceased treatment and were lost from observation before the rate returned to normal, but in several such cases reliable follow-up reports were obtained.

Figure 1 shows the course of seventeen patients,

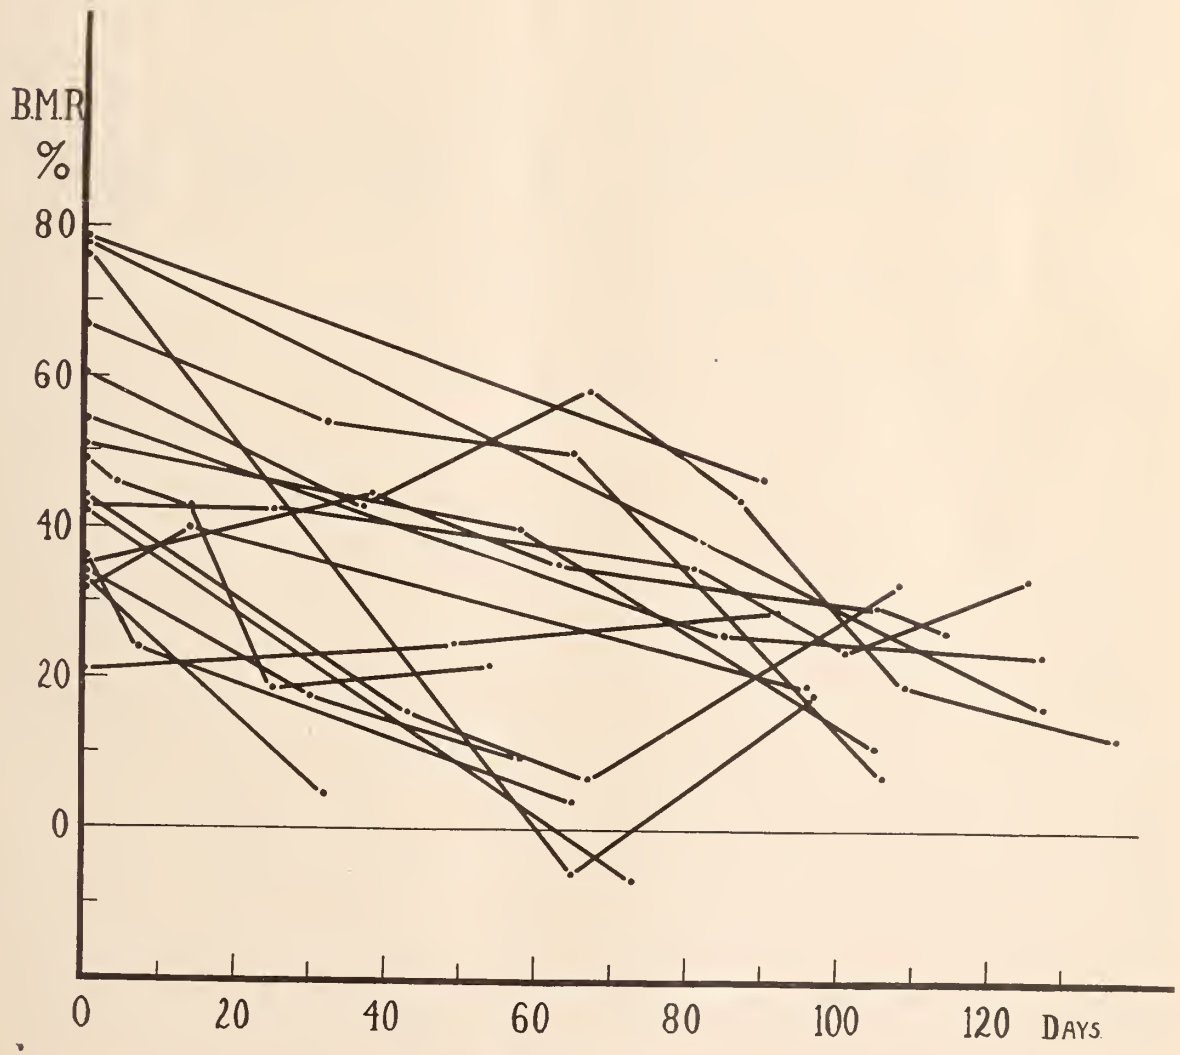

Figure 1

Course of seventeen patients with Graves disease treated with Roentgen ray. Estimations of the basal metabolic rate were made at monthly intervals in the majority of cases. Five have come down to less than plus 10 per cent in less than four months; five others have reached less than plus 20 per cent in the same time. Four of those with rates remaining above plus 20 per cent at the last observation have since reported themselves well. Three with rates above plus 20 per cent are still under treatment.

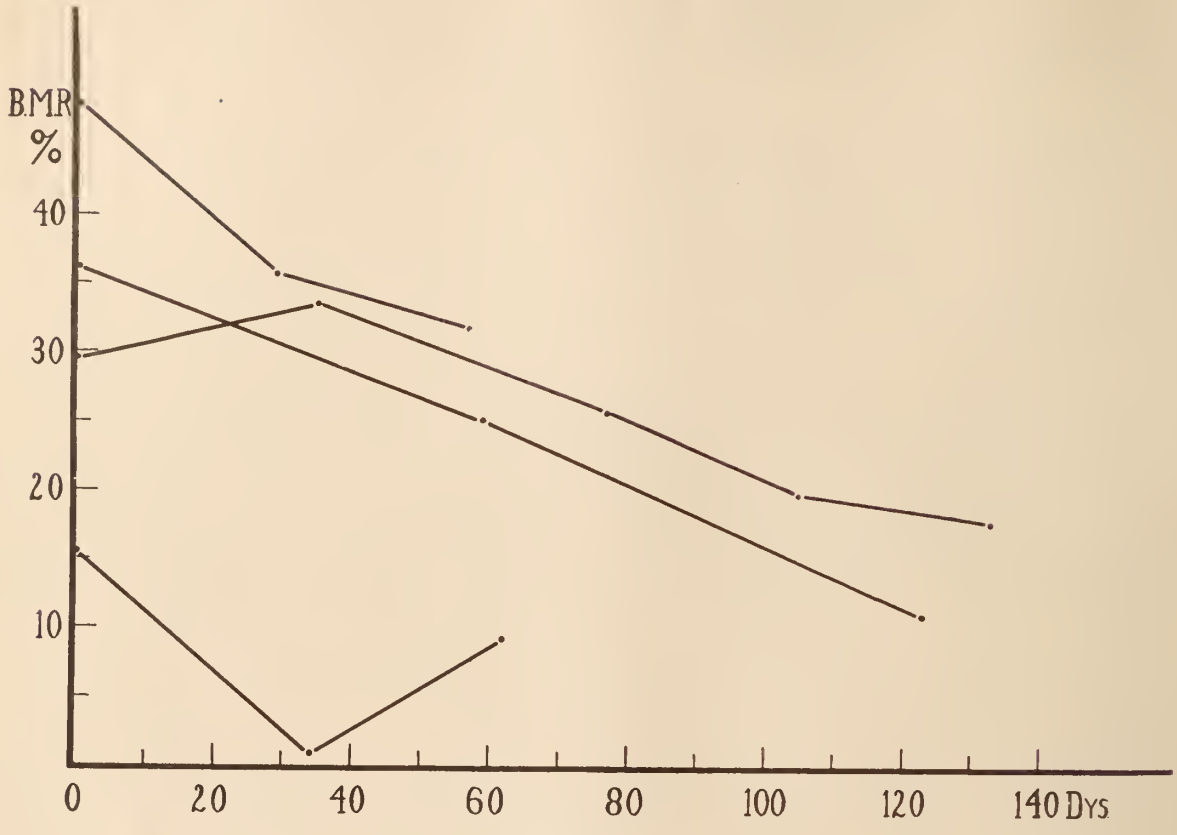

Figure 2

Course of four patients with toxic adenomata treated with Roentgen ray. Two are relieved of their toxic manifestations; one is improved but not well, and one is still under treatment.

who were observed for four months or less. It may be observed that most of them reach less than plus 20 per cent within that time. Four of those who do not have reported themselves cured. Five are still under observation.

Attention is directed to the two instances where the basal metabolic rate dropped below the zero line at the first estimation of the rate following treatment. These are both recent cases and are still under observation. One received three and the other four treatments over the whole gland at an interval of three weeks rather than weekly treatments over different portions of the gland, as was the former technique and that used in the greater number of cases herein reported. The reduction in rate was rather startling and more than could be ascribed to spontaneous improvement, for it occurred too rapidly. Although no myxoedemas had resulted from X-ray treatment alone up to this time, it was feared that the more intensive form of treatment might be producing that undesirable result in these two patients. However, a second estimation of the rate in one case showed it to be plus 18 per cent, and the other patient, who is out of the city, reports herself feeling fine, and will report for a determination of her rate upon returning to San Francisco.

Full realization of the natural course of Graves' disease has raised some skepticism in the writer's mind as to what part the Roentgen ray really played in the improvement and reduction in metabolic rate observed in these patients. But observation of the two cases cited above has convinced me that, in some cases at least, Roentgen-ray irradiation is capable of producing marked and rapid reduction in the metabolic rate which is accompanied by corresponding general improvement.

Only six patients with definite adenomata have been treated. Two are cured, two showed no change and were advised to submit to surgical removal of the tumor. One of these has been operated upon, but the other has so far refused operation. One is still under observation, and the remaining one has been lost from sight, though she showed improvement while under treatment. Two of these patients had uterine fibroids, illustrating an association which seems to be more than accidental.

The course of four of these patients is shown in Figure 2. Two of these had fibroids. The one whose curve is highest has ceased uterine-bleeding under X-ray treatment, but refuses surgical aid for the toxic adenoma which shows no regression under X-ray. The patient whose last rate was plus 18 per cent also had fibroids, which have been successfully removed subsequent to the last estimation of her basal metabolic rate, and she is reported as being in excellent health and without thyrotoxic signs or symptoms. The patient whose initial rate was only plus 16 per cent had a large adenoma of the right lobe, with definite toxic symptoms. One

irradiation produced the drop in rate noted and a decrease of two centimeters in the neck circumference. These were accompanied by abatement of subjective symptoms.

*One patient died three months after double ligation.

Table I summarizes the result of Roentgen irradiation in fifty thyrotoxic patients. Forty-three were treated at St. Luke's Hospital, and the records of seven are from private practice and the Stanford medical wards at the San Francisco Hospital. There were no deaths and no myxoedema in cases treated solely by Roentgen ray. Only one patient, whose initial basal metabolic rate was 112 per cent above normal, was kept in bed more than a week or two. About half of the patients followed their usual occupations, although rest was advised and they were warned against fatigue.

Only approximate accuracy in the estimation of results can be attained. In every case where it was possible, the statement of the patient or attending physician was used as a basis. Experience has taught the writer to be very cautious in saying a patient with exophthalmic goiter is cured. None so classified in this report, however, have since had a recrudescence. The cases indicated as showing no change during X-ray treatment were so classified, because they were operated on before treatment had been persisted in long enough to produce marked improvement. Even these patients showed improvement in most cases, but acceptance of the attending surgeon's estimate of the value of Roentgen irradiation has made the classification of "no change" seem advisable. It at least affords more excuse for operation.

Figure 3 shows the metabolic rate changes in nine patients who were operated upon. One re-

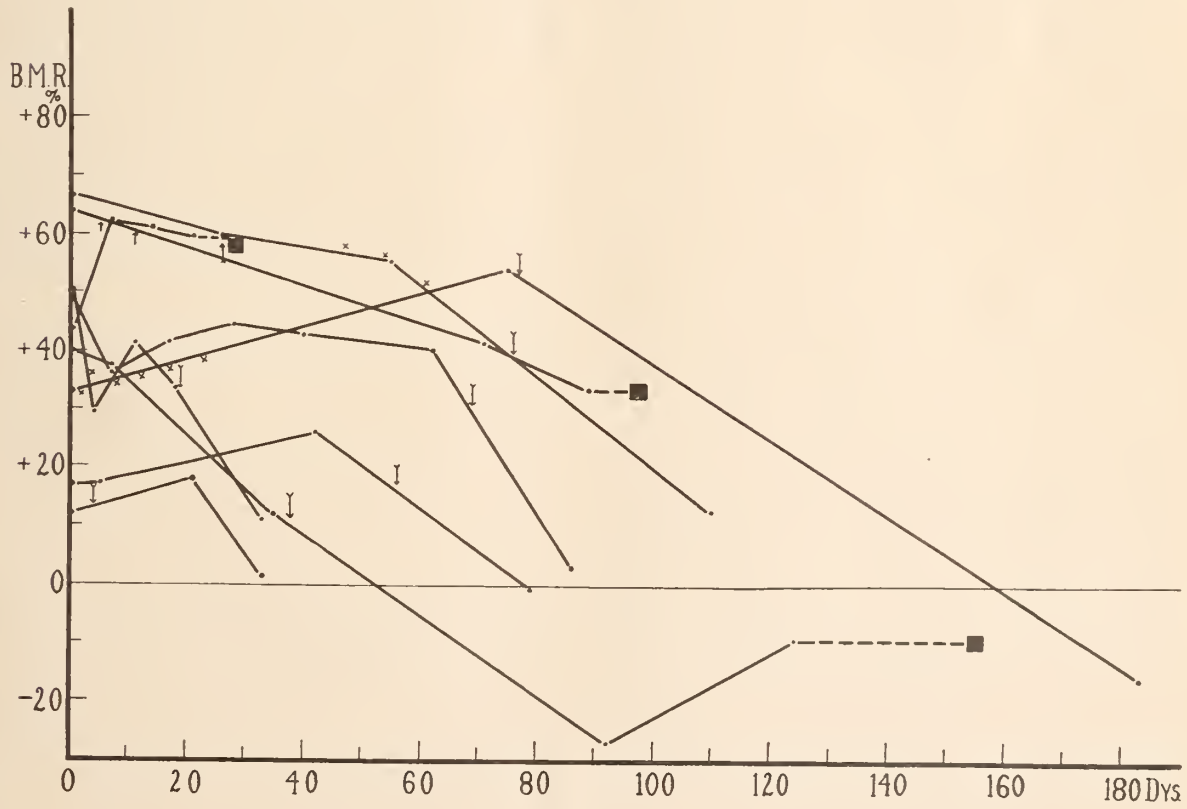

Figure 3

Course of nine patients with Graves' disease submitted to operation. Large arrows indicate sub-total thyroidectomy, small arrows ligations. X indicates Roentgen ray treatments which four of the patients received prior to operation. Black squares indicate death. Both patients whose rates dropped to points below the zero line had received Roentgen ray exposures before operation, and both developed myxoedema after operation. One of these two subsequently died.

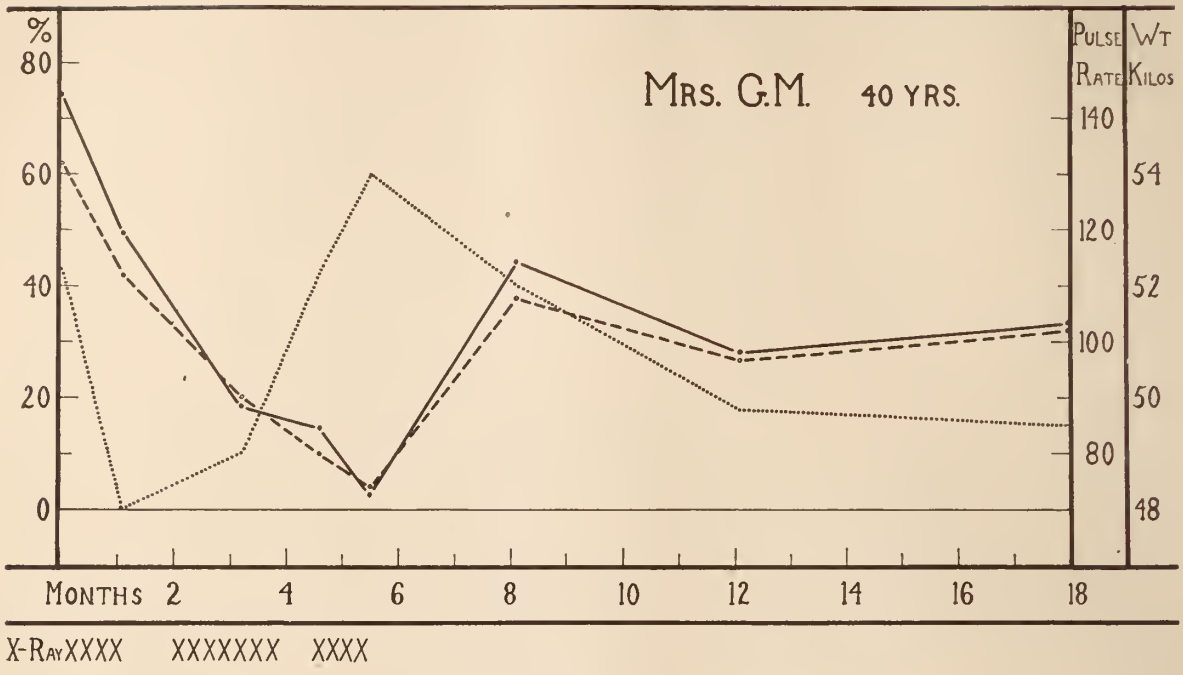

Figure 4

Course of patient Mrs. G. M., 40 years of age, observed for one and a half years. Solid line, basal metabolic rate. Broken line, pulse rate. Dotted line, weight in kilos. This patient had had a sub-total thyroidectomy three years prior to the date of the first estimation of her basal metabolic rate, which was plus 74 per cent.

ceived only double ligation, with a slight drop in the rate, but death supervened three months later as a result of thyrotoxicosis, though the metabolic rate was only plus 33 per cent eight days before death. A toxic psychosis was a marked feature in this case. There were two other deaths, one occurring the day following operation on a patient whose basal metabolic rate was plus 59 per cent. Most of the patients showed rates very close to normal limits a few weeks after operation. Two had rates below minus 10 per cent. One of these had a prior lobectomy, but still presented thyrotoxic signs and symptoms, having a rate of plus 35 per cent when he entered the hospital. Under rest in bed and X-ray treatment, this rate fell to plus 12 per cent by the seventh week, which was thought to be a propitious time for removal of the remaining lobe. The day following operation the patient had a tetanic seizure, which recurred along with convulsions and periods of unconsciousness up to the time of death. He lived for four months after operation, during which time his basal metabolic rate fell to minus 27 per cent, but was raised to minus 11 per cent by administration of thyroxin.

During the period covered by this study there were performed twenty-nine thyroidectomies and two ligations on thirty patients in St. Luke's Hospital. Table 2 gives the complete data. These data include the cases illustrated in Figure 3, these being the only ones whose basal metabolic rates had been estimated before and after operation. It may be noted that there were thirteen cases of exophthalmic goiter and three of toxic adenoma, and that three out of the four fatalities were in this group. The other death resulted from hemorrhage at operation on a non-toxic goiter. The operative mortality for all classes is 13 per cent, and for thyrotoxic cases a little more than 18 per cent. This series is too small to warrant any conclusions, but it is probable that the average mortality rate among thyrotoxic patients treated surgically is between 15 and 25 per cent, except in such clinics as Crile's and the Mayo's.

In evaluating the different therapeutic procedures employed in dealing with thyrotoxicosis, especially Graves' syndrome, there is a proneness to forget that spontaneous cures are frequent and that there is a strong tendency for the disease to run a fairly definite course marked by periods of improvement alternating with recrudescences of more or less severity. Recrudescences do not occur in some cases, but they seem to be the rule and it seems difficult to prevent them by any known method of treatment, including sub-total thyroidectomy and Roentgen irradiation. An illustrative case will be cited to make this clear:

Case 310—Mrs. G. M., age 40, Italian housewife, about eleven years ago consulted a physician, who diagnosed exophthalmic goiter and advised operation. She declined and called another physician, who also advised surgical intervention and refused to treat her unless she consented to operation. She persisted in her request for medical treatment, and the second physician consented to try a substitute for surgery. He treated her with camphor mono-

bromate and ergot, and to his surprise she recovered. In six years she again consulted him and presented the typical picture of Graves' disease. Operation was advised and on February 27, 1918, the right lobe, isthmus, and portion of the left lobe were removed. She made a satisfactory recovery. Because her trouble had first come on with childbearing, she was advised not to become pregnant again following operation; but, believing she was cured, in 1922 she again became pregnant and experienced a return of all her old trouble. At this time she came under my observation, being referred for an estimation of the basal metabolic rate, which proved to be plus 74 per cent. She then presented the classical signs of Graves' disease.

Figure 4 shows her course from that time to the present. She aborted at six months, and was given X-ray treatment. The metabolic rate returned to normal in five months, being accompanied by a gain of fifteen pounds in weight and a decrease in pulse rate from 132 to 72. Tremor, goiter, and eye-signs also disappeared. The patient was again cured. Three months later the rate was plus 44 per cent, with a subsequent drop as shown on the chart. She then had some teeth removed under local anesthesia, which resulted in so incapacitating her that she was confined to bed for three months. The attending physician ascribed her condition to cocaine poisoning. The last estimation of her metabolic rate was on September 25, 1923, when it was plus 33 per cent. She said then that four months prior to this her heart beat very hard and fast, she lost weight, and was so nervous she could not have cooperated enough to have a test made to determine the metabolic rate. Since she was a practiced subject by this time, one may assume that the rate must have been much higher at about fourteen months in Figure 1 than the straight line connecting the last two observations indicated.

This case illustrates the influence of pregnancy on Graves' disease, as well as the tendency of the disease toward recrudescence. Furthermore, this patient was "cured" once by medicines and rest and again by surgery and the rest incident thereto, and a third time by Roentgen rays. In spite of all this she refuses to remain cured, but continues to present the signs and symptoms which we call thyrotoxic. Obviously, the cause of her disease has not been removed. It is interesting to note that this patient presents no evidence of myocardial damage. There is no irregularity of pulse and no signs or symptoms of decompensation.

CONCLUSIONS

1. The Roentgen ray seems to be effective in reducing the metabolic rate, together with the toxic signs and symptoms in thyrotoxic patients.

2. Determination of the basal metabolic rate affords the best check on the result of therapy and should be made routine in treatment with X-ray.

3. A period of three to six months is necessary to secure marked improvement or return to normal. The higher the initial rate the longer must be the period of treatment.

4. No patients are made worse by irradiation and no myxoedemas resulted therefrom.

5. No deaths have occurred in this series of fifty cases in patients treated with X-ray alone.

Relation of Pruritus of Anus to Chronic Diseases of Abdominal and Pelvic Viscera—In many of those chronic diseases of the stomach associated with dyspepsia, chronic gastritis, J. F. Montague, New York (Journal A. M. A., November 17, 1923), asserts there is added to the clinical picture the condition known as anal pruritis. This is particularly true in cases associated with much gastric fermentation. In these cases, a cure or relief of the gastric condition often brings about a parallel relief in the pruritus. Medical literature reports the association in some cases of carcinoma of the stomach with pruritus; and many other chronic diseases of the gastro-intestinal tract, such as chronic colitis, chronic constipation and fecal retention, have also been observed to have an apparent relation with the causation of pruritus of the perineum. In a closely similar manner, an identical apparent relation has been seen to exist in some patients with chronic diseases of the genito-urinary tract. As examples of this, chronic endometritis, chronic prostatitis, hypertrophied prostate and chronic urethritis may be mentioned. Of the other chronic visceral diseases which at times appear to bear a relation to this condition, obstructive derangements of the liver, such as hypertrophic cirrhosis of the liver, are notable instances. Chronic cholecystitis, chronic nephritis, cystic calculus and neoplastic growths of the liver have each contributed their share of examples of this relation to pruritus of the anus or perineum. J. F. Montague believes that all cases of pruritus of the anus can be divided clinically into two classes: The one, a direct pruritus (pruritus ani) due to the direct irritation of the peripheral nerve endings in the pruritic zone, in which cases the source of irritation actually causes a primary pathologic condition whose direct nature can be demonstrated by the abolition of pruritic sensation by local anesthetization or superficial neurotomy; the other, an indirect pruritus (anal pruritus) due to the perception of the pruritic sensation which in consciousness is referred to the pruritic zone, an area which is at the inception of the pruritus devoid of any pathologic condition at all. This phenomenon is due to the transference of an irritable stimulus from the visceral afferent nerves to a normal somatic afferent nerve channel or pathway, and the consequent misreference or error in localization of the sensation. This indirect pruritus, although devoid of local lesions at its inception, induces a desire to scratch which results in the pathologic changes previously noted; namely, first, a traumatic, chronic dermatitis, and in many cases, secondly, an infective chronic dermatitis. These secondary pathologic changes in the tissues of the pruritic zone lead to an added component of direct pruritis. As a matter of clinical fact, sooner or later in all these cases of indirect pruritis there is superimposed the element of direct pruritis. In this type of pruritis, local therapeutic measures are not indicated unless the patient's efforts at relief, such as scratching and rubbing, have induced a direct pruritis either of a mechanical or an infective nature.

MENINGITIS OF OTITIC ORIGIN*

By J. FRANK FRIESEN, M. D., Los Angeles

In presenting the subject of otitic meningitis, I am limiting the scope to the recoverable types of meningitis caused by middle ear infections. The meningitis of meningococcic origin is excluded.

Leptomeningitis following a middle ear infection, producing all of the typical meningeal symptoms, was at one time regarded as a hopeless condition, but the last few years the prognosis has become more favorable in the light of so many records of authentic recoveries.

It is only more recently that a differential diagnosis between a diffuse purulent meningitis and other forms has been accurately determined.

In analyzing these recoverable types of meningitis more closely, we first recognize the fact that they are secondary to meningeal irritation or an intracranial infection, usually of otitic origin.

If the involvement is extradural and the infection does not extend beyond the dura, a localized pachymeningitis results, in which the pia and arachnoid have escaped actual infection and no pus or bacteria are found in the spinal fluid. The cause of this type of meningitis is a meningeal irritation from an adjacent infective focus. Eagleton speaks of these cases as a "protective meningitis." Plautt and Schottmuller have classified them as a "sympathetic meningitis," and Sharp, as "serous meningitis."

If an infection is slowly spreading into the subdural spaces in the course of a middle ear or mastoid disease, then there is set up sufficient tissue reaction to wall off and limit the suppurative inflammation in the pia and arachnoid. This circumscribed or localized purulent meningitis may follow practically the same course clinically as a diffuse process.

During the last year several patients with otitis meningitis followed by recovery, have come under my observation. I will give a few brief case-reports, which possibly will convey a clearer impression of the localized or circumscribed form of meningitis than the description.

Case 1—B. G., female, 8 years of age, was admitted to the Los Angeles General Hospital, August 20, 1922, with the diagnosis of a chronic left middle ear infection and an acute intracranial invasion.

The ear had been discharging intermittently for five years. A year ago she had an operation for the removal of an aural polyp; also the tonsils and adenoids.

Her symptoms on admission were pain in the left ear, headache, and restlessness of several days' duration.

The examination disclosed a definite cervical rigidity with a suggestive Kernig. A lumbar puncture was done, the spinal fluid was turbid and under increased pressure. Microscopic examination revealed numerous puss cells, few lymphocytes, but no bacteria. The culture was sterile. Another examination of the spinal fluid five days later gave the same report.

The child was operated upon. The left mastoid filled with a large cholesteotoma. Further exploration revealed an extra-dural abscess.

The patient had a stormy career during her stay in the hospital, but finally made a complete recovery.

Case 2—M. M., a male 18 years of age, was admitted to the Los Angeles General Hospital October 2, 1922, with a history of pain in the left ear for two weeks. The examination disclosed an acute left mastoiditis with the classical symptoms of meningitis such as stupor, rigidity of the neck, and a positive Kernig.

The report of the examination of the spinal fluid was as follows: Pressure of the fluid, slightly increased. Slight turbidity, 1226 cells per cmm., globulin negative. The fluid did not reduce Haynes solution. Direct smear showed numerous pus cells, but no bacteria. Culture showed no growth.

A simple mastoidectomy was performed and pus found in the mastoid antrum, the mastoid entirely sclerosed, and all cells absent. The dura and sinus were uncovered, with no evidence of further involvement. A smear and culture of the pus showed the staphylococcus albus. A blood culture proved negative.

The patient became worse after the operation, and all of the meningeal symptoms were more marked. He was comatose at times and difficult to arouse. Several spinal punctures were done at regular intervals, and quantities of fluid varying from 20 cc. to 45 cc. removed at one time. The patient made a perfect recovery and was discharged October 29.

Case 3—F. A., a girl, 9 years of age, entered the Los Angeles General Hospital January 16, 1923, acutely ill with all signs and symptoms of a cerebrospinal meningitis.

The left ear was discharging, and she had acute mastoiditis on the same side.

A lumbar puncture was done and 20 cc. of cloudy fluid under increased pressure removed. Fifteen cc. of anti-meningococcic serum was introduced by gravity. Examination of spinal fluid; turbid, globulin positive 1500 cells per cu. mm. A smear showed a few grams positive cocci (staphylococci) (apparently contamination); also a few pus cells. A subsequent culture proved to be sterile.

A simple mastoidectomy was performed. The mastoid cells were filled with pus. The sinus and dura apparently were not infected. A culture of the pus from the mastoid showed a growth of non-hemolytic streptococci.

The patient made an uneventful recovery, and was discharged two weeks after entering the hospital.

Clinically, these patients have the classical picture of a true meningitis, and the symptoms may vary from the mild to the severest type, such as the elevation of temperature, headache, drowsiness, stupor, rigidity of the neck, Kernig's sign, etc.

Mygind, of Copenhagen, reports a series of 210 cases of otogenic meningitis, with a recovery of 28 per cent after operation. Chronic suppurations of the middle ear were decidedly more frequently the cause of the benign (recoverable) meningitis than that of the malignant (fatal). In a chronic case there is a slow walling-off process going on, and the prognosis is decidedly better than in the acute cases. Streptococcus infection was predominant in the benign cases, while the pneumococcus infection played a comparatively important part in the malignant cases.

The lumbar puncture is very significant. As a rule, in the benign, or recoverable, cases the cerebrospinal fluid is clear or slightly turbid, with moderately high pressure. The cells are usually polymorpho-nuclear, and there is a moderate increase in the albumin content. Bacteria are usually absent.

If there is a known or suspected middle ear infection, together with the findings of a spinal fluid as has just been described, one must consider the possibility of an epidemic, tuberculosis or syphilitic

* Presented to the Los Angeles County Medical Association, October, 1923.

meningitis, having no causal relationship to the ear suppuration.

The malignant or fatal cases of meningitis reveal a turbid fluid with very high pressure, and bacteria are usually present.

Yet there are exceptions to this rule, and cases have recovered where the turbid cerebro-spinal fluid showed the process of bacteria. Gradenigo has reported two cases of typical meningitis that showed the presence of staphylococci in the spinal fluid, with recovery after operation.

If bacteria are found to be present on culture of the spinal fluid, this should not be held as absolute proof unless confirmed by a subsequent lumbar puncture and culture.

On the other hand, the absence of bacteria in a turbid spinal fluid does not rule out a diffuse leptomeningitis. Yerger reports eleven cases of diffuse leptomeningitis seen at necropsy in which cultures had been made, and only four had revealed the presence of bacteria.

Recent investigations have proven that the cerebro-spinal fluid is a circulatory medium, and the character of the fluid obtained by lumbar puncture does not always indicate the state of the leptomeninges in the spinal canal.

Most observers believe that these cases of recovery have belonged to the circumscribed form of purulent meningitis, and that diffuse leptomeningitis is a hopelessly fatal disease which the surgeon is powerless to relieve.

From a bacteriological point of view, the pneumococcus leptomeningitis is regarded as the most fatal type. This pneumococcus is often described as the streptococcus mucosa capsulatus. The fulminating character of this type is usually due to a secondary blood sepsis. The streptococcus and staphylococcus meningitis are much more common, but not so virulent. The least virulent is the meningococcic meningitis.

When an ear infection reveals meningeal symptoms, a lumbar puncture should be made for diagnosis, and where there is an increased intracranial pressure, the puncture should be repeated for therapeutic purposes.

Where the bacteriological and clinical diagnosis of the meningitis has not been firmly established, an intraspinal injection of anti-meningococcic serum should be administered at the time of lumbar puncture, especially if there is any suspicion that an epidemic meningitis may co-exist with the aural lesion.

If the history and examination of the ear or mastoid reveals an acute or chronic suppuration, the mastoid should be thoroughly exenterated, the dura and sinus uncovered, and drainage established. In the majority of cases the path of infection travels by local extension to the sinus and dura, with a resultant sinus-phlebitis and dural infection.

In old aural suppurations a cerebral or cerebellar abscess is a possibility, with a secondary meningitis. The labyrinth may be the pathway for the meningeal involvement.

At times it is difficult to establish a path of infection, either at operation or at necropsy.

The successful cases reported in the literature have established the fact that meningeal drainage will save many, which otherwise would terminate fatally. Especially is this true when the route of intracranial invasion is through the tegmen or inner table of the mastoid. When the disease spreads through the labyrinth, the results are not so good.

It is my opinion that, even in apparently hopeless cases, surgical intervention is justified on the ground that the evacuation of pus from the intradural spaces, together with relief of tension offered by lumbar puncture will occasionally result in the recovery of cases which would otherwise terminate fatally.

INDIVIDUALITY AND ENVIRONMENT AS ETIOLOGICAL FACTORS IN THE PSYCHONEUROSES*

By CHARLES E. NIXON, M. D., San Francisco

The progress of medical practice has been notably retarded by the failure of some physicians to realize that the primary object of their attention should be the individual and not the particular anatomical or physiological disturbance from which the patient is apparently suffering. How frequently some isolated deviation from the average is seized upon with the greatest enthusiasm and on this finding is predicated the patient's entire difficulty. "High blood pressure," "anemia," "murmur," are terms that too often give complete satisfaction. As new laboratory methods and refinements of physical examination are added to the already lengthy examination routine, the individual is more and more lost sight of in the frantic search for physical or objectively demonstrable abnormality. It is not uncommon to see long records where almost every known procedure in medical practice has been done and not one word written about the patient as an individual—as to his reactions as a whole.

The failure to recognize this broader viewpoint and thereby to be of infinitely greater service to those seeking our help has been due partly to the unfortunate conception conveyed by the terms "organic" and "functional." If, on examination, a condition dignified by the title of "organic" is found the physician regards it as being important and demanding attention; however, if the difficulty is one of the so-called "functional neurosis" group the patient is not infrequently told that there is nothing the matter with him; to "forget it" or, at most, he is told to get out for some exercise and is given some injections of iron. The student is thoroughly impressed with the dictum "never make a diagnosis of a neurosis until you have ruled out all possible organic diseases"; he is taught to regard laboratory findings, especially the more complicated tests, as being of the greatest importance; indeed, so awed is he by these mysterious reactions that the history and physical examination are hastily passed over in the frantic rush for the laboratory reports.

This narrow and altogether erroneous conception will persist until physicians learn that there are three things to be considered in dealing with a patient and, while in this paper I am referring especially to the psychoneuroses, this applies as well

* Presented to the Section on Neuropsychiatry.

to every other field of medicine. The three factors entering into every case are the *individual,* the *environment,* and the *adjustment* of internal relations to one another and to environment.

Man is a highly complex organism in which all structures are more or less closely related. *Individuality* is the result of the particular form, function, and grouping of the various organs and tissues. Personality has been the term commonly used to express the makeup of a person, but because this word is thought of more in reference to the psychic aspect I have suggested the use of the term *individuality* to convey a more comprehensive conception expressing thereby the physical and mental status and the reactions of a given person. People are grouped on the basis of physique as robust, frail, obese, slender, muscular, or asthenic; from the intellectual standpoint, as very superior, superior, normal, or dull. Likewise, groups are made according to the emotional, endocrine, moral or social status or to the possession of unique traits. It is, however, the particular combination of all these phases of a person that gives him his individuality and accordingly no study of a patient is complete without a consideration, separately and as a whole, of all of these factors. It is just as important, perhaps more so, to know that man is temperamental, unsocial, egocentric, timid, inclined to excessive worry, impractical, of mediocre mentality, or has a feeling of inferiority as it is to be cognizant of a blood pressure above the average or of an existing arteriosclerosis.

Among people who are considered as "normal" and who are economically and socially independent we find great variation, and even abnormality, of structure and function. Health does not depend upon the absence of all abnormality, but upon an adequate adjustment of the various structures and functions, and upon the individual's success in maintaining his adjustment to his environment in spite of the pathological condition. Thus, a person may have a heart lesion, but if the heart is able to compensate for this so that internal relations are not disturbed, the individual leads his usual life; likewise a man may be of the "shut-in" type or egocentric or dull and yet be able to compensate for these peculiarities and so lead a normal life. The crux of the situation is not the presence of some abnormality but whether there is an adequate adjustment of internal and external relations. To use the words of Herbert Spencer, life is "the continuous adjustment of internal relations to external relations."

Using again the heart lesion as an illustration, the involvement of the organ may be so severe that it is not able to compensate for the additional load thrown on it, and the patient is unable to carry on his usual activities; in the familiar phraseology of pathological sociology, he is unable to adjust himself to his environment. If further internal adjustments are impossible then the environment must be modified.

The application of this conception of disease and its treatment is especially applicable to the psychoneuroses and is essential to a proper understanding of these conditions. The etiology of the psychoses and neuroses has been attributed to almost everything—infections, intestinal kinks, anemia, enlarged prostates, heredity, poor environment, domestic or business troubles, mother or father fixation, sexual repression, lack of sexual repression, and so on ad infinitum. Unquestionably, any one of the conditions mentioned may be an important etiological factor, but it is not the existence of the condition per se that causes the psychosis or neurosis; the disturbance develops because the *individuality* is such that there is difficulty in making an adjustment to the environment. Stewart Paton has suggested that the term "insanity" be discarded and the term "maladjustment" be used instead, for, as he aptly says, "Disease is an imperfect adjustment of which mental disorders are a special but not specifically different type."

We are all potential psychoneurotics; most of us do not actually become such because our defects of individuality are not so marked, or our environment is so sufficiently simple that we can adjust ourselves to our environment. In some the margin of safety is very great—they are endowed with good bodies and minds, they have a stable personality, their instincts do not bring on too many conflicts—in other words, the individuality is so good that the environment may be very bad without the development of a psychosis or a neurosis; in others, however, there are personality defects, or physical or mental stigmata that make necessary a very suitable environment to prevent the manifestation of such a disturbance.

Three illustrations, in the way of brief case records, will perhaps further elucidate this viewpoint.

A middle-aged man with a large family had been economically independent until the last year; he had recently become depressed, anxious and nervous; he stated that it always seemed he was just barely making a go of things before the present trouble, and in the last year he found his circumstances in life too much for him. The psychiatric examination showed a mental age of ten years, and the physical examination revealed a moderate arteriosclerosis with a comparatively high blood pressure. Because of a rather good personality and a good physique, he had previously been able to adjust himself to his environment in spite of the handicap of intellectual inferiority, but with the additional stress of an arteriosclerotic condition there came a break, with the resultant psychoneurosis. His usual occupation carried with it a fair amount of responsibility, so the most essential part of this man's treatment was to have him engage in work with little responsibility and not too strenuous from a physical standpoint—in other words, to modify his environment.

A highly successful engineer had an important position in a large corporation. While under considerable strain he developed an attack of manic-depressive insanity. On recovery he returned to his former work and had another episode, and on recovery again returned to his position and a third time had a mental upset. After this last attack he gave up mine engineering and took a position as a driver on a milk-wagon. He has been doing this work for several years without a recurrence of his

trouble; another example of a too complex environment being a factor in the development of a psychosis.

The third case is a man, age 35 years, with a wife and two children. He was artistically inclined, but lacked technical training to make a living as an artist. He was impractical and had other personality defects that made him an economic dependent. For years the Charities had contributed largely to the family support, making up the deficiencies in the wife's earnings. While the wife was working he would care for the children, playing much as a child and puttering with his paintings. As a result of the conflicts arising from his failure to support his family or even to make an attempt at any practical work, he developed a severe neurosis, and as the result of his insistence that he had pulmonary tuberculosis together with some indefinite signs he was given numerous physical examinations, each one aggravating his neurosis. To make this brief I have to omit many interesting details, but the ending was the adjustment of internal relations or the modification of his individuality by psychotherapy, giving him some insight into his condition and causing him to recognize that he could not earn a living through his art work, but that it was incumbent upon him to support his family through any work he could find and do, his environment was simplified by the supervision and interest of a very intelligent social service worker; with the exception of one break following a mild attack of influenza he has entirely supported his family for several years through his employment on a humble job. He has been encouraged and helped with his painting, with the hope that later some work may be found where his artistic ability may have further development and outlet.

(Flood Building.)

DISCUSSION

Walter C. Alvarez, 177 Post Street, San Francisco—Some physicians do not use laboratory or Roentgen-ray help because it is not available or because their patients are too poor. Others do not use these tools because they do not know that some of them exist; they do not know how to handle them, or what they are for. On the other hand, there are many pseudo-scientific individuals who, especially when a consultation is pending, like to order blood cultures and counts, blood chemical work, metabolism determinations, Wassermanns, stool examinations, and Roentgen-ray plates of everything in the body. Sometimes, for lack of any directing mind, the particular procedure which would easily make the diagnosis is the only one which is omitted. Thus, an acquaintance of mine with leukemia came to me with a hundred dollars' worth of Roentgen-ray and laboratory reports. His diagnosis had been missed by a number of physicians because, through some oversight, a blood-smear had not been looked at.

The writer never likes to order any laboratory or Roentgen-ray examinations until a careful history has been taken and perhaps the physical examination made. The diagnosis may then be clear and the patient may be saved further expense. If doubts remain, the laboratory procedures should be designed to clear those doubts. Then the essential thing is to follow clues as they appear. To illustrate: A typical neurasthenic whose only complaint was lack of "pep" gave no clues from history-taking or from the physical examination. The urine, however, showed some white and red cells. Where did these come from? Massage of the prostate showed pus, but no red cells, so plates of the kidneys were taken and they showed two large "silent" stones.

The true physician must be a splendid student and a rapid reader to absorb much of many sciences; he must have wonderfully good judgment to sift the evidence, to pick out the essentials and to decide what is best to do with the individual; he must have great human sympathy, kindliness and friendliness or he will never bother himself about environmental problems; and finally, he must be a physical giant or he will be too tired most of the time to attempt anything but a snapshot diagnosis and a palliative treatment. Nixon's appeal is a good one, but it has always seemed to me that such exhortations must go unheeded so long as we physicians partake so largely of the mental, moral, and physical weaknesses of humanity. To be sure, as Stevenson says, we share "as little as any in the defects of the period," but some of us haven't Class A intelligences (only four out of a hundred men in the American white draft had); some of us are lazy, and almost all of us find it burdensome and annoying to think. So long as we are made that way we will continue trying to delegate the making of the diagnosis to the laboratory man and the roentgenologist.

Henry S. Whisman, University of California Hospital, San Francisco, Cal. — Modern medicine has been dominated by the materialistic dogma. According to this formula there must be a correlation of the symptom-sign complex with an organic, mechanically demonstrable deviation from the norm. This has meant the intensive study of the function of the part to the exclusion of the function of the whole, with an utter disregard of the principle of integration. Hughlings Jackson long ago spoke of the physico-chemical, the sensori-motor, and the psychic or symbolic levels, each transcending the other through integration, with a final expression in the behavior of the human being as we know him. The clinical picture of disease must then be a reaction, not of a single part or organ, but of the organism as a whole. Every individual has his own peculiar type of reaction, conditioned by inherited, constitutional factors on the one hand and his life experiences on the other. The result of a defect of adjustment is always a symptom constellation which is determined by the extent and character of the defect and the reaction-type of the individual. The defect may be at the physiological level, and thus a part-disorder, so-called organic disease, or it may be at the social psychological level, a maladjustment of the person to his environment. The clinical picture may be, and often is, the same. A defect of adjustment in the social or psychological sphere is naturally and automatically, and usually unconsciously, expressed by discomforts and inadequacies in the physiological realm. The keynote to a correct estimation of the situation is, therefore, not only a careful survey of the status of the various organs, but imperatively also a study of the personality with its reaction tendencies.

When the defect has been found to lie in an organ, demonstrable by some instrument of precision, physicians have always been ready to attempt a readjustment by pharmacological or mechanical measures. They have been less ready, and often unwilling, to look upon the symptomatology as a possible expression of a defect of adjustment of the individual as a social unit. The physician must broaden his viewpoint and extend the scope of his investigations and therapeutic efforts in order to meet the problems of psychobiological medicine. A sizing up of the situation demands no complicated technique. A few common-sense questions designed to bring out the nature of habitual reactions to the ordinary, concrete situations of life, incorporated in a paragraph in the anamnesis, would in most cases supply the data. Even the casual observer of the signs of the times may readily see that these are real problems and since they come so largely within

the sphere of activity of the physician, it is only right that he, rather than the charlatan, should make the effort to meet them.

Clifford W. Mack, Livermore Sanitarium, Livermore, Cal.—The writer of the article on the psychoneuroses is dealing with a phase of medical practice that should be of the utmost concern to the medical profession today because ignorance or neglect of the subject will result in many failures that will be to our discredit. In these times of charlatanism, cults and near-doctors of all sorts, many of these psychoneuroses under the guise of other diagnoses will be manipulated, classed as cured, leaving others then with real organic diseases to expect the same help that will not be forthcoming and delay the early assistance that medicine could render. The number of patients with psychoneuroses and the number of patients with organic diseases combined with psychoneurotic symptoms must be a large percentage of those entering a doctor's office. Hence, if our work is to be successful we must grapple with this problem more intelligently.

In the first place, I wish to state my complete agreement with the conclusions of the author that a study must be made of the individual personality, the emotional reactions and the factors in the patient's environment as well as a study of the physical status of the patient. I am glad of the courageous manner in which he asks the diagnostician not to tell the psychoneurotic patient that "there is nothing the matter with you." The statement in one case coming to my knowledge led to a pathological depression with an evolution as follows: The patient reasoned: "I have certain feelings and symptoms which incapacitate me and make my life miserable. The best doctor in town, after searching tests with elaborate apparatus of the most modern type, finds no disease. Hence, my sickness is unique and beyond the pale of present-day methods of medical science. Hence, I am indeed hopeless and beyond the power of human aid." This state of depression is often the result of the habit of thought of the physician leading him to deal only in physical manifestations, concluding that no further investigations can be made after a thorough physical examination.

It would be a sad mistake to belittle the physical survey and the wonderful assistance that refinements in diagnosis has brought to us, as it is the rock upon which medicine rests. The essayist very aptly points out the lack of logic in concluding that a certain train of symptoms is always due to deviation from the normal found in the body. The neurasthenic patient has a group of subjective symptoms and at the same time may have certain pathological changes in the body without there being any real connection. The skill in diagnosis that we must display is not the finding of things, but in placing the proper significance on them in the individual case. In a searching survey of a hundred persons, for example, probably not more than a small fraction would be without some demonstrable abnormality. There might be slight anemia, change in the character of the blood-cells, disturbances of the gastrointestinal tract such as constipation or enteroptosis, pelvic disorders in malpositions of the uterus, without any of them having any direct bearing upon the group of subjective symptoms which brings the patient to us. We consider ourselves lucky if we find some definite pathology in the body which is impairing the health of the person to such an extent that nervous fatigue is likely to ensue because such a finding can be attacked directly.

We discredit ourselves, however, if we follow the path of least resistance and fix upon any abnormality that may be present for the indication of our treatment, instituting thereby some formidable procedure like a surgical operation, the extraction of teeth, etc., or refined therapeutical measures which, after completion, leave us with as miserable a patient as we had before, and, in some cases, with the symptoms very much accentuated. As it appears to me, we must think of the receptivity of the sensorium in every human being in our estimation of subjective symptoms. The receptivity may be increased or diminished by certain physical states, and certainly by the inherent temperament, the personality, and in short, the thing which is called by the writer the "individuality." Also, this receptivity may be influenced materially from time to time by environmental factors which make it necessary that studies be made of them in each individual patient. In other words, a disease such as a psychoneurosis may consist of ordinary somatic impressions of everyday life activity, such as fatigue, sensations from the digestive tract, etc., thrusting themselves upon the mind of the person with such vividness that attention is given to them by consciousness, whereas ordinarily they would be ignored.

It is undoubtedly true that even in real organic diseases we have a psychogenic phase which must be considered, as no two human minds react in the same way to the same amount of somatic pathology. In other words, the lesion in an organ in some individuals does not create a train of symptoms that in another type of mentality would be registering in consciousness frequently. In the consideration of the psychoneuroses we must also consider psychogenic symptoms interlaced with those produced by the histopathology.

THE ADULT EQUIVALENT OF THE FROELICH SYNDROME

By GEORGE KNAPP ABBOTT, M. D.

Adiposity with scanty menstruation or amenorrhoea are common in gynecologic practice. Many such patients show no other evidence of illness, and in the absence of gross pathology of the female organs little has been accomplished in their alleviation. Certain patients with scanty or absent menstruation with nervousness may be benefited by the use of extract of whole ovary or corpus luteum. Others with a distinct thyroid factor may obtain relief from thyroid feeding with or without ovarian extracts. Endocrine dysfunctions affecting menstruation are various and varied. If each such disorder could be reduced to a definite syndrome with specific endocrine therapy, these problems would be easy of solution by careful history-taking and thorough examinations. In the present state of our knowledge such is not now entirely possible. However, any contribution may be welcomed which tends to separate from the mass of such disorders a few cases of apparently common origin with common symptoms and definite results of endocrine therapy. Such is the endeavor of this study. Five patients with an apparently common etiologic factor and similar symptomatology have been selected.

These cases appear to the writer to be a nearly complete adult counterpart of the juvenile disorder known as the Froelich syndrome. The outstanding features are adiposity, scanty menstruation or amenorrhoea, with headache and lassitude. With but little exception, this symptom group is present with all the five patients. The onset in all cases followed closely upon an attack of influenza or measles. In the course of a few months all showed a rapid and remarkable gain in weight ending in a definite adiposity. Lassitude is marked in all, amounting in some of the patients to almost total inability to maintain physical effort for even an hour or two. Exhaustion occurs after both ner-

vous and muscular effort. Headache is present in four, and severe in three. This is constant or nearly so, worse at menstrual dates, and often so severe as to be designated unendurable. It may be bitemporal, frontal, or occipital, and sometimes is located at the top of the head. The onset in one patient was during puberty, and so this one shows a little of the juvenile type, though not markedly so. Three of the five patients showed practically identical symptomatology, and these three obtain definite relief under pituitary feeding.

EXAMINATION

In addition to the usual procedures of a detailed history and physical examination in all cases, special attention was paid to symptoms and findings reputed to be of endocrine origin. Sugar tolerance was high in all, basal metabolism within normal limits, and X-ray of the sella turcica indicated no alteration in size or contour. Special inquiry was made into the matter of focal infections because these are notably common sequels of such acute infections as influenza. Though benefit followed the removal of such foci, yet the main symptoms were but slightly affected.

The symptom group, characteristic of this type of hypopituitarism, is sufficiently well illustrated by a synopsis of case record of patient No. 5, so that we may avoid the tedium of reciting all in detail.

A TYPICAL CASE

Case No. 5 (9817 St. Helena Sanitarium and Hospital, April 15, 1921). A widow, age 23. Has one child age 2. The presenting symptoms are amenorrhoea, adiposity, and nearly constant headaches, with periodic exacerbations at menstrual dates. The family history is negative. The past history shows attacks of measles, scarlet fever and mumps, with frequent tonsillitis. Tonsillectomy was done in 1914, and appendectomy in 1917. An attack of influenza occurred in 1919. The menses have been regular, except the past one and one-half years she has had but five or six periods. The present illness began six months after influenza, when she missed the next five consecutive periods and has missed many since then; others have been scanty. The gain in weight began at the same time, twenty pounds in the first three months, then fifteen in the next year. Much of the adiposity is about the hips. Headaches began four months ago and are frontal and at vertex, and much worse at menstrual dates. They have continued more than half the time for the last three weeks. She is free in the morning; they begin at noon and cease only with sleep.

Examination showed large remnants of both tonsils. Other items were largely negative or normal, except as to adiposity. A diagnosis of hypopituitarism was made and the patient given a dry extract of whole pituitary, 1 grain reinforced with anterior pituitary 1 grain, and whole ovary 2 grains, each three times a day. April 21, 1921, a secondary complete tonsillectomy was done. As shown by the subsequent course, the headaches, which were relieved by the pituitary feeding, returned if it was omitted for two to four weeks consecutively.

May 7, 1923, the patient writes that the first three months of a recent pregnancy (second marriage) she was forced to take pituitary extract for two or three days at a time, and then could go about two weeks before another headache. No headaches occurred the last six months of pregnancy, and no pituitary extract was taken during this time, and none for six or seven months following confinement. At this time the headaches began again and she was advised to use ovarian extract, but with indifferent results. She returned to the use of pituitary extract, which she takes for a few days, and can then go two weeks without headaches, which are otherwise worse at her periods.

The other patients showed a very marked lassitude with the occurrence of the headaches. In two they were constant or nearly so, with no diurnal variation in severity. One patient gained forty pounds in five months, with a total gain of sixty pounds since the onset, which began six months after an attack of influenza. This patient was nearly free from headache, but would easily sleep fifteen hours out of the twenty-four, and was irritable and melancholy. In another patient the amenorrhoea and gain in weight were such as to simulate pregnancy. Experience showed little or no benefit to be derived from ovarian extracts in any of these patients. This was in sharp contrast with the results of corpus luteum therapy in that type of periodic headache previously described by the writer. In one patient the headache and lassitude were so severe that 2 grains of pituitary extract had to be taken four times a day to give relief. Little, if any, change in any of the five patients was observed in either the obesity or amenorrhoea, even when corpus luteum or whole ovary were added.

CONCLUSIONS

1. There is a type of hypopituitarism in adults of subacute onset which in many respects resembles the juvenile Froelich syndrome.

2. It appears to be caused by such acute infections as influenza and measles.

3. Its symptom complex is the rapid production of adiposity with scanty menstruation or amenorrhoea, headaches, and marked lassitude.

4. The headaches and lassitude are relieved by feeding whole pituitary, which must be repeated at intervals. These symptoms are uninfluenced by ovarian extracts.

5. The adiposity and amenorrhoea are but slightly, if at all, influenced by the pituitary feeding. The same lack of effect follows the use of ovarian extracts.

Abstract from Report of Industrial Accident Commission—According to the Industrial Accident Commission, out of approximately one million workmen employed during 1921 there occurred 62,273 injuries causing disability lasting longer than one day and 550 industrial deaths, representing 6,829,294 total days of work lost. It also meant the payment of compensation in the sum of $3,924,582. In 1922 the reported injuries mounted to 83,246 and the deaths to 700. The figures for 1923 are not yet available, but undoubtedly will show a proportionate increase.

ADENOMATA OF THE THYROID GLAND *

By EDWIN H. SCHNEIDER, M. D., Los Angeles

There are three kinds of goiter, adolescent or colloid goiter, adenoma and exophthalmic goiter.

My reason for choosing adenomata of the thyroid gland as the subject of my paper is because this is the most prevalent form of goiter seen by the physician, because its etiology is probably least understood and because every physician does not always recognize the general pathology of this type of goiter. True adenomata of the thyroid gland are benign tumors recognized as palpable, spheroidal, circumscribed masses, occurring either single or multiple. The average age at which they make their appearance is at the twenty-third year. From the adolescent or colloid and exophthalmic goiters it is readily recognized by the fact that the enlargement is always asymmetrical and nodular. Histologically, adenomata are readily divided into two classes, encapsulated fetal adenoma and encapsulated adult adenoma. This division is made according to whether the tissue takes the structure of the fetal thyroid or the adult thyroid. Adenomata of the adult form are by far the more frequent. A non-degenerated adenoma upon section shows a homogenous structure and may take on all the changes which have been noted in the thyroid tissue outside the encapsulated tumor. Granular, hyaline, fibrous, cystic, hemorrhagic, calcareous and necrotic degeneration occur within these tumors early and frequently. Malignancy is present in about 1.6 per cent.

Virchow and Wolfler were unable to decide what enlargements were to be considered as tumors and what are merely diffuse overgrowths of physiologically adult tissue. Billroth, Virchow, and Wolfler believe that adenomata arise from embryonic cell rests, i. e., the Cohnheim theory. David Marine, in regard to the etiology of adenomata says: "Cohnheim's conception offers the best explanation of the origin of these tumors when one enlarges it to include the different physiological ages of the development of the main thyroid mass, and that the stimulus for tumor growth is the same as for that of the thyroid as a whole." L. P. Wilson says: "While it may be true that adulte adenomata do develop from fetal rests, there is insufficient evidence to demonstrate this beyond peradventure." Adenomata, according to Marine, occur only in thyroids which show a general hypertrophy or hyperplasia.

What is the stimulus which produces an overgrowth of the thyroid gland as a whole and directly or indirectly produces adenomata? A few decades ago great stress was laid upon the influence of altitude and inorganic matter, particularly calcium in the water supply, in the production of goiter. More recent experiments and more careful observations tend to show that adenomatous goiter can be produced by many different agents, inorganic and organic, acting as poisons. Marine, in a recent publication, speaking of adolescent goiter, says: "We at present must fall back on the view that thyroid hyperplasia is a compensatory reaction arising in the course of a metabolic disturbance and immediately depending on a relative or an absolute deficiency of iodine." A most common factor which increases the need of iodine is an infection. Organic matter is increasingly asserting itself as an important cause, and it is this agent that I wish principally to discuss as one of the etiological factors in adenomata of the thyroid gland. Wilms, in 1910, showed that the residuum of filtered water derived from goitrous districts when added to the usual and harmless water and administered to dogs, guinea pigs, and monkeys produced goiter in these animals. In India during the rainy season, when organic matter is rapidly disseminated, the number of goiters among the whites and natives is greatly increased.

Switzerland, which stands first in its proportion of goiterous individuals, uses human feces in their natural state as fertilizer. Kocher has repeatedly urged the importance of this causal agent in the production of goiter. Suzuki produced enlargement of the thyroid gland in rats by feeding them with cooked rice mixed with rat feces, and also by injecting the latter subcutaneously. McCarrison observed a similar result in animals allowed to drink only water polluted with feces. Marine produced goiter in brook trout placed in polluted water. A great many more experiments could be quoted to prove the relation of organic matter to goiter, but, while the ingestion of organic matter may bring into activity a large number of pathogenic agents, Jaboulay, Klebs, Kocher, Lustig, McCarrison, Riviere, Waters and others have laid stress on some pathogenic organism or its toxin as an exciting cause of goiter. Hirsch's conclusion, as regards the etiology of endemic goiter in his "Handbook of Geographical Historical Pathology," says: "The absence of results to all these inquiries about the genesis of goiter and cretinism—inquiries which have extended to every influence perceptible to the senses that could be brought into the consideration of the question before us—warrants the conclusion that in these diseases we have to do with a specific agent, a veritable morbid poison, and that endemic goiter and cretinism have to be reckoned among the infectious diseases."

Adami thinks that if micro-organisms cause the malady they do so indirectly by forming injurious products in the water; thus goiter would be the result of an intoxication instead of an infection.

Edward C. Rosenow found a streptococcus in goiter removed at operation. Cultivating the streptococcus and injecting it into the mediam vein in the ear of rabbits, he has produced hemorrhages and lesions in the thyroid gland of these animals. He says: "Strains of streptococci from rheumatic fever, myositis and cholecystitis produce hemorrhages in the thyroid gland commonly, while those from other sources rarely do so." Bloodgood says: "The histological picture of chronic thyroiditis is usually found in the compressed thyroid tissue in the capsule and outside the capsule of the adenoma. As the histological structure of non-degenerated adenomata resembles in structure the surrounding

* Presented to the Section on Surgery at the Fifty-second Annual Session of the California Medical Association, San Francisco, June, 1923.

extra capsular tissue, we must determine why certain portions of the hypertrophic or hyperplastic tissue become encapsulated and undergo early degeneration. We know that adenomata occur in thyroid glands which show a general hypertrophy and that the stimulus for tumor growth is probably the same as that for the thyroid as a whole.

From a consideration of the above experimental facts, it would seem that one or more bacterium or its toxin is the causative factor in most cases of goiter. In 1887, Gregory stated that nature has three ways in protecting the organism against noxious agents: First by ingestion; second by encapsulation; and third by extrusion. That the second method of protection, that of encapsulation of a focus of pyogenic organisms or their toxins, may be the cause of the formation of adenomata seems very reasonable and is further strengthened by the fact that hemorrhagic, fibrous, cystic and calcareous degeneration occur so readily within these tumors. An infection elsewhere in the body may directly or indirectly, by producing a deficiency of iodine, stimulate the thyroid gland as a whole and produce an adolescent, colloid or exopthalmic goiter. Adenoma is a local, circumscribed, a walled-off tumor, a disease of part of the thyroid gland. We could, therefore, expect to find the causative factor locally—that is, within the tumor itself. That pathogenic bacteria are not more frequently isolated from these tumors is not surprising when we remember the usual chronicity of this condition, the generous blood supply of the thyroid gland and the natural antitoxic properties of the thyroid secretion.

In the examination of over 3000 patients with adenomata, I find that over 80 per cent give definite histories of a previous acute infection. It is not unusual to hear a patient say, "I noticed a small lump in my throat a few weeks after a severe sore throat." Examination of these patients often reveals chronic appendicitis, chronic tonsillitis, blind root abscesses, pyorrhea, sinusitis, chronic otitis media, chronic arthritis, chronic bronchitis, chronic constipation, chronic cholecystitis, and pulmonary tuberculosis. The symptoms produced by adenomata depend upon the size and location of the tumor or tumors and the degree of hyperthyroidism. A small adenoma lying against the trachea may produce great dyspnea. This occurs rather frequently in single adenoma arising from one of the lower poles of the thyroid gland. Again, the tumor mass may be the size of one's fist and yet produce little or no discomfort. Pressure symptoms are far more likely to occur in adenomatous goiter than in the other forms because of their tendency, in addition to their general growth, to project nodules which directly or indirectly produce compression of some neighboring structure as the trachea, oesophagus, blood vessels, and nerves.

According to Matthews, paralysis or paresis of one vocal chord is present in 17 per cent of goiters coming for operation. About 25 per cent of adenomata sooner or later, on an average after fourteen years, develop symptoms of hyperthyroidism. In the early stages of hyperthyroidism the symptoms are like those seen in any toxemia; that is, malaise, lack of endurance, loss of strength, nervous instability, loss of weight, free perspiration, rapid pulse, and a tendency to hypertension. In more advance cases the heart becomes the chief organ affected. Thirty per cent of adenomatous goiter have an enlargement of the heart over one-half inch. The ultimate damage to the heart, liver, kidneys, and nervous system may be just as great as that occurring in acute hyperthyroidism, due to exophthalmic goiter. Why it takes an adenoma about fourteen years to produce symptoms of hyperthyroidism we do not know, but these are the facts, and only by heeding them can we avoid the deleterious effects of this insidious and dangerous disease. Symptoms of myxedema may supervene when the surrounding thyroid tissue has been destroyed by pressure atrophy or by the useless use of the X-ray for treatment.

TREATMENT

A spontaneous disappearance of an adenoma rarely, if ever, occurs. They are, as a rule, but slightly responsive to medical treatment. I believe one is justified in treating medically for a few months a small adenoma of recent origin, but it is absurd and even harmful to treat medically an adenoma of long standing, with pressure symptoms, or with symptoms of hyperthyroidism. Kocher has shown that goiter patients having prolonged iodin treatment show hyperthyroidism earlier than cases not treated at all. Enucleation is the method of choice, since these tumors can now be removed so safely that death from operation is merely accidental. Of course, cases with marked myocarditis have the same risk as any other major operation would have in the presence of this condition. If our infectious or toxic theory as to the origin of adenomata is correct, and most modern evidence points that way, treatment should consist in the removal of all foci of infection both primary and secondary. I believe the mere enucleation of adenomata is not sufficient to produce a cure, and before or after operation a careful search must be made for the etiological agent and it also removed.

Charles C. Chapman Building.

DISCUSSION

Frank H. Paterson (Twohy Building, San Jose)—The presentation of this paper is timely, for the reason that, despite recent advances in our diagnostic methods, goiters of the adenomatous type remain all too frequently unrecognized until severe grades of pathologic physiology have developed. Because these adenomatous or so-called "toxic goiters" represent such varying stages and degrees of partial hyperthyroidism, their diagnosis requires the greatest skill and judgment. The hyperthyroidism of adenoma does not develop until fifteen to twenty years after its appearance and usually persists for a period of several years before the surgeon is consulted. It is in these cases that heart and kidney damage are frequently as extensive as in the exophthalmic types of goiter, and the surgeon is, therefore, more concerned with the ability of the heart and kidneys to functionate than with the contingency of post-operative hyperthyroidism. It is important to differentiate between Graves' syndrome and toxic adenoma of the thyroid—in the former X-ray therapy appears to exert a beneficial influence, at least recourse thereto seems justifiable prior to operation, while in the strictly adenomatous forms, where the cause lies within the thyroid, surgical removal can be depended on to effect a cure.

In adenoma after the thyroid rests become active, the average metabolic rate is plus 35 per cent, whereas in exophthalmic goiter the average runs over plus 50 per cent. While it is conceded that the greatest service we can render, in this, as well as most other ills, is along such lines of prevention as have been made possible through the researches of Marine and others, the surgeon will be, for some time to come, confronted with the problems presented in the advanced conditions until both the profession and the laity are more generally acquainted with the advantages of prophylaxis.

Albert H. Rowe (119 Thirteenth Street, Oakland, Cal.)—Why adenomata of the thyroid which contain fairly normal acinar tissue and which produce thyroxin apparently normal in activity arise in the thyroid is a problem. The iodine deficiency theory of the origin of colloid and adenomatous goiters, to my mind, is sufficient to explain the origin of goiters without taking into account the infection hypothesis which Schneider favors. However, much evidence, as outlined in his article, necessitates the consideration of the latter possibility. Toxic adenomas of the thyroid are insidious in onset, and usually are overlooked except by the specialist who is actively engaged in thyroid diagnosis. Even large adenomas may be held down within the thyroid parenchyma, making them difficult to see and even to palpate. Even minute adenomas may produce hyperthyroidism, and it has been my experience that any thyroid which is definitely palpable and which is firm and slightly irregular and lacking at all in symmetry may contain adenomata. Patients with such thyroids, who have a pulse rate above 85, and a history of even slight increase in nervousness or loss of weight and an increase in subjective body heat, should routinely have a careful metabolic rate determination. In these cases where the average rate is not apt to be over 20 or 30 per cent, the technic of the metabolic rate test should be carefully performed and the result checked up by a clinician who is constantly in touch with pathological thyroid material. We frequently see patients who have received incorrect thyroid diagnosis based purely on metabolic rate determinations which have not been skillfully performed. All toxic adenomata require surgical treatment, and the results obtained are often magical. When the adenomata are encapsulated, enucleation is sufficient. However, a different adenomatosis of the entire thyroid gland is not uncommon, which condition requires the subtotal thyroidectomy which is now done by all surgeons for hyperplastic goiter. Postoperatively, the clinical condition of the patient should be followed with the help of metabolic rate determinations, in order to ascertain that the hyperthyroidism has been properly controlled or that a hypothyroid state does not occur as a result of the surgery. In my opinion it is wise to enucleate adenomata, which are not toxic, since they can be easily removed with local anesthesia, and this before any toxic damage to vital organs has occurred.

H. H. Searls (University of California Medical School, San Francisco)—The classification suggested by Schneider is the one commonly used today, except that a distinction is usually made between the adolescent, or simple hypertrophy, and the colloid goiter. Pathologically, simple hypertrophy gives us a microscopic picture within normal limits, while the colloid shows markedly distended alveoli packed with heavily staining colloid and lined by flattened epithelium. The well-developed colloid goiter shows such a different picture under the microscope from that of the typical adolescent, that a separation of these two types in the classification is warranted.

There does not appear to be sufficient evidence to credit the development of adenomata to an infectious factor when it has the pathological characteristics of a true benign encapsulated tumor of thyroid tissue. Should this hypothesis be accepted, then a similar etiology would have to be considered in similar tumors of other tissues of the body. Schneider states that examination of 3000 patients with adenomata showed 80 per cent with history of a previous acute infection. Could not a similar history be obtained in 3000 cases of fibroid of the uterus, for instance, or breast tumors either benign or malignant?

The harmful results of the X-ray treatment of adenoma of the thyroid cannot be too strongly emphasized. There is very positive evidence that it does not have any action on adenomas, and merely injures the surrounding thyroid tissue. Frequently, particularly in the larger adenomatous goiters, the surrounding glandular tissue has been severely injured by the pressure of the contained adenomas, and in such instances the added insult of X-ray therapy results in the development of myxodema.

THE EFFECTS OF POSTURE ON RELAXATION UNDER ANESTHESIA

By CAROLINE B. PALMER, M. D., San Francisco

The importance of posture under anesthesia is commonly acknowledged as having a bearing upon respiration, circulation, strain on muscles and joints, and pressure on nerves. Less commonly the effect upon relaxation and the required depth of anesthesia for surgical operations is considered, but in every-day practice the subject is disregarded to an astonishing degree.

Surgeons ordinarily, when making an examination for a suspected pathological condition of the abdomen, for example, place the patient in a posture which gives the greatest possible degree of abdominal relaxation, but the actual operation is frequently performed upon a patient in such a posture that the abdominal muscles are on a considerable tension. This naturally necessitates a much more profound degree of anesthesia, and is sometimes the determining factor in the use of a toxic anesthetic such as ether, instead of a non-toxic anesthetic such as nitrous oxid and oxygen.

(1) The ordinary dorsal position on a perfectly flat surface, often with a very thin inadequate pad between the patient and the table, is one of considerable strain. This is greatly increased in the case of muscular or fleshy patients. (2) Simply using a pillow of the proper size to bring the head in line with the body adds greatly to the patient's comfort by relaxing the neck muscles. It is not sufficient to use the same size pillow for all patients, for naturally one that would be satisfactory for a slender patient, such as the one shown in the slide, would be entirely inadequate for a larger patient. This seems almost absurdly simple, but I venture to say that not all hospitals provide pillows of various sizes for their operating-tables. (3) Flexing the thighs to a greater or less extent adds greatly to the patient's comfort, and by easing the tension on the abdomen increases relaxation. Frequently when this is done, patients say, "Oh, that's better." The use of a small firm pillow under the back decreases the probability of postoperative backache, but here again, it is necessary to have pillows of various sizes. Too large a pillow increases tension. It is a safe rule that, unless the back pillow is comfortable while the patient is awake, it is not of the correct size or is not properly placed.

(4) To further increase abdominal relaxation,

it is sometimes of advantage to elevate the thorax to some extent. In the picture I purposely accomplished this by means of pillows as suggesting that an especially constructed table is not required.

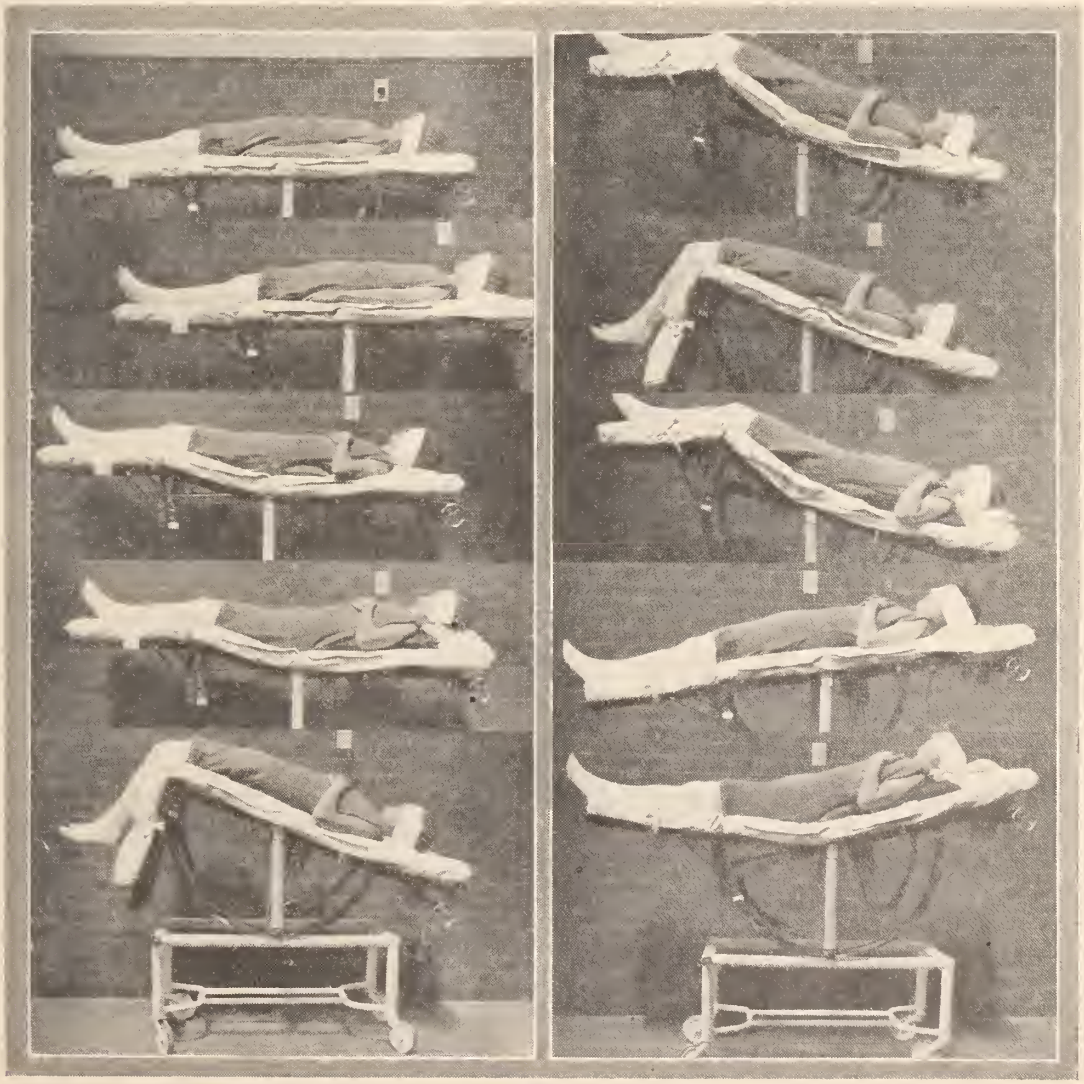
(5) The ordinary Trendelenburg position is one of considerable strain, and certainly in this posture the abdominal muscles are on a definite tension. When we were taking the picture for this slide, the model remarked that the posture was decidedly uncomfortable, but as soon as we flexed the thighs and supported the legs (6), she volunteered the information that the posture was comfortable. The simple experiment of raising and lowering the legs shows definitely the relaxation of abdominal muscles with the legs raised and supported as in this illustration, and the tension of the same muscles when the legs are lowered (7). The use of the back pillow in this pernicious type of Trendelenburg position may decrease post-operative backache, but certainly does not add to abdominal relaxation.

(8) Raising the thorax in what I venture to call the correct Trendelenburg position sometimes assists in abdominal relaxation just as it does in what I venture to call the correct dorsal position (4 again). (9) The reversed Trendelenburg position causes a degree of strain which actually interferes to some extent with respiration.

(10) By flexing the thighs, raising and supporting the legs, and slightly raising the thorax in addition to the inclination of the table, the entire anesthetic condition is changed for the better, and there is a definite increase in relaxation.

I sent this series of pictures to D. A. Sargent of The Sargent School for Physical Education, Cambridge, Mass., and asked his opinion as to the effect of the changes of posture here shown. I quote a portion of his reply: "What you accomplish by the suggested change of position seems to be the relaxation of the flexors of the femur and those of the trunk and the neck, which of course relieves more or less the tension on the abdominal wall."

At Stanford University Hospital, as a result of observation in a series of more than 10,000 cases, we have come to believe that due attention to posture during induction and maintenance of anesthesia pays large dividends in ease and rapidity of induction of anesthesia; greater relaxation; less profound degree of anesthesia required; better condition of patients after operation; and greatly decreased post-operative discomfort.



EDITORIALS

1924 STATE MEETING

All members who desire to read papers at the State meeting should communicate immediately with the secretaries of their sections. Each section holds but three meetings and, in consequence, has time for a very limited number of papers.

A few secretaries have already sent in their programs. Will all members who have papers to submit send the title and abstract of their papers to their section secretaries at once, and the completed manuscript not later than February 15? After that date, papers are no longer acceptable for the 1924 meeting.

PAINLESS INTRAMUSCULAR INJECTION OF NEOARSPHENAMINE

The chief objection to the use of neoarsphenamine by intramuscular injection has been the local inflammatory reaction resulting in considerable pain. If neoarsphenamine, and similar products, could be administered intramuscularly without the local reactions, it would be a distinct step forward in the therapy of syphilis. It would practically abolish the dangers attendant upon intravenous injections, and permit easy and safe administration in children in whom intravenous injections are sometimes technically difficult, if not impossible.

The problem of rendering intramuscular injections of neoarsphenamine painless and without local inflammatory reaction has been recently studied by Freud of the Pharmacological Institute in Vienna, with distinctly promising results. In dogs, Freud found that the intramuscular injection of 0.15 gm. of neoarsphenamine in 5 per cent alypin nitrate containing 5 to 10 per cent acacia produced only a slight rubefaction at the site of injection, while the same dosage of neoarsphenamine injected alone caused marked infiltration of the tissues and rubefaction. Out of ninety-one adult patients injected intramuscularly with 0.15 to 0.45 gm. neoarsphenamine in 7.5 per cent acacia containing 5 per cent alypin, only six, or 16 per cent, showed rubefaction, while 30 per cent of patients injected with 0.05 to 0.15 gm. neoarsphenamine without acacia and alypin showed local reactions. So far as the colloid (acacia) was concerned, the best results were obtained with 7.5 per cent acacia. Good absorption of neoarsphenamine was preserved and pain was reduced. Ten per cent acacia retarded the absorption too much. The role of the alypin in Freud's mixture is simple and quite evident, but that of the acacia is more complex. According to Freud, the acacia serves two objects: firstly, it supports the action of the local anesthetic, and, secondly, it protects the neoarsphenamine against the decomposing and precipitating influences of the added local anesthetic (alypin). Thus, it seems that Freud's mixture is not a case of empirical polypharmacy, for it rests on the application of scientific principles derived from the physical chemistry and pharmacology in the improvement of therapy. From the practical standpoint, and most important of all, is the claim that the clinical results from the intramuscular administration of neoarsphenamine in the acacia-alypin mixture are at least as good as from intravenous administration, and free from the dangers of the latter.

Freud, P.: Arch. f. exp. Path. Pharm. 1923, 97:54. "Über Verhinderung der entzündlichen Reaktion nach intramuskulärer Neosalvarsan-Einspritzung."

WHY NOT SOLVE SOME REAL PROBLEMS?

The most important known essentials to prevention of disease and the prolongation of life are neither numerous nor hard to understand. Most of our modern literature deals with matters that would be of more or less minor importance if we would only correct a few of our fundamental failings, for the most part quite generally ignored.

The interesting article by Anna Rude on the Midwife Problem (Journal A. M. A., November 12, 1923) calls attention to one of the murderous customs of the dark ages that is still prevalent. If it is true—as it undoubtedly is—that obstetrics, including prenatal care, delivery of the child, and after-care of both mother and child, constitutes the practice of medicine, why should there be a midwife problem? Why should there be midwives or any other classes of inadequately educated or, more often, ignorant people carrying on this exacting specialty of medicine—with or without the sanction of the law?

Rude tells us what we suspect is only part of the story, that there are over 40,000 midwives or what not practicing obstetrics in the United States. In other words, there are one-third as many incompetents practicing in a difficult field of medicine as there are physicians.

The end-results of this situation can only be guessed at, but certainly they are not creditable.

CALIFORNIA'S SITUATION

According to Rude, there are 104 midwives authorized to practice in the state who attend 8 per cent of maternity cases. Although the author does not estimate that any unauthorized persons are practicing, it is a matter of common knowledge that there are many of this class, and that when necessary certain persons will sign the birth certificates for them, just as certain persons authorized to practice do sign death certificates for patients whom they never saw and who were attended by unlicensed practitioners.

There is no excuse for inadequately educated persons practicing obstetrics or any other branch of medicine in California, because we have one physician to each 500 of population, and they are so well distributed that, in practically all instances, good services may always be obtained. This is particularly true for a condition that requires service at a rather definite date well known in advance by the patient and the doctor.

What is needed in California, and to a much greater extent in some other states, is for some powerful organization to attack and solve this and other major health problems instead of trying to surround them with alleged safeguards.

SELLING "ELIXIRS OF LIFE"

A considerable portion of the Edwin Smith Papyrus written in the seventeenth century before Christ is devoted to discussion of

"The incantation for transforming an old man into a youth of twenty."

The subject was not new then, but can be traced back through further centuries until, like other historical data, it becomes lost in the mazes of mythology and antiquity. During nearly 4000 years since the early written accounts, there are numerous and more or less connected references in the literature of efforts and methods of restoring sexual youth to the aged. At almost every stage of world development are records of alleged discovery of the true elixir of life and its sale to the public by ubiquitous Ponce de Leons. Many of the vendors profited greatly by these sales, just as they are profiting now by promoting one or another of the numerous and "only sex restorers" offered for sale to a gullible public.

Amulets are still sold as in the days of Babylon. The "Fountain of Youth" wells of Egypt and of the Irish folk tales are always in the land of Bimini just around the corner. Sorcerers still bend over blue flickering braziers and vamp youth back into the aged as they did in the days of Hermippus.

The youth-restoring milk from the blended male and female goats of antiquity has been replaced by an easier but no more certain use of the goats' sexual organs.

Aged flappers, male and female, with the sagging tissues of their necks "hooked up" by surgeons, and their exposed wrinkles ironed out by massage until they look like billikens, insure plenty of propaganda that is utilizable as "news." As "exhibits," they apparently bask in the notoriety they gain from the pathetic exposition of their pictures and senile statements to the public. Their careers are usually short, because the old arteries go on hardening; the creaking joints continue to stiffen, and the brain continues to soften all the more rapidly because they are unnaturally speeded up and not allowed to grow old gracefully.

This remarkable opportunity, of publicity ready-made and a mad world trying to defeat God's edict, proves too much for some physicians who themselves fall for the glitter of gold and the tinsel of notoriety. This is the most sickening phase of the whole situation.. The attitude and conduct of some physicians in California and elsewhere is casting reflection upon other members of a creditable profession and is causing many people who look to physicians for guidance, to jeopardize their health and squander their funds for a new youth that is no more attainable by the use of monkey glands, goat glands, or what not, than it was for those other silly fools who followed the incantations of the Nile doctors.

Two European "doctors," Steinach and Voronoff, now appear to be jockeying for first place in advance propaganda preparatory to making a fortune out of the health and lives of our citizens. One of them appears to be waiting for his much-advertised monkey farm in Africa to become sufficiently populated with the strong healthy males of the species, while the other is to be accompanied by his own surgeon who will perform the "difficult," "new" operation that is old and is performed several hundred times a month in our country, to prevent propagation of the unfit.

In the meantime and while awaiting the arrival of these elderly "leaders" who apparently have not healed themselves, we are being entertained by the vulgarities of "little Voronoffs" from the ranks of our local profession. Their "press agents" are making them notorious; their disgusting, nauseating practices are damaging the standing of a humanitarian profession, and many silly, often senile, citizens, rich and poor, are being duped by alleged remedies for sexual impotence.

Our medical societies expel members who follow other cults, and they ought to expel advertising alleged "gland specialists." This not only for the honor of their profession, but for the cause of better medicine for all citizens.

Nothing in this editorial is intended to reflect upon the splendid research work going on in many places but which is not put forth prematurely by propagandizing specialists for their own aggrandizement and to the detriment of the public in health.

ECONOMIZING IN STATE "HOSPITALS"

According to news dispatches from Sacramento, as a result of the economy program of Governor Richardson, the cost of care of the patients in Napa State Hospital has been reduced from $21.75 in November, 1922, to $19.24 in November, 1923.

This information, which apparently is given out as something to be proud of, should be challenged in the name of those who are not able to speak for themselves. Such shamefully inadequate costs can be arrived at only by "special" methods of accounting or by rendering poor service to the sick. Every person who has the responsibility of providing a living knows that neither the 72 cents a day for 1922 nor the 64 cents a day for 1923 are sufficient to provide good housing, clothing, subsistence and other costs for healthy people, much less those who require all of these things and medical, surgical, nursing, laboratory and other forms of care in addition.

In no branch of medicine has greater progress been made than in the treatment and management of neuropsychiatry patients. The splendid results that are being reported from a few Government hospitals elsewhere and many private ones from everywhere are not attained at a cost of a few cents a day. The daily per capita actual cost of the minimum of good institutional, medical, surgical, nursing, X-ray, dietetic, laboratory, and other care of these patients is expressed in dollars instead of a fraction of a dollar. This regardless of the character of management or ownership of the institution rendering the service.

The ultimate cost to taxpayers is not so much greater for efficient care than it is for the custodial care still too prevalent in politically controlled "hospitals." This is because a much higher percentage of the patients become much improved and

many recover and are restored to usefulness when adequate treatment is given. Then, too, some healthy physicians and nurses cannot serve long and maintain their mental poise in some of these so-called hospitals that give such care to patients as is possible at a cost of a few cents a day.

The demands and criticisms of whole-minded patients and their friends in other classes of hospitals exert a powerful influence toward the constant improvement of these hospitals. There is no such chance in hospitals for those whose minds are darkened and where visiting periods are so rigidly controlled. This should make us all the more solicitous for the welfare of the benighted patients. Every known possibility for improvement in the mental and physical condition of each of these patients should be patiently exhausted before they are treated as derelicts.

Efficient "hospital" care of the mentally irresponsible is one thing and the "custodial" care of the hopelessly demented is another and much less expensive service. Both are necessary. No government should have the right to place patients in the "custodial care" class until they have been carefully studied by staffs of competent physicians under real hospital conditions and all hope of their betterment under any circumstances has been given up.

We do not believe that the people of California desire or, if they knew, would tolerate less than we have indicated for their fellow citizens who are unable to speak for themselves. Intelligent persons will very well know that adequate hospital and professional service is not, and cannot be, rendered at a cost of a fraction of a dollar a day.

The facts as to what is being done and what is not being done are matters of record, but until such time as some powerful and active civic organization becomes interested in the question, publication of additional facts would serve no useful constructive purpose.

WHY "POSITIVE HEALTH"?

The double negative has long been subjected to the attacks of grammarians for the very simple reason that its meaning is exactly the opposite of that intended. The double positive is not in such ill-repute because it is seldom used and only Shakespeare, with his "most unkindest cut," is permitted to use the double superlative without censure, if not without comment.

There is a double positive recently come into common usage by certain health workers, however, that ought to be consigned to the graveyard of things-that-never-should-have-been, and that is the phrase "positive health." Surely, disease in itself is negative and, consequently, health must be positive. Why paint the lily?

Some American medical journals are guilty of using this deplorable term, and at the recent International Health Education Conference in San Francisco it was lipped with great frequency. Of course, it is understood that the phrase is intended to cover generalities, but when we have so many words with which to be specific and so many health subjects that require exactness, why should we positive the positive so glibly and so meaninglessly?

Health education is vastly more than the imparting of mere generalities. Pupils must receive their education in health by means of simple, direct statement of fact. The teacher who can talk only in vague generalities cannot teach. The public, furthermore, wants and will get its health information in definite terms. Leaders in the advance of the public health movement of today must know exactly the message that they have to give, and they must know how to present it in clear, simple, direct, plain Anglo-Saxon. Heavier pressure on the positive alone will never eliminate the negative, and ostrich-like methods in not recognizing disease will never result in the promotion of the public health.

COLORADO'S "MATERNITY LAW"

Colorado has a new "Maternity Law." It has some interesting features. Provisions are made for the expectant mother during the last six months of her pregnancy. The infant's welfare is assured during its first six months after birth. The operation of the law is in the hands of the Children's Court, over which Judge Ben Lindsay presides. Either the mother or friends may make application for relief, which includes all varieties, from cash to medical and hospital care. All proceedings are conducted in the most confidential manner. Physicians and hospitals and nurses are paid for their services.

Unmarried mothers are given the same confidential care as others, including loss of identity in maternity hospitals. Infants of unmarried mothers will be placed in homes upon request. The law also gives the court wide authority in dealing with the father responsible for an illegitimate child.

It is claimed for this law that it requires no enlargement of government machinery and that its benefits are easily and confidentially available without red tape to any mother unable to pay the necessary costs of adequate assistance.

The power of the court to require fathers to accept financial and other responsibility for their illegal children is expected to reduce the cost of operating this law to the taxpayers.

This all sounds too good to be true.

PERSONAL PUFFERY

No conscientious physician can examine large press-clipping services and read the great number of letters that pour into the office of any medical organization without becoming gravely concerned over the tendencies of so-called "education of the public" in medical subjects. The movement for Medical and Public Health Education for the Public is as old as medicine itself. There are on file in libraries plenty of resolutions and discourses upon it dating back through the centuries. We have recently read some that might be republished today, as new and as appropriate as they were when originally presented centuries ago.

Of course the public should be informed—as far as they are capable of comprehending without medical education—upon all subjects pertaining to

better health. A review of what has been, and what is being, produced along this line indicates rather depressing conclusions. Much is being put out that is inaccurate in this or that particular point, depending upon the source of the alleged information. Many of the subjects discussed and conclusions drawn for the alleged benefit of the public are controversial even among physicians themselves. The result is that, if one collects the press clippings, the "release stuff," the text-books and brochures of all sorts that are being put out upon some phases of the question, he can find just as great a variety of opinions as those already existing in the minds of the public. In other words, we are not clarifying public opinion at all, but actually confounding the confusion that already exists.

On the other hand, some of the educational material, and particularly that which is given out in an impersonal way, is accurate, reliable, well digested, and well presented. It is unfortunate that this class constitutes only a small fraction of the other kind.

In addition to the confusion that is being confounded by the inaccuracies and general character of much of the medical educational literature, we have the lack of sufficient knowledge among the "educators." It, of course, should be obvious that a teacher in the field of public health and medicine, regardless of who is being taught, must first himself have sufficient knowledge of the subject he is teaching to present it clearly and accurately. It probably would not be an overstatement to say that not one out of a hundred of those "informing" the public upon medical and health subjects knows what he or she is talking about. We thus have another explanation as to why the general public is confused about even the simplest subjects of medicine and public health.

This also accounts, to a very remarkable degree, for the prosperity of quackery of one sort or another at the present time—a prosperity never before seen in the history of the world. Our modern medical frauds are no different in their fundamental operation from those of earlier times. Cultists and quacks rely upon the ignorance and superstition of the people they propose to serve. Inaccuracies and confusion in supposedly authentic "educational material" and the lack of education of the instructors themselves, as shown by examination of their sayings, give to quacks chances which they never before had.

Another danger in this situation, which has been pointed out recently by many thoughtful writers, is that the controversial points in public health and medicine, as well as the froth and more or less immaterial points, are receiving the maximum amount of attention, while the essential and major subjects are being neglected or relegated to places of secondary importance. Questions like vaccination against smallpox, inoculation against diphtheria, pure water and air, and food supplies, general sanitary conditions, exterminating disease-bearing insects, and many other fundamental problems, are receiving scant attention; whereas propaganda as to the use of monkey glands, cancer specifics, tuberculosis specifics, and similar movements, receive tomes of publicity and dogmatic conclusions from ignorant or commercially interested persons.

Finally, the worst feature of all is the personal puffery that is being put out by certain doctors, groups, and clinics for their own aggrandizement and the promotion of persons toward which the propaganda directs the arrow. The great injury of this sort of unethical puffery is being more and more felt by conscientious physicians, and they resent it for themselves and because it detracts from public confidence in the profession as a whole. The editor of this Journal receives many letters from physicians criticizing the conduct of some physicians, clinics and organizations for this type of propaganda, and if the feeling in the hearts of the majority of good physicians were known to some of these personal puffers it might cause them at least to use more subtle means of self-advertisement and self-aggrandizement.

Some of these doctors come out boldly under their own names and often with their photographs, while others hide their heads in a clinic or some other organization and imagine that their real motives will not be understood. Brothers, it takes a great deal more subtlety than some of you are using to fool the general public—much less physicians.

SAN FRANCISCO COUNTY MEDICAL SOCIETY APPROVES ADULT HEALTH CENTER FOR THE UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL

The Out-Patient Department of the University of California Medical School and Hospitals has established an "Adult Health Center" for the "periodic examination of apparently normal individuals." This movement, as explained in the following outline of policy, was presented to the board of directors of the San Francisco County Medical Society at its meeting on October 9, and approved by them for the county society:

Adult Health Center, University of California Medical School

The Out-Patient Department of the University of California Hospital is establishing, under the jurisdiction of the Department of Medicine, an Adult Health Center for the periodic examination of apparently normal individuals. The purposes are: (1) To detect early disease processes, faulty hygiene or other conditions which, if not corrected, may result in impaired health; and (2) to educate the medical student in normal variations in health and early symptoms and signs of disease.

The Adult Health Center will examine indigents or those of small means who are unable to pay for the services of a physician. The fee will be $1, to include an examination of urine, stool, blood, Wassermann, and vaccination for smallpox. Applicants who are found ineligible for the examination by reason of ability to pay will be referred to their family physician.

The examination offers no special problem, and is one that any physician may undertake in his private office. Emphasis will be placed on corrective measures when defects are noted. Physicians will be welcome.

The Adult Health Center will extend the work which has been going on for years in the Department of Pediatrics and Obstetrics of this and other medical schools, to the adult group in the Department of Medicine. Such work has

embraced the clinics for well babies, children of pre-school and school ages, the prenatal care of mother and child, and care of the mother for at least a year after delivery. These activities will be continued.

Of course, every physician and every physicians' organization is interested and concerned in providing facilities for medical and public health care of all people, of all ages, everywhere. The American Medical Association has approved the policy and provided a plan, including physicians' office records. for the periodic examination of "apparently normal individuals." A number of private organizations, well financed, are in the field to accomplish this purpose through various forms of membership or insurance policies. Hundreds of members of the California Medical Association are now engaged in doing this work for one organization or another, as well as for the members of their own clienteles.

It is illuminating to note the advance among groups, clinics, and municipal health organizations of one sort or another in the development of this field. Some of them limit their work to people who can pay for the service in fees of from $1 up; others are altruistic enough to offer service only to those who are able to pay $1 or less.

Two years ago the California Medical Association, through its House of Delegates, passed a resolution making every physician's office in the state a "health center." That resolution, with explanatory comment, was published in the November, 1922, number of the California State Journal of Medicine, and is as follows:

Health Centers

Resolutions adopted by the House of Delegates of the Medical Society of the State of California on May 17, 1922.

Whereas, It always has been and is the primary purpose of physicians to give trained, scientific, sympathetic service to all of their fellow-citizens who need medical advice and to **furnish this service to all alike, regardless of the social or financial standing of the patient,** and

Whereas, It never has been and is not now necessary to interpose any agency not under the direct supervision and control of competent members of the medical profession between the physician and his patient. Co-operation in agencies where such medical supervision and control does not exist often proves detrimental to the interests of both patients and physician, and

Whereas, In order to re-emphasize these policies and practices to all citizens of California, and to counteract the influences going about the State to the effect that consideration by physicians for those needing medical advice can be obtained only by applying to some non-medical organization, and in order that the public may be fully informed and free to call directly upon the physician of its choice, with the assurance of sympathetic and confidential consideration, therefore, be it

Resolved, By the California Medical Association and representatives of all county and other constituent organizations, in convention assembled, that the office of each of its 4000 members throughout the State is a "health center" of the kind that means the best medicine and public health advice that physicians can give; **this upon the basis that those who can pay in full should do so, those who can pay part should do so, and those who are unable to pay should have the service without cost.**

Resolved, That in order to secure special financial consideration, the patient is requested to execute and sign a paper showing his socio-financial status and setting forth briefly the reasons why he must ask for special financial consideration, this being the policy now being followed by honest clinics and welfare organizations.

Physicians' Offices As "Health Centers"

One of the important resolutions passed unanimously by the House of Delegates at the last annual meeting of the State association was printed on the front cover of the November, 1922, Journal. Contained in the minutes of the House of Delegates, as part of that resolution, is the following note:

"The State society will supply each of its members with appropriate blank forms for this purpose, and will furnish one to any citizen who desires to use it. One of these forms presented to any member of the State society in any part of the State will insure the courtesies and special consideration that his condition warrants and, in addition, he will receive the same sympathetic, confidential, constructive help that is given to the person who is able to pay fully for all that he requires. In carrying out this program, physicians reserve the right, when they think wise, to check up on the accuracy of the applicant's statements in an unobtrusive and sympathetic manner, in exactly the same way as those reports are now being checked up by clinics and other welfare organizations. Members also reserve the right to refer applicants for special consideration to other physicians under the same conditions and for the same reasons that they would refer patients paying regular fees. Any sick person in any part of the State of California who fails, for any reason, to secure adequate medical attention is requested to communicate with the secretary of the State Medical Society, 1016 Balboa Building, San Francisco."

It is the general impression among physicians, and the resolution itself so states, that it is a re-emphasis of the practices and policies of physicians everywhere at all times.

There are two outstanding features of this resolution, the most important being that **physicians are ready to render service to any person requiring professional care; that those who are able to pay the physicians' regular fees for this service should do so, those who are able to pay part should do so, and those who are unable to pay any of the fee should have the service just the same;** all services, regardless of the status of the patient, to be rendered in the same high grade, confidential, sympathetic manner. The other important feature in the resolution is that it never has been, and is not now, necessary to interpose any agency not under the direct supervision and control of competent members of the medical profession between the physician and his patients.

It has been said by some that, if the spirit of this resolution were applied, physicians would not be able to give adequate care to all of the ambulatory sick in this State, particularly in certain congested centers. The facts are, that members of the medical profession **now** take care of all of the ambulatory sick, as well as those who are bedridden and require more time, and, furthermore, the problem in the aggregate is not as large as some people seem to think. If all the sick people in the State of California, of whatever class, kind and condition, were divided up equally among the seven thousand educated physicians practicing in this State, they would have less than twenty sick people

each to look after. If the ambulatory patients were so divided, the doctors' offices of this State would average less than ten visits per office per day.

The primary consideration in the carrying out of this or any other resolution or policy of the medical profession is, that the sick people, regardless of class of sickness, their place of residence or any other consideration, should have adequate medical care. This medical care should be available to all ambulatory patients in physicians' offices and to all others in their homes, hospitals or wherever else they may be. The resolution of the State Association is an effort to make these facilities available in a practical manner.

If the terms of this resolution were carried out in good faith—as they are being carried out by some members of the State Association—there would be little room or little excuse for more elaborate and pretentious clinics. There is in San Francisco County, for instance, one physician to each 500 of population, which is four times as many as necessary to give the public health advice and treat all the sickness that occurs in the population, provided this work could be allocated. Many of these physicians, members of our society, have very small incomes, and many of them, if they would follow the terms of the resolution of their own State Association, might develop a future clientele and make many friends, by the examination of apparently normal individuals for very small fees.

Careful work has shown that among the population of any community periodic examination shows the necessity of a certain amount of professional work in more than three-fourths of those examined. This periodic examination is a very important service to a community; it ought to be done by physicians in their offices, but if physicians are not willing to do it upon the basis of accepting a fee commensurate with what the person is able to pay, then it is perfectly proper that clinics of state or municipal organization undertake the service and employ physicians to do it.

If it is necessary for clinics to do this work for people who are unable to pay more than $1 for each service, it is likely that the large volume of medical work which is developed by these clinics will be performed by the hospitals and members of the clinic making the original examinations. This is a most important point and ought to have serious consideration by physicians who have spent large sums of money and made many sacrifices to get an education.

Another point that must not be lost sight of in making periodic examination is that the record of the examination should be available to the physician who is going to treat the patient in any illness that may be discovered by the examination, and also to other physicians who may later be called upon to treat the patient.

Between the efforts of various insurance companies, life extension institutes and similar organizations, groups of physicians and individual physicians who are now and long have been engaged in making periodic examinations, and the crop of "periodic examination clinics" that are sure to develop, the people of San Francisco ought to be well served in their examinations.

COUNTY NEWS

ALAMEDA COUNTY

Fabiola Hospital — New Maternity Building Opened—On December 15 Fabiola Hospital opened its new Maternity building for inspection by the public. A luncheon was given for the staff in the nurses' home, attended by about 160 physicians, including several guests from San Francisco and other nearby points. Throngs of people visited the building from 2 to 5 in the afternoon and were served with tea. Mrs. J. P. H. Dunn, assisted by other members of the board and members of the staff, explained the workings of the new department to the visitors.

The new unit contains 21 private rooms, 29 ward beds, 2 cubicle wards of 5 beds each, 2 two-bed wards, 5 three-bed wards. There are two delivery rooms, two nurseries, one isolation nursery, two doctors' rooms, as well as a complete X-ray and deep therapy treatment department. The cost of the building and equipment was approximately $260,000. During the last ten years the hospital has done $113,000 worth of free and part-pay work, there being a daily average of ten free and part-pay patients treated during 1922.

Dr. Liliencrantz, president of the staff, presided at the luncheon, and called upon Daniel C. Crosby for a brief outline of the history of Fabiola Hospital, and Dr. Crosby responded as follows:

In 1876, when Oakland was a small community—scattered over a large area with few of the usual municipal advantages and improvements which characterize many smaller communities of the present day—a man was severely injured upon one of its streets. The injury was a terrible one and the County Hospital, such as it was, was ten miles away, and there was no ambulance and no trained people to transport him. Transportation in a lumber or hay wagon meant death in all probability, and the by-standers stood aghast.

Mrs. R. W. Kirkham, who had recently come to Oakland to make her home, passed that way, shared in the horror and anxiety of the by-standers, and with much surprise learned that Oakland possessed no hospital of any sort. Her comment was short and direct and pregnant with meaning, "Then Oakland must have a hospital."

There were then in this community, as there are always in all communities, people of philanthropic instincts and altruistic vision who were willing to make and lead others to make practical applications of their philanthropy and altruism. Eighteen women, of whom Mrs. A. Liliencrantz, Mrs. I. E. Nicholson and Mrs. Alice Cameron still survive, organized a hospital and dispensary association, and, being closely allied with several enthusiastic homeopathic physicians, called their new venture "The Oakland Homeopathic Hospital and Dispensary Association."

From small beginnings, great enterprises grow—as the oak from the acorn. The acorn of development of Fabiola was a tremendous need, which awoke a fine enthusiasm, and each woman of the original eighteen subscribed $50 for a life membership. This limited sum of $900 in money and a limitless wealth of the milk of human kindness constituted the nucleus from which the present institution has evolved.

The declared object of the association was to provide a home for the sick, worthy poor, entirely without means or for those with limited means, but no home. Two free beds were to be maintained, and for such other beds as could be provided, a fee, graduated in proportion to the patient's means, was to be charged for medical attendance and hospital care. The corps of medical attendants were to give their services without fee.

A small house secured at Nineteenth and Market

streets, painted, cleaned and refurnished by the hands of Mrs. H. C. Taft, Mrs. W. W. Standiford and Mrs. Wallace Everson, was turned into a hospital and dispensary, and here the first patient, a homeless, young woman, late in pulmonary tuberculosis, was cared for for six months until her death. Even her burial was attended to by the association. After another protracted case, which terminated fatally, the County Board of Supervisors voted $40 per month to the association on condition that it care for all cases referred by the board.

After one year of this experiment, the Hospital Association having lost $100 in the process, this stipulation and agreement was discontinued, and from that time the board of directors have depended upon their own efforts and the community interest which they have been able to develop to maintain their enterprise.

The list of contributions in the early years is very interesting (three quarts of milk for two months; a basket of fruit; two dozen towels; a chicken; ten dollars; and innumerable items of necessities in small amounts) and shows that, while these women were working in a small way, their interest and oneness of purpose was always emphasized. When a child's bed was contributed and a few toys were given to interest the child, there was much glee at the increased facilities.

By 1883 the hospital had outgrown its quarters; a house at 1057 Alice street was purchased and the good work went on. However, after a lapse of three years this place was no longer adequate and new arrangements were necessary. When the inadequacy of the Alice street location became apparent, the need of material change appealed to two men whose names must be inscribed with gratitude whenever the interests of Fabiola Hospital are considered. Anthony Chabot, with a generosity typical of him, presented to the association the two and one-half acres upon which the institution now stands and Frederick Delger contributed $5000 toward the erection of a building.

Following these two red-letter events in the history of the institution, the annual report of 1887 announces that "we are about to erect a hospital building after the models of the most eminent sanitary engineers." This building was erected in due time and now constitutes the old building of the present group, and is the one which must, within the next few years, be replaced by a fireproof structure.

Up to January, 1887, as many free as pay patients had been cared for in the hospital and this was rendered possible by the very generous support which had been given the institution by a gratefully interested public.

At this time, feeling that the public should know and understand that the institution was not devoted entirely to homeopathic practice of medicine, the name was changed from "The Oakland Homeopathic Hospital and Dispensary Association" to "Fabiola Hospital Association." The name "Fabiola" was chosen because of the noble Roman matron who in the fourth century went about the city of Rome caring for the sick poor and established the first hospital in the world. "How far the little candle throws its beams." Of the woman Fabiola, Leckie said, "The charity planted by that woman's hand overspreads the world and will alleviate, to the end of time, the darkest anguish of humanity."

By 1887, eleven years after its inception, this enterprise of altruism, philanthropy and mercy was established beyond peradventure and steps were taken to bring to fruition a larger plan, because the association had earned the confidence of the community.

It will be a matter of interest to Oaklanders that when the present site was purchased and given by Anthony Chabot, the only objection voiced to the location was that it was too far from the center of things in the city. The success which crowned the efforts of the good women in charge of the hospital's destinies did not come without great labor and economy on their part, and the institution always had to look at both sides of the family shilling, for at the end of the tenth year, in 1886, the treasurer's report shows a balance on hand of 45 cents.

In 1908 the new surgery, as it is called, was erected and the second phase of the hospital's existence was made manifest and offered another milestone of record of the results of patience, economy and industry, even while combined with altruism and philanthropy.

So many women have given their best thought and time and energy to the welfare of Fabiola Hospital that it is difficult to single out any one of them. However, the names of four stand out: Mrs. Kirkham, whose thought gave birth to the enterprise; Mrs. John Yule, who for twenty-four years guided the destiny of the board and to whose untiring efforts, more than to the efforts of any other one, must be credited the erection of the first or main building of the present plant; Mrs. Remi Chabot, who directed the activities of the institution from 1908 until 1916; and Mrs. J. P. H. Dunn, who succeeded her mother in 1916 and under whose able leadership the hospital has prospered and grown in size and in quality until now the institution is opening one of the most modern maternity hospitals in the West.

A good modern hospital must have well-equipped clinical laboratories, X-ray laboratories, operating rooms, adequate nursing service and good kitchens in charge of trained dietitians, and all of these we now have. We can hardly compare the little rooms at Nineteenth and Market streets with the present plant, but for that reason all the more must we bare our heads to show the respect due to those women and to the professional staff which made the first beginning possible.

The hospital situation has changed greatly in the intervening years. The Alameda County Hospital, under the trained leadership of a noted hospital authority and with a highly competent professional staff, is no longer the poor house of an older day, and, while still housed in the old building at its old site, is now a splendid institution and before long will be housed in the new Highland Hospital, which will be second to none in the West. Dr. Samuel Merritt devoted much of his fortune to the admirable institution which bears his name and the mercy of his bounty will be exercised as long as this city lasts. The Sisters of Providence have come to Oakland and met another phase of the city's needs in the effective way that their training and opportunities permit them. Both of these and the smaller excellent hospitals about the bay are rendering much free service to the needy sick.

The Oakland Homeopathic Hospital and Dispensary Association may well be proud to acknowledge the Fabiola Hospital of the present day that, without special endowment, without outside support of great moment, thrives under the direction of a devoted board who seek no monetary reward and who, out of the earnings of the institution, have been able year after year to render more than a thousand dollars a month of free service to the needy overtaken by illness.

The torch lighted in 1876, marking the way for untold numbers to health and well-being, is still burning and is carried high to keep bright the traditions of the pioneers of Fabiola.

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary)—The annual meeting of the society was held at Hotel Oakland, November 21. A banquet was served, followed by a theater party at the Orpheum, for the following members and guests: Dr. and Mrs. C. L. Abbott, G. M. Bumgarner, H. L. Carpenter, P. C. Campbell, C. R. Leech, E. B. Fitzpatrick and C. R. Blake; Dr. J. T.

Breneman and daughter; L. St. John Hely, Hall Vestal and F. L. Horne, and Miss Agnes Driscoll of the Cottage Hospital.

The following officers were elected for 1924: President, Hall Vestal; vice-president, G. M. Bumgarner; secretary-treasurer, L. St. John Hely.

The subject of group insurance was discussed.

FRESNO COUNTY

Fresno County Medical Society (reported by John D. Morgan, secretary)—The regular meeting of the Fresno County Medical Society was held at the General Hospital of Fresno County on December 4. Forty members were present.

Leo Eloesser of San Francisco spoke on "Surgical Treatment of Septic Condition of the Chest."

James H. Bryant, of Hume, has been elected to membership. Thomas M. Hayden of Fresno was elected to honorary membership. The following resolution was adopted:

"Whereas, After thirty-five years of practice of medicine and surgery in the city and county of Fresno. Thomas M. Hayden has retired from active practice and,

"Whereas, During the entire existence of the Fresno County Medical Society, Thomas M. Hayden has been an active member and an untiring worker in the interests of ethical medicine, now therefore be it

"Resolved, That as a token of esteem and honor held for Thomas M. Hayden by the members of Fresno County Medical Society he is herewith elected to honorary membership in the society; be it further

"Resolved, That a copy of this resolution be spread on the minutes of the society and a copy sent to Thomas M. Hayden with the best wishes of the society."

KERN COUNTY

Kern County Medical Society (reported by P. J. Cuneo, secretary)—Vice-President Moore, in the absence of President Sabichi, presided at the meeting of the society held November 15 in Bakersfield, at the Kern County Hospital. The following members answered to the roll call:

Bacon, Goodall, Gundry, Compton, Rogers, Morris, McNamara, Smith, Hamlin, McKee, Moore, Cuneo, Veon.

Miley B. Wesson of San Francisco was the guest of the society and gave a talk, illustrated by many lantern slides, on "The Kidney and Ureter," which was followed by extended discussion led by Gundry, Moore and McNamara. Hamlin, Morris and McKee were appointed a committee to arrange for the annual banquet, to be held at Stockdale on December 20. It was voted to have the ladies present and follow the meeting by a dance. The January meeting will be held at Taft. Veon, Bacon and Smith are to have charge of the February session.

M. F. Frandy, late of Maricopa, was given a transfer to the Santa Barbara County Society, as he is now a resident of Guadalupe. Kern county regrets to lose Frandy as a member but wishes him all success in his new location.

Leland Ellis has been at Santa Barbara for the last six weeks in attendance upon his mother, Dr. Kathyln Ellis, who has been very ill.

N. Portoghese is now located at San Diego.

E. A. Schapor, who holds membership in our society, although he resides in San Francisco, paid us a visit recently.

C. W. Kellogg, retired, has returned from a several months' absence at Moro Beach.

New Kern County General Hospital—The new hospital being erected at Bakersfield is now about half complete, and the board of supervisors have awarded a bid of $111,000 for the new Home for the Aged, which is to be a unit of the General Hospital plant, erection to be started at once.

In the past year it has been the policy to isolate all patients with communicable diseases in the General Hospital, and it has been found highly advantageous, as it has reduced contagiousness 50 per cent.

LOS ANGELES COUNTY

Murphy Memorial Hospital, Whittier—Work has started on the addition to the Murphy Memorial Hospital, and under the personal supervision of Colonel Simon J. Murphy it will proceed until the new wing is ready to turn over to the city for furnishing. This new gift by Colonel Murphy will cost considerably over $100,000 and will add forty beds to the capacity of the hospital, or a total of ninety. The new wing is being built on the southeast end of the main building and will be four stories in height. Colonel Murphy is quoted in the press as saying: "Our slogan shall continue to be, 'Everything for the patient.' I have been well satisfied with the attitude of the people of Whittier in regard to my wishes to make the standard of this memorial hospital as high as possible, and I believe the hospital staff has been a most decided help in realizing this ambition. For these reasons I am more than happy to be able to again help in giving to Whittier one of the best hospitals on the coast."

Hollywood Hospital—On November 11 members of the staff, officers and employes and the friends of the hospital in general inspected the new plant, after they had been entertained at a ham-and-egg breakfast at the institution. The hospital will have 150 beds, a nurses' home and a laundry.

Seaside Hospital, Long Beach—This excellent hospital is owned and operated by physicians. The earnings of the hospital above 6 per cent are utilized in giving service to those unable to pay. A year ago arrangement was made with the public welfare department of the city by which the hospital would operate an outpatient department for the poor. The hospital furnishes space, equipment and staff and hospital personnel. The welfare department supplies a social service investigator and worker and pays the cost of the medicines and other extras. Three hundred and eighty-five thousand were treated during the year; there were 1202 examinations, 408 special treatments, 102 operations, and 44 patients were fitted with glasses. The public health nurse and social worker connected with the department made 941 home visits to patients.

MERCED COUNTY

Merced County Medical Society (reported by Brett Davis, secretary)—Monthly meeting held in Merced, November 8, with the following present: W. C. Cotton, J. L. Mudd, D. W. Zirker, Brett Davis, C. W. Kohl, E. R. Fountain, Frank W. Yokum, W. E. Lilley, A. S. Parker.

H. A. L. Ryfkogel of San Francisco presented the subject, "The Acute Abdominal Symptoms," first giving the physiology of the gastro-intestinal tract, then the acute conditions of appendicitis, perforation of gastric or duodenal ulcer, biliary and renal colic and acute pancreatitis, differentiating them and stressing the importance of not giving an opiate before a diagnosis is made and not giving laxatives, food or drink while symptoms are acute.

Brett Davis has resigned as city health officer of Merced, and A. S. Parker has been appointed in his place.

There has been a small epidemic of scarlet fever in Merced during October and November.

Merced Hospital, Merced—This newly constructed and equipped hospital was formally opened on November 20. The hospital was financed by a sale of stock under the plan proposed by the League for the Conservation of Public Health, whereby any earnings above 6 per cent must be utilized in rendering service to people unable to pay. The hospital has thirty beds and cost $60,000. After its completion the trustees leased the hospital to Miss Iva E. Trumbell for a period of five years.

ORANGE COUNTY

Santa Ana Valley Hospital Association—Plans are under way to raise an increased amount of funds for financing the new Santa Ana Valley Hospital. Approximately $125,000 is already on hand, but an effort will be made by a committee of seventy-five to sell another $150,000 worth of stock.

PLACER COUNTY

Placer County Medical Society (reported by Robert A. Peers, secretary)—The Placer County Medical Society held its annual meeting in the Masonic Hall, Auburn, December 1. The following members were elected as officers for the year 1924: President, H. N. Miner; vice-president, J. A. Russell; secretary-treasurer, Robert A. Peers; associate secretary, Charles J. Durand; delegate, Sidney J. Talbot; alternate, Harry M. Kanner.

Case reports were made by G. H. Fay, J. G. Mackay, H. M. Kanner, L. B. Barnes, W. L. Whittington, Robert A. Peers.

Owing to the fact that this was the annual meeting, no literary program was presented.

SAN BERNARDINO COUNTY

San Bernardino County Medical Society (reported by E. J. Eytinge, secretary)—The society met December 6 at the San Bernardino County Hospital, with thirty members present, forty-seven absent, and five guests. R. S. Gibbs opened the program with a paper on "Some Special Conditions of Pregnancy"; discussion was opened by W. D. Lenker. Clifford McKee of Los Angeles gave a paper on "A Study of the Uterine Scar following Cesarean Section," and discussion was led by H. W. Mills. Norman Williams of Los Angeles took as his subject, "Cervical Repair on Ninth Day Post-partum"; discussion opened by C. G. Hilliard.

The following new members were welcomed into the society: Walter F. Pritchard (by transfer from Napa County), A. N. Kerr and V. L. Minehart of Arrowhead Springs, and Lenore D. Campbell of Loma Linda.

SAN DIEGO COUNTY

San Diego County Medical Society (reported by Robert Pollock)—In few communities are the relations between the organized medical profession and that of dentistry more closely and harmoniously affiliated than in San Diego. On Tuesday evening, December 11, the members of these two professions, with their wives, enjoyed together an excellent dinner at the San Diego Hotel, after which the following social program was presented : Three-minute speeches by J. E. Jennison, M. D., retiring president of the medical society, and W. E. Walsh, D. D. S., retiring president of the dental society; reading of the elections of the day, the polls having closed at 5 p. m.; brief talks by the newly elected presidents, Andrew J. Thornton, M. D., and F. G. Titus, D.D.S.

The program up to this point was interspersed with vocal numbers by the Orpheus Male Quartet, which were thoroughly enjoyed, and culminated in the address of the evening on the "Meaning of Citizenship," by John P. Buckley, D. D. S., of Los Angeles, ex-president of the American Dental Association. Afterward dancing was enjoyed by those present until a late hour.

Complete returns of the day's election follow:

Medical Society—President, A. J. Thornton; vice-president, Mott H. Arnold; secretary, George B. Worthington; treasurer, C. O. Tanner; councilors, F. H. Carter, M. C. Harding, H. A. Thompson; certified milk commission, W. W. Crawford, R. J. Pickard, R. G. Sharp, H. A. Thompson, A. B. Wessels; delegates, T. O. Burger, W. W. Crawford, Robert Pollock, George B. Worthington; alternates, M. C. Harding, J. C. E. Nielsen, L. H. Redelings, Martha Welpton.

Medical Library Directors—E. A. Blondin, M. M. Doria, W. H. Geistweit, Jr., M. C. Harding, D. R. Higbee, R. A. Lush, R. J. Pickard, Robert Pollock, L. H. Redelings, Harvey Stallard, W. E. Walsh, George B. Worthington; secretary-treasurer, C. O. Tanner, M. D.

U. S. Naval Hospital, San Diego—Plans have been completed for a $500,000 addition to the Naval Hospital. This splendid hospital is well located in Balboa Park and is one of the newest and best constructed and best managed of modern hospitals.

SAN FRANCISCO COUNTY

San Francisco County Medical Society (reported by J. H. Woolsey, secretary)—During the month of November the following meetings were held

Tuesday, November 6—Committee on Medicine—Pediatrics—(1) An unusual case of suppurative myositis, Samuel Hanson; (2) An epidemic due to streptococcus infrequens, Edith Boyd; (3) Management of meningococcus meningitis, E. C. Fleischner.

Tuesday, November 13—General Meeting—Nomination of officers for 1924. The Question of Pregnancy in: (1) Nephritis, Alice F. Maxwell; (2) Cardiac disease, Adelaide Brown; (3) Pulmonary tuberculosis, G. H. Evans.

Tuesday, November 20—Committee on Surgery—(1) Some problems in ano-rectal surgery, A. J. Zobel; (2) Citrate blood transfusion and report of 250 cases, E. L. Bruck and LeRoy Brooks; (3) Demonstration of apparatus for reduction of fractures of femur, James Eaves and Paul Campiche.

Tuesday, November 27—Committee on Eye, Ear, Nose and Throat—(1) Demonstration of cases, instruments and methods; (2) A few notes on Halle's clinic with especial reference to his endonasal surgery, Robert D. Cohn; (3) Present aspect of postgraduate and clinic work in Vienna, Warren D. Horner.

William W. Wymore Appointed to the Board of Health—Mayor James Rolph, Jr., has again demonstrated his wisdom by appointing a well-known member of the San Francisco medical fraternity upon the board of health of the City and County of San Francisco. Doctor Wymore graduated from Cooper Medical College in 1895 and during all his professional life he has been engaged in the active practice of his profession in San Francisco. He was a captain in the medical corps of the U. S. Army during the World War. The vacancy which Doctor Wymore is to fill is caused by the completion of fourteen years' service in that position by Dr. George B. Somers.

It may be predicted with confidence that safe, sane, conservative, legitimate medicine and public health will continue to make progress along the right lines with men like Wymore controlling the activities of the City and County Board of Health.

Saint Luke's Hospital Clinical Club—At the regular meeting of the Saint Luke's Hospital Clinical Club of December 4, E. S. Kilgore discussed cardiac neuroses. A. C. Gibson spoke on pan sinusitis and suggestions for treatment at the meeting held December 18.

St. Joseph's Hospital—On December 12 St. Joseph's Hospital staff held its monthly meeting with a varied program. R. M. H. Berndt, T. James and William Quinn presented case histories of patients with post-operative myocarditis, broncho-pneumonia and embolism.

Ethan Smith spoke on hospital notes made on a six months' vacation, including observations in Victoria, Vancouver and Winnipeg, Canada, and in Michigan and Ohio.

W. T. Cummins, director of the clinical laboratories, reviewed the work of his department, showing an increase in different lines, from 75 per cent to 500 per cent. He described new colored sheets for future reports, L. Crowe, director of the X-ray department, gave a resume of his work, and suggestions for future progress. H. Unsinger outlined

the augmented requirements for the library and Newman read the financial account.

On January 9, the "Modern Treatment of Lymphangitis" will be presented by Harry C. Coe, and "Surgical Treatments in Syphilis" by Howard W. Fleming.

University of California Medical Society (reported by William J. Kerr, secretary)—The regular monthly meeting of the University of California Medical Society, held in Toland Hall, University Hospital, on Thursday, November 22, 1923, was attended by more than one hundred members and guests.

J. H. Woolsey of the Department of Surgery presented a case of jejunal ulcer which had followed gastro-enterostomy in a patient suffering from ulcer of the duodenum. The frequency of the condition and symptoms which suggest the possibility of such an ulcer were discussed. Specimens of similar ulcers were shown as well as ulcers at the region of a gastro-enterostomy which apparently resulted from the use of silk as a suture material. A. E. Rockey of Portland was present and discussed the presentation.

Herbert M. Evans of the Department of Anatomy spoke of the vitamin known as vitamin X which he and his co-workers have been able to isolate from plants and food materials. He showed the effect on rats of removing this substance from the diet—the fertility of the animal was seriously interfered with. When the foods containing this substance were added to the diet of these same rats, fertility was re-established.

While Dr. Evans did not feel that this vitamin was much of a factor in the ordinary diet, yet it was of some interest in showing the effects of diet on fertility.

The next meeting of the society will be held Thursday, January 24, 1924. Karl F. Meyer will speak on "Medical and Non-Medical Experiences in Europe During the Past Year," and Drs. Rusk and Woolf will present something of pathological interest.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by Alex C. Soper, Jr., secretary)—The regular meeting was held Monday, December 10 at the Cottage Hospital, President Means in the chair. Present: fifteen members, two guests, and three internes.

President Means gave a report on his conference with the City Council in the matter of public health questions, and their cordial reception of the aims of the society. Matter also discussed by Freidell, Bagby and O. C. Jones of Lompoc.

George F. Farman of Los Angeles gave a paper on "Some types of chronic recurrent pyelitis and their treatment," which was discussed by Wills, Freidell, Pierce and Sansum.

It was moved by Pierce, seconded by Hotchkiss, that a vote of thanks be extended to Farman for his excellent paper. Passed unanimously.

It was moved by Bagby, seconded by Schurmeier, that the annual banquet in January be held at the Hotel Samarkand. Passed unanimously.

SISKIYOU COUNTY

Siskiyou County Medical Society (reported by C. C. Dickinson, secretary)—At the last regular meeting of the Siskiyou County Medical Society, held in Yreka, November 12, 1923, the following officers were elected for the ensuing year: President, C. W. Nutting, Weed; vice-president, F. B. Lucas, Hilt; secretary-treasurer, C. C. Dickinson, McCloud.

SONOMA COUNTY

Sonoma County Medical Society (reported by N. Juell, secretary)—On December 13 the society met at Petaluma with twelve members present, twenty-five absent; four visitors. E. W. Cleary of San Francisco delivered an address on "Fractures," with illustrations.

Fifty dollars was voted to be sent to aid suffering German medical men. G. S. Holeman was transferred to Centerville, Alameda county. G. W. Mallory, a charter member of this society, was re-elected to membership.

The following officers were elected for 1924: President, Alfred A. Thurlow, Santa Rosa; vice-president, A. M. Thomson, Sonoma; secretary, N. Juell, Santa Rosa; treasurer, R. M. Bonar, Santa Rosa; censors, F. O. Pryor, Santa Rosa, J. H. McLeod, Santa Rosa, J. W. Cline, Santa Rosa; delegates, H. L. Rogers, Petaluma; alternate, F. O. Pryor, Santa Rosa.

The meeting was followed by a banquet.

STANISLAUS COUNTY

Stanislaus County Medical Society (reported by R. E. Maxwell, secretary)—The Oakdale members of the society entertained the members of the society and their ladies at a turkey dinner, which was served by the culinary department of the Oakdale high school. The following members were present: C. J. Bemis, C. E. Benson, J. A. Cooper, F. R. DeLappe, E. V. Falk, C. E. Finney, E. F. Hagadorn, F. R. McKibbon, President E. R. McPheeters, J. W. Morgan, secretary pro tem, C. E. Pearson, F. J. Peters, E. F. Reamer, B. F. Surryhne, and J. A. Young.

H. G. Mehrtens of San Francisco read a paper on "Neuro-Syphilis, with Technique of Swift-Ellis Treatment." The subject was exceptionally well handled.

E. G. Allen was admitted to membership in the society.

A committee on insurance was appointed, following talks on the subject by representatives of the Medical Protective and Aetna companies.

A vote of appreciation and thanks was given the Oakdale school board for the use of the school for the meeting.

Roentgen-Ray Intoxication—S. L. Warren, San Francisco, and G. H. Whipple, Rochester, N. Y. (Journal A. M. A., November 17, 1923), state that evidence from animal experiments and scattered clinical observations is convincing that the human intestinal mucosa is peculiarly sensitive to the hard and short-wave length Roentgen rays. A similar condition obtains in the common laboratory mammals. It is probable that the intestinal epthelium is at least as sensitive as the skin epithelium, and it may be more so when its increased distance from the Roentgen-ray target and the intervening body tissues are considered. Erythema doses or larger doses given over the abdomen or intestinal areas may cause injury to this sensitive intestinal epithelium. The authors urge particular care should be used when "cross-fire" is used over areas including intestinal coils, as the loops may be seriously injured. Local Roentgen-ray injury to intestinal coils may not give rise to severe clinical intoxication, but may cause ulcers that are no less chronic and dangerous than are the familiar Roentgen-ray skin "burns." It is very desirable that all cases in which erythema or larger doses are given over the abdomen be very carefully studied and reported so that our knowledge as to the danger limits may be comprehensive. Until such time, we must use the data obtained from controlled animal experiments. Such experiments indicate that the intestinal epithelium is quite sensitive to hard irradiation. These facts should receive careful consideration by the radiologist who contemplates radiotherapy of abdominal areas (for example, pelvic tumors).

THE FUNCTION AND PROPER FIELD OF ACTIVITY OF THE PUBLIC HEALTH OFFICER

In promoting the betterment of public health, Leverett D. Bristol, Olean, N. Y. (Journal A. M. A., Nov. 24, 1923), says the private practitioner and the public health official must co-operate to bring about desired results. While special functions and fields of activities of health officers and private practitioners may differ, their objects and aims are the same—to promote positive health for all members of society and to relieve the more unfortunate persons of disease and suffering. The local board of health is the oldest and the most responsible public health unit. As its chosen executive officer, the local health officer should be the public health leader and educator of his community. In those States having laws permitting the employment of county health officers or general district health officers for counties, such health officers possess all the powers and duties conferred on local health officers within their particular jurisdictions.

There are two forms of State health organizations, one in which the power and authority is vested in a State board of health, consisting of several part-time officials, which employs a secretary or executive officer usually on a full-time basis. Some of the more progressive States, have reorganized State health work in such a way that the chief power is vested in a commissioner who has the assistance of an advisory council. The outstanding need in entire future health programs is that which has to do with rural public health and sanitation, and its adequate development throughout the State. In general, it may be said that, while there has been a gradual decline in the death rate in the cities, the death rate in country communities has remained fairly stationary.

In addition to carrying on educational work, State health authorities may have other important functions and fields of activity, such as: (1) investigation and research of various kinds; (2) epidemiologic and laboratory diagnostic service; (3) standardization of methods and forms; (4) fixing of professional standards for the qualifications of health officers; (5) supervision of schools or courses of instruction for health officers; (6) popular publicity work; (7) the control of communicable diseases or nuisances affecting more than one community or district; (8) the recording of vital statistics; (9) the inspection and control of foods and drugs; (10) the examination and control of public water supplies and sewage disposal plants; (11) supervision over the manufacture of antitoxins and vaccines; (12) supervision over hospitals and sanatoriums for tuberculosis; (13) supervision over maternity, infancy and child hygiene work, and (14) supervision over public health nursing service.

The most essential requirement for the ultimate success of public health administration, local, State and Federal, is a sympathetic co-operation between the private practitioners of medicine and surgery and the public health authorities. The private practitioner of medicine is potentially the most important unit in public health work. If the private practitioner has failed in the past to take his proper place and to assume his true function in preventive medicine, it is because of the fact that he has thought too much of his individual rights and prerogatives and too little of his obligations and responsibilities to the public. His chief obligations are.

1. Legal obligations, including: (a) The prompt and accurate reporting of births, (b) The prompt and accurate reporting of deaths, (c) The prompt and accurate reporting of all diseases required to be reported. 2. Professional or moral obligations, including: (a) Early and accurate diagnosis, (b) Prompt and efficient treatment, (c) Education of his patient as to the patient's future needs, and as to the patient's own relation to the health of the community, (d) Co-operation with the constituted health authorities.

What is needed is not "State medicine," but organized medicine; medicine which is organized in such a way that, while it remains largely in the hand of private practitioners, it will reach rich and poor, city folk and country folk, children and adults, not only after disease has gained a foothold, but before disease has become apparent, and while the individual is yet well and strong. The practitioner of the future must work and think more in terms of physiology and less in terms of pathology.

In the medical schools of the past and present, the departments of pathology have been and still are the outstanding and most popular departments, while those of preventive medicine have had to fight for existence. In the medical schools of the future, the departments of pathology must naturally fade into insignificance compared to the growing departments of physiology, hygiene and preventive medicine. Let the curriculum makers give less time to the "dead house" and cirrhotic livers and more time to the houses of the living and the principles of hygiene.

SAFE MILK

There is less public discussion about "safe" milk than there was a few years ago. Recognition of the importance of milk as a food and of the fact that it has to be carried long distances to market has established the principle that milk sanitation is a necessity. The procedures involved have at length become fairly well "standardized." Foremost are:

1. Prevention of all possible contamination by those handling the milk on the farm and in the dairy and by proper care of the cow. The utmost refinement of this plan is observed in the production of certified milk or its equivalent, produced and cared for under exceptionally sanitary conditions, and constantly supervised and inspected by a medical milk commission.

2. Pasteurization by one of a variety of commercial methods. Its use has greatly increased in recent years. The general tendency is toward the pasteurization of all market milk except the certified milk, and in some large cities it is compulsory.

Tuberculosis is the commonest disease with which cows are affected, and therefore demands particularly careful consideration in connection with milk, although the other possibilities of milk-borne infectious agencies are not by any means negligible. It is pertinent to inquire from time to time, therefore, whether commercial pasteurization conducted, as it must be, on a large scale, actually destroys tubercle bacilli.

A careful investigation in a representative American city has shown the presence of these microorganisms by actual inoculation tests in specimens of the raw milk of average quality delivered to city dealers. It was also demonstrated that pasteurization by the holding process between 142 and 148 F. for thirty minutes destroys the tubercle bacillus in the milk. The commercial process of rendering the milk safe can readily be made efficient; it should never be allowed to fail wherever dependence is placed on pasteurization.—Journal A. M. A., Nov. 24, 1923.

A New Procedure for Performing Litholapaxy—Albert E. Goldstein, Baltimore, and J. Fletcher Lutz, Glenn Rock, Pa., (Journal A. M. A., December 8, 1923), are of the opinion that in an uncomplicated case of vesical calculus lithotrity or litholapaxy is the operation of choice. They have devised a method by which the operation is made a safe and rapid procedure, and at the same time visualized without the aid of the cystoscope. This is performed by combining litholapaxy with fluoroscopy in an air medium. The operation is always under the control of the eye, making it a rapid and safe procedure. Accidents and burns are negligible.

YOUR STATE JOURNAL

The journal of your State society is your own publication and the official organ of your own society, writes F. C. W. in the A. M. A. Bulletin of October, 1923. As such it deserves your active support. If it is not so good as you think it should be, you can help to make it better. The State journal serves for the publication of scientific papers presented at the meetings of the State association and of county district medical societies, for recording and commenting on professional and organizational activities, for maintaining contact between component societies and their members throughout the State and for keeping its readers informed about the comings and goings and the fortunes, good or bad, of their fellows in the State; and it serves also as a forum for the discussion of professional problems of the times.

You can lend real support and constructive assistance to your State journal in many ways. A few suggestions as to how your personal assistance may be extended are here offered:

1. See that what you write contains more than just a grouping of quotations and trite observations. Make it reflect your personal experiences and results. Strive to make your every-day work produce something that will be helpful to your fellows in their professional labors and try to impart to them the worthwhile things that you have learned in the pursuit of your professional duties.
2. Read the editorials in your journal, and if you have personal opinions that are not selfish, tell the editor about them. Discuss with him and with your fellow-members the problems of the day in your community and State, and record your judgment as to the best solution of these problems.
3. Urge the officers of your county medical society to report the meetings of the society and the activities of the profession in the county to the journal. If these officers are overburdened, offer them your aid in the preparation and transmission of such reports.
4. Let your friends in the profession throughout the State know what the physicians in your community are doing. Send news notes and items of social interest to the editor of the State journal. Your professional friends are interested in you, and the State journal can promote and maintain friendly associations throughout the State if you will help do it. Your friends want to know when you are married, when you become a proud father, when your community honors you, when good fortune shines on you, and, yes, when you are dead. If you are not heard from, they may think you dead.
5. Your annual dues and the dues of your fellow-members in the State medical association do not produce nearly enough money to pay the cost of your State journal. The editor and his associates are constantly busy making up the difference, by securing advertising contracts. These can be secured, but they cannot be continued in force unless the other persons interested in them, the advertisers, receive returns on their investment in your journal. Those products advertised in the State journal are dependable, because none but reputable concerns are permitted to advertise. When you buy what is advertised in your State journal, you buy standard products.
6. Read your State journal from cover to cover. Probably this should have been our first suggestion. At any rate, it is desired to impress you with its importance. The reaction will come which will bring about improvement in a poor journal, if any such there be, and will make a good journal better if the members of the State association will read it. Even in the poorest, there will always be found something helpful.

No matter how busy you are, your State journal and The Journal of the American Medical Association should be read at the first opportunity after they are received. The busier you are, the more you need to read them. The physician who does not read these journals is the man who does not progress—in fact, he is the man that retrogresses.

It is hoped that, in thus calling the attention of the readers of the Bulletin to the State medical journal, an expression of renewed interest in their State medical publications will be evoked from our Fellows. As this interest manifests itself, we will witness the development of a greater solidarity and greater unity of purpose, and of effort in medical organization and in scientific progress.

The Treatment of Neurosyphilis—The problem of the treatment of neurosyphilis according to H. C. Solomon, Boston (Journal A. M. A., Nov. 24, 1923), is to destroy the spirochetes that are present in the nervous system. The nervous tissue is walled off from the general body structures, and this leads to a relative impermeability of drugs placed in the general circulation. However, some penetration takes place, the amount apparently varying in different individuals. There is a group of neurosyphilitic cases that react well to mild systemic treatment. Others require more intensive systemic treatment. There are many, however, that are not improved to any extent by systemic treatment with arsphenamin, mercury or iodid. Some of these cases do well, however, when medicaments are given directly into the cerebrospinal fluid or when spinal drainage is used. Theoretically and practically, it seems advisable to place the medicament as near to the site of pathologic change as possible, utilizing the lumbar subarachnoid space, the region of the cisterna magna and the ventricles as conditions indicate.

No definite rules can be laid down as to which type of treatment will produce the best results in a given case. A classification based on the reaction to treatment does not coincide with the older ideas of tertiary syphilis of the nervous system as contrasted with parasyphilis, because some cases of tabes and paresis react quite well to relatively mild systemic treatment, whereas some cases of the meningovascular group do poorly on the same type of therapy. It is more difficult on the whole, to get satisfactory results in cases of tabes and general paralysis than in the meningovascular type, and the former usually require quite intensive treatment, making use of the cerebrospinal fluid pathway. There still remains a group of cases that cannot be satisfactorily modified by treatment with arsphenamin, mercury, the iodids and blood serum. The immunity of the patient plays a large role in the results obtained, and various procedures that may increase the immunity responses have a place in the treatment of neurosyphilis. Of great importance are all hygienic procedures that improve the general condition of the patient. Some favorable reports have been made from inducing febrile reactions by inoculations with malaria and relapsing fever. The hope for the future rests either in the method of inducing greater immunity on the part of the patient or in developing drugs with greater power of permeation into the nervous tissue.

The Treatment of Urethral Stricture by Excision—The history of urethral stricture as it is recorded in medical literature is reviewed by Granville MacGowan, Los Angeles (Journal A. M. A., December 1, 1923), and the technic of its repair is discussed in detail. In the author's operation, the intention is to restore the tube by approximating its cut ends in their entire circumference, and this, he says, is best achieved not by the laying of a circular stitch, such as was done by Mayo Robson with success after the excision of an annular stricture where the loss of structure was not more than one-fourth inch, and as was the practic of König, but by slitting the urethra and spongy body both anteriorly and posteriorly into three strips, or ribbands, one posterior and two lateral, using great care not to mangle the tissues and to have clean incisions. MacGowan reports no failures from the use of this method.

Utah State Medical Association

University of Utah Medical School Inspected—A committee appointed by the Utah State Medical Association has made a thorough inspection of the University of Utah medical school. This committee, composed of leading doctors of the State, was created last June at the suggestion of President George Thomas, of the university, and Ralph O. Porter, dean of the medical school. It is to inquire into the work given at the medical school, thereby permitting constructive suggestions and criticism, and to actively co-operate in making the first two years of the university medical course equal to similar work at any medical school in the United States.

Although the committee has not yet made an official report, it was evident from the remarks of the individual doctors that they were well pleased and in some instances very much surprised at the quality of work required of medical students.

Dr. Porter declares that lack of active co-operation between the medical school and the medical profession of Utah has in the past hindered the proper development of the school, but judging from the interest now shown by the doctors, that difficulty has largely been overcome.

During the past year many changes have been made in the school. The faculty has been materially strengthened, and much needed equipment added. Classes are limited to twenty-five students, and the selection is made purely on the basis of scholarship.

Members of the committee were: J. W. Morrell of Ogden, president of the Utah State Medical Association; J. C. Landenberger of Salt Lake, former president of the association; Sol Kahn, president-elect of the association; Francis A. Goeltz, president of the Salt Lake County Medical Society; Robert Hampton, Salt Lake; E. F. Root, Salt Lake; H. P. Kirtley, Salt Lake; Clarence Snow, Salt Lake. They were accompanied on their tour of inspection by Dean Porter and President Thomas.

New Members of Utah State Medical Association—A. A. Anderson, Templeton Bldg., Salt Lake City; P. M. Chase, McCornick Bldg., Salt Lake City; R. G. Frazier, Bingham Canyon; B. L. Kesler, Bountiful; Paul Richards, Bingham Canyon; George E. Robison, Boston Bldg., Salt Lake City; G. W. Rutledge, Kaysville; Henry Rite, Sugar House; John W. Sudgen, Judge Bldg., Salt Lake City; F. R. Slopanskey, Boston Bldg., Salt Lake City; George A. Anderson, Springville; B. C. Linbaugh, Pleasant Grove; L. C. Potter, Provo; L. D. Stewart, Payson; A. G. Stoddard, Spanish Fork.

Salt Lake County Medical Society (reported by F. F. Hatch, secretary)—The last regular meeting of the Salt Lake County Medical Society for the year 1923 was held on December 10.

The secretary F. F. Hatch, read his report which was accepted with the following corrections:: That Roy Groesbeck ends his service as censor of the society with this meeting; that the late A. S. Bower's death be noted in the secretary's report with the additional information that the society's regrets were submitted to the family at that time; that the delegates now in office remain on the rolls until new ones are elected in June, 1924.

The treasurer's report by V. J. Clark was read and ordered filed.

Report of the Library Committee was given by Chairman W. R. Tyndale. In speaking concerning this committee, S. C. Baldwin reported that the transactions of the American Orthoepedic Association could be had for the asking. It was moved, seconded and passed that Baldwin's recommendation be added to the report and the report filed.

The Medical Legal Committee, with E. F. Root as chairman, gave a verbal report, which was accepted and a motion was made accepting it, which was carried.

The Liability Insurance Committee reported, B. W. Black, chairman, that this or a similar committee be held over as they have been in office only two weeks, and should complete the work started. Moved, seconded and carried that the report be accepted and the committee continued.

The Committee on Public Health and Legislation was reported on by John Z. Brown, the chairman, orally, which report was accepted by the society.

The amendment to the By-Laws, as stated fully in the last meeting's minutes, was accepted and carried unanimously, making the fiscal year of the society begin January 1 with dues payable then, and making members delinquent on February 1. This means delinquent members would have to pay $12 dues—an additional $2 for reinstatement, the regular dues of the society being $10.

Motion was made appointing an Auditing Committee. Seconded and carried and the chair appointed A. A. Kerr, chairman, L. N. Ossman and Edward LeCompte as this committee.

There was a discussion of the Baby Clinic by Thomas Clark, who made a motion to appoint a committee to study the Baby Clinic in the City Board of Health's Department and consult with Christopherson and Commissioner Barnes in regard to its continuance. This motion was amended by M. M. Nielson, that the committee investigate all hospitals treating charity cases. The amendment was accepted in the original motion and was carried unanimously.

The officers for the year 1924 were elected as follows: A. A. Kerr, president; John Z. Brown, vice-president; M. M. Critchlow, secretary; Joe Jack, treasurer; F. A. Goeltz, censor.

Utah County Medical Society (reported by Fred R. Taylor, secretary)—At the last regular meeting of the Utah County Medical Society, G. Gill Richards of Salt Lake gave a very interesting and comprehensive paper on the Insulin Treatment of Diabetes. His paper was supplemented with case reports and an exhibition of some of the common diabetic foods.

The following new members were admitted to membership in the society—J. W. Bergstrom, Cedar City; George C. Nelson, Loa: George H. Mott, Santaquin; Thomas D. Rees, Nephi. Plans were also completed for the handling of the Utah County Free Clinic.

Weber County Medical Society (L. R. Draper, secretary)—The annual banquet and election of officers of the Weber County Medical Society was held at the Weber Club, Ogden, Utah, Tuesday evening, December 18. In place of the usual program of after-dinner speakers, a short vaudeville performance was given, which was enjoyed by all members and visiting physicians.

E. G. Hughes councilor of Provo; A. A. Kerr, president of the Salt Lake Medical Society, and Samuel Baldwin of Salt Lake were guests at the meeting.

Preliminary arrangements were made for a closer co-operation between the Weber County Medical Society, the Salt Lake County Society and the Utah County Society.

The following officers were elected for the ensuing year: President, W. A. Whitlock, Layton, Utah; vice-president, F. K. Bartlett, Ogden; secretary and treasurer, L. R. Draper, Ogden.

Nevada State Medical Association

ABSTRACTS FROM NEVADA MEDICAL BULLETIN

(Editor, Horace J. Brown, 14 Thoma-Bigelow Building, Reno, Nevada)

November 15—It may seem a little early to begin talking about the 1924 meeting but your incoming officers are so anxious to please you in the matter of the time and place for holding it that they feel that it is not too soon to begin asking your wishes about it. We want to so arrange it that the greatest possible number can attend, and we would like to have an expression from every member. Eight of our members favored us with papers at the last meeting and we hope to have twelve next year. On a recent visit to the editorial office of the California Journal, they requested the names of our members, with their specialties designated, so that they can ask us to write discussions of papers to be published by them. Our members will be asked to discuss the papers read at our recent meeting. Each of our members will receive a copy of the December issue, complimentary, and the January issue will go to all that have paid dues in advance at the new rate of $7 per year. The new arrangement of membership and the California Journal for $7 seems to be quite popular, as we have had five new applications for membership recently. Here-to-fore county secretaries have sent $3 for each member to the State Association but for 1924 they should send $5, and we hope they will remit promptly, when they collect the dues, so that the secretary can send the names of those paid in advance to the California Journal.

December 1—The California Medical Journal is undoubtedly one of the best State journals and we should be able to get lots of good ideas out of it during the coming year. Each issue will have a page set aside for our use and we can fill all, or any part of it with news and announcements of especial interest to Nevada. Dr. George L. Servoss, 150 N. Virginia street, Reno, will be the Associate Editor for this State and he will appreciate it very much if all those that have news items, or other interesting matter, will send same to him. We mentioned in a previous issue that professional cards will be accepted for the advertising columns, at the rate of $30 per year or $20 for six months. There are several of our members that will probably wish to take advantage of this offer, and they can either write to Dr. Musgrave or to our secretary. We had the opportunity to ask three members from various points in the State as to where the 1924 meeting should be held and they are unanimous in naming Bowers Mansion. They all seem to have had quite an enjoyable time out there and want to go back again. We would like to hear from every member on this subject, and also as to the time for holding the meeting, as we want to set the time and place as early as possible in the New Year. We have the promise of two papers as a starter for the program and hope to hear from several other prospective essayists in the near future. Don't forget that you must have your dues paid in advance if you expect to receive the California Journal and if your conscience hurts you about 1923 dues you can relieve it by sending a check for $12 to the secretary. Please don't delay as the retiring secretary would like to turn over a clean set of books to his successor.

Nevada News Items

M. R. Walker, Reno, has been appointed assistant surgeon for the Southern Pacific Co., for the Reno district.

Anna B. DeChene, Reno, has been appointed Councilor for Nevada of the Medical Womens' National Association.

The following officers were elected for 1924 by the Washoe County Medical Society: President, Rodney H. Richardson; vice-president, L. V. Smith; secretary-treasurer, V. A. Muller; councilors, G. L. Servoss and C. W. West.

C. W. West, retiring president of the Washoe County Medical Society, entertained the members of that body at his home, following the monthly meeting on December 4.

Five applicants appeared before the Board of Medical Examiners on November 5, four of whom passed and one failed.

F. F. Owens, Ely, College of Physicians and Surgeons, New York, 1896, was found dead in his office on November 23. He was 51 years of age.

W. F. Boylan, Bridgeport, California, Eclectic Medical Institute, Cincinnati, 1891, died November 26, after a few days' illness from heart disease. He was 55 years old.

The following new members have been admitted to the association since the annual meeting: R. S. Tillotson, East Ely; W. H. Frolich, East Ely; J. H. Hastings, Pioche; George Pearn, Jarbridge, and George R. Magee, Yerington.

D. A. Smith, Mina, has been appointed county physician of Mineral county. J. W. Davis has resigned.

J. B. Wilson has removed from Lovelock and will locate at some point on the coast, probably at Los Angeles.

New Experiments on Rejuvenation—The Journal has commented on the experiments of Steinach and others in the rejuvenation of animals presumed to follow ligation of the vas. Recently Macht and Teagarden of Johns Hopkins University have perpormed similar operations on six rats, all more than a year old and showing definite signs of senescence. These were compared with two other animals used as controls. Fourteen additional rats were studied by special methods involving the use of animals operated on and adequate controls. The details of the method leave no doubt as to the scientific character of the experiments. After ligation, a number of the rats showed distinct improvement in general appearance and behavior. They were more active, and several developed a new coat of fur. These changes persisted only for several weeks, however, and the animals gradually relapsed into their usual senile state. Also distinct improvement in muscular co-ordination and muscular efficiency of the animals was noted, but this was temporary, lasting only a few weeks. It is the belief of the observers that all the changes noted seemed to have been the results of the operation; they assert, nevertheless, that this cannot be said positively without numerous additional experiments. This work would seem to confirm the impression now prevailing that the various rejuvenation experiments constitute at best only a temporary stimulus, and that the inevitable result is relapse, if not, perhaps, a shortening of life because of additional burdens thrown on a senescent organization.—Journal A. M. A., Nov. 24, 1923.

Expect to be called a standpatter, but don't be a standpatter. Expect to be called a demagogue, but don't be a demagogue. Don't hesitate to be as revolutionary as science. Don't hesitate to be as reactionary as the multiplication table. Don't expect to build up the weak by pulling down the strong. Don't hurry to legislate. Give administration a chance to catch up with legislation.—President Calvin Coolidge's political creed.

BOOK REVIEWS

Non-Surgical Drainage of the Gall-Tract. A treatise concerned with the diagnosis and treatment of certain diseases of the biliary and allied systems, in their relation to gastro-enterology and general clinical medicine. By B. B. Vincent Lyon, M. D. 640 pages. Illustrated. Philadelphia and New York: Lea & Febiger. 1923. Price, $10.

Although this volume of 623 pages is entitled the non-surgical drainage of the gall-tract, the author states in his preface that he has two major purposes, the first to present to the medical profession in more complete form the diagnostic and therapeutic value of non-surgical drainage of the biliary system, etc., and the second to present the author's plan of a systematic and practical method of studying the gastro-intestinal tract as a whole. He then proceeds at great length and in great detail to accomplish his major purpose, with here and there a pause for the development of some minor purpose, such as a six or seven-page discussion of Giardia infection.

Approximately 150 pages are devoted to the diagnostic and therapeutic uses of non-surgical drainage of the gall-tract, with an additional 123 pages of illustrative case histories.

There can be no question but that this procedure has a definite place in the study and treatment of biliary tract disease, but it remains for the future to determine its exact value. From the diagnostic standpoint, the procedure requires extreme care and attention to detail, as emphasized by the author, but even then I fear the findings, especially the bacteriologic, may be misleading.

The remainder of the book is devoted to chapters on the embryology, anatomy, histology, and physiology of the biliary system and to various chapters dealing with methods of study and treatment of gastro-intestinal condition in general and biliary-tract conditions in particular.

The whole subject matter is well presented, but I believe would have been of greater service if the author had kept strictly to the first of his major purposes, reserving the second for a separate volume.

W. W. B.

A Manual of Proctology. By T. Chittenden Hill. 279 Pages. Illustrated. Philadelphia and New York; Lea & Febiger. 1923. Price $3.25.

A short practical compendium, containing considerable information and considerable misinformation. Some of its statements are founded on hearsay evidence accepted by the author with too little inquiry. However, the book tells what to do and how to do it in a simple and readable way, so that it will probably find a large audience. L. E.

Alcohol and Prohibition, In Their Relation to Civilization and the Art of Living. By Victor G. Vecki, M. D. Philadelhpia and London: J. B. Lippincott Company.

This book ought to have a wide circulation; certainly every physician ought to read it, and other citizens will find much in it to think about. Not all physicians will agree with everything that Vecki says, but they certainly will give him credit for an honest expression of opinions, presented in an interesting and attractive manner. W. E. M.

The Tonsils—Faucial, lingual, and pharyngeal. With some account of the posterior and lateral pharyngeal nodules. By Harry A. Barnes, M. D. Second edition, 217 pages. Illustrated. St. Louis: C. V. Mosby Co. 1923. Price $5.

This is a well-edited, readable book. The chapters on histology and pathology are excellent and much the strongest. The chapters on surgery are not of the same high standard and all will not agree with the author's views on the relative merits of local and general anesthesia, methods of inducing local anesthesia, position of patient during operation, and methods of controlling post-operative hemorrhage.

A Primer for Diabetic Patients. A brief outline of diabetic treatment including directions for the use of insulin, sample menus, recipes, and food tables. By Russel M. Wilder, M. D., Mary A. Foley, Dietician, and Daisy Ellithorpe, Dietician. Second edition, 119 pages. Philadelphia: W. B. Saunders Co. 1923.

An excellent little manual. It tells the patient exactly what he should know. He has a homely way of putting information that is peculiar to the Mayos. It is equally well suited to a diabetic college professor or a diabetic Minnesota farmer.

L. E.

BOOKS RECEIVED

Alcohol and Prohibition in their Relation to Civilization and the Art of Living. By Victor G. Vecki, M. D., San Francisco. Philadelphia and London: J. B. Lippincott Co.

Collected Reprints, from the George Williams Hooper Foundation for Medical Research. The Department of Medical Research of the University of California Medical School, San Francisco. Volume VII, 1922-1923.

Hygiene and Public Health. By Louis C. Parkes, M. D., Consulting Sanitary Adviser to H. M. Office of Works, Fellow of the Royal Sanitary Institute, and Henry R. Kenwood, C. M. G., M. B., Chadwick Professor of Hygiene in the University of London. Seventh edition with illustrations. Philadelphia: P. Blakiston's Son & Co., 1923.

Mental Disorders, an Introduction to the Study of. By Francis M. Barnes, Jr., M. D., Associate Professor of Nervous and Mental Diseases in the St. Louis University Medical School, etc. Second Edition. St. Louis: C. V. Mosby Co., 1923.

Diagnostic Methods. A guide for history taking, making of routine physician examinations and the usual laboratory tests necessary for students in clinical pathology, hospital internes and practicing physicians. By Herbert Thomas Brooks, M. D., Professor of Clinical Medicine, College of Medical Evangelists, Los Angeles, formerly Professor of Pathology, College of Medicine, University of Tennessee. Fourth edition, with fifty-two illustrations. St. Louis: C. V. Mosby Co., 1923.

Modern Aspects of the Circulation in Health and Disease. By Carl J. Wiggers, M. D., Professor of Physiology in the School of Medicine of Western Reserve University, Cleveland Ohio. Second edition, thoroughly revised. Illustrated with 204 engravings. Lea & Febiger, Philadelphia and New York, 1923.

A Treatise on Orthopaedic Surgery. By Royal Whitman, M. D., Surgeon to the Hospital for Ruptured and Crippled; Consulting Orthopaedic Surgeon to the Hospital of St. John's Guild, etc., seventh edition thoroughly revised. Illustrated with 877 engravings. Lea & Febiger, Philadelphia and New York, 1923.

Local Anaesthesia Methods and Results in Abdominal Surgery. By Hans Finsterer, Surgeon-in-Chief, Vienna Hospital of the Brothers of Charity,

Authorized English version by Joseph P. F. Burke, M. D., Attending Surgeon, Buffalo Hospital of the Sisters of Charity and Buffalo City Hospital. Forty-two illustrations. New York: Rebman Co.

The Medical Department of the United States Army in the World War, Volume V. Military Hospitals in the United States. Prepared under the direction of Maj. Gen. M. W. Ireland, M. D., Surgeon General of the Army, by Lieut. Col. Frank W. Weed, M. C., U. S. Army. Washington: Government Printing Office, 1923.

A Critical Examination of Psycho-Analysis. By A. Wohlgemuth, D. Sc. (Lond.) New York: The Macmillan Co., 1923.

Diseases of the Skin. By Richard L. Sutton, M. D., Professor of Diseases of the Skin, University of Kansas School of Medicine; former chairman of Dermatological Section of the American Medical Association; Assistant Surgeon, U. S. Navy, retired. With 1069 illustrations and 11 colored plates. Fifth edition, revised and enlarged. C. V. Mosby Co., St. Louis, 1923.

Nutrition and Clinical Dietetics. By Herbert S. Carter, M. D., Assistant Clinical Professor of Medicine, Columbia University, Consulting Physician to Presbyterian Hospital, Lincoln Hospital, Skin and Cancer Hospital, New York; Paul E. Howe, Ph. D., Associate, Rockefeller Institute for Medical Research; Howard H. Mason, M. D., Associate in Diseases of Children, Columbia University, New York, Visiting Physician, Children's Service, Presbyterian Hospital, New York. Third edition, thoroughly revised. Lea & Febiger, Philadelphia and New York, 1923.

A Manual of Proctology. By T. Chittenden Hill, M. D., Instructor in Proctology, Harvard Graduate School of Medicine, surgeon to Rectal department, Boston Dispensary. Illustrated with 84 engravings. Lea & Febiger, Philadelphia and New York, 1923.

The Treatment of Diabetes Mellitus, with observations based upon three thousand cases. By Elliott P. Joslin, M. D., Clinical Professor of Medicine, Harvard Medical School· Consulting Physician, Boston City Hospital. Third edition, enlarged, revised and rewritten. Illustrated. Lea & Febiger, Philadelphia and New York, 1923.

Diseases of the Skin. By Frank Crozer Knowles, M. D., Professor of Dermatology, Jefferson Medical College; Dermatologist to the Philadelphia General, The Presbyterian, The Children's and The Babies' Hospitals. Second edition, thoroughly revised. With 229 illustrations and 14 plates. Lea and Febiger, Philadelphia and New York, 1923.

Kurzes Lehrbuch der Chemie in Natur und Wirtschaft, von Prof. Carl Oppenheimer, Dr. phil. et. med., Berlin. nebst einer Einführung in die Allgemeine Chemie, von Prof. Johann Matula in Wien. Georg Thieme, Verlag, Leipsig, 1923.

Uber Hysterie, von Dr. Ernst Kretschmer, Privatdozent für Psychiatrie in Tübingen. Leipsig, 1923. Verlag von Georg Thieme.

Medizinische Psychologie, Ein Leitfaden für Studium und Praxis, von Dr. Ernst Kretschmer. Zweite Auflage. Mit 22 Abbildungen. Leipsig, 1922. Georg Thieme, Verlag.

Diagnostische Technik für die ärztliche Praxis, ein Handbuch fur Ärzte und Studierende. Herausgegeben von Professor Dr. Julius Schwalbe Geh. San.-Rat Mit 380 Abbildungen. Leipzig, 1923, Verlag von Georg Thieme.

HOSPITAL EXTENSION WORK

The following schedule of operative and dry clinics in the teaching schools and accredited hospitals of California will be found of service to graduate physicians in general practice who desire to avail themselves of the opportunity for observation and study:

Stanford University Hospital, San Francisco
(Operative Clinics)

Practical work in clinics and laboratories open to physicians during July, August, and September.

Surgery — Tuesday, 8 a. m. to 12 m.; 1:30 p. m. Thursday, 8:30 a. m. to 12 m.; 1:30 p. m. Saturday, 8:30 a. m. to 12 m.; 1:30 p. m.

Genito-Urinary — Monday, 8:30 a. m. to 12 m.; Friday, 8:30 a. m. to 12 m.

Gynecology — Tuesday, 1:30 p. m.; Wednesday, 8:30 a. m.; Friday, 1:30 p. m.

Nose and Throat—Monday, 1:30 p. m.; Wednesday, 1:30 p. m.

Orthopedic (Class)—Monday, 2 p. m.; Friday, 10 a. m. to 12 m.

Eye—Wednesday, 1:30 p. m.

Stanford University Medical School, San Francisco
(Medical Clinics)

General Medicine—Wednesday, 11:30 a. m.

Obstetrics and Gynecology—Saturday, 11:30 a. m.

Clinico-Pathological Demonstrations — Monday, 11:30 a. m.

Colloquia at San Francisco Hospital

(Programs posted in Lane Medical Library and County Medical Society Library.)

Medical—Friday, 10 a. m.

Surgical—Thursday, 9 a. m.

University of California Hospital, San Francisco

Medicine—Ward rounds, daily, 10 a. m. to 12 m.; general staff rounds, Wednesday, 10 a. m. to 12 m.; amphitheater clinics, Saturday, 10 a. m. to 11 a. m.; clinical pathological conference, Saturday, 11 a. m. to 12m.; out-patient clinics, daily; examination of apparently healthy adults, Thursday, 10 a.m. to 4 p.m.

Surgery—Operative, phone supervisor operating-room; ward rounds, Thursday, 10:30 a. m. to 12 m.; amphitheater clinics, Saturday, 9 a. m. to 10 a. m.; clinical pathological conference, Saturday, 11 a. m. to 12 m.; out-patient clinics, daily.

Pediatrics — Ward rounds, daily, 9 a. m. to 10 a. m.; general staff rounds, Friday, 9:30 a. m. to 11:30 a. m.; out-patient clinics, daily, mornings; asthma clinics, Monday, Wednesday and Friday afternoons; examination of apparently well babies, Wednesday, 2 p. m. to 4 p. m.

Obstetrics and Gynecology—Operative, phone supervisor operating-room; ward rounds, Monday, 9 a. m. to 10 a. m.; Friday, 9 a. m. to 10 a. m.

College of Medical Evangelists, Los Angeles
(Clinics at Los Angeles General Hospital)

Surgery—Monday, 8:30 a. m. to 9:45 a. m.; Tuesday, 8:30 a. m. to 9:45 a. m.; Friday, 8:30 a. m. to 11:15 a. m.

Medicine — Monday, 8:30 a. m. to 11:15 a. m.; Tuesday, 8:30 a. m. to 9:45 a. m.; Wednesday, 8:30 a. m. to 9:45 a. m.; Thursday, 8:30 a. m. to 12:30 m.

Conference—Friday, 8:30 a. m. to 9:45 a. m.

Pediatrics — Monday, 8:30 a. m. to 9:45 a. m.; Tuesday, 8:30 a. m. to 9:45 a. m.; Wednesday, 8:30 a. m. to 9:45 a. m.; Thursday, 8:30 a. m. to 11:15 a. m.

Obstetrics — Monday, 9:45 a. m. to 11:15 a. m.; Friday, 9:45 a. m. to 11:15 a. m.

Nervous and Mental—Tuesday, 8:30 a. m. to 11:15 a. m.

Tuberculosis—Friday, 9:45 a. m. to 11:15 a. m.

(Clinics at White Memorial Hospital, Los Angeles)

Surgery:	
Clinics	Monday, 8 a. m. to 12 m.
Clinical lecture	Monday, 11:30 a. m. to 12:30 p. m.
Tonsillectomy	Sunday, 8 a. m. to 12 m.
	Tuesday, 8 a. m. to 12 m.

University of California, Los Angeles

The Los Angeles Medical Department of the Uni-

versity of California extends the courtesy of its clinics, which begin daily at 12 noon, for a period of three days. Physicians desiring such courtesy are given, on request, cards of admission by the superintendent of the dispensary.

Accredited Hospitals

The following accredited hospitals receive visiting physicians at operations, and furnish telephonic schedules of the day's work upon request:

Livermore—The Livermore Sanitarium.

Los Angeles—California Lutheran Hospital, Children's Hospital, Los Angeles County Hospital, St. Vincent's Hospital.

Oakland—Samuel Merritt Hospital.

San Diego—St. Joseph's Hospital.

San Francisco—Children's Hospital, French Hospital, Mary's Help Hospital, Mount Zion Hospital, St. Luke's Hospital, Southern Pacific General Hospital.

San Leandro—Alameda County Hospital.

MORE ABOUT THE FAMILY PHYSICIAN

In a consideration of the general practitioner it will be necessary to discuss the opportunities which he enjoys, and the problems and difficulties which beset him. In their work, not all general practitioners are resourceful and sure of themselves. This fault is due in some instances to inadequate early training, but in a majority of men it is due to laziness and failure to take advantage of the opportunities afforded all physicians. From the time of his graduation until he retires from work, the whole professional life of the physician affords opportunities to study morbid processes as evidenced by anatomic changes and altered function and so to manage and treat the patient that partial or complete restoration occurs—dependent, in part, on the nature of the malady. The physician who makes all possible use of his daily clinical opportunities learns something new and useful every remaining day of his professional life.

Membership in and active participation in the work of the county medical society is of great educational benefit to the physician. It affords personal contact with fellow-practitioners in the courteous discussion of medical subjects and professional problems, promotes mutual respect and good-will, and is a potent factor conducive to increased self-respect and self-reliance on the one hand, and to a decrease in the size of the hat, if imaginary megalocephaly makes one a nuisance to his fellows.

With due regard for the value and need of all the splendid ultrascientific laboratory and instrumental methods of physical and functional diagnosis in investigatory medical work, they are needed in the routine clinical care of not to exceed 20 per cent of all the patients of any urban or rural community. Unfortunately, many lay people have been made to believe and apparently a large number of physicians think that the routine application of the ultra-scientific methods of diagnosis is necessary in the majority of cases. The fact is that the diagnosis can be made in fully 80 per cent of all cases by a resourceful general practitioner who will efficiently use his brain, special senses, hands and an always available simple and inexpensive laboratory and instrumental equipment.

A majority of practitioners do not make written records of their patients: these are absolutely essential to accuracy in diagnosis and efficiency in practice. To obtain an efficient history and make a record require time. Many practitioners have told me they could not afford the time to do this. My own experience justifies the statement that this is a mistake. Accurately written records, brief though they be, properly filed to be available for future reference, are time-savers of the future weeks, months, and years.

The conscientious practitioner will make a careful, general physical examination of practically all patients who seek his services. An occasional patient with a slight ailment, and especially those with slight injuries or lesions requiring surgical treatment, are exceptions. But with many patients the present complaint is often an expression of an older morbid process which has been disregarded by the patient or overlooked by the physician. Daily practice in technic and judgment is the program which every physician must follow to become a skilled diagnostician. The practitioner can gain much by observing others at work in organized clinics or by taking post-graduate courses in diagnosis, when these are available; but the efficiency of the practitioner in diagnosis is mainly dependent on his own industry and determination to make the most of his own clinical opportunities.

There is a growing custom in urban practice for general practitioners to have the routine laboratory examinations, such as urinalysis, blood estimations and other simple tests made and the results interpreted for them at the numerous available commercial laboratories. In my opinion, this is a great fault in practice; it would be quite as rational for the practitioner to depend on available organized clinics for the physical examinations and diagnosis of patients.

But whether one is a practitioner in the city or in the country, the economic conditions peculiar to each can be greatly improved by one's own efforts. The fundamental principle which each practitioner must adopt to overcome his economic embarrassment is to improve himself professionally. To accomplish this, I believe he must steadily follow the methods of clinical practice and other self-educational opportunities which I have outlined. I sincerely believe that, if he will do this, he will attract to himself a large number of patients, will receive more adequate financial reward, and will find real enjoyment in his work.

Many years ago an observing philosopher said: "The pathway to the door of the qualified man, desirous of giving honest, efficient service to the public, is worn smooth by the passage of many feet."

I believe that the preservation of the general practitioner, as the most important factor in the field of practice, is dependent, chiefly on himself. He must keep abreast of the advance of modern medical knowledge and practice, chiefly by his own efforts. If he strives to improve and help himself he will be successful; will justify his importance in the medical field, and will attract the ill and injured to his door because of his professional individual superiority as compared with men in narrower fields of practice, alone or in public or private groups.

The American family home has been and must continue to be the very foundation of this nation. Bolshevistic socialism, anarchy, and public discord cannot exist in a nation of family homes. The integrity and perpetuation of this nation is dependent chiefly on the maintenance of family life; and the continuance of the family home demands the preservation of the family physician, the general practitioner.—Frank Billings, M. D., Journal A. M. A.

The future of human civilization depends primarily upon the rearing of its children. These children will require more and more education to fit into this gradually enlarging scheme, but above all they will need health education so that they can gain personal comfort, release from suffering, and a longer period of productive life after the necessary prolonged periods required for adequate mental training. It will take at least another generation before a majority of us in any land can even think biologically. We cannot hope to control many eugenic factors, so that our efforts must be largely directed to changing the environment of the human animal.—Ray Lyman Wilbur, M. D.

WHY DOCTORS BUY WORTHLESS AND FRAUDULENT SECURITIES

By SAMUEL O. RICE
(Educational Director, Investment Bankers Association of America.)

Physicians who number bondmen, investment bankers, among their patients frequently complain that bondmen squander their health.

"The heads of three bondhouses," my family doctor said to me the other day, "are patients of mine, they and several subordinate officers of other houses, and I'll be hanged if they aren't more careless with their health than is all the rest of my practice put together. They'll work like demons for months at a time and then try to make up for the loss of daily exercise and common-sense routine by trying to crowd a year's recreation into a few weeks. They'll eat, and drink, too, a lot of stuff that's bad enough at home, but is doubly damaging when they take frequent business trips, with irregular hours, heterogeneous food, and the unavoidable strain of an exacting business. They are the worst spendthrifts of health that I know among intelligent men."

"At least they are not as bad as doctors," I replied to my friend's amazement. "When they need medical service you've got to admit they don't go to quacks for it. They go to the reputable profession and to recognized specialists, don't they?"

"What has that got to do with it?" the doctor asked. "Physicians can't avoid irregular hours, but they're not—"

"The argument is," I interrupted, "on the use of common sense, isn't it? You say that bondmen don't use common sense about health. But as lax as they are in that, they are not as lavish in squandering health as physicians are in squandering money in so-called investments. Bondmen at least exercise common sense enough to realize that it requires a doctor to exercise medical judgment for them. How many physicians realize that it requires a 'doctor' of investments to select investment securities dependably? Ever hear of an investment banker being swindled by a quack practitioner? How often are physicians swindled by quack investment schemes?

"There are just two reasons why doctors, as a class, are notable for buying worthless securities. One of them is their failure to realize that, in seeking good, sound investments, you have to do exactly the same thing you do in seeking health—consult an honest, competent practitioner."

"What's the other reason why we buy worthless securities?" my friend asked with a smile. "Because doctors are not business men?"

"That's the reason usually given, but I don't believe there's anything to it. The second reason is too much optimism."

"There isn't one of you who doesn't believe that next year's practice is going to be a whole lot more remunerative than this year's. Your first years of practice, when you started with nothing and gradually built up your income, taught you that. It's firmly fixed, perhaps subconsciously, in every doctor's mind. It's a life thought-habit of the profession, besides being a somewhat common human trait."

"Well, if things are going to be better next year, I'll just take a few hundred dollars of the stock of this patent electrical device or in that new serum outfit, you argue. Thousands of little oil and mining companies have been organized in the last few years among little groups of friends in every town, city and hamlet in the United States, and have blown up after losing the money put into them. I'll wager that in every such little venture 90 per cent of them have had one or more physicians as stockholders. As a profession, you are so confoundedly optimistic you let your optimism run away with your better judgment, and you accumulate a lot of nondescript interests in a number of things you know nothing about and that have little or no value when your widow tries to realize on them."

"Yes, I guess some of that is possibly true," my friend admitted.

"True, of course it's true. Six months ago I had a little ready money and I asked you to send me your bill. I telephoned you twice. I got that bill last week, six months after I had put my little ready money into some sound investments selected by an investment specialist and not by inexperienced friends or an easy-talking promoter. Now, when I'm shy of cash, you optimistically send me a bill. I'll bet you $4 you are going to buy a new car. You are careless about collections, partly because it is in the code of your profession not to be mean and grasping. I honor you for that, but your eternal optimism is also a part cause. Oh, you say, I'll get more money next month; if not from Jones, from Smith. And you base your investments on the same kind of careless optimism."

"I'm serious in this, Roy. You wouldn't have a bit of sympathy for me if I disregarded the common sense that the medical profession has patiently drummed into the public for years, the fact that the public must consult reputable, competent medical advisors. You'd have a silent contempt for me if I let some quack or gaudy fake practice in my family, or if I answered a cure-all medical advertisement.

"The so-called intelligent public has learned its lesson in medicine, that of consulting reputable practitioners. It is just as important that the medical public learn the same lesson as applied to investing their money. You nor no other physician can judge an investment security dependably, if you continue attending to your legitimate vocation. Even if you had time to do it, very frequently you haven't the facilities to determine the worth of a security. Investment banking is such a highly specialized calling that I doubt if any man has the ability to perform the investment banker's work without adequate training in the work.

"Physicians should be the first persons in the world to recognize this fact, but, strange to say, many of them do not. As a consequence, they are notably heavy losers in bad investments And the cure for this bad investment condition is the same as in a human pathological condition—consult the reputable specialist who is competent to treat the case."

LECTURE FOUNDATION IN PREVENTIVE DENTISTRY

The inaugural lectures under the Carnegie Grant will be given in Los Angeles on the evenings of January 3 and 4, at the College of Dentistry, University of Southern California, and will be open to the professions only. In San Francisco, the professional lecture will be given on January 7, at the College of Dentistry, University of California, at 3 p. m., and the public lecture in the Italian room, St. Francis Hotel, on the same day, at 8:15 p. m. The public lecture will be repeated in Wheeler Auditorium on the Berkeley campus, on Tuesday evening, December 8, at 8:15 p. m.

The title of the professional lecture will be "Progress and Outlook for the Prevention of Dental Disease." The title of the public lecture will be "Dentistry and Health."

This course of lectures will be delivered by Arthur D. Black, Dean of Northwestern University Dental School, Chicago, Ill. Black is widely known, internationally as well as nationally, and is a leader in this great movement in America.

Our civilization cannot survive materially unless it be redeemed spiritually. It can be saved only by becoming permeated with the spirit of Christ and being made free and happy by the practices which spring out of that spirit. Only thus can discontent be driven out and all the shadows lifted from the road ahead.—Woodrow Wilson.

MEDICAL ECONOMICS

Why not let our advertisers help you?

New Canyon Sanatorium Annex—This issue of the Journal contains a page advertisement for the new Canyon Sanatorium Annex for the treatment of of tuberculosis, at a rate of $15 a week for patients unable to pay the regular charges. Increasing facilities for the treatment of tuberculosis in sanatoriums at rates that can be afforded by people of ordinary incomes will do much in the campaign against this insidious disease. Doctor Ralph B. Scheier, medical director, states that the present unit is only a beginning and that others will be added as the demand warrants, until there is accommodation for 100 patients. Continuing in his discussion of this project, the medical director says:

"Cases of selected type only will be admitted to the annex. A rate of $15 per week will be charged. This rate includes medical attention, nursing supervision, bed and board. In order to make possible a rate which is less than the cost of maintenance a plan has been instituted by which the deficit will be met by the profit which accrues from Canyon Sanatorium. In bringing this venture before you we feel that a big sociological problem is being solved, and trust that you will give this project the editorial comment which it deserves.

"This project has been made possible through the support of the medical profession. Seven years ago Canyon Sanatorium started with five beds. It might be interesting for you to know that our success has in a large measure been made possible by bringing Canyon Sanatorium to the attention of the medical profession by advertising the sanatorium in the California State Journal of Medicine."

Medical and Scientific Reference Books—We are pleased to call attention to an advertisement in this issue of the Journal showing the establishment in San Francisco of a firm interested exclusively in promoting the sale of medical and scientific literature. Large Eastern cities have for many years had numbers of stores of this kind. San Francisco has needed a movement of this kind for a long time, and it is a pleasure to see that Mr. Stacey has taken a step in the right direction.

The Radiodor—Attention of physicians and hospitals is called to the advertisement of the Radiodor now being carried in the Journal. This electric vaporizer was shown at the conference of the hospitals of California held in San Francisco recently and at the American Medical Association annual session, and is being used by many hospitals and physicians. The Journal would be glad to have comment on the use of this instrument from physicians and hospitals.

The More Practical Functional Tests of the Liver—Max Einhorn, New York (Journal A. M. A., Nov. 3, 1923), reviews the various tests proposed for estimating liver function such as the general activity of the liver, which can be demonstrated by the color reaction which is produced by the liver in the bile after the entrance of various substances into its circulation. The permeability of the liver can be studied by the method devised by Abel and Rowntree and later on improved by Aaron, Beck and Schneider, by injecting tetrachlorphenolphthalein. The faculty of the liver of utilizing the biliary pigment, when the latter in returning from the intestine by the portal system, has reached the former organ, is best ascertained by testing the urine for urobilinogen. The albumose-storing power of the liver is determined by Widal's test based on the well-known fact that after the ingestion of food there is usually an increase of leukocytes present in the blood. This test Einhorn says does not at present appear to us that it will prove of much assistance. The storing faculty of the liver for sugars and fats is best investigated by the sugar tolerance tests and by the lipase content of the blood. The presence of galactose can be elicited by Nylander's test, or by the usual Fehling or Benedict test for sugar. The fat-storing ability of the liver may be tested by examining the blood for its lipase content. While all these functional tests give hints as to the workings of the liver or its failure to work, these alone will never enable one to make a diagnosis of any special disease of this organ.

The Blight of Standardization—In discussing this subject, President Eliot said: "A new blight is afflicting education and industries in the United States. . . . Its name is standardization. . . . It is obvious standardization has become a dangerous adversary of progress in both education and industry. The ideal in education is to develop the utmost possible variety of individual attainment and group attainment; just as the true goal of democracy is the free development of the utmost variety of capacity in the individual citizen. . . . The true educational goal is the utmost development of the individual's capacity or power, not in childhood and adolescence alone, but all through life. Fixed standards in labor, in study, in modes of family life or of community life, are downright enemies of progress for the body, mind, and soul of man."

DEATHS

Barber, David Cassat. Died at Blythe, December 2, 1923, age 61. Graduate of Miami Medical College, Cincinati, 1886. Licensed in California, 1886. He was a member of the Los Angeles County Medical Association, the California Medical Association and a fellow of the American Medical Association.

Callanan, Joseph Ignatius. Died at San Francisco, November 20, 1923, age 34. Graduate of the Stanford University School of Medicine, San Francisco, 1916. He was a member of the San Francisco County Medical Society, the California Medical Association and a fellow of the American Medical Association.

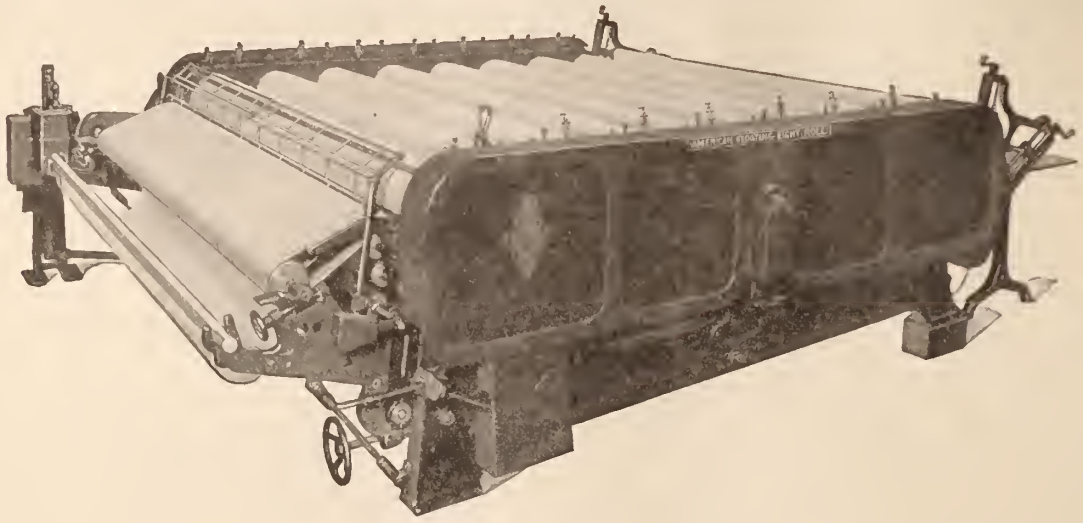
Edwards, Samuel G. Died at Los Angeles, November 11, 1923, age 55. Graduate of the Medical College of Ohio, Cincinnati, 1893. Licensed in California, 1900. He was a member of the Los Angeles County Medical Association, the California Medical Association and a fellow of the American Medical Association.

Fehlen, August. Died at San Francisco, November 13, 1923, age 63. Graduate of Cooper Medical College, San Francisco, 1894. He was a member of the San Francisco County Medical Society, the California Medical Association and the American Medical Association.

Friedman, William Lloyd. Died at Oakland, December 1, 1923, age 51. Graduate of the Baltimore Medical College, 1897. Licensed in California, 1898. He was a member of the Alameda County Medical Society, the California Medical Association and a fellow of the American Medical Association.

Owens, Frederick Francis. Died at Ely, Nevada, November 23, 1923, age 51. Graduate of Columbia University College of Physicians and Surgeons, New York, 1896. Licensed in Nevada, 1901. He was a member of the Nevada State Medical Association and the American Medical Association.

Thomas, Clifton A. Died at Albany, Oregon, October 10, 1923. Graduate of the Kansas City Medical College, Missouri, 1905. He was formerly a member of the San Francisco County Medical Society, the California Medical Association and the American Medical Association.



It Is Cutting Ironing Costs in California

The American Floating Roll Ironer—*a machine that irons body clothes as well as flat work*

SEVERAL California institutions are effecting really notable reductions in ironing costs through the use of a new laundry machine which irons body clothes as well as flat work, with flat-work ironer speed and economy.

This machine is The American "Floating Roll" Ironer, which is pictured above. Among well known institutions on the Pacific Coast which use and endorse it are:

The Napa State Hospital, Imola: a 6-Roll.
Preston School of Industry, Iona: a 4-Roll.
St. Vincent School, Santa Barbara: a 2-Roll.
House of the Good Shepherd, Seattle: a 6-Roll.

You will find that a "Floating Roll" ironer in your laundry will give you much more work at a far lower cost, and at the same time it will make the question of laundry labor less of a problem.

Full particulars gladly will be sent on request.

The American Laundry Machinery Company

Norwood Station, Cincinnati, Ohio

Los Angeles San Francisco Seattle

Back to the Parent—If we have one burning faith among us it is that children belong in homes of their own with other children and the companionship of their parents. The failure of society in general is measured chiefly by inability to save the parents and so permit them to live that they can provide homes worthy of the name, where health will come as a matter of course rather than as an accidental blessing. It is a part of the philosophy, the tradition, the instinct, the religion of all of us that we owe the child not only shelter and food and clothing, affection, an education and training for work, but protection and guidance in health. Organization of services for children en masse, and provision through private and public institutions and agencies for health teaching and supervision will not carry the load which must be placed directly where it belongs—upon the family household.—Haven Emerson, The Survey.

CALIFORNIA STATE JOURNAL OF MEDICINE

1924 Meeting of the California Medical Association

THE 1924 MEETING of the California Medical Association will be held May 12-15, at the Biltmore Hotel, Los Angeles. The program is rapidly nearing completion and promises to be an unusually good one. All members who desire to take part in any phase of the program should communicate promptly with the secretaries of their sections, listed in the back of this and every number of the Journal. In accordance with the announcement made in the January number of the Journal, the program will be closed February 15, and papers cannot be accepted after that date.

PASADENA, CALIFORNIA

AIRPLANE VIEW OF GROUNDS

A SANITARIUM FOR THE TREATMENT OF ALL FORMS OF NERVOUS DISORDERS AND GENERAL DISEASES

SIXTEEN MILES FROM LOS ANGELES, HEART OF THE ORANGE BELT

MAIN BUILDING

LOCATION—Situated in the foothills of the Sierra Madre Mountains, just outside of the city of Pasadena, is this beautiful sanitarium. It is surrounded by a natural live-oak grove of 20 acres, with lawns and gardens, ideally adapted to rest and enjoyment. Large central building and cottages all modernly equipped. Homelike and comfortable.

Rooms With or Without Baths Dairy and Poultry Plant Private Bungalows and Sleeping Porches
Climate Ideal Outdoor Sports and Recreation Cuisine Excellent

EQUIPMENT—Special equipment for aiding in a correct diagnosis. The Laboratory, Hydrotherapy and Electricity Departments are important adjuncts to the general Sanitarium treatment. All forms of baths are given, including the famous Nauheim.

CLASS OF PATIENTS—All forms of nervous disorders and general diseases are treated. Special attention is paid to Gastro-Intestinal disorders and Circulatory System. No Tuberculosis, Epilepsy or Insanity received.

BOARD OF DIRECTORS—Norman Bridge, M. D., H. C. Brainerd, M. D., W. Jarvis Barlow, M. D., F. C. E. Mattison, M. D., Stephen Smith, M. D.

ANNOUNCEMENT

In response to the oft-repeated suggestion from our friends, we are glad to announce the opening of our X-Ray Department which is operated in conjunction with our Clinical Laboratory.

All technical features of this department are in charge of A. S. Dominguez, Ph. D., who has had many years' experience in this work in continental clinics and several local hospitals. Our equipment comprises a powerful transformer such as designed for the Bellevue Hospital, New York, with complete facilities to do all roentgenological procedures, such as radiography of bones and joints, gastro-intestinal and pulmonary studies by fluoroscopy and roentgenograms, sinus work and treatment of surface conditions, as skin carcinoma, acne sycosis, etc.

Our experienced staff will give special attention to the interpretation of findings and their application in diagnosis and treatment, thus assuring you a valuable and dependable service.

This new department now completes our diagnostic facilities and in conjunction with our clinical laboratory we are able to offer you a most complete diagnostic service.

It will be our aim to give the profession the same dependable radiological service that they now receive from our clinical laboratory, both in promptness and efficiency.

We invite consultation and correspondence.

Importance of Complete Examination of the Cerebrospinal Fluid—The most important single sign of cord compression, and by all odds the most reliable, in the opinion of William Jason Mixter, Boston (Journal A. M. A., December 29, 1923), is that evidence which is obtained from the cerebrospinal fluid. At the Massachusetts General Hospital every patient suspected of cord tumor is prepared for puncture of the cisterna magna, as well as for lumbar puncture, and lumbar puncture is performed. Pressure readings are made, pulse and respiratory oscillations are noted, and the patient is directed to cough and to draw a deep breath. Next, the jugular veins are compressed, and finally a small amount (usually 5 cc.) of fluid is withdrawn. Notes are taken on the behavior of the fluid in the manometer during all these procedures. A portion of the fluid withdrawn is tested with alcohol for excess of protein. If the information obtained in these various ways gives definite evidence of block, puncture of the cisterna magna is not done. If there is absolutely no evidence of block, either chemical or dynamic, puncture of the cisterna magna is not done. If, however, there is the suspicion of block, either chemical or dynamic, the cisterna magna is punctured, combined readings are made, and fluid is drawn from both needles for quantitative examination of protein and for Wassermann examination and study of the cells. If tumor of the cauda equina is suspected, two lumbar punctures, one usually between the twelfth dorsal and first lumbar vertebrae and the other between the fourth and fifth lumbar vertebrae are performed. Occasionally, sacral puncture with injection of physiologic sodium chlorid solution into the epidural space, with observation of dynamic changes in the lower manometer, is also deemed advisable.

Colfax Hospital for the Tuberculous

Convalescents with normal temperature taking the cure. A November Morning.

SITUATED in the foothills of the Sierra Nevada Mountains at Colfax, California, one hundred forty-four miles east of San Francisco on the Ogden route of the Southern Pacific Railway. Operated in conjunction with the Cottage Colony of the Colfax School for the Tuberculous and intended for the accommodation of those patients who are unable to bring attendants and live in the Colony. Patients are given daily medical supervision and enjoy the advantages of all approved modern methods of treatment. Terms reasonable. For further particulars apply to

ROBERT A. PEERS, Medical Director

Colfax, California

"Without research no scientific discoveries or inventions have been made"

VICTOR X-RAY RESEARCH—A GUARANTEE

IT is research that has brought about the remarkable progress in roentgenological apparatus.

The wonderful X-ray apparatus of today, which has done so much to aid both the diagnostician and therapist and which has made it possible to *control* X-rays even more accurately than the effects of a drug are controlled, is due in a large part to research systematically conducted in behalf of the Victor X-Ray Corporation. Moreover, results of this research are embodied not only in Victor apparatus made for the hospital and specialized laboratory, but in simple equipment for the general practitioner.

No other manufacturer has so large an investment in research as the Victor X-Ray Corporation. A considerable portion of its earnings is reverted annually to be applied in physical and engineering investigation, to the end that the art of roentgenology may be advanced and results made more and more certain.

This large investment in research is a guarantee for the future. It is contributory in a large degree to the unquestioned supremacy of the American roentgenologist. It is a guarantee of the Victor X-Ray Corporation's permanency—a guarantee that X-ray users may confidently look to it for technical advances which will aid them in making the X-rays even more valuable than they now are.

When research so conducted is productive of apparatus with which the roentgenologist may realize a higher grade of work, thereby increasing his efficiency, then the prices of Victor apparatus are moderate indeed. Consider the importance—to both you and your patient—of that vital ten or fifteen per cent higher efficiency, from the standpoint of diagnostic and therapeutic results.

Giving us an opportunity to advise with you concerning your individual X-ray problem, does not obligate you in any way

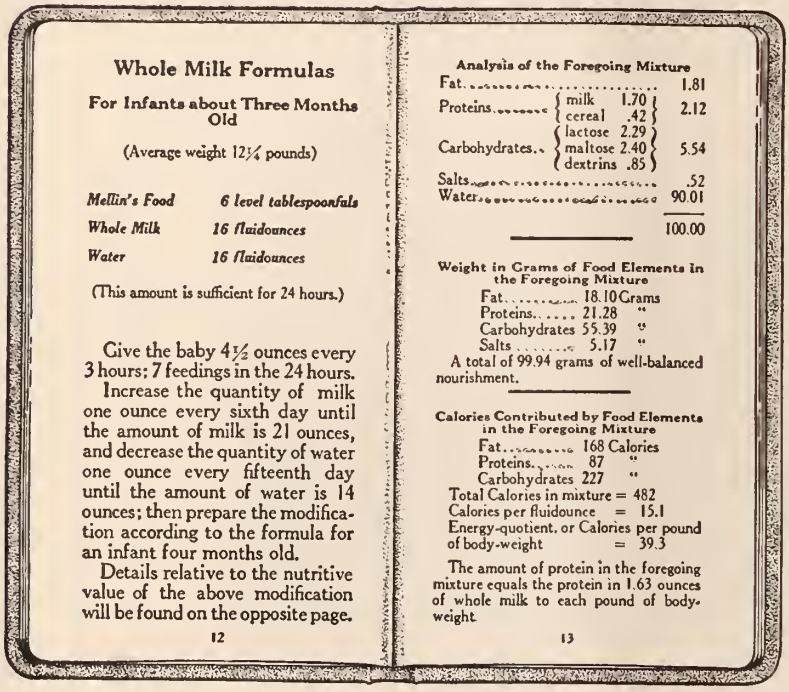
"Formulas for Infant Feeding"

New Edition



Whole Milk Formulas

For Infants about Three Months Old

(Average weight 12¼ pounds)

Mellin's Food	*6 level tablespoonfuls*
Whole Milk	*16 fluidounces*
Water	*16 fluidounces*

(This amount is sufficient for 24 hours.)

Give the baby 4½ ounces every 3 hours; 7 feedings in the 24 hours.

Increase the quantity of milk one ounce every sixth day until the amount of milk is 21 ounces, and decrease the quantity of water one ounce every fifteenth day until the amount of water is 14 ounces; then prepare the modification according to the formula for an infant four months old.

Details relative to the nutritive value of the above modification will be found on the opposite page.

12

Analysis of the Foregoing Mixture

Fat			1.81
Proteins	milk	1.70	2.12
	cereal	.42	
Carbohydrates	lactose	2.29	5.54
	maltose	2.40	
	dextrins	.85	
Salts			.52
Water			90.01
			100.00

Weight in Grams of Food Elements in the Foregoing Mixture

Fat	18.10 Grams
Proteins	21.28 "
Carbohydrates	55.39 "
Salts	5.17 "

A total of 99.94 grams of well-balanced nourishment.

Calories Contributed by Food Elements in the Foregoing Mixture

Fat	168 Calories
Proteins	87 "
Carbohydrates	227 "
Total Calories in mixture	= 482
Calories per fluidounce	= 15.1
Energy-quotient, or Calories per pound of body-weight	= 39.3

The amount of protein in the foregoing mixture equals the protein in 1.63 ounces of whole milk to each pound of body-weight.

13

A thoroughly revised edition of our book, bound in leather, is now ready, and a copy will be mailed to physicians upon request.

To give some idea of the magnitude of this new work and how well it keeps step with the progress in infant feeding, we display two pages of this 80-page book. It will be noted that the formula adjusted to age and weight, together with simple instructions for progressive changes, is given on the left-hand page, and on the right practically every detail relative to the balance of nutrition is stated. This plan is followed throughout the book, thus giving information of daily usefulness not accessible in any other work of this nature.

Special formulas calculated to meet conditions other than normal, with suggestions for their practical application, broaden the scope of the work, which in its entirety marks a distinct advance toward a better understanding of infants' nutrition.

Mellin's Food Co.

THE STANDARD
LOESER'S INTRAVENOUS SOLUTIONS
CERTIFIED

LOESER PRESTIGE

☼ ☼

The respect that Loeser's Intravenous Solutions enjoy among the medical profession is not based on any single phase of excellence. This alone could not sufficiently account for the universally high estimation in which these solutions are held.

This esteem goes beyond the technical excellence of the solutions themselves. It is deeper than any appreciation of excellence alone could make it.

It goes, in fact, down to the bedrock of unshaken confidence in the name; a firm conviction that the name Loeser is synonymous for the original research which overcame prejudice and made intravenous injection a safe and practical office procedure.

"Certified"

Clinical Reports, Reprints, Price List, and the "Journal of Intravenous Therapy" will be sent to any physician on request.

Another Reason for Forest Conservation—An editorial in the Journal Indiana State Medical Association of October, 1923, says: "We have received a reprint of a discussion pertaining to testicular grafting by Serge Voronoff of Paris, in which he states that after considerable experience (favorable) he now employs for grafting only adult chimpanzees and cynocephalic monkeys, whose puberty and virility are unmistakably evident. He maintains that glands thus provided will surely continue their function in the human organism. What a boon for the decrepit old codgers who are searching for the fountain of youth! But monkeys and chimpanzees are not found on every sassafras tree, and the supply is not likely to meet the demand. Furthermore, are we destined to see a lot of monkey-faced progeny with a propensity to hang by their tails to the limbs of our trees in our parks. Fine outlook for us if those testicular grafters (and grafters probably is a good name) succeed in giving monkey youth to some of our numerous sexual corpses."

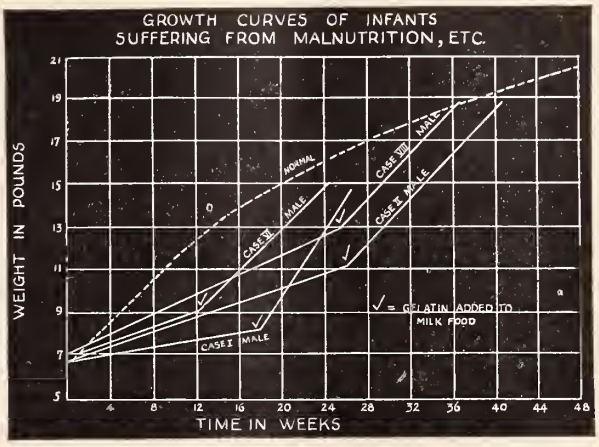
The Value of "Gelatinized" Milk in Mal-nutrition



HERE is an exact chart showing the growth curves of four infants suffering from malnutrition, resulting from imperfect assimilation of the milk nutriment—the most valuable of all foods. Note the sharp angle of recovery after plain edible gelatine was added to the milk formulae.

The colloidal action of the gelatine prevented excessive stomach curding of the milk and insured the proper absorption of all the milk nutriment, besides supplying the Amino-Acid, Lysine, essential to healthy growth.

Gelatinization of the milk does not interfere in any way with any formula prescribed by the physician, but does, on the other hand, greatly augment the efficacy of every milk diet whether for infant or adult.

That Gelatinized Milk is one of the most important advances in dietary practice has been fully demonstrated, not only for infants, but also in all child and adult cases where impaired digestion prevents perfect nutritive assimilation. The only precaution necessary is to use a pure, unflavored, unsweetened granulated gelatine, of which the highest known standard is

KNOX
SPARKLING
GELATINE

"The Highest Quality for Health"

For the Perfect Gelatinization of Milk

Put one tablespoonful of gelatine in one-half cup of cold milk and let it soak for 10 minutes. Place the cup in boiling water, stirring until gelatine is fully dissolved; then add this dissolved gelatine to the quart of cold milk or regular formula, from which you have taken the original one-half cupful.

In addition to the family size package, Knox Sparkling Gelatine is put up in 1 and 5 pound cartons for special hospital use. A trial package at 80 cents the pound will be sent on request.

— *sincere and honest service*

This perhaps characterizes an ideal policy as well as anything we might say. Here, we strive to be a little more thorough, a little more attentive to every detail of your requirements than you yourself believe necessary.

A policy such as this is not easy to maintain, but it IS maintained here at all costs. You are thereby certain to receive a little better work and a little better service at all times from a Riggs Organization.

True success lies not so much in doing something that has never been done before, as in doing the ordinary everyday tasks a little better than anyone else ever dreamed of doing them.

* * *

The instructions on your prescriptions are law unto our workmen. Glasses are made up in every detail precisely as you order them.

To a commanding officer, Lincoln wrote, "He who does something at the head of one regiment will eclipse him who does nothing at the head of a hundred."

* * *

Providing good vision for your fellow-man is one of the highest forms of human service. As optical prescription specialists, we are grateful for the privilege of aiding in this good work.

When you send your prescriptions to us, you will find our people take a personal interest in doing the work exactly as you request.

Adequate equipment is essential to success. It is a part of our business to furnish the scientific instruments you require.

* * *

Our lines of equipment are complete, of latest design, and in full accord with the present high standard of modern practice. Write us for further particulars.

A letter dated October 17, 1861.

"Dear Sir:

"The lady bearer of this says she has two sons who want to work. Set them to it if possible. Wanting to work is so rare a want that it should be encouraged.

"A. Lincoln."

In our shops we maintain what we choose to call "triple inspection." For such it is. All materials are inspected not once, but three times.

* * *

All goods are inspected on arrival and any below our standard of first quality are refused. They are again inspected when taken from stock.

Finished glasses receive final inspection covering 18 points of manufacture, each one of which must be right before delivery is made.

* * *

Your prescription requirements are here filled as carefully as if done under your direct supervision. To compare our work and service with that of others, will you please send a trial Rx soon?

Alum Rock Sanatorium

For the Treatment of Tuberculosis in All Its Forms

THE SANATORIUM adjoins Alum Rock Park in the eastern foothills of San Jose, 900 feet above sea level, and overlooks the entire Santa Clara Valley. The climate is ideal throughout the year. The distance from San Francisco by rail or motor is fifty miles. The buildings are situated in the center of a beautiful ten-acre tract under cultivation. A hedge of eucalyptus partly surrounds the place and there is a great variety of flowering shrubs, citrus and pine trees. The aim of the Staff is to give tuberculous patients intensive individual treatment and each case will be carefully studied with this end in view.

As the result of consistent research and refinements in the methods of production, The Dermatological Research Laboratories have very greatly improved upon the original arsenicals.

Neoarsphenamine, D. R. L., as now offered, is meeting the requirements of the most exacting members of the medical profession. The world has never before known a drug of greater excellence. Government specifications for such products are high but *Neoarsphenamine, D. R. L.,* runs from 75 to 100% above them, as toleration tests show.

While allowing a wide margin of safety for the patient, *Neoarsphenamine, D. R. L.,* is practically the equal of Arsphenamine for therapeutic effectiveness.

A handy package of *Neoarsphenamine*: 10 ampules, with an equal number of ampules of distilled water included without additional charge, in these sizes: 0.9, 0.75, 0.6 and 0.45 gram. Ask your dealer. Whether *Arsphenamine, Neoarsphenamine* or *Sulpharsphenamine,* let it be the reliable D. R. L. brand. Booklet on "The Treatment of Syphillis" sent on request.

Colfax School for the Tuberculous

EXPERIENCE has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the Sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

ORIGINAL ARTICLES

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

The author of an article appearing in the JOURNAL *is entirely responsible for all statements and conclusions. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the language and method of presenting their subjects. All manuscripts will be carefully read, but editorial privileges will be exercised only to a very limited extent. It is believed that the manner of presentation of any subject by any author determines to no small degree the value of his conclusions. Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented by the author as little disturbed as possible by the editors. However, the right to reduce or reject any article is always reserved.*

THE PRINCIPLE AND TECHNIC OF DRAINAGE IN THE SURGERY OF THE GALL-BLADDER AND THE BILE TRACT *

By ANDREW STEWART LOBINGIER, M. D.,
Los Angeles

Our present understanding of the relationship between infection of the gall-bladder and infection of the liver and its ducts, due to a better interpretation of their related pathology, will in future greatly modify the surgery of the gall-bladder.

For many years there has been a feeling among clinical observers that the surgery being done for conditions commonly found in the gall-bladder was only partially meeting the requirements in the case; that gall-stones were largely an incident in cholecystitis and that the infection and tissue changes found in the wall of the gall-bladder would be found in greater degree and significance in the liver itself. It did not seem reasonable that inflammatory changes could be present in the wall of the gall-bladder without the hepatic ducts sharing in these inflammatory changes. Riedel, as far back as 1888, described a tongue-like process of the right lobe of the liver, which since then has been known as Riedel's lobe. It was associated with cholecystitis and was thought to be due to an enlargement of the liver. Naunyn, in 1892, quotes Charcot as noting the enlargement of the liver in gall-stones. Langenbach was of the opinion that this enlargement of the liver was only present with obstruction of the choledochus, but Fink believed that in every case of infection of the biliary tract, the liver would be found to be enlarged. Mayo-Robson found the liver enlarged in the later stages of infective cholangitis and believed this condition might be complicated with diffuse hepatitis and cholecystitis. Quincke considers an enlarged liver a common attendant of cholelithiasis, and Grube and Graff found hepatitis almost invariably associated with cholecystitis and gall-stones.

All of these clinical observations were made of the living pathology by men of the widest experience in diseases of the liver and gall tract. The significance of these observations has been so suggestive that many of us have been able to confirm these opinions in our own experience. But there has remained a confused state of mind as to the channels through which infection was conveyed and precisely what changes occurred in the histology of the liver when it became infected. Twenty-five years ago Cushing conducted a series of experiments to discover the channel through which infection occurred in the gall-bladder in enteric fever. Since that time a large amount of experimental work has been directed toward determining whether the infection was by extension along the mucous lining of the intestine upward into the gall-ducts and gall-bladder or was from clumps of bacteria being swept through the veins or lymph channels from a distant focus of infection into the wall of the gall-bladder and interlobular spaces of the liver. J. Koch found in the submucous reticulum of the gall-bladder of a man who died of typhoid clumps of bacilli, which stained like the Eberth bacillus and which he concluded was the bacillus typhosus. No bacteria were found in the lumen of the gall-bladder, and Koch concluded that the cholecystitis of enteric fever was due to haematogenous infection, and this embolus was deposited in the submucous area of the gall-bladder. Chiarolanza partly confirmed Koch's conclusions. Experimental work has been done by Chiari, Letienne, Girodi, and Pawlowsky on the entrance of various bacilli to the bile tract, all of them with varying conclusions, but most of them holding the belief that this transmission is embolic. Rosenow, in 1916, conducted a series of interesting experimental studies on the transmission of streptococcus infection. The study we are particularly interested in here was on the "Etiology of Cholecystitis and Gall-Stones and Their Production by Intravenous In-

* Presented to the Section on Surgery at the Fifty-second Annual Session of the California Medical Association.

jection of Bacteria." His conclusion was that the wall of the gall-bladder was infected haematogenously. But none of these studies conclusively determined what part the liver shared in the infection of the bile tract.

In December, 1917, Evarts A. Graham reported a series of experimental studies before the Chicago Surgical Society on "Hepatitis: A Constant Accompaniment of Cholecystitis." This proved to be the beginning of a systematic study, later to be joined in collaboration by Peterman and Priest in an experimental contribution on "The Association of Hepatitis With Experimental Cholecystitis and Its Bearing on the Pathogenesis of Cholecystitis in the Human." A still later contribution by Peterman of experimental studies on "Cholecystitis and Its Complications" constitutes altogether the most conclusive evidence yet offered on this subject. We may only summarize here the conclusions of these investigators.

Graham's conclusions are as follows: "In 30 cases of biliary tract disease which have come to operation, a distinct enlargement of the liver has been present in 26, or 87 per cent. In the remaining four cases, there has been definite gross evidence of previous or existing pathological change in the liver, other than an enlargement. During the course of the operation, small pieces of liver tissue have been removed for bacteriological and microscopical study. The result of these examinations may be epitomized as follows:

1. In cases of acute or sub-acute cholecystitis there has constantly been found in the liver microscopical evidence of inflammation.

2. The hepatic inflammation is characterized by leucocytic infiltration of the interlobular or periportal sheaths; in the more severe types of inflammation, the infiltration may involve also the parenchyma at the peripheries of the lobules and be associated with more or less oedema, slight necrosis, and moderate fat infiltration.

3. Cultures from both the liver tissue and from the bile in the gall-bladder have usually revealed the same organism from each of the two different sources.

4. In chronic cholecystitis the liver microscopically often presents a picture practically identical with that of an early case of cirrhosis.

5. The inflammatory reaction appears to be chiefly a pericholangitis.

6. The gross enlargement of the liver is probably usually due to oedema. The enlarged livers in this series have always diminished markedly or returned to normal size after appropriate surgical treatment. Marked cirrhotic changes have been shown to occur in the liver, even when there has never been a stasis of bile."

The importance of these findings in relation to the pathogenesis of cirrhosis of the liver in general is discussed.

From the standpoint of the diagnosis of obscure or doubtful cases of biliary tract disease, the presence of an enlarged liver is of the greatest importance.

Inspired by the study by Sudler of the lymphatic distribution to the gall-bladder, Peterman shows that, not only is the infection of the gall-bladder haematogenous through the portal system in which the liver coincidentally shares, but that this infection may occur through the lymph vessels as well, and that we may have a lymphogenous as well as a haematogenous origin of cholecystitis and cholangitis. As a prelude to his own experimental studies, he cites a voluminous bibliography covering more than 30 years of clinical and experimental observation on the infection of the gall-bladder, bile-ducts, and liver. In this latest contribution he divides the study into six parts: "Part 1 consists of a review of the literature on experimental cholecystitis; in Part 2 is submitted the experimentation directly concerned with establishment of experimental cholecystitis and its relation to hepatitis; Part 3 contains a consideration of cholecystitis in its relation to appendicitis; Part 4 consists of a review of pancreatitis and its relation to cholecystitis, with a report of investigation; in Part 5 a survey of clinical cases is offered, and Part 6 is a general discussion."

A resume of the literature on experimental cholecystitis shows:

"1. Intravenous injection of organisms if in sufficient amount is always followed by the appearance of these organisms in the bile. The organisms are probably carried to the liver in the blood stream, excreted in the bile and carried at the same time, among other places, into the wall of the gall-bladder by the blood stream and lymphatics.

2. The intravenous injection of virulent organisms in sufficient amount produces a cholecystitis in a high percentage of cases.

3. The organisms after intravenous injection may be demonstrated in the bile one-half to two minutes after injection, and may be found in the gall-bladder after the blood has become sterile.

4. Simple injection of organisms, even in large amounts into the lumen of a normal gall-bladder, does not usually produce a cholecystitis.

5. Injection of virulent organisms into the lumen of a gall-bladder in sufficient amounts after ligation of the cystic duct and vessels regularly produces a cholecystitis.

6. Although cholecystitis may be due to a haematogenous infection, it is not infrequently lymphogenous in origin.

Cholecystitis is constantly accompanied by hepatitis. The character of the lesion in the liver is determined to a certain extent by the origin and course of the disease in the gall-bladder."

We cannot include all the divisions of Peterman's last contribution in this review, but the Part 3 which discusses appendicitis and peptic ulcer associated with cholecystitis is of especial interest to us in this discussion.

For many years the clinical relationship between appendicitis, cholecystitis and gastric and duodenal ulcer has been noted by surgeons.

"In 1901, Adrian asserted his belief that appendicitis was a haematogenous infection. In the 1904 Mount Sinai Hospital Report in seven cases of ulcer operated, three showed foci of infection in the area drained by the portal vein. Ochsner re-

ported, in 1906, four cases of pyloric ulcer, two of which were associated with infection of the bile tract, two with appendicitis, one case having both lesions. There were 13 cases of bile tract infection, of which four had pyloric ulcer and seven appendicitis. Deaver in 1907 reported 36 cases of ulcer, 15 of which gave a history of typhoid, bile tract infection, dysentery or appendicitis."

"In 1908 Moynihan reported 205 cases of ulcer, 16 of which required surgery in the bile tract. The appendix was not examined. In his work on Duodenal Ulcer, he reported 62 cases of ulcer, 25 of which had chronic appendicitis, one required biliary drainage, and a later study showed in 14 cases of ulcer 12 chronically inflamed appendices, the other two patients were too ill to permit detailed study. Moynihan, in 322 ulcers operated upon in 1910-11, found 111 chronically inflamed appendices, and asserted it as his belief the appendix should be removed in 90 per cent of the cases of diseases of the bile tract and of peptic ulcer."

Peterman gives voluminous citations of the clinical reports and studies of numbers of other observers, including McCarthy and McGrath, Augustana Hospital report 1910-1911, Pilcher, Mitchell, and Rosenow, all of which show the close relationship between infection in the vermiform appendix and the bile tract, as well as ulcer of the stomach and duodenum, and quotes Deaver as presenting the modern and generally accepted dictum "that in case of gall-bladder infection whether there are calculi or not, operation should include removal of the appendix and the examination of other abdominal viscera for associated disease." After consideration of the close relationship through the lymphatic system between infective conditions in the appendix and bile tract with the pancreas, Peterman concludes that these infections, secondarily, of the pancreas are most commonly (30-Med. Record, p. 47, 1919) brought about through the lymph channels.

He concludes with the clinical and laboratory study of 130 cases of disease in the human gall-bladder in the surgical service of Barnes Hospital. These cases were unselected, and his "object in reviewing them and the sections was to study in detail the pathological findings in gall-bladder disease and its complications. . . . Thirty-three cases were critically analyzed and studied in greater detail, which included study of the gall-bladder wall and sections of the liver removed at operation. In seven other cases which came to autopsy, the liver was studied microscopically. . . . "

Cholelithiasis (with or without complications) as a pre-operative diagnosis was made 92 times, and stones were found in 79 cases. Cholecystitis, exclusive of stones, was diagnosed in 30 instances. . . . Twenty gall-bladders were reported not markedly abnormal. All, however, showed pathological changes on section. The liver was found involved in 82 cases. . . . "In 82 cases of liver involvement, 69 were enlarged or oedematous, 5 showed adhesions alone, and 8 were atrophic or scarred." . . . "The chief interest in the study of these cases was the frequency and the nature of hepatic involvement. . . . In a complete study of 33 cases the liver was found involved in every case. . . . In the acute cases there was a pericholangitis, at times a general hepatitis with infiltration of polymorphonuclear leucocytes in the interlobular spaces especially around the bile-ducts. . . . In the chronic cases there was observed an increase in connective tissue elements in the periportal or interlobular spaces with a moderate infiltration of mononuclear leucocytes."

This author's conclusion is that "cholecystitis probably begins in most instances as an infection within the wall of the gall-bladder, and doubtless is secondary to a hepatitis. This infection may be acquired from the appendix, intestines (typhoid, dysentery), or it may be secondary to any infectious focus within the body. The infection may then spread easily by the lymph stream to the wall of the gall-bladder and the complications then follow."

He quotes Mallory's studies of the liver in typhoid, and adds "the frequency of cholecystitis with and following typhoid is thus readily explained." So that with this overwhelming assembling of clinical and experimental evidence based upon exact microscopical study, one feels that this group of careful and conservative investigators is fully justified in the final conclusion that "the emphasis so commonly placed on the appearances and changes in the mucosa of the gall-bladder would seem to be misdirected."

It is obvious that these recent comprehensive clinical and experimental studies in the pathogenesis of infection of the liver and bile tract lead to one conclusion. This conclusion brings into sharp relief the fact that we have been dealing surgically with only a small part of the infected bile tract when we have removed the gall-bladder or stones from the gall-bladder and ducts. The greater, and in very many instances, the more important infected areas—the liver and the hepatic ducts—have received little or no attention. We are compelled then, by the logic of these findings, to take a new view of the pathology of the organs in the right hypochondrium and to consider surgical procedures which shall be more adequate in reaching this infection and overcoming it.

The pathology by which we have been governed in the choice of cholecystectomy or cholecystostomy has been found to have a far wider significance, and we shall discover in the principle of drainage the basic method of treatment.

John B. Murphy more than 20 years ago urged on a reluctant profession the merits of this treatment. In that day the bile itself was regarded as the principal carrier of the infection, and Murphy drained the bile through the gall-bladder from the hepatic ducts until repeated cultures showed it to be sterile. With the knowledge definitely determined that infection is haematogenous or lymphogenous primarily to the liver, and secondarily to the gall-bladder, ducts and bile, the principle of treatment by drainage is just as definitely determined for us. This does not mean that pericholecystitis with adhesions, cysticus and necrotic oedema shall not always require cholecystectomy. There is

no other procedure to be considered in those conditions; but in cholecystitis with or without stone, in cholangitis and hepatitis, in splanchnic paresis and a failing myocardium, which are the usual concomitants of this infection, some form of prolonged drainage, with a judicious use of chologogues, will very likely be the treatment of the future. Kehr has suggested drainage of the liver by placing a small tube in the common hepatic duct. It is by no means easy to do without leakage, and a tube retained sufficiently long to accomplish the desired result will almost invariably cause an ulcer and later a stricture in the duct. We have found in our experience, and recommend as more practicable and free from any reasonable objection, the removal of the major portion of the gall-bladder, leaving sufficient of its neck to tie in securely a small firm-walled drain in the cystic duct, maintaining this drain in place for a period of at least 20 days.

It may be necessary to continue the drainage for six weeks or two months, the governing factors being the chronic congestion and enlargement of the liver and the character and degree of bacterial infection of the bile. We would urge careful attention to the technical details of the method of drainage which, for the first time, we here recommend. The cystic artery should be ligated separately.

The gall-bladder is dissected away from the liver, clamped off, and cut an inch and a half from the common duct. If the mucosa strips easily, it is better to remove it down to the cystic duct. The drainage tube should be tied in with two purse-string ligatures of twenty-day chromic catgut, the end of the drain being one-half inch short of the common duct. The raw edge of the amputated neck may be covered in with omentum or the serous coat turned in as in cholecystostomy.

If the gall-bladder is acutely septic, a temporary Penrose drain, to be withdrawn after a few days, should be placed under the liver above the right kidney. If this technic is followed carefully there should never be leakage of bile or infection of the peritoneum.

This operation may be done rapidly and securely and is adapted to practically every form of infection of the gall tract. It disposes, without further argument, of the tiresome discussion of cholecystostomy and cholecystectomy, for it compasses the principle of both of these procedures. It *is* a cholecystectomy and it accomplishes all and more than the usual cholecystostomy does in drainage of the common and hepatic ducts. And best of all, it drains and reduces the infection in the liver and pancreas, the *raison d'etre* for practically all gall-bladder surgery. We commend this operation, therefore, with sincere conviction, because it is founded upon sound pathology and because we cannot escape the conclusion which the majority of clinical and experimental observers working in this field now confirm: that our hope of accomplishment in the future treatment of infection of the liver, pancreas, and bile tract, must lie in the rational application of *drainage*.

Merritt Building.

TUMORS OF THE TESTICLE*

WITH SPECIAL REFERENCE TO DIAGNOSIS AND TREATMENT

By FRANK HINMAN, M. D.; ADOLPH A. KUTZMANN, M. D., and THOS. E. GIBSON, M. D.
(From the Department of Urology, University of California Medical School.)

The difference between the two operations of simple castration and castration with radical resection of the preaortic lymph zones for malignant tumors of the testicle is so great that reasons for ever attempting the latter must be fundamentally sound. The principle that any surgical attack of cancer anywhere in the body must be whole-hearted or not at all is of universal belief, and justification of such a radical principle has arisen through the hard-earned improvements in the results of the treatment of cancer in general. A life saved now and then from an otherwise hopeless and miserable end encourages the patient and surgeon to take great risks. The advent of the Roentgen ray and radium therapy somewhat undermines this surgical principle, but medical men should carefully consider facts and conclusions. A careful and truthful scrutiny of results by all methods is essential, and a comparison from time to time of such reviews establishes the best and soundest methods of treatment.

The physician or surgeon is seldom called on to make a diagnosis or to treat malignant tumors of the testicle. Nevertheless, even in those exceptional instances, the extreme malignancy of this type of tumor and the inadequacy of simple castration should be fully appreciated by all. The surgical ease of castration and ignorance of end-results but poorly excuses the neglect of more efficient methods, even though they are beset by more difficulties. This paper is but a brief summary of a recent and complete analysis of results obtained by castration, radio-therapy and the radical operation,[1] and there follows from this familiarity with the literature and personal experience with these cases, certain fundamental inferences of diagnosis and of selection and classification of cases which may be useful. The diagnosis is not simple, mistakes are costly and surgical exploration should be unhesitatingly resorted to in all cases of doubt. The loss of a few months in making a diagnosis too often means the loss of a life. Once the diagnosis is firmly established, a recognition of individual conditions is essential, in some cases radical operation is clearly contra-indicated, while in other cases it may be directly indicated. The interest of the patient warrants a conservative presentation of the facts and an intelligent recognition of them by the general practitioner as well as the specialist.

DIAGNOSIS

The diagnosis of testicular tumors is chiefly a matter of exclusion. They present no pathognomonic signs or symptoms. Syphilis, hydrocele and tuberculosis present the chief problems of differentiation.

* Read before the San Francisco County Medical Society, May 29, 1923.

1 Hinman, Gibson and Kutzmann: The Radical Operation for Teratoma Testis. Surg. Gyn. and Obs., Oct., 1923.

Figure 1—Photograph showing typical mixed tumor or teratoma of the testicle measuring 6x4.5 cm. Note variegated cystic structure characteristic of teratoma. No normal testicular substance remains.

Gumma simulates tumor more often and closely than any other condition, and it is well never to forget that generalized lues and testicular malignancy may coexist. A positive Wassermann or antiluetic therapy should not be cause for too long delay. It is preferable to remove a gumma, as has been done, than to delay in the removal of a malignant tumor.

Hydrocele and hematocele occasionally present great difficulties in differentiation. The pathognomonic signs of transillumination and fluctuation may fail in hematocele, while certain teratomata in which cartilage and mucoid material preponderate may transmit light and be fluctuant. Trauma as the important factor in hematocele may have been absent, and its significance relative to tumor is about as great anyway. Hydrocele in conjunction may completely mask the presence of tumor, and yet, on the other hand, simple hydrocele may present hard indurated areas due to organization and absorption. Of considerable help often is puncture drainage of the tunica vaginalis, which then permits more accurate palpation of the testicle. There is at present in our pathological museum a specimen of gumma of the testicle associated with hydrocele of the tunica vaginalis and a large cyst of the epididymis, all of which exemplifies some of the diagnostic difficulties that may be encountered.

Tuberculosis more rarely presents difficulties and then only in those rare instances of massive epididymo-orchitis, in which the mass may equal in size that of a large testicular tumor. The radical operation has been performed by mistake on such a tumor mass, even in co-operation with an expert pathologist.

Clinically, we consider all tumors of the testicle as malignant. They have been placed essentially in two groups: The Teratoma (Fig. 1) and Seminoma (Fig. 2). Their pathological morphology has been entered into elsewhere.[2] In Figure 3 will be seen the relative incidence of each type of tumor to age. Clinically, it is practically impossible to differentiate the type of tumor.

In view of the difficulties in diagnosis, the extreme malignancy of these growths and the simplicity of an exploratory examination, the interest of the patient demands that every testicular enlargement which is in any way suspicious, should be immediately inspected surgically and when necessary, its exact nature determined by microscopical study. Delay in these cases proves fatal.

TREATMENT

The treatment of benign tumors of the testicle may be briefly dismissed with a simple castration. The occurrence of benign tumors of the testicle is so rare, however, that it is essential to consider them all as malignant until proved otherwise. Our present knowledge of diagnosis, clinical course and

2 Hinman, Gibson and Kutzmann: The Radical Operation for Teratoma Testis. Surg. Gyn. and Obs., Oct., 1923.

Figure 2—Photograph showing cross-section of typical seminoma of the testicle measuring 5x7 cm. Note characteristic solid, opaque, uniform structure. The right half of the specimen shows a narrow remnant of normal testicular substance (a) which has not yet been replaced by tumor.

prognosis of malignant tumors of the testicle emphasizes that an early and accurate diagnosis of every testicular enlargement is essential. In every case of reasonable doubt there should be no hesitation in exposing the tumor to surgical inspection and whenever necessary performing castration and subjecting the tissue to immediate microscopic examination by an expert pathologist. Hematocele and massive tuberculosis require surgery so that the only possible sacrifice by adopting this policy is that of an occasional gumma of the testicle. Too many malignant growths are apt to be neglected through the uncertainty of diagnosis. Repeated tappings and prolonged observation should be discarded in view of the simplicity of exploration.

The prognosis of tumors of the testicle is a poor one. We will briefly sketch through the present forms of treatment—castration, radio-therapy (radium and Roentgen ray) and the radical operation—and their results.

Castration even with an early diagnosis is a dismal failure. There is sufficient statistical data to show the procedure of simple castration is quite inadequate. It is obvious that this procedure in order to cure must antedate metastatic extension. This it has done only in about 15 to 20 per cent of cases, and the ultimate mortality of 80 per cent after this surgical procedure certainly is appalling. It is at once apparent that castration is very inadequate and must be supplemented by radio-therapy or more radical surgery if any betterment in results is to be achieved.

Radiation in itself has given anything but encouraging results, as evidenced by the work of Barringer and Dean in New York. They do report, however, one remarkable case in which there were large abdominal metastases, and the patient living and well three years and five months since having been first seen.

The Roentgen ray has also been used. Orbaan's (Holland) is the only available systematic study. Here we find reported nine cases, six of which are dead and the remaining are living with metastases. Of interest here also is a case of the senior author. Large retroperitoneal masses which were not palpable through a thick muscular abdominal wall were discovered upon retroperitoneal exposure. The patient received nine Roentgen ray treatments which have kept them stationary. He was seen recently by one of us and was found to be active and working, with no evidence of metastases and to have gained 30 pounds in weight since his operation 23 months ago. While the reports of radio-therapy are too few to prove or disprove its value, nevertheless, its use as a palliative measure in conjunction with surgery as curative seems justified by the few brilliant results recorded.

The poor results following castration have stimu-

lated surgeons in this country and elsewhere to apply the well-recognized and fundamental principle in the treatment of malignancy, namely, the removal of the growth with its draining lymphatic area; in this case it is the testicular tumor and the retroperitoneal iliac and preaortic lymph glands. An analysis of the findings and results of this extensive procedure appears elsewhere.[3] We believe that a period of four years or more has elapsed in a sufficient number of cases to prove its merits, the results over castration having been improved by 100 per cent.

It is, therefore, seen that, as soon as the diagnosis is once established, one of two lines of procedure should be instituted; either a palliative course of treatment by castration supplemented by radium or Roentgen ray therapy in cases with palpable abdominal masses or an wholehearted attack of the problem by removing the primary growth with radical resection of the draining lymphatic area.

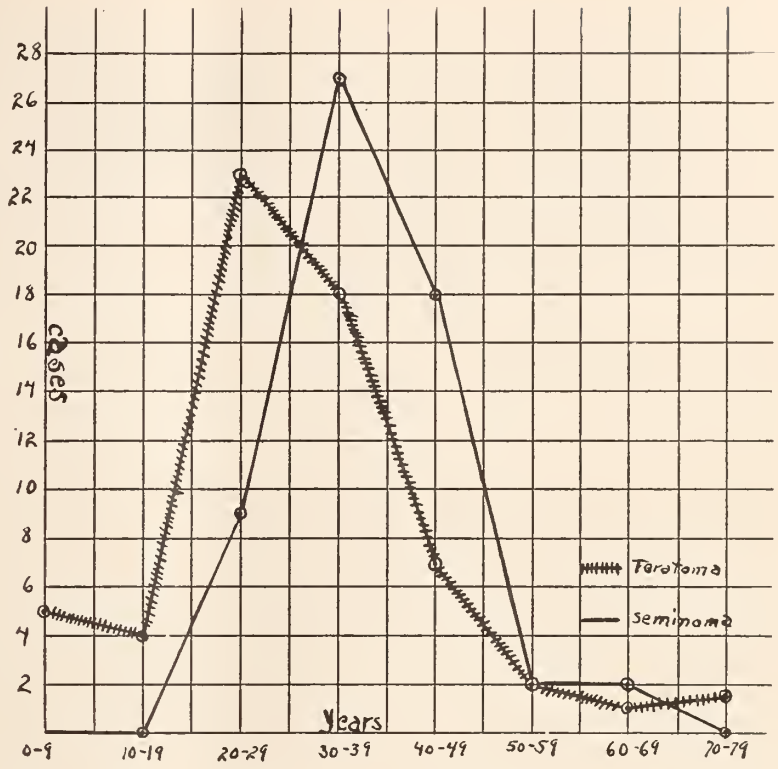

Figure 3—Chart (from Chevassu) showing age incidence of seminoma and teratoma. Note that there are five teratomas under the age of 5 years; no seminomas under the age of 20 years, and only one under 27 years.

A certain number of cases coming for treatment will have clinical evidence of abdominal metastases. The radical operation should not be attempted in these cases because experience has proven them inoperable. Radium packs and Roentgen ray therapy as used by Barringer or Orbaan should be attempted with the hope of checking the malignancy and prolonging the patient's life. In all other cases showing no clinical evidence of metastases, the treatment should at once be radical.

Unfortunately, some of these cases will have inoperable retroperitoneal masses revealed at operation. Such cases will then have to be treated palliatively with radium and Roentgen ray. Radiation of the open wound at the operation table is a commendable procedure in these cases, as well as in those in whom the radical resection has been successful. The group for radical surgery will become larger as diagnosis becomes earlier and more accurate.

A small number of cases might be cured by simple castration, provided metastases have as yet not taken place, but because of the impossibility of recognizing them clinically, they should, in the interest of the majority, be unhesitatingly exposed to the risk of radical surgery. The immediate mortality is less than 10 per cent, and will undoubtedly diminish as more knowledge and experience of the operation is obtained.

[3] Hinman, Gibson and Kutzmann: The Radical Operation for Teratoma Testis, Surg. Gyn. Obs., Oct., 1923.

SUMMARY

1. Tumors of the testicle affect all ages, but are most common between 20 and 50 years. The seminome occurs rarely in children, while the teratoma is the more frequent. Duration of these tumors is variable due to the frequency of periods of latency and quiescence in their development. The duration of the growth or its clinical characteristics furnish no index as to whether or not metastases have occurred.

2. Diagnosis is chiefly a matter of exclusion. Hydrocele, massive tuberculous epididymo-orchitis, and gumma offer the chief difficulties in differentiation.

3. From the pathological standpoint, malignant tumors of the testicle are clinically best divided into two groups—seminomas and teratomas.

4. Simple castration cures but 15 to 20 per cent of malignant tumors of the testicle. From statistics on castration (Chevassu) the teratoma gave a less favorable prognosis.

5. The inefficacy of simple castration has led to the development of the radical operation—complete resection of the primary growth and its draining lymph area. The radical operation at present has already improved the results by 100 per cent—(15 to 30 per cent).

6. Radio-therapy appears to be a valuable therapeutic and palliative adjunct in the treatment of malignant tumors of the testicle.

GOITER IN THE GREAT BASIN

By GEORGE W. MIDDLETON, M. D.
(From The Intermountain Clinic, Deseret Bank Building, Salt Lake City, Utah

From the standpoint of incidence of goiter, Utah and the contiguous States show a great variation in their widespread, sparsely settled territory. Thus, in the Virgin Valley of Southern Utah, it is so common that fully 75 per cent of the women have some form of thyroid enlargement, and because of the isolation of that part of the State some of these women have enormous goiters, which they carry to their graves untreated.

In the Salt Lake Valley, on the contrary, although goiter is present, it is a relatively uncommon condition.

In geological times, a considerable area of the Great Basin was occupied by an immense inland sea. At first this was a fresh water body larger than Lake Michigan, with an outlet into Snake river probably as large as the Niagara river. But as aridity of climate developed, the outlet was cut off, and the great lake became saline. The Great Salt Lake is the remnant of that once mighty inland sea.

Considering the distribution of goiter as a world problem, it does seem that the proximity of saline waters confers comparative immunity. As one follows the narrowing periphery of the great prehistoric body of water which once occupied these mountain valleys, the incidence of goiter gets less and less the nearer you approach the vanishing point, which is the Great Salt Lake. This is no doubt due to the fact that salt, as it occurs in nature, nearly always carries a certain percentage of iodine, and the saline content of soil, and of vegetables that grow from soil, increases as you approach their most recent deposit.

Whatever the cause of goiter, whether iodine deficiency or the presence of iodine reducing bacteria, Utah furnishes abundant evidence that it is associated with drinking water.

I know personally of two families, in parts rather widely separated, in each of which two girls had reached their later teens without developing goiter, but in each of which goiter rapidly developed when they changed their abode only a few miles and went into a goiter district for the purpose of attending school.

In St. George, a town of Southern Utah, with a population of approximately 3000, goiter was quite unusual for more than half a century from the time of its founding, until a water system was installed and the Cottonwood water diverted from the Pine Valley Mountains. Since the advent of this new water supply many women are developing goiter, and what was for a long time an immune district has now become an endemic goiter region.

In an incomplete survey of Iron County, Dr. M. J. Mcfarlane reports that approximately 44 per cent of school children in the grades have goiter, and Dr. O. Sundwall reports that goiter is very prevalent in Sanpete County. The capriciousness of the geographical distribution of goiter is indicated by a report from Dr. Curtis, who found 6 per cent in school children of Payson and 67 per cent in school children of Santaquin, two towns only six miles apart.

Unfortunately, no comprehensive data of goiter incidence is available, though such information is being obtained by various agencies.

Of our own 213 cases embraced in this report, there is a distinct tendency to incidence in certain distinct valleys, though the majority of the counties in the State are represented, and a number have come from adjoining States.

These observations are isolated and not controlled, but suggest that in this Rocky Mountain region the next few years may develop facts of importance in the knowledge of goiter.

Although this sparsely settled intermountain country does not furnish materials for large goiter clinics, as the Great Lakes country does, we have our due proportion, and our experience shows that the same principles as to causation, variety, percentage of toxicity, and results of greatment obtain with us as with other people.

During the last two and a half years we have seen and treated 213 cases of the various types of goiter, not including hypothyroidism or the inflammatory conditions. Of these, 75 were of the toxic variety and 138 of the non-toxic type. Of these cases, 111 were treated surgically, 128 operations, including ligations, being performed on them. The remainder, largely of the colloid type, were not operated.

SURGICAL MORTALITY

Upon these 111 cases, 111 thyroidectomies and 17 ligations were performed. There were no deaths from ligation, and two deaths, or 1.8 per cent, from the thyroidectomies.

Sixty-nine per cent of these cases were toxic, and many of them extremely toxic. Of the two deaths, one was a case of simple goiter developing tracheal collapse some hours after the operation. Apparent symptomatic improvement detered us from doing the tracheotomy which might have saved her life. The other fatal case was a severely toxic one which failed to respond in the least to weeks of rest and medical treatment. As she was going from bad to worse, the operation was done as a last resort.

In this series there were two cases so toxic we dared not operate them. One of these cases refused to submit to a long period of preoperative treatment, and died later after operation at the hands of another surgeon. The other died in the hospital without operation, showing marked gastro-intestinal symptoms, with jaundice and cardiac failure.

RESULTS OF SURGICAL TREATMENT

Of these 111 operated cases, we have been able to secure reports from 70 cases at intervals after operation varying from two months to two and a half years. In the big majority of the cases the results were striking and the patients most grateful. Nothing more dramatic has occurred in our experience than the physical and mental change that comes over the subject of hyperthyroidism in the few weeks following a successful thyroidectomy. One sees the woman who was an emaciated nervous wreck, with palpitating heart and trembling hands, transformed into a normal person,

with vitality restored and the joy of living reflected from her countenance.

The replies from these 78 patients may be summarized as follows:

	No. of Cases
Cured of goiter—health entirely restored	38
Greatly benefited	18
Benefited	13
Benefited, but some return of goiter	1
Died after operation	2
Unable to secure report	22
Not improved	3
Too recent to report	11

Gain of weight was striking in the successful cases, averaging 20 pounds; one gained 60 pounds.

Of the three cases that claimed no improvement, one, although gaining in weight, complained of menorrhagia and suffered from focal infection in tonsils and sinuses, and the other two had complicating conditions which marred the picture.

A few of the cases reporting moderate or marked improvement from thyroid surgery were still not in perfect health. It is our impression that focal infection, which in the borderline thyroid cases may make the thyroid diagnosis doubtful, may persist after a successful thyroidectomy and prevent a perfect return to health. No post-operative goiter case presenting signs of focal infection should be allowed to get entirely away from observation until the bacterial focus has been cared for.

PREOPERATIVE PREPARATION

We have come to feel that the most important factors in preparation for operation are a period of rest in bed and fluids to the limit of the absorbing power of the patient. We give calcium carbonate for the possible prevention of post-operative tetany. More recently, following the lead of Plummer, we have been giving Lugol's solution, but the period of its use has been too short to arrive at any conclusions as to its value. Except in those cases showing objective cardiac failure, preoperative digitalization has seemed of little value. In one case with non-paroxysmal auricular fibrillation quinidine was used to restore normal rhythm before operation.

SURGICAL TECHNIQUE

In the very toxic cases we attach considerable importance to the form of deception first announced by Crile, of taking the patient to the operating-room under the anesthetic, without letting her know that she is to be operated. We have tried operating in the patient's room, but have concluded that, unless one is doing enough of the very hazardous cases to develop good team work with the force on the floors, it is better to take the little extra time and transport the patient to the operating-room.

Following the lead of Crile, we have used the method of giving the amount of nitrous oxide gas and oxygen to produce analgesia, and supplementing with ½ of 1 per cent novocain used locally. The patient is thus carried through the operation without loss of consciousness, except possibly for a brief period of time when each separate lobe is being elevated.

We have nearly always divided the neck muscles transversely, and believe we get the best exposure in that manner.

We are convinced that safety in operating on the thyroid depends upon a few fundamental things: First, careful selection and preoperative preparation of the patient; second, thorough comprehension of the anatomy, and third, good team work on the part of the operating force.

In the "Wild West" we used to speak of men who were "quick on the trigger." Only that type of mentality which is quick on the trigger should attempt goiter surgery.

We have had our full share of the hemorrhagic type of goiter, and I know of no condition that can make a greater demand upon the alertness and resourcefulness of a surgeon. To have tissues crumble at every touch, and well out blood in an avalanche from every conceivable point, is a spectacle to try the stoutest heart. We have only two suggestions to make to the surgeon confronted with such a predicament; first, the almost reckless disregard of consequences in dislocating the lobe from its bed, and second, after dividing the isthmus, to mattress through from side to side each separate bloc of tissue before separating it from its posterior attachment.

We believe that the frequent observation of blood pressure and the general condition of the patient, by a competent observer, throughout the operation, has enabled us to stop in time several operations where life was threatened by shock or hemorrhage; in these cases gauze-packing was applied, and the operation not completed until the next day.

We feel sure that this procedure has materially lessened our mortality.

As we look over our own results, we do not seem to have gotten such striking improvement from preliminary ligation as one is led to expect from a perusal of the literature. In fact, considering the added complication of adhesions, and the delay and expense to the patient, I am convinced that primary thyroidectomy would have been better in a number of our cases. Of course, some of them are so bad that one turns to anything that will break the brunt of a difficult shock-producing operation. But we shall do more primary thyroidectomies in the future.

POST-OPERATIVE COMPLICATIONS AND TREATMENT

Post-operative hemorrhage has been infrequent, but occasionally serious enough to lead us to have all suspected cases typed for transfusion prior to operation. Hyperpyrexia has occurred in only two cases; here the application of chopped ice and copious intravenous fluid infusion seemed of great value. Tetany in greater or less degree occurred in three or four cases. Calcium seemed to control the symptoms at once, and there was no serious consequence. Paroxysmal auricular fibrillation has been not infrequent. Quinidine has been of value in its treatment. In one case an apparently permanent fibrillation occurred after operation; normal rhythm was restored by quinidine, and is maintained six months after operation.

Perhaps the most interesting condition after

operation is that described of late as hypoglycemia. In five cases this clinical picture developed. The urines showed the presence of much acetone and diacetic acid. Unfortunately, at this time we had not begun to make blood sugar or carbon dioxide determinations, but the relief from intravenous glucose, as in the Johns Hopkins cases, was very striking.

NON-OPERATIVE TREATMENT

In a few cases of toxic goiter we have tried X-ray treatment, but without much effect. The medical treatment of the non-toxic (colloid) type in young people by means of iodine has been very gratifying, in a few cases surprisingly large goiters melting away. But we learned that we were too impatient for quick results, and that cases apparently not improved at first would show great improvement if seen a few months later.

We are much interested in the preventive work done by Marine and Kimball, and adopted more recently by the Swiss Government. Heber J. Sears, of the Department of Hygiene and Preventive Medicine of the University of Utah, is going into a survey of three of our most involved counties, and a detailed effort will be put forth to adopt Marine's plan of prevention.

T. B. Beatty, chairman of the State Board of Health, is bringing an expert from the Rockefeller Institute to make a survey, and take into consideration a campaign for the application of preventive measures.

Maccarison has said that 5 per cent of children born of goitrous mothers will be cretin imbeciles. We are recommending all pregnant women to take the same small preventive quantity of iodine that we are giving school children, in the belief that in this way some cases of imbecility may be avoided, and the unborn child may be started on its course with a properly functioning thyroid.

We are fully aware of the fact that in these sparsely settled districts we cannot speak with the authority that comes from the study of large numbers of cases, but so far as our experience goes we are essentially in accord with the deductions drawn from the larger studies. We are zealous advocates of the surgical treatment of all forms of toxic goiter, and of all those which will likely become toxic, or which otherwise are pathological. We are also enthusiastic over the preventive treatment and of the medical treatment of goiters which are not surgical, especially in children and young adults.

Left Superior Cervical Sympathectomy Under Local Anesthesia in Angina Pectoris—In the case reported on by Jay Harvey Bacon, Peoria, Ill. (Journal A. M. A., December 22, 1923), there has been effected a complete relief from all severe symptoms. The results have justified the means used in this case, and Bacon regards the operation as a justifiable procedure in those severe cases of angina pectoris that do not respond to rest and diet and the administration of nitrites. The incision over the anterior border of the sternocleidomastoid muscle gives a quick easy approach, and it may be safely attempted under local anesthesia when the condition of the patient will not justify the use of a general anesthesia.

SPONTANEOUS PERIRENAL HAEMATOMA

CASE REPORT WITH COMMENT

By LEON JOSEPH ROTH, M. D., Los Angeles

J. B., male, age 48, cement worker by trade, entered St. Vincent's Hospital, Los Angeles, December 29, 1922, complaining of severe back pains and recurrent presence of blood in the urine. He was thin and cachectic and so weak he could barely walk.

Temperature, 98.6; pulse, 110; respirations, 22; blood pressure, S-112 D-100; blood count, reds 3690000; whites, 18285-14628. Hemoglobin, 60-65.

Past History — Usual diseases of childhood, typhoid fever and rheumatism. The arthritis is now becoming more noticeable in the elbow-joints. About ten weeks ago he was given serum treatment for rheumatism, which caused some digestive disturbances and vomiting. Patient denies venereal diseases. Cervical lymphatics (presumably tuberculous) have been removed. Fracture of the skull, 1919, is reported by the patient. Apart from these conditions he has been in fairly good health and has been doing light work. Although previously constipated, he has had diarrhea for the past few days. Appetite poor due to alleged stomach disorders. Sleeps poorly. Does not drink, smoke, or use drugs.

Chief Complaint—Dull and continuous pain in small of back on both sides for past three weeks. Pain does not radiate, usually appearing toward evening, persisting through the night and disappearing about daybreak. No associated nausea or vomiting, although has had emesis independently of pain. He does not know when blood first appeared in the urine. He says urine has been clear at times, and at other times there is a recurrent "total" haematuria. Denies any trauma whatsoever. There is no dysuria. Nocturia, previously absent, has persisted since beginning of back pains. Apart from this no further definite information is obtainable. The more or less constant complaint is of very severe pain in the lumbar and left hypochondriac regions.

Physical Findings — Pupils dilated, slightly irregular, but react readily to light and accommodation. All teeth out; scars on both sides of neck from previous adenophathies, and one large anterior cervical lymphatic present. Chest symmetrical, good expansion; resonant throughout; no rales, No enlargement of the heart. Sounds loud and regular; slightly roughened first sound at apex, not transmitted; aortic second sound markedly accentuated, probably due to arteriosclerosis. There is decided muscular resistance and tenderness in the epigastric region and left hypochondrium; soreness along the spines of lumbar vertebra. The knee-jerks, tricipitals, bicipitals, and achilles are absent. Babiniski reaction not present; Wassermann reaction negative. A working diagnosis of malignant kidney was made.

Progress Record—The patient was kept under observation to note the persistence of haematuria and pain and secure the temperature record. On

January 1, 1923, pathological disturbances in the kidneys are still apparent and complications were suspected. However, the patient was too weak for special urological examination.

January 4 — Relative diminution of resonance over left chest was noted; heart displaced slightly to the left, with a systolic murmur best heard in pulmonary valve area. The abdomen was quite rigid throughout; nothing can be made out on palpation except vague tenderness. On this date the knee-jerks were not obtainable. The patient was very ill. There is marked weakness and a certain amount of dyspnoea; holds himself very rigidly and complains of pain in lower spine and in thighs when moved.

January 5—There was a severe attack of pain in the left hypochondriac region running through to the back. This pain resembled a kidney colic. The temperature dropped to 95; in shock; perspiring freely; morphine required.

January 6—There was a second attack of pain in left kidney region, but not so severe as the first attack. There was a marked rigidity, in left hypochondrium and in the back at same plane, with tenderness both superficial and deep. The left lung shows numerous rales throughout and an increase in the area of dullness. The heart murmur has increased in intensity and is rough in quality.

January 9—The patient had another attack of acute pain in the left hypochondriac region. It is possible for first time to palpate indefinitely a mass in left side of the abdomen, but no borders can be made out.

January 10. — Fluoroscopic examination of the G. I. tract was negative.

January 11—The mass in the left side of the abdomen can now be more definitely appreciated. It extends from the margin of ribs above and deep in to below iliac crest and over almost to the midline of the abdomen. It cannot be moved and is tender to deep pressure.

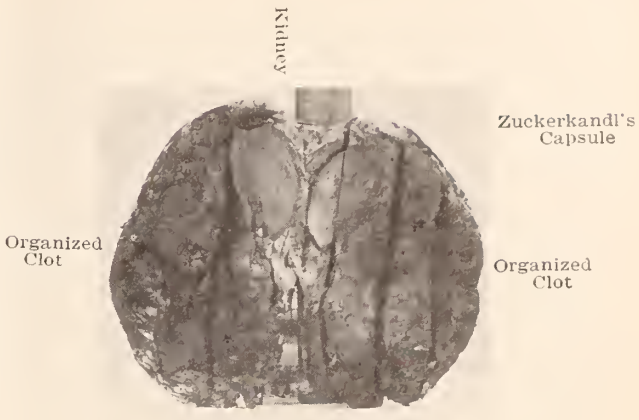
January 13—The patient's general condition is slightly better with less pain.

January 15 — Slight general improvement continued. Diagnosis has not been possible on account of fear of collapse if cystoscopy were attempted. There was a leucocytosis and a rise in temperature to 100. The patient suffered from two severe attacks of acute pain in the left side of the abdomen during the night. It required two injections of morphine to relieve the pain. During the morning of January 16, the patient suddenly began to fail. The pulse became thready, respiration shallow, and death occurred within the hour.

NECROPSY BY DR. C. W. BONYNGE

No other gross pathology noted apart from large flat left kidney, which is completely surrounded by partly fresh and partly old laminated clots; all contained within Zuckerkandl's capsule and replacing perirenal fat.

The kidney structure shows absence of definite pyramids and has appearance of fibrous nephritis. The entire mass is about the size of an infant's head. There are loose clots and fluid blood in left iliac fossa caused by leakage through bottom of capsule. No evidence of pathological lesions that would indicate origin of hemorrhage.



Perirenal Haematoma.

COMMENT

Taking into consideration all of the findings in this case, supplemented by failure, after careful search, to detect any pathological lesion responsible for the hemorrhage, it seems proper and reasonable to classify it as a spontaneous perinephritic haematoma.

Essentially a lesion of some variety existed, but in the limited number of reported cases, as in this, the predisposing factor escaped observation. There was no evidence of lithiasis, neoplasm, tuberculosis, aneurism, suprarenal disease or haemophilia. A nephritis of fibrous type was present.

A venturesome explanation might be the rupture of a small sclerotic artery. The right kidney was normal.

A correct diagnosis during the early stage of the disease was practically impossible, and at the time when this might have been made the patient's condition was so grave as to forbid an examination.

927 Pacific Mutual Building.

DISCUSSION

W. W. Cross, M. D. (Fresno)—Upon examining kidneys, which have been the source of hemorrhage into the urinary tract, it is often impossible to find the source at any particular portion of the kidney substance examined. This is true in kidneys with decided gross pathology. In those that have for years been the seat of disease, in which colon infection is usually present, the process having a range of involvement from a portion of one kidney to the entire organ or to an involvement of both sides may be present. In such kidneys copious hemorrhage may be an initial symptom leading to a study which uncovers a marked chronic disease. Observation made during the study of such cases reveals distortion of the kidney pelvis, frequently attended with changes in the ureter. The cortical area is always reduced in size, cysts are frequent, while connective tissue production varies. In many instances an acute nephritis has been grafted upon the process immediately before the specimen is obtained.

The description of the gross specimen in this case is not sufficient for one to draw a very decided opinion. Some help should be derived from a study of sections made for microscopical examination. The fact recorded in the necropsy that the capsule had an opening through which fluid blood had leaked is suggestive as a possible explanation for perirenal hemorrhage. The pyramids in the specimen have

to a decided extent lost their form, demonstrating an old process. Whether perirenal hemorrhage has been observed or described in such cases matters not, for it is quite within the realm of possibility for such hemorrhage to come to the surface of the kidney. The trauma that would be necessary to bring such a condition to pass as described need not be severe. Statements on the part of the patient regarding injury are frequently misleading. Diseased kidneys in which the producing activity of the connective tissue elements have not been stimulated to a great extent are easily wounded and require a slight amount of injury to produce hemorrhage. Blocking of the ureter following slight trauma could easily force blood from a hemorrhage through the parenchyma of such a diseased kidney. That the hemorrhage in this case is one from a kidney which has been the seat of disease for many years is conclusive.

Charles P. Mathé, M. D. (Phelan Building, San Francisco)—In the case presented in this report one notes the history of backache, pain and resistance in the left hypochondriac and lumbar regions associated with recurrent attacks of hematuria of three weeks' duration. Following an attack of shock in which the pulse became accelerated and the temperature diminished rapidly, a growing tumor was noted to appear in the left hypochondrium, increasing to such a size that it filled the space between the ribs and the iliac crest and extended to the midline. The rapid increase in size of the tumor might suggest a fairly large renal hemorrhage in which the blood became encapsulated within Gerota's fatty capsule.

The case illustrated two points: (1) The consensus of opinion of the inadvisability of making complete urological studies on extremely debilitated patients, and (2) the question of early surgical intervention in the case of severe renal hemorrhage.

Some surgeons advise against surgical intervention to control renal hemorrhage in extremely debilitated cases. Others maintain that the occasional beneficial result in these cases is worth the chance. In 1921 Bugbee reports an operation on a case of carcinoma of the left kidney associated with a large calculus which had severe hematuria. The pulse was 130 and of poor force and volume, and the hemoglobin 30 per cent. However, the hemorrhage was controlled and the patient's life prolonged by nephrectomy. However, as the patient has nothing to lose and much to gain, it may be well to attempt a quick, clean nephrectomy in these cases in order to control exsanguination.

Pathological examination of the kidney revealed a definite pathological lesion, fibrous nephritis which had existed a sufficient length of time to cause a distortion in the arrangement of the pyramids. This lesion could cause a small microscopical hemorrhage of the kidney parenchyma which forced its way through a poorly developed kidney capsule. The determination of the rupture of a small sclerotic artery or an area of hemorrhage in a chronic nephritic kidney can often only be made by a thorough microscopical examination of the kidney. Because of the presence of blood in the urine the hemorrhage probably passed through the renal parenchyma and perforated the pelvis.

Doctor Roth (closing)—The description of this tumor is intended as a contribution to the sparse literature on the subject. The gross specimen is unquestionably a pure perirenal haematoma of long standing. I think the leakage into the left iliac fossa was due to an acute hemorrhage which ruptured the attenuated proper capsule of the kidney or broke through the anatomical opening of Zuckerkandl's capsule. The pelvis could not have been ruptured because haematuria was not constant and not always coincident with the external bleeding.

It is regrettable that the photograph was not seen by Cross and Mathé. Cross justly states that the description is not sufficient to permit of drawing a decided opinion, and Mathé brings up the vital point regarding intervention, and no doubt feels in such cases that whatever is done is wrong. I think that, apart from the laboratory findings regarding hemoglobin, etc., the physical appearance and condition of the patient is of great value in making a decision as to whether or not to explore.

How One Rural Community Maintains an Efficient and Economic Laboratory Service—Pomona, Calif., has a population of 15,000 and Pomona Valley another 10,000, who are attended by about 30 educated physicians. This territory is served by the Pomona Valley hospital, located at Pomona. This hospital has a normal capacity of 40 beds and a daily average of about 25 patients. The hospital is dependent absolutely upon the fees collected from patients for its maintenance. There is no staff, and patients are accepted only in charge of their own physician, who must be a licensed doctor of medicine, graduated from an acceptable medical university. The hospital assumes no dictation in the treatment of any of its patients, except that they must be treated by an educated physician. The hospital does not provide any laboratory service nor an anesthetist. These latter problems are handled as follows:

By a mutual agreement, each physician pays into the laboratory a fixed sum each month, in return for which he may send in all the laboratory work he wishes. Each physician makes such charge to the patient for this service as he deems proper and looks after the collection of the same. Whenever the record of his work at the laboratory shows that he is not paying a sufficient monthly stipend, this is increased by mutual agreement, according to the records for perhaps six months previous. In the same way the doctors have mutually agreed to engage the pathologist for all their anesthetics, for which the pathologist must make his own charges and collections. As a matter of courtesy, we usually see to it that these bills are the first to be paid by the patient.

The pathologist equips and maintains the laboratory, and the hospital rents him the necessary rooms at a minimum charge. All the ordinary tests are made in the laboratory and an affiliation with one or more of the large city laboratories enables our pathologist to engage their services in occasional instances where unusual and intricate procedures may be necessary.

This plan has worked so successfully and harmoniously for the past ten years that we should be very reluctant to give it up under any circumstances. —Joseph K. Swindt, M. D., Better Health.

One Year of Common Colds and Associated Infections—In discussing this subject the Metropolitan Life Insurance Co., in its Statistical Bulletin of November, 1923, gives the following figures: The amount of absenteeism in large business and industrial establishments due to minor illnesses is seldom appreciated until the facts are thoroughly reviewed. The common "colds" are among the chief sources of lost time. In a group of about 6700 clerical employes of the Metropolitan Life Insurance Co. at the Home Office, during the 52 weeks ending July 28, 1923, 2824 "colds" which involved disability for work were reported to the Medical Division, which cares for the health of the clerical staff. These disabling affections occurred at a rate of 420.7 per 1000 employes for the year. The average days of disability for this illness per person on the payroll for the year was .9, and the average days per case were 2.2. In all, there were 6233 days lost in the year from these conditions, which included head colds or coryza, acute bronchitis and tracheitis. Other associated conditions were excluded because of the impossibility of determining in how many cases they were associated with common colds.

INCIDENCE OF INTESTINAL PARASITES

By MARSHALL C. CHENEY, San Francisco
(From University of California Medical School.)

Attention has been drawn recently to the prevalence in temperate climates of amebic dysentery, as well as less disabling parasitic infections of the intestine. In order to ascertain the incidence of these infections in San Francisco and the Bay region, it was decided to examine the stools of 1000 cases of all sorts, both medical and surgical, following the technic of Kofoid and Swezy. During the two years (May 1921, 1923) in which this series was being collected and analyzed, preliminary reports were given out from time to time (Medical Clinics of North America, September, 1922, and June, 1923). In this paper the entire number will be considered.

Table 1. Pathogenic Parasites in 1000 Medical and Surgical Cases

E. Histolytica—	
Acute dysentery	13
Chronic or carrier	36
Giardia	34
Chilomastix	35
Trichomonas	17
Balantidium coli	1
Craigia	3
Spirochaetosis	3
Hookworm	11
Ascaris	6
Strongyloides	3
Oxyuris	2
Total cases	164

Per cent, 16.4.

Taking all the parasites to which even the slightest pathogenicity has been assigned, it is seen (Table 1) that there were 164 cases. This gives an incidence of 16.4 per cent, but a somewhat lower figure would be more nearly correct, because some of the patients were referred for examination on account of suspected parasitic disease of the intestine, and so did not come in the "ordinary run" of a general practice.

Table 2. Non-Pathogenic Parasites in 1000 Medical and Surgical Cases

E. coli	65
E. nana	28
E. councilmania	13
Trichiuris	10
Blastocystis	innumerable

Harmless parasites of the intestines are encountered even more frequently than the pathogenic varieties (Table 2). These must be recognized, because resemblance to pathogens may lead to an incorrect diagnosis, followed by useless or even harmful treatment. We have included E. councilmania infections among the non-pathogenic varieties, even though there is some evidence that the parasite occasionally produces an ulcerative colitis. It is very difficult to differentiate this ameba accurately from E. coli, and usually no symptoms can be definitely ascribed to its presence in the intestine. Trichiuris in large numbers may produce symptoms, but as ordinarily encountered nothing can be attributed to the worm. Blastocystis is present in at least 50 per cent of the specimens examined. It is of little or no importance, except that it may be confused with amebae or even flagellates, or may mask the presence and hinder the detection of really pathogenic parasites.

Table 3. Mixed Parasitic Infections in 1000 Medical and Surgical Cases

Combinations of amebae, flagellates, and worms, all pathogenic	8
Combinations of pathogenic and non-pathogenic	19

Mixed infections are fairly common (Table 3). When more than one pathogenic parasite is present in the intestine, it may be difficult to assign the agent of the symptoms. When non-pathogenic parasites are present, together with one or more harmful varieties, the real source of the symptoms may be entirely overlooked, unless very careful stool examinations are made. In general, however, the parasite that was responsible for the symptoms, or at least its cysts or ova, was found in enormous numbers in the stool.

Table 4. Stools of Non-Parasitic Cases

	Normal	Abnormal
Gall-bladder disease	32	0
Peptic ulcer	28	0
Chronic appendicitis	11	0
Acute appendicitis	2	0
Colitis	9	0
Visceroptosis	10	0
Pernicious anemia	6	0
Pelvic disease	7	0
Arthritis, all forms	14	0
Epilepsy	11	0
Carcinoma of stomach	1	4
Carcinoma of colon	3	3
Pellagra	3	1
Cholangitis	2	0
Cirrhosis of liver	2	0

With the exception of flagellate disease in children, all the patients with so-called pathogenic protozoa or helminths in the intestine had symptoms referable to the parasite. Those infected with non-pathogenic parasites had no such symptoms and their stools were normal, unless there was a non-parasitic lesion of the gastro-intestinal tract. Patients with well-defined disease not due to protozoa or worms at times had symptomatology suggesting intestinal parasites, but their stools were generally normal (Table 4), except in ulcerative conditions of the colon, or with bleeding lesions higher up.

Table 5. Results of Blood, Urine, and Wassermann Tests in 100 Cases

	Negative	Positive
Blood Wassermann test	95	5
Urine (routine tests)	85	15
Blood (routine wc, reds, hgb, smear)	85	15

To see whether routine examination of the stool gave results commensurate with the findings in routine blood and urine examinations, the percentage of "positives" in the last hundred cases of all sorts entering the office for diagnosis was plotted (Table 5). It is evident that abnormalities are not found any more frequently in blood and urine than in the stool. This is an argument for routine examination of the stool. The more complicated tests should be left to special technicians and com-

mercial laboratories, as in blood and urine examination.

CONCLUSION

Disabling disease of the intestine (amebic dysentery) and minor diseases due to pathogenic protozoa and helminths are fairly common (10 to 15 per cent of all cases in general practice). Routine stool examination is the sole means of absolute diagnosis of these infections, and requires no more time than the ordinary routine blood and urine tests.

210 Post Street.

DISCUSSION

Alfred C. Reed (350 Post Street, San Francisco)—It is a pleasure to know that the human protozoa are receiving careful study in California, and that their importance is being recognized. Such a report as this is striking confirmation of the belief that we have been overlooking an important clinical field. The protozoa are difficult to recognize and do not produce characteristic symptoms. I am inclined to differ with Cheney in one particular, rather in his statement than in what I believe to be his intent. This is in regard to the pathogenicity of the flagellates and amebas of the human intestines. We hardly are familiar enough with these organisms yet, and study of them is too difficult to permit us to assume a final knowledge of their clinical and pathologic results. It seems to me safer to consider that all the protozoa, at least potentially, may be harmful though in a varying degree, of course, and often in proportion to the mass of infection. The judgment as to whether treatment should be instituted requires nice study in each patient. As Cheney says, it is often useless and may be harmful. In our series at Stanford and in private cases, we have found a majority of E. histolytica patients complaining of constipation and not of diarrhea. Nor is a history of dysentery or even of diarrhea obtainable in all patients who harbor histolytica. Protozoal infestation can no longer be regarded as a purely tropical affection. An incidence such as indicated in the paper under discussion demands attention. This is the situation in California. We very much need careful studies correlating the presence of protozoa with pathology and especially with clinical symptoms of disturbed physiology. Intestinal protozoa can injure the body in various ways other than that reflected by a diarrhea or dysentery. It is probably with these less obvious methods of damage that we have chiefly to deal clinically in California and temperate climates.

John V. Barrows, M. D. (Chapman Building, Los Angeles)—This paper is of particular interest and importance, because it considers intestinal protozoa of all kinds. It is of great value, because it studies these organisms in their relationship to disease generally.

A brief discussion permits only fragmentary remarks which I shall direct chiefly to the tables compiled. The incidence of 16.4 per cent is only slightly lower than given in my article before the society in 1921. However, I find the chilomastix by far the most predominating organism in my series of 750 protozoan infested cases.

The classification of non-pathogenic parasites is a subject of considerable disagreement among clinicians and protozoologists. It would be very difficult to prove that the parasites enumerated in Table 2 are "non-pathogenic." I think Musgrave rightly said, "They are a heap in bad company."

Table No. 4 is certainly based on inadequate analyses. In recent years I have seen no cases of colitis, pernicious anemia, or chronic arthritis in which I could call the stools normal. I desire to add that most cases of chronic appendicitis, epilepsy and such skin manifestations as pellagra on the average have very abnormal stools.

Table No. 5 stresses very nicely the need of routine stool analysis. I believe I am able to add that these infections, when marked by a fair degree of toxemia, show a helpful diagnostic blood picture. The haemoglobin and red cell count are low. The total leucocytes are depressed in number to a fair degree of leucopocnia, unless there is some intercurrent infection. The polynuclear cells are definitely decreased. The total mononuclear percentage is decidedly increased. A typical picture approximately runs: Hb. 70 per cent; wbc. 6000; rbc. 3,400,000; polynuclears, 50 to 55 per cent; monos, 45 to 50 per cent.

Cheney is to be congratulated on having given to the medical profession a very valuable piece of work.

M. C. Terry, M. D. (921 Consolidated Building, Los Angeles)—Cheney's interesting paper, and particularly his Table No. 1, showing 16 per cent of intestinal parasitism in the ordinary run of unselected cases in a general practice, has led us to go over our files to see what per cent of the requests on our laboratory are for stool examinations. We find it has been 2½ per cent in the last two years.

Our percentage of positive findings is higher than in Cheney's table, as would be expected; the last 100 cases, not counting cultures and other special requests, and not counting repeated examinations in the same case, have shown 30 per cent of protozoan or helminthic infection.

For comparison we collected the last 500 Wassermann tests, exclusive of those from hospital and group practice where the test is made routinely, and we found that these made up 37 per cent of our work. These 500 Wassermann tests gave us 20.7 per cent of positive results (three plus and four plus), while 135 Wassermann tests done routinely from a general practice, during the same period, gave us 5.2 per cent of positives.

Herbert Gunn, M. D. (350 Post Street, San Francisco)—Cheney's very interesting paper, the result of an enormous amount of work hardly appreciable by one who has not made this sort of examinations himself, emphasizes two very important and generally unrecognized facts; first, the prevalence of various parasites in the intestinal tract and, second, the value of routine stool examinations as compared with routine blood and urine examinations.

The term "amebic dysentery," as generally used to cover all amebic infections of the intestinal tract, is a misnomer and should be discarded, as it implies the presence of an intestinal flux which generally is not present.

One not infrequently hears the excuse given for failure to examine a stool that the patient gave no history of having had a diarrhea or dysentery.

Intestinal amebiasis, a name given it by Musgrave many years ago, is far more correct. This may be supplemented by the terms, with dysentery, acute, chronic, carrier, etc.

The classification of the flagellates with the pathogenic parasites I do not believe is warranted with the evidence we have at hand at present. In my own experience, which covers a considerable number of these infections, there has been an entire lack of symptoms referable to the flagellates.

Cheney wisely remarks that one must be able to differentiate between the pathogenic and non-pathogenic parasites, in order to avoid useless or even harmful treatment.

I would add that parasites which have not been fairly definitely shown to be pathogenic and which produce practically no symptoms, unless they can be eradicated by simple treatment, should not be generally treated. I have seen several patients who have been decidedly harmed by prolonged attempts at removal of flagellates.

Cheney states that the patients with pathogenic parasites had symptoms referable to the parasites, also that patients with well-defined diseases not due to protozoa or worms at times had symptomatology suggesting intestinal parasites, etc. It seems to me

that this should be supplemented by the statement that not infrequently parasitic infections produce symptoms which are mistaken for various other complaints, for example—chronic appendicitis, cholangitis, peptic ulcer, gall-bladder disease, colitis, pernicious anemia, malaria, intestinal tuberculosis, etc. I have seen a number of cases of amebiasis mistaken for chronic appendicitis and several such errors where hookworm and ascaris were the causes.

Doctor Cheney (closing)—There is little doubt of the pathogenicity of E. histolytica, Balantidium coli, and the hookworm. These cases alone, amounting to 6.1 per cent of the series, are sufficient reason for making a routine stool examination, which is the sole means of absolute diagnosis of these diseases. The routine test need not consist of anything more than a five-minute examination of a wet smear.

As we have no certain cure for flagellate infections, with the possible exception of Giardiasis, it is difficult to say whether they are pathogenic or not. There is no way to contrast the condition before and after the eradication of the parasite.

The Doctor and the Press—Now that medical publicity and the place the physician may occupy in it is receiving so much attention, it is interesting to see the reactions of newspaper editors. In discussing this subject Richard J. Finnegan, editor of the Chicago Journal, says: "The history of medicine in the United States is one of the most glorious contributions to modern civilization. Rome was great in lawyers and orators, but weak in doctors. It used to be the boast of pompous Romans that the Roman empire lived for 600 years without a recognized medical profession—but look where the Roman empire is today.

America would not be what it is at this hour without American medicine. This great profession has created and perfected itself, without undue interference or direction from legislatures, trotting to the beck and call of lay minorities that do not appreciate the devotion to the high calling, the self-abnegation and the fine sense of ethics, honor and public welfare that have marked the careers of American physicians and surgeons. . . .

The secret of the success of American medicine has been its freedom of initiative for the individual and the bounty of reward allotted to pre-eminent accomplishment resulting from years of study and labor.

I need not tell you that in recent years the world-wide tendency to government paternalism is beginning to assert itself against your citadel. You could tell me more instances than I could assemble to prove that statement. You could cite the example of Russia, England, Germany and other countries where medicine and surgery have been commercialized and governmentalized, to the detriment not only of the profession, but of the people and the countries. . . .

If the newspapers printed all the publicity puff that comes to them, from a third to a half of their space would be used to accommodate free advertising masquerading as news. Some of it is printed, of course, but the ordinary reader has no conception of the amount of time consumed in the newspaper office in eliminating the press agent's handout.

There is a frenzy for publicity. It touches not only business, but reaches into the homes of the high and the lowly. . . .

The American frenzy to appear in print can be pictured in no better phrase than 'a violent appetite' to bask in the spotlight. To get a picture or a speech in the paper seems to be life's sole ambition to some people. In fact, psychologists and police declare that certain of Chicago's most common crimes committed by girls and boys are inspired by a certain bug that they pick up in the swirl of this moving picture age. They have a violent appetite for notoriety."

POSSIBILITY OF REMOTE EFFECTS IN HEAD INJURIES—A CASE REPORT *

By CHARLES E. MORDOFF, M. D., Fresno

It is the unusual and obscure, in injuries, which keeps the interest of the physician in industry alive to the possibilities in industrial surgery. The case here reported has been of the utmost interest to those who have been actively engaged in treatment, and deserves the attention of all industrial physicians.

Frank H., a robust, very well nourished and developed man, age 48, a blacksmith and miner by occupation, was injured March 16, 1921. He was engaged in straightening a length of drill-steel, using a compressed-air hammer. The steel broke in a flaw, and a piece about a foot long struck him in the face, across the bridge of the nose, and over the right eye. He was "knocked out" for a few minutes, and suffered severe headache following the injury. He went immediately to the first-aid station and was given emergency treatment. The following day he reported to the first-aid nurse that he felt some better, but still suffered from headache. He continued at work suffering continuous headache, which he attributed to the noise of the machine. After three days, headache persisting, he drew his time and left the job without again visiting the first-aid station and without the knowledge of the first-aid nurse.

After leaving the work, he drifted about the State, seeking to obtain light employment, suffering continuous headache, until the latter part of May, when he had to leave a job near Fresno, and, his money having given out, he applied for admission to the Fresno County Hospital. He was found there about July 1, by the legal department of the company for which he had worked at the time of injury, and the medical department was notified.

When visited at the hospital, he was found to be suffering intense pain, especially in the right frontal and temporal regions, with a feeling, as he described it, "as if it would sometimes tear the top of my head off." This pain extended entirely around the right orbit. There was intense photophobia of both eyes, but more especially noticeable in the right. Conjunctival inflammation was very marked. This condition had obtained for several weeks, and treatment had been directed toward the correction of "herpes of a branch of the fifth nerve."

He was at once removed to another hospital and placed under the care of Dr. D. H. Trowbridge, where under active treatment the eye condition rapidly improved, and he was discharged from treatment about September 15, 1921.

At the beginning of this treatment, general physical examination revealed nothing. Wassermanns were negative, as were all other laboratory tests. Special examination: Vision, R. 20/200; L. 20/20. X-rays of the skull were negative for fracture. There was impairment of touch, pain and temperature sense in the distribution of the right infra and supra-orbital nerves.

After discharge, he worked for a time on a

* Presented to the Section on Industrial Medicine and Surgery at the Fifty-second Annual Meeting of the California Medical Association, San Francisco, June, 1923.

mining claim in Northern California. On October 25, 1921, he returned, complaining of diminishing vision and continuation of pain about the right eye, the right frontal and temporal regions, with a sense of numbness. In order to check up the case as to compensability, he was sent to Drs. Walker and Walker for examination of his eyes. The report of this examination showed: "Vision, R. 3/60, L. 6/60 without glasses, and with glasses, R. 5/60, L. 5/15. Ophthalmoscopic examination revels right eye, cornea slightly roughened, iris reacting well to light, vitreous very hazy and full of large dark floating bodies, with a very blurred picture of the retina and disc. The left vitreous also very cloudy and full of floaters, with one patch of choroiditis to the temporal side of the macula region. Both eyes have the appearance of having been struck by some object on the outside, which has disorganized the vitreous to a great extent."

Following this examination and one month later, he was sent to San Francisco, where he was examined by Dr. Otto Barkan, who reported as follows: "Both eyes show marked myopic astigmatism. Vision, right, —3.5 equals 1.10; left, —3.5 equals 3.10. Without correction, right, J —4; left, J —7. Correction of astigmatism improves vision with difficulty. Both cornii show old scars, and corneal astigmatism is due to injuries with foreign bodies at some previous times. There are small pigmented deposits on the posterior surface of the cornea, showing the scars must be old, presumably antedating the injury of March, 1921. Ophthalmoscopic examination shows some coarse vitreous opacities and atrophy around the disc, and increase of pigment in the macula region. In the left eye also a small sclerosed patch, one disc diameter from the macula. All these changes are due to myopia of long standing and have nothing to do with the accident. Conclusion: The reduction of vision in both eyes, right more than left, is due to cornal scars, and to myopic changes, the former playing the greater role in the right eye. As the patient claims to have seen better with the right eye before the accident, it may have been that some scarring might have been caused by same. The major part, however, I believe to antedate the injury of March. In all other respects the ocular findings, visual field, etc., are normal. The right infra-orbital nerve is somewhat tender on pressure. The pain described by the patient, however, is not caused by ocular involvement."

The results of these examinations, together with absolutely negative general physical findings, left us no nearer the solution and diagnosis of the trouble. Further consultation was decided upon, and he was entered as a patient in the University Hospital, San Francisco, under Dr. Fred H. Kruse, for the purpose of observation, examination and diagnosis. He was examined here by Drs. Kruse, Naffziger, Abel Johnson and Ruggles. General physical and laboratory findings were all negative. X-rays of the skull showed no evidence of fracture at the base, or through the mastoid or ear regions, but there was questionable evidence, in Dr. Ruggles' opinion, of a small linear fracture of the inner table over the right eye. This opinion was not concurred in by Drs. Kruse and Naffziger. A fracture so localized would not give the symptoms complained of, viz., pain about the orbit, and right frontal and temporal regions, with numbness extending over the right temple.

Dr. Naffziger, after some consideration, came to the conclusion that the nature of the pain, the distribution of the sensory disturbance, could only be accounted for by injury to the sensory root of the fifth nerve, where it lies in the petrous portion of the temporal bone, that there might be a very small fracture, not demonstrable by X-rays, or by a small clot at that point, caused by the accident.

It has not before been mentioned that specialist examination in 1921 revealed the presence of a small discharge from the right ear. Dr. Johnson's examination, at University Hospital, confirmed previous eye findings. The only demonstrable infection was found in this otitis media purulenta, which at this time existed in marked degree, with the probability that the mastoid cells were involved to some extent. The vestibular apparatus was normal, and there was no evidence of injury to the eighth nerve. Hearing was distinctly impaired on that side. It was Dr. Johnson's opinion that the pain complained of might be due to this infection, and it was decided that the best procedure would be to clean it up first.

The patient was accordingly returned to Fresno, where Dr. Trowbridge performed a radical mastoid operation January 18, 1922. The middle ear was found to be filled with a mass of granuloma tissue, with some involvement of the mastoid cells. Early in the operation the lateral sinus was exposed, but not opened. Post-operative recovery was good, with a radical clearing up of the pain which had continued for so long, in the frontal and temporal regions. Vision improved markedly, to a point where the patient could read comfortably, and he felt better in every way. After about three weeks, however, he began to complain of pain in the right occipital region. At the same time a cough appeared, accompanied by a profuse expectoration of pus, and a septic temperature, and repeated chills. Treatment was unsuccessful until an autogenous vaccine was used, when recovery was fairly rapid, so far as his septic condition was concerned. The pain continued in the occipital region, and Dr. Trowbridge became convinced that the lateral sinus must be infected, and an exploratory operation was decided upon. The sinus was exposed at the site of original operation, and found to be thoroughly organized into a degenerating clot. This was followed posteriorly, almost to the torcular herophili (about one inch). The clot was removed and the sinus packed. At the same time, the internal jugular vein was removed down to the clavicle. Convalescence was somewhat slow, although the occipital pain disappeared, and the patient was finally discharged in May, 1922.

Since then he has been working on his mining claim, intermittently, and for some time was entirely free from pain, but has never been relieved of the numbness in the distribution of the infra

and supra orbital nerves. Vision is distinctly impaired in both eyes, more in the right. Hearing is entirely lacking in the right ear, and somewhat impaired, although to no great extent in the left.

Our belief that the pain, frontal and temporal, had been due to the middle ear and mastoid involvement, because it was relieved following operation, has been shattered. During the past several months this pain has returned, relief having been obtained only during a period of about three months.

This man has been a model patient, co-operating in every way, to the fullest extent, in our efforts to afford him relief, and is distinctly not a neurotic type, so that any element of psychosis or psychoneurosis may be disregarded in the consideration of findings.

The conclusion in this case must be that the pain and sensory disturbances are due to some injury to the sensory root of the fifth nerve, and not to any middle ear or mastoid involvement; that the visual defects are due to myopic astigmatism, pre-existing, although the company has accepted liability for reduction of vision, as well as loss of hearing in the right ear. There is a question whether the otitis media, pre-existing, was lighted up by the injury.

No prognosis can be given as to whether recovery will occur, or of the factor causing the pain and sensory disturbances.

206 Edgerly Building.

DISCUSSION

D. H. Trowbridge, M. D. (Fresno, Calif.)—When Frank H. first came under my observation he was a patient at the Fresno County Hospital. I found him almost blind, suffering from a chorioretinitis with cloudy vitreous, both eyes. He complained of considerable pain, particularly in the right side of the head. Under treatment this cleared up and his vision became very much better, although he still complained of pain. At this time he was also suffering from a chronic suppuration of the right ear. This condition also cleared up, and he was discharged as practically cured.

It was impossible to state whether the injury he suffered while in the employ of the San Joaquin Light and Power Company was the cause of his trouble, but the company gave him the benefit of the doubt and settled all expense incident to his treatment.

Although he was discharged as practically cured, he still complained of pain in his head and was examined by one or two specialists in San Francisco, who were of the opinion that the pain was due to the chronic suppurating right ear, although there was no tenderness, no vertigo, nor any other signs to indicate serious involvement.

Hearing for the watch was very deficient, being 1/72 in either ear. Hearing for voice sounds was very good.

Acting on the advice of our confreres in San Francisco, we decided to do a radical mastoid operation. The operation elicited very little of interest except there was no sequestrum present, and a general sclerosed mastoid. The lateral sinus was notable for the fact that it was placed particularly near to the external auditory canal rather farther forward than usual. It was exposed, but not injured in any way during the operation. The patient made an uneventful recovery, but in about two weeks he suffered a marked chill, followed every other day by a succeeding chill until he had suffered three. This made us suspicious of a lateral sinus infection, although the chills occurring at such regular intervals suggested that the trouble might be due to malaria. Blood test was negative for malaria plasmodia; patient seemed very toxic, white blood count being 16,000; furred tongue, etc., and inasmuch as he suffered another chill we decided the trouble must be sinus thrombosis. He was taken to the operating-room and anesthetized by Dr. Mordoff. I then opened the lateral sinus and found it full of clots. This was an extremely interesting case, inasmuch as the entire lateral sinus was thrombosed and was dissected out entirely back to the anastomosis with the torcular herophili. Before removing the lateral sinus I removed the internal jugular vein, first ligating it above and below. The wound was closed and the patient made an uneventful recovery. The hearing in both ears remains about the same. I think patient still complains of some pain, so it is still a question whether or not the pain was entirely due to the chronic middle ear trouble. The right ear at this time is perfectly dry, all suppuration having ceased.

TUBERCULOSIS IN PREGNANCY

By GEORGE H. EVANS, M. D., San Francisco

There can be no question but that pregnancy in the tuberculous woman constitutes a serious complication fraught, oftentimes, with disastrous consequences to the patient. This statement has become almost axiomatic, and without careful analysis it would seem that a corollary of this would demand in all such cases prompt termination of pregnancy in the interest of the mother.

Unfortunately, the duty of the therapeutist is not so clearly defined, and while there is general acceptance of the premise, much confusion exists regarding the indications for radical treatment.

A consideration of this question presents various angles other than purely medical, for there are in each case sociologic and economic problems to be faced which qualify our decision in the given patient.

In order to better comprehend the subject, it may be well to briefly consider our attitude toward marriage in the tuberculous. The dictum of the French clinicians: If a girl, no marriage; if a wife, no pregnancy; if a mother, no suckling is, in the main, correct. Ordinarily, one must agree that the actively tuberculous woman is poorly equipped physically to undergo the stress of marital life with its attendant child-bearing. Economic factors must, however, play an important part in reaching a decision in a given case. The woman, who by reason of her social and financial status is losing the fight against the progress of her disease, will unquestionably be benefited by a marriage which will place her in a more comfortable position, with improved hygiene and living conditions, under the fostering care of her protector. Those of us who have before us, constantly, tuberculosis in the working woman need no emphasis of this fact. Our clinics abound with those whose sole hope of arrestment of their disease can only be brought about by a change in their conditions of living. Indiscriminate prohibition of marriage to tuberculous women is unjust. This, of course, does not apply to those acute or rapidly progressive, or far advanced cases, but in the latent, slightly active, or old fibroid cases where economic and social conditions are favorable, one should hesitate before refusing consent.

The danger to the child born of a tuberculous

mother must have consideration in any discussion of this subject. It is generally admitted that placental transmission of tuberculosis is so rare as to be considered negligible. Modern students of phthisiogenesis are agreed that the child is born free of tuberculous infection, and, contrary to a popular impression, usually of the same weight and vigor as those born of non-tuberculous mothers. The danger to the infant resolves itself into the preventive measures which should be taken at birth. These necessitate the immediate removal of the new-born child from the infected mother and its feeding by a wet nurse, or proper artificial feeding. Drastic though this procedure may appear, it is justified by results, for most of these infants may be safely brought up in this way. Any measure short of this exposes the infant to almost certain massive infection. The difficulty of carrying out this radical measure is freely admitted, for we have not yet reached the point where the prevention of tuberculosis in the infant is carried out with the intelligence displayed by the dairyman in protecting his calf from its diseased mother.

The non-pregnant tuberculous woman presents a problem where, fortunately, we are able to advise with directness. Experience clearly demonstrates the harmful effects of pregnancy on the tuberculous lesion. To quote from Douglass and Harris:

"There are numerous factors responsible for the aggravation of tuberculosis during pregnancy and the puerperium. Pregnancy makes increased demands on metabolism, oxygenation and innervation, on circulation and elimination. The point of least resistance, in these cases a quiescent pulmonary lesion, is put to the test and the latent tuberculous focus breaks down. The presence of the gravid uterus interferes with respiration and the aeration of the blood; the nausea and vomiting of pregnancy tend to interfere with assimilation; the prolonged muscular exertion of labor, the loss of blood and its attending exhaustion, the use of the anesthetic, auto-infection by the aspiration of infected material from an old focus in the lung into healthy portions, and the possibility of toxins being thrown into the system from the placental site are all serious factors. In addition to these factors, we have in most cases the strain of subsequent lactation, and the responsibility incident to the care of the child.

"Occasionally we see that, during the pregnant state, the tuberculous process apparently improves and the general condition of the patient is strikingly ameliorated. This is true, however, only of the fibroid type, which (it has been observed) is hardly modified at all either during gestation or after delivery. This is responsible for the traditional view held until recent times that pregnancy may sometimes arrest tuberculosis, and because of this belief writers of former generations (like Cullen) recommended marriage to tuberculous women. Grissole, however, in 1849, published an article of such force that it shook the dogma which until then had remained firm."

Our position in these cases should be uncompromising. All tuberculous women should avoid pregnancy unless the disease is in an early stage and has been arrested for at least two years. Even then it should be advised against unless the social and financial status allow of the proper care of the patient during pregnancy and the puerperium, and the carrying out of the proper preventive measures in the interest of both mother and child.

What to do with the tuberculous woman who becomes pregnant, or the pregnant woman in whom tuberculosis makes its manifestations for the first time, or the woman with arrested tuberculosis who suffers a reactivation of her old tuberculous process during the early months of pregnancy, is a problem frequently confronting the physician. Norris and Landis quote Bacon, who, in 1913, stated that 32,000 tuberculous women become pregnant annually in the United States, and that between 44,000 and 48,000 women of the child-bearing age die of tuberculosis every year.

In reviewing the literature on the subject for the last few years, one is impressed and confused by the differences in opinion as to the effects of tuberculosis on the pregnant woman, as personal experiences differ. Earlier observers taught that tuberculosis had a beneficent influence on the pregnant state, and today there are many who believe that, except in the far-advanced disease, pregnancy and child-bearing do not exert an unfavorable influence. On the other hand, there are those who demand the immediate termination of pregnancy in all cases of tuberculosis. Schauta has described three groups: The first would abort every woman that has tuberculosis; the second would abort no woman, but would give her the best of treatment and allow her pregnancy to progress; the third would treat every case individually. The latter would seem to be the plan that conservatism would suggest.

In order to determine the course to pursue in a given case, it is necessary first to determine the injurious effects of pregnancy on the tuberculous lesion. Here a careful study of the literature must impress one with the fact that pregnancy can only be looked upon as a serious complication interfering with the patient's chances of improvement in direct ratio to the activity of the tuberculous lesion. Norris and Murphy recently have compared a group of tuberculous non-pregnant women from the Henry Phipps Institute, with a group of pregnant tuberculous women, with results which are interesting. Of the non-pregnant women there was improvement in 45 per cent as compared with 18 per cent of the pregnant ones. Thirty-four and seven-tenths of the non-pregnant died, while 44 per cent of the pregnant ended fatally. This was an analysis of 104 cases. Unfortunately, for a statistical study, therapeutic abortion was only performed in seven cases.

In which cases should pregnancy be terminated as a therapeutic measure and when can pregnancy progress to completion are questions difficult to satisfactorily answer. Regret at consenting to abortion, in my personal experience, has probably been as frequent as regret at having withheld consent to a procedure which might have improved the condition of the patient, and possibly avoided a fatal

outcome. We are unable at present to differentiate between the cases which will stand the effects of the strain of pregnancy, and those which will not. Notwithstanding this, there are certain indications for interference which it may be well to emphasize.

In the early months of pregnancy, should tuberculous activity first present, the duty of the attendant is clearly to empty the uterus of its contents and place the patient under the approved modern treatment for the actively tuberculous. According to Norris, 65 to 70 per cent of such cases will be benefited, provided this treatment is *applied promtply*. European authorities, particularly Kehrer, claim a much higher percentage of improvement through early therapeutic abortion, even in the first and second stage cases.

Undoubtedly, results are largely dependent on the method of procedure. Curettage in the first six to eight weeks and later vaginal hysterotomy under gas and oxygen anesthesia are the methods of choice.

In the farther advanced cases, and in all those where pregnancy has advanced to the fourth or fifth months, operative measures will usually prove useless, and in the main harmful. This does not mean that the condition of these patients is a hopeless one. It is here that modern scientific sanatorium care is demanded. The tuberculosis sanatorium of the future must have as an essential part of its equipment a maternity department where approved care can be given the pregnant, and the proper facilities provided for delivery and safe progress through the puerperium. Aside from the hygienic rest regimen, suitable cases should be submitted to lung compression. It appears to me that here lies one of the most valuable indications for this therapeutic procedure. Undoubtedly, one of the chief reasons for the increased activation of tuberculous lesions at the time of confinement lies in the violence inflicted on the diseased lung consequent to the abrupt displacement of the diaphragm coincident with the emptying of the uterus. Pneumatic compression will go far in avoiding the sudden expansion of the lung, preventing the attendant absorption of toxic material and possibly passage of bacilli into the blood stream and lymph channels. Labor should be made as easy as possible and, in many instances, induced two weeks before term.

Aside from the danger to the child already referred to, the welfare of the mother demands that she be spared the strain attendant upon the nursing and care of the infant.

Missing the Trees in Studying the Forest—In this modern day of big things, when our eyes are so much on mass movements and governmental and social machinery, the individual has almost been lost sight of. We see the perspective, and we fail to discern the finely chiseled features of the man standing among the many. In thinking of society so much, we think too little of the individual. Individuals make society; society does not make individuals.—(W. S. Rankin, Hygeia, September, 1923.)

Life, like heat, is a mode of motion, and progress consists in discarding a good thing when you find a better.

FRAUDULENT DIPLOMAS AND STATE LICENSES

By C. B. PINKHAM, M. D.
(Secretary Board of Medical Examiners)

The medical profession of the State of California no doubt is interested, as is the profession throughout the United States, in the recent exposé of the issue of fraudulent diplomas and the granting of questionable licenses to practice by certain examining boards in the United States.

The colleges recently reported as having issued questionable diplomas are the National University of Arts and Sciences Medical Department, the St. Louis College of Physicians and Surgeons, both located at St. Louis Mo., and the Kansas City College of Medicine and Surgery, Kansas City, Mo.

It is related that there has been a wholesale traffic in high school credentials, university degrees, and medical diplomas carried on by a certain clique in Missouri reported as composed of Professor W. P. Sachs, "former examiner for the Missouri Department of Public Schools and former dean of the National University of Arts and Sciences of St. Louis"; Dr. Ralph A. Voigt, spoken of as the master-mind of the ring and reported registered as a graduate of the St. Louis College of Physicians and Surgeons, St. Louis, Mo.; Dr. Robert Adcox, retired physician and surgeon of St. Louis, and Dr. D. R. Alexander, dean of the Kansas City College of Medicine and Surgery. From this clique, a St. Louis Star reporter, Harry Thompson Brundidge, under the name of "Harry Thompson," purchased:

1. Credentials evidencing the equivalent of a high school diploma.

2. A diploma of the National University of Arts and Sciences Medical Department dated May 23, 1916 (the institution having closed in 1918).

3. A diploma of the Progressive College of Chiropractic dated Chicago, Ill., March 1, 1923.

It is further related that Dr. D. R. Alexander, dean of the Kansas City College of Medicine and Surgery, has been giving out diplomas of his school in a questionable manner, having some arrangement whereby graduates of his school successfully passed the Eclectic Board of Examiners of the State of Connecticut, the questions of examination reported as having been obtained in advance.

According to Governor Templeton of Connecticut, who checked over several examination papers written by various applicants before the Eclectic Board in his State, the answers to questions of these several applicants were exactly alike word for word, showing a preconcerted plan which has been confessed by certain successful applicants.

Past reports allege questionable procedure in the instance of the Eclectic Examining Boards in Arkansas, Florida, and Georgia.

The profession in California is interested in knowing whether any of the products of the diploma mills have gained entry into California, and it is the belief of the examining board of this State that we have not been imposed upon, for the Board of Medical Examiners of California carefully guards

against imposition by individuals who present either a fraudulent diploma or a certificate issued by any medical examining board shown to be involved in the issuance of questionable licenses.

A recent survey of the records of the Board of Medical Examiners, both as to applicants for written examination and as to applications based on licenses issued by other States, discloses that:

1. During the past ten years graduates from the St. Louis College of Physicians and Surgeons, St. Louis, Mo., have been admitted to written examination in California as follows: 1915, 1 passed (graduated 1910); 1916, 2 passed (graduated 1910 and 1915); 1923, 1 failed.

2. During the past 10 years 32 graduates of the College of Physicians and Surgeons of St. Louis, St. Louis, Mo., have been licensed on reciprocity from the following States. Of this group 29 presented diplomas dated PRIOR to 1917: Colorado, 1; Georgia, 2; Illinois, 8; Indiana, 1; Iowa, 2; Missouri, 13; Nebraska, 1; Oregon, 1; Pennsylvania, 1; Washington, 2. Total, 32.

3. No graduates from the Kansas City College of Medicine and Surgery have been admitted to a written examination in the State of California from 1914 up until December 31, 1923. However, three have been admitted during that interval on reciprocity based on certificates from Arkansas in 1917.

The Pacific Medical College of Los Angeles, whose diploma has never been recognized in California, has been mentioned in connection with the diploma mill.

Reporter Harry Thompson Brundidge, during his negotiations for a medical diploma, stated that he had received a letter from Dr. Ralph Voigt containing the following significant sentence: "I have gone to the west coast for completed stock so you can have less trouble and be better off"; that he later called on Doctor Adcox, who handed him a telegram from Voigt reading in part as follows:

"Alex agrees to issue final paper on Pacific for honorable cause two fifty."

Doctor Adcox then made the following explanation of the message:

"Ralph's telegram means that Doctor Alexander has agreed to give you a diploma based on the credits obtained for you by Ralph from the college on the Pacific Coast, but that he wants $250 for doing so." (St. Louis Star, October 18, 1923, p. 2, col. 4.)

Thompson stated that he later went to Kansas City, and met Doctor Voigt, who made the following statement during the ensuing conversation:

"I'm looking for your diploma in every mail. . . . That bird in California certainly works slow, but he's certain, and the stuff he puts out is A-1. Dr. Alexander has promised to issue another diploma to back up the California degree." (St. Louis Star, October 19, 1923, p. 3, col. 6.)

The Kansas City, Mo., Journal of October 20, 1923, published an interview with Charles A. Johnson, a student and helper at the Kansas City College of Medicine and Surgery, who relates:

"In the room I used as an employee of the college, I (Charles Johnson) heard the sale of two diplomas discussed by Doctor Alexander and pupils in the school (Kansas City College of Medicine). These diplomas were to be purchased for $300 each and were to be on the Pacific Medical College of Los Angeles, Calif., which went out of business in 1916, I understood."

It is interesting to note that United States Senator Royal Copeland, M. D., has caused to be introduced in Congress a resolution calling for an investigation, specifically as to whether or not the United States mails have been used in a scheme to defraud, i. e., by carrying on negotiations in relation to the sale of fraudulent diplomas.

As a sequel of these disclosures in the issue of fraudulent diplomas and State certificates, it is related that Connecticut has revoked some 30 licenses to practice in that State, with more to follow; that New York has undertaken a "house-cleaning"; that the authorities of Arkansas have joined, and that other States will follow.

The Board of Medical Examiners of California has but recently been brought into court to compel admission to examination of a graduate of the Kansas City College of Medicine and Surgery, whose dean, D. R. Alexander, was reported in the St. Louis Star of October 15, 1923, as arrested in connection with the fraudulent diploma expose.

135 Stockton Street.

PECULIAR MANIFESTATION OF FOCAL INFECTION. TREATMENT AND APPARENT CURE. THREE CASE HISTORIES *

By WILLIAM A. SHAW, M. D., Elko, Nevada

There are few physicians and surgeons in the State of Nevada who do not come in contact considerably with people of Spanish descent. I am presenting three cases of apparent focal infection with peculiar symptoms, all born in Spain.

Case S140—Juan Assoriguina was brought to me by several fellow countrymen who hoped that in some way I could prevent him from being taken to an insane asylum. The man presented a variety of melancholic symptoms which at times bordered on decided insanity. Physical examination was negative, except for a marked tonsillar infection with hypertrophy. There was a moderate leucocytosis. After some observation I could offer nothing except to advise tonsillectomy. This was done and the patient given ordinary eliminative treatment. He left the hospital one week after the tonsillectomy, apparently normal in his mind within a month and today is practically a normal citizen.

Case EGH594—Louis Guisasola was brought to me by a friend March 1, 1923, complaining of forgetfulness, marked melancholia and nervousness. His friend stated that he had been melancholic for several months, for the past month becoming decidedly worse and at times having a tendency to suicide. Physical examination disclosed nothing, except a marked lacunar tonsillitis, chronic hypertrophic type, and blood examination a moderate leucocytosis. After considerable observation I ad-

* Read before the Twentieth Annual Meeting of the Nevada State Medical Association, Reno, September 28 and 29, 1923.

vised tonsillectomy, and this was done April 24, 1923. The patient left the hospital the day following the tonsillectomy, was given no other treatment, but was observed for a period of several months. He is now herding sheep and is, according to report from his employer, doing well.

Case EGH665—Pedro Usatorre. This man was brought to me by his uncle, who stated that he had been out of his mind for several months and that on the morning when he was brought to me he had been found in a local barber shop with a knife in his hand, stating that he was going to kill anyone who opposed the idea that he was the chosen servant of God. This patient had a wild, staring look from his eyes, flushed cheeks, a marked follicular tonsillitis, a slight rise in temperature and a very moderate leucocytosis. He was placed in the hospital, and under eliminative treatment the temperature subsided, but he still had a marked variety of hallucinations, delusions and illusions. Two days after admittance to the hospital the tonsils were removed. He left the hospital four days later and reported daily for observation and was treated with a sedative current of electricity for several weeks. He gradually improved insofar as the nervous symptoms were concerned, until today he is practically normal.

The laboratory report from each patient was chronic amygdalitis, hypertrophic and encapsulated.

This small but interesting group of cases was emphasized more strongly in my mind on account of the fact that there seems to be a rather high percentage of insanity among the Spanish people, and particularly the sheep herders in this country.

The only deductions I can draw are that, in a climate like ours in Elko County, where tonsillitis and various throat inflammations are prevalent, these men become subject to a chronic focal infection, namely, tonsillitis, absorption from which causes symptoms of auto-intoxication and a resulting influence on the minds of these subjects, with a train of symptoms such as is outlined in these case histories. These men were all sheep herders and consequently were much alone out in the hills with their sheep. My opinion is that the condition resulting from focal infection made them feel weak and they, being alone and having considerable time to study their own feelings, and being ignorant of the cause of their inability to properly perform their work, became infected, so to speak, with the idea that they were going insane and did become temporarily so.

Oculists, Optometrists and Optical Firms—Epoch-making acts usually are not recognized as such until long after their occurrence. As a rule, their significance is appreciated only after their effect upon subsequent events has had time to manifest itself. But it is possible that we who are at present engaged in the practice of ophthalmology may be witnessing such an epoch-making act, in the position recently taken by a well-known wholesale optical house. Briefly stated, this firm has closed out all of its accounts with optometrists, and has announced that it will fill prescriptions only when they are signed by members of the medical profession. In addition, it proposes to inaugurate a campaign, by means of which the public will be educated as to the differences between oculists and optometrists, and the essential limitations of the latter.

Heretofore, oculists have always been on the defensive against the attacks of the optometrists. In common with other "get-knowledge-quick" groups of pseudo-medical practitioners, the optometrists have been waging an offensive (in both senses of the word) campaign to obtain legal recognition in the several States of the Union, and hardly a year passes without the oculists of some State being compelled to appear before its legislature to combat their activities, sometimes, unfortunately, to no avail. Whenever the oculists have appeared in an active capacity, it has been before some medical society or in some medical journal, informing their confreres of facts which they already know. They have been barred from the public press, partly from fear of appearing unethical, and partly because the public press, from motives of self-interest, or otherwise, has refused to present their side of the question. This anomalous position has long been recognized, and at the 1921 meeting of the American Academy of Ophthalmology and Oto-Laryngology, a committee on publicity and service was appointed to consider the question of the proper method of acquainting the public with necessary medical facts. This is a step in the right direction, and if it is assisted by the action of the non-medical organizations, so much the better. The present status of refraction is an evolution from the days of the itinerant spectacle vender; but the instruction of the consumer has not kept pace with the progress of those whose duty and privilege it is to supply them with correcting lenses. Anything which tends to alter this state of affairs should be welcomed.

Another phase of this firm's action is its refusal to supply lenses to optometrists. Oculists in the smaller cities, and those in the larger ones who supply their patients with lenses through the medium of wholesale optical houses have been forced to obtain such lenses, etc., from the same firms which supply optometrists. Not only is this true, but it is stated that some firms make a special, lower price to optometrists, thus introducing the element of unfair competition. Optometrists are organized for action; oculists for science. If oculists would realize what a force their united numbers could exert, by patronizing firms which cater exclusively to them, a revolution would be brought about in the attitude of other firms. They would realize that oculists would have a choice between "fair" and "unfair" firms, and many of them would undoubtedly swing into line. A decided check would be given to the activities of optometrists, for when an army is engaged in preventing the turning of its flank, it has little leisure for aggressive action. When a firm states by words and acts that it does not desire the accounts of a certain group of men, such action exerts a moral force beyond its immediate and direct results. In defending themselves from the implications produced, optometrists will hardly have time to attempt new inroads on the medical profession.—C. L., in American Journal of Ophthalmology.

A modified Rib Resection Operation for Empyema—To secure proper drainage in empyema, George Schwartz, New York (Journal A. M. A., December 15, 1923), believes that rib resection is necessary. Osteomyelitis of the rib occurs in 4 per cent of the cases, resulting in long-standing fevers, anemia and protracted convalescence, and requiring a secondary operation for a cure. The reason why necrosis of the rib occurs is that the open ends of the rib are exposed, are constantly being bathed in pus, and are involved by continuity of the infection. Heretofore, no means has been devised of sealing up these open ends to prevent contamination, thus closing up an avenue of infection that gives rise to a general sepsis. The operation is very simple and takes only a minute more than the usual procedure. It entirely removes the 4 per cent chance of a rib necrosis and reoperation, and may save months in convalescence. The bone-wax seals up the end of the open rib, and the muscle-flap gives added protection.

EDITORIALS

OUR GOVERNOR'S ANTI-QUACK ANNOUNCEMENT

If press dispatches are accurate, Governor Richardson has at last been aroused by the well-directed efforts and publicity of the League to the menace of quackery in California. We read in the press that our Governor is now going to weed out all impostors, fakes and quacks and close all "diploma mills." If this be true and truly carried out, we will review the Governor's good work gladly and lead the chorus in peals of praise.

Although we are eager to accept the anti-quack announcement at face value, facts prevent us and demand a large discount. We recall that one of Governor Richardson's administration bills, introduced at the last Legislature, would have placed the State Board of Medical Examiners, Board of Dental Examiners, State Board of Pharmacy, and Board of Veterinary Medicine under a lay director with power to issue licenses to and suspend or revoke licenses of the members of the various professions named. We remember that when the Governor's budget was the storm center of discussion, during the weary wasteful days of the last Legislature, the Health Board and the Board of Medical Examiners protested cuts made in their appropriations and stated that amounts allowed by the Governor would prevent them from carrying on their work with any degree of efficiency. We recall his veto of the anti-quack bill and the excuses offered. No one will question that the reduced activity of the State boards against unlicensed "doctors" during 1923 is in strong contrast to the Board's activity of 1922 and preceding years. It is stated on high authority that the Board's activity had to decrease because of lack of financial and other support.

Whether the Governor is now merely making a graceful "gesture" or is really changing his attitude will be determined by deeds and not by his announcements. In reference to the quackery problem, the road of duty is before the Governor plain and direct. Those entrusted with official power are false to their duty and responsibility if they license the uneducated and untrained, the mentally and morally unfit; but they are more false to duty and invade the rights of the citizens if they tolerate the unlicensed to prey upon the public.

If the Governor really intends to carry out his anti-quack announcement and protect the public, he will start right by prosecuting all those who are attempting to treat for money, diseases, injuries and deformities of the men, women and children of California in defiance of the laws of California. No sensational quiz or probe is required, for the names and addresses of many such "doctors" must be known to the Board. To find the names of a charming variety of unlicensed "doctors," who are apparently practicing in defiance of law with impunity and immunity, is not difficult.

As far as we are able to observe, such "doctors" are undaunted by the Governor's anti-quack announcement and continue to let their electric lights shine before men and their ads attract the shekels.

No matter how many gubernatorial "gestures" are made, and no matter how much partisan applause they receive, pantomimic warfare will not protect the public from "diploma mills" and the unfinished products which they are grinding out. It requires real laws and real enforcement of real laws to protect the public from misrepresentation, imposition and fraud of the many varieties of spurious healers and cultists masquerading under the title of "doctor." The loose use and abuse of the word "doctor," and the deplorable condition which enables a so-called college or "diploma mill" to be legally chartered for less money than a quack receives for one of his dangerous treatments, must be remedied by the next Legislature before any anti-quack announcement can be considered seriously.

SAFETY OF THE HYPODERMIC ADMINISTRATION OF DIGITALOID PREPARATIONS

The administration of the digitaloids subcutaneously is almost universally held to be undesirable, if not unsafe, because of the pain and the local inflammatory reaction, resulting in abscess formation. This is true especially of strophanthin; hence, the usual practice of intravenous injection of the digitaloid glucosides, or administration of the galenicals and dry digitalis by mouth. The intravenous route has its obvious objections, and the oral may be slow, irregular and inefficient. The hypodermic and intramuscular routes would offer several advantages, namely, ease of administration and promptness of absorption, especially in emergencies and in conditions precluding administration by mouth, and in such conditions as stasis of the hepatic and portal circulations. What has been hitherto thought undesirable and unsafe has been rendered practically feasible and safe by the recent work of Freud and Meyer of the Pharmacological Institute in Vienna on animals and patients.

Freud and Meyer showed that the digitaloids can be injected subcutaneously for their usual effects, and with impunity. This was accomplished by adding local anesthetics to the digitaloid solutions to be injected. Freud and Meyer used novocain (procain) and alypin in 5 per cent strengths. Firstly, they showed that dogs, which were found to be highly susceptible to experimental abscess formation from digitaloids alone, could be injected with mixtures of the same digitaloids and the anesthetics without local inflammatory reaction. The digitaloids that were tested were digitoxin, digipuratum, digalen, strophanthin, cymarin, and squills. All of these, except digitoxin, were injected subcutaneously together with procain (0.02 to 0.03 gm.) without producing pain and local inflammatory reaction. Then the Viennese pharmacologists tested the mixtures on patients with multiple sclerosis, neuritis and hemiplegias, and confirmed their results on dogs. For this purpose one side of the

body was used as control (without the anesthetic) and the other side was used for testing the digitaloid-anesthetic mixture, using pain and local inflammatory reaction as criteria. Under these conditions Freud and Meyer found that only 25 out of 138 patients injected with digitaloids together with local anesthetics (usually 5 per cent procain) showed evidences of inflammation, while 32 out of 37 controls without anesthetics showed marked inflammatory reactions. Strophanthin was injected together with procain in 55 out of 63 patients without local inflammation and pain.

Freud and Meyer conclude that digalen, digipuratum, squills, cymarin, and strophanthin can be injected subcutaneously without irritant effects, and that the indications for therapy of cymarin and strophanthin are extended and their use made easier and safer. In view of the practical importance of the subject, confirmation of these results is highly desirable in cases without the limitations enjoined by disease in the series employed by Freud and Meyer.

Freud, P. and Meyer, H. H.: Deutsch. med. Wochn., 1922, No. 37, "Über nicht zündende Subkutaninjektion entzündlich wirkenden Heilmittel."

ARE OPTOMETRISTS TECHNICIANS OR DOCTORS?

There are two classes of "optometrists." Members of one of these groups consider themselves technicians or prescription opticians of other days. The other and far larger group consider themselves "eye specialists." They do not confine their activities to the technical work of correcting by glasses errors of refraction in healthy eyes of healthy people. Too many of them are undertaking work which they have not been educated to do with safety.

"Optometrists" who wish to undertake the responsibilities of "eye specialist" should be required to have education comparable to that of other ophthalmologists. The others should continue their very necessary and important work as prescription opticians.

Sad stories are told of the injuries done to citizens, and children in particular, by "fitting glasses" to eyes that would have spoken clearly to the educated person of important diseases calling urgently for skilled care of more than the eye. The use of blue and red light electricity and other forms of therapy, without correct diagnosis of diseases producing eye symptoms as one of their manifestations, is frequently responsible for serious consequences to the patient.

The eyes are most important organs of the body, which cannot be separated into parts for purposes of diagnosis and treatment of diseases and abnormalities by those who have not had adequate education and training in the anatomy, physiology, pathology, and clinical manifestations of disease and abnormalities as they affect the entire human organism.

This is precisely what is being done in ever-increasing volume throughout this country. California is well forward in this movement, as it is in other movements calculated to provide inadequate medicine for the citizens of the State. This situation is destined to do much harm for an indefinite number of years, until the public some day in some way is made to understand.

A particularly discouraging and distressing feature of the problem is the recent action of the great State University in introducing the teaching of this branch of medicine under the department of *Physics*. This is the culmination of years of effort by the optometrists. Heretofore, the faculty of the medical school has insisted that, if optometrists were to be taught to practice medicine or to be technicians in a medical field, they should have adequate special education given by the medical school faculty.

Unquestionably, the department of physics will teach the mechanics of the subject better than it has been taught before. But they and their students apparently fail to understand that only a certain percentage of errors of refraction occur in otherwise healthy people. Honesty and fair-dealing demand that someone should determine before glasses are fitted, whether the eye trouble in any patient requires mechanical correction only. If optometrists wish to make this determination for themselves, they should have more medical education. Otherwise, they should recognize themselves as technicians, as some of them do, and limit their work to the fitting of glasses in patients who have been examined by those qualified to make diagnoses.

Many of the better educated among the optometrists realize their limitations. Some are limiting their work accordingly, and others are taking time to prepare themselves for wider responsibilities by better education.

The larger and more militant portion of their powerful organization are out for further expansion of their legal privileges by political rather than educational prestige. They claim the "eye for the optometrists," and in the language of the street, they are "getting away with it." They have recognition by the State Board of Education. They promote organizations to prevent blindness, give clinics, and otherwise follow the usual channels of publicity and propaganda.

It is exceedingly unfortunate and regrettable that the authorities of the University of California should have endorsed a situation that unquestionably will sooner or later cause them embarrassment.

THE INCIDENCE OF INTESTINAL PARASITES

Under this title there is published in this number of the Journal an article by Marshall C. Cheney of San Francisco, with discussion by Alfred C. Reed, John V. Barrow, and Herbert Gunn. Editorial comment upon the subject is made at this time because it is one that does not receive the attention by physicians in general that it deserves.

Aside entirely from the question of parasitism, there is a great deal of evidence of inestimable value to physicians that may be acquired by careful and accurate routine examination of stools. Such routine examination with appropriate stain-

ing methods will tell a story of the functioning of the intestinal canal that may not be obtained in any other way. As to the presence of parasites of various kinds and their significance, there is room for the accumulation and utilization of much more knowledge than we at present possess.

Amebiasis is far more prevalent in all parts of the world than it is generally considered to be. Its symptoms are exceedingly protean in character and the diagnosis of injury being done by the parasites themselves is not at all easy even in the hands of one skilled in this work. Unfortunately, a half century ago amebiasis was associated in the minds of the public, and even of some physicians, with dysentery. This idea is still too prevalent. As a matter of fact, dysentery, or frequent bloody mucous stools, is a comparatively rare symptom properly chargeable to the ameba. When bloody flux does occur in connection with an infection by ameba it is nearly always due to some concurrent bacterial infection rather than to the ameba.

This is not the time nor the place to go into the question of so-called harmless ameba, further than to state that these parasites, whatever their zoological classification, when persistently present in the intestine undoubtedly produce consequences not yet realized by even the most expert men working in this field. Our study of this particular group of parasites and the pathological conditions for which they are responsible is only in its infancy.

As to the flagellates, again it is doubftul whether any of them are harmless. It is probable, on the other hand, that many of them do not always produce symptoms which we recognize and place correctly. Mass infection undoubtedly has something to do with the distinctiveness with which flagellates manifest their presence, and it probably also has a good deal to do with the question of their relative significance in otherwise healthy people or those suffering from other diseases.

The writer of this editorial has long since been convinced that all intestinal parasites have a very definite influence on the character and virulence of the bacterial flora; on the splitting up and absorption of substances from the intestinal mucosa and upon the mucosa itself, by constant irritation, if in no other way. In view of our present knowledge, it is a little bit hazardous to blame these parasites for a certain group of specific symptoms, and it is equally hazardous in many instances to call them harmless because a certain group of described symptoms are not present.

THE DIPHTHERIA PROBLEM IN CALIFORNIA

During 1922 some 600 deaths occurred from diphtheria in this State. The record to date indicates that approximately the same number will die during 1923. These deaths represent some 7000 cases of this disease, and there probably were that many more carriers, which would bring the grand total of those who had infection up to some 15,000 or more during the year.

All of the deaths could have been avoided and all the suffering of those who did not die could have been avoided, by the application of simple knowledge well and widely known throughout the State. In avoiding diphtheria our people would at the same time avoid the numerous complications and after-effects that have their origin in the primary infection of diphtheria. Of those who recover from the disease, many now go through life with crippled organs, kidneys, hearts, arteries, nervous systems. Not only is the knowledge of how to avoid this disease widespread, but the facts are beyond question.

Would it not be worth while for some of our civic organizations to get behind the boards of health, start an extensive campaign and rid ourselves of this pestilence? Here is a real opportunity for some organization to do some worthwhile work. It would not be spectacular and would have but a small amount of news value, but it would save many lives, besides securing better health for many thousands annually.

THE COSTS OF HOSPITAL SERVICE

One session of the Third Annual Conference of the Hospitals of California was given over to a discussion of the problem of supplying adequate hospital care to those unable to pay the costs of such service. Discussion of the subject aroused wide interest and was freely commented upon in news items and editorials in the press.

A committee was appointed to study the subject and make its report at the Fourth Annual Conference, which will be held in Santa Barbara some time during this year. The committee is already at work, and will shortly send out a questionnaire to all the hospitals of the State asking for certain necessary data for the compilation of the report. An enormous amount of data is already in the files of the Hospital Betterment Service Bureau of the League for the Conservation of Public Health relating to every hospital in the State. However, it has been difficult to get sufficient financial data, and a satisfactory report on the problem will only be possible if the majority of the hospitals will furnish the data requested.

Obviously, the problem of reducing hospital costs cannot be considered without knowledge of what present costs are and at least the principal items which enter into this cost. We must not lose sight of the fact that all hospitals, as individual units, have been studying this problem carefully and taking advantage of every possible short-cut toward the reduction of costs for many years. This, of course, is necessary because even at present rates less than 10 per cent of the hospitals of the State make interest on their investments, much less a profit on the services rendered. The vast majority of them as they are now operated must have assistance in order to balance their accounts at the end of the year.

Any consideration of hospital costs, furthermore, must start with a uniform understanding of what constitutes good hospital service. The minimum requirement is facilities for giving good general hotel care, laboratory services of all kinds, pharmacy services, X-ray services, salaries and other

compensation of house officers, nurses and other employes, and other departments personnelled and equipped to render various other special services.

There has been, and is, considerable complaint from patients against the more or less lengthy list of "extras" that forms part of practically all hospital bills, and certainly forms part of the cost of operating each institution. These same people do not protest particularly when they are assigned a room in a hotel at $4 per day and find on their account when they leave extra charges for food, telephone, messenger, laundry, and perhaps a dozen other services that have been rendered for them. This method of charging and cost accounting is the only fair one that can be instituted. It, of course, would be easy to establish a round figure covering all assembled costs of hospital service, and to quote this as a daily rate to any and all patients. If this were done, patients who have very little service would be paying part of the expenses of those who demand and require a great deal. So we must continue to make hospital bills according to this so-called European plan for the same reason that hotels and other businesses follow this same system.

One great trouble in devising methods for decreasing the cost of hospital service is found in the fact that comparatively few hospitals, including the majority of those operated by the government, have accounting systems that explain in any sufficient detail their financial situation. Inadequate, incomplete and deceptive accounting systems explain to a very remarkable degree the vast difference in the quoted and often-published cost of service to the sick in hospitals, this whether the institution be a so-called State Hospital that proposes to render all service at 62 cents a day or a high-class public or private hospital where the actual costs of service are $5 or more per day.

In order to make its report of any particular value, it will be necessary for the committee to have total costs and the distribution of costs by departments of a large number of hospitals. A few of the principal items to be considered in this respect are:

The value of the hospital site.

The value of the buildings and improvements.

The interest on outstanding debts, whether notes, mortgages or what not.

The interest on bonds for those municipal and other hospitals that are bonded, this interest to equal at least the interest being paid on the bonds.

The amortization charges allocated by months necessary to retire these bonds when they mature.

The cost of repairs, alterations and replacements in buildings, equipment and furnishings, depreciation of plant and equipment.

The above is a list of items rarely given consideration in hospital accounting, and almost never in government hospitals that talk so much of cheap rates and free treatment.

In addition to these items, of course, there must be included information as to the cost in salaries and wages; the equipment and upkeep of each essential department, including X-ray, clinical and pathological laboratories, pharmacy, physiotherapy and other mechanical therapeutic departments; subsistence and dietetics; the expense of setting up operating rooms, anesthesia and anesthetics, and many others. Also there are to be considered the general cost of adequate insurance of all kinds, which is no small item in hospitals; taxes, water, telephones, transportation, housing and other compensation in addition to salary necessary for employes, and numerous other items of professional, technical, and hotel expense.

All of the items mentioned in this general discussion and many others will be incorporated in a questionnaire shortly to be sent to all the leading hospitals, and it is hoped, for the sake of the welfare of the sick and in the interests of economical worthwhile service to them, that the committee may have the co-operation of all hospital authorities and of the public in general.

"FAKE DOCTORS" AND "DIPLOMA MILLS"

The exposure by a newspaper of the sale of high school certificates and medical diplomas in Missouri has grown into a national scandal. The wide discussion of the facts in all varieties of current literature should shock our people into a realization of their neglect of their responsibilities.

The conditions which make this form of trafficking with health a profitable business for the unscrupulous have not been fully brought out, and constructive remedies which, after all, should be the outcome of the publicity have not received sufficient attention.

Four fundamental forces are concerned in the problem of who shall practice the prevention of disease and the treatment of the sick. These are:

Education,

State laws,

Law enforcement,

Moral or ethical activities of medical organizations.

MEDICAL EDUCATION

Under the leadership of the Council on Medical Education and Hospitals of the American Medical Association, and with the co-operation of the Association of American Medical Colleges and the Association of Medical Examining Boards, great progress has been made in establishing high standards for accredited medical schools and for the attainments of the students. The present requirements for accredited schools and their graduates, as well as the machinery by which these requirements are maintained, modified or advanced, are quite satisfactory and are generally understood. The principal difficulty is, that the movement is a purely moral force, established and maintained by physicians and medical schools for their own purposes, and it has no legal standing.

Through the influence of boards of medical examiners and medical organizations, constant attempts have been made over many years to bring State laws into harmony with the moral forces of medicine. No State has laws which back up these

moral forces adequately upon all points. Some States approximate the requirements, but in most of them the "doctors" laws are hodgepodges of amendments and court rulings filled with holes through which the clever rascal can enter and become "legalized" to treat the sick.

The laudable efforts of the American Medical Association and its co-operative bodies to advance requirements in education, educational institutions, State laws and law enforcement are one basic excuse for constant attack upon this organization by every medical charlatan and political trickster in all of the States. This is the principal basic reason for the much-quoted allegation that the American Medical Association is a "medical trust."

STATE LAWS

There are just as many different laws regulating medical education and practice as there are States. Not one is all that it should be, and the frequent changes made in most of them by legislative enactment and court decisions make the situation as complex and difficult as possible. Many informed persons will regret that extensive organized publicity similar to that regarding uniform divorce laws could not be applied to the question of uniform medical practice laws. One excellent movement in this direction is well under way through the activities of the National Board of Medical Examiners. This is another of those moral forces being fostered by medical organizations, whose policies would be endorsed and protected in any adequate State law. This has been done by several States.

The prevailing underlying principle which seems to be reflected in most State laws is that of filtering the end-product, or young graduate, through a political sieve as the proof of his fitness to practice medicine. They do not pay sufficient attention to the character, quality or quantity of the student's education, nor the provisions of his "college," in finances, plant, equipment or personnel, for giving adequate instruction. In California, for example, any five persons can incorporate a "college" or "university" for less than $20, and they can issue legally any diploma that can be issued by any university. There is no adequate legal requirement as to the quantity and quality of physical provisions for teaching nor the attainments of teachers. There are more than a score of "colleges," "schools" and "universities" operating *legally* in this State alone that can award any "degree" they choose. They are awarding "degrees" of D. C., D. O., D. O. M., D. O. S., and others which will permit the recipients to practice medicine under one or more of the numerous boards authorized to grant licenses to treat the sick.

Other laws provide that if one intends to use drugs in treatment, he must have completed a minimum of six years' study above high school. But if one only uses physical agents, whether punching the spine or squirting blue lights on the eye, he is required to study less than two years.

In spite of the charge so frequently made that California is the faker's paradise and the proving ground for "reformers," conditions just as inadequate as ours obtain in a number of other States.

LAW ENFORCEMENT

Even the Volstead Act is being more generally and more effectively enforced than are the laws regulating the treatment of the sick, such as they are, in most of the States. One only need examine the classified telephone directory of most cities to get an idea of the variety and number of unlicensed practitioners. Enforcement of the "doctors" laws is also about as unpopular as enforcement of the Volstead Act. The enforcement in many States is most unfortunately the duty of medical examining boards made up of physicians. If these boards do their duty, the onus of enforcement is charged against the medical profession. If they fail in their duty, the medical profession is blamed for the periodic scandals as they occur. All prosecutions and other enforcement activities should, of course, be in the hands of the police and other State and local law enforcement officers. This would fix the disagreeable responsibilities where they belong and relieve the medical profession of another of the alleged reasons for calling it a "trust."

MORAL RESPONSIBILITIES OF MEDICAL ORGANIZATIONS

The *moral* standards as distinguished from *legal* standards governing the practice of the healing art, including education and regulation of standards of all the agencies of medicine, constitute a great tribute to the American Medical Association and all of its subsidiaries and all of its co-operative contacts. This tribute is all the more impressive when we realize that the majority of the 150,000 educated physicians of the country are members of the organization and recognize the superior *moral* standard rather than any of the lower and usually inadequate standards fixed by law in the various States. Many of the thousands who are not now Fellows of the A. M. A. are eligible and should join their organization. That comparatively small group of doctors of medicine who, although they are privileged by law to practice medicine, are not eligible for membership under our *moral* standard, as well as all the groups of inadequately educated barnacles of medicine, should be made to stand out clearly for exactly what they are.

Our medical associations undoubtedly will stand firmly for the maintenance and constant improvement of our educational, moral and social standards. They undoubtedly will continue active in trying to improve the legal standards until they conform more generally to the educational standards.

Our leaders who have been elected and appointed to positions of trust deserve more wholehearted support and more universal encouragement than they are accustomed to receive.

The present and any other "medical" scandals reflect in a most discreditable manner upon the political and legal machinery of many States, while at the same time they help, by contrast, to show more widely the soundness of our organizational policies and their importance in protecting public health and in providing ethical, adequately educated physicians for our citizens.

If Connecticut, Missouri, or any other State

wishes to safeguard the health of their citizens they can do so by enacting the model medical practice act drawn by the Bureau of Legal Medicine and Legislation of the American Medical Association and by making the minimum educational requirement the degree of Doctor of Medicine from a college accredited by the Council on Medical Education and Hospitals of the A. M. A. These steps and the selection of enforcement officers who will enforce laws will insure the best of protection in public and private health.

WHO WILL EMPLOY AND DIRECT PHYSICIANS OF THE FUTURE?

Physicians who are interested in the general problem of better medicine and better public health for everyone, as distinguished from the clinical side of their work, will get some interesting information from an article by Willard S. Small, dean of the College of Education, University of Maryland, published as Bulletin No. 33 of the Department of the Interior at Washington.

Under the sub-heading of School Health Supervision, Professor Small says that two tendencies are noted in the administrative development of this work. These are "the broadening of the scope of medical inspection into school health supervision, and *recognition of the educational department as the logical administrative authority*." This phase of his subject is further elaborated in the pamphlet.

He recognizes that the public health and medical work among school children is done under four kinds of administrative authority, (a) the educational authorities; (b) public health authorities; (c) private and voluntary health organizations, and (d) multiple authority. He states that administrative control of this particular branch of medical practice and public health is most frequently in the hands of departments of education and least frequently under the control of boards of health.

In his tabulated work he does not distinguish between the medical work done by physicians and that done by nurses.

The author is particularly pleased to note that during recent years most of the new laws and revision of old laws pertaining to health problems of the school specify them as part of the program of departments of education and not of departments of health or otherwise under medical control.

Documents of this character and other release propaganda received by editors from all sorts of sources are certainly interesting to physicians, whether they be practicing preventive or curative medicine, or both as they should be. They indicate very clearly the direction in which medicine in the United States is very rapidly moving.

Stanford University Medical School (reported by W. Ophuls, dean)—The faculty of the Stanford Medical School has recently been especially interested in a possible revision of the pre-medical requirements and of the curriculum in the medical school. So many subjects are now required in the pre-medical curriculum that the students have lost almost entirely the possibility of electing courses that they may be especially interested in. It is hoped that in some way these rather excessive special requirements may be cut down and the students be given greater latitude in their preparation. This subject was discussed very thoroughly at a joint conference of the two medical schools in San Francisco, which was held on October 17, 1923, and there is now a joint committee working on it.

The committee of the medical faculty on revision of the medical curriculum has reported as follows:

The committee recommends—

1. Closer correlation in the work of the various departments and courses, and intra- and inter-departmental conferences on the content and aim of courses.

2. That more emphasis be placed upon the training needed by the general practitioner, but that we exert ourselves to the utmost to encourage disciples in the various branches of medicine.

3. That the work of the fourth year in medicine and also, so far as practicable, in other clinical departments, be so arranged that students can act as clinical assistants in the wards and out-patient clinics instead of attending lectures and demonstrations.

4. That the required work in the specialties be confined to their bearing on the needs of the general practitioner, but that the teaching be done by the various specialists concerned after consultation with their respective departmental staffs.

5. That greater emphasis be placed on the teaching of hygiene and public health, and that we earnestly recommend the establishment of a department of hygiene and public health.

6. That, in order to improve the services of our students at accredited hospitals, the dean be requested to appoint a committee of five to inquire of and to confer with ex-interns, regarding the nature of their services and suggestions for improvement of the same.

7. That the work in physical diagnosis and pathology now given at Stanford University be transferred to San Francisco.

8. That all required work be reduced by 8 per cent. This report has been adopted by the medical faculty.

The recommendation of the committee will mean that the medical students will come to San Francisco one quarter earlier than they have heretofore.

The medical school has received from an anonymous donor $300 as part payment for a fellowship in physical therapy.

The following course of popular medical lectures on "The Internal Secretions" is now being given in Lane Hall on alternate Friday evenings:

January 4.—"Active Principles Derived from the Glands of Internal Secretions," by P. J. Hanzlik.

January 18.—"Thyroid Disease," by Clement H. Arnold.

February 1.—"The Secretion of the Anterior Hypophysis, by Herbert M. Evans.

February 15.—"Hypophyseal Disturbances in Man," by E. B. Towne.

February 29.—"Insulin and Diabetes," by D. E. Shepardson.

March 14.—"The Effect of the Sexual Cycle on Voluntary Activity in the White Rat," by Professor J. R. Slonaker.

Professor Ludwig Aschoff of Freiburg has been selected as Lane medical lecturer for the year 1924, and Professor Vittorio Putti of the University of Bologna, the famous orthopedist, has been named Lane medical lecturer for 1925. Professor Aschoff will probably deliver his lectures during the last week in May.

The Lane Hospital is carrying on special work on insulin, under a grant from John D. Rockefeller Jr., of $10,000.

COUNTY NEWS

ALAMEDA COUNTY

Alameda County Medical Association (reported by Pauline S. Nusbaumer, secretary)—The annual meeting of the Alameda County Medical Association was called to order by the president at 8:20 p. m., December 17, 1923, at the Ethel Moore Memorial building.

The following program was presented:

Posterior Duodenal Diverticulum—Medical Aspect. W. H. Strietmann.

Posterior Duodenal Diverticulum—Surgical Aspect. Charles A. Dukes.

Esophageal Carcinoma of Long Standing—Lantern Slides. Fletcher B. Taylor.

These papers were generally and ably discussed. At the close of the scientific program, Dudley Smith offered a glowing tribute to the memory of the late W. L. Friedman. The retiring officers and chairmen of the various committees gave their annual reports. Refreshments were served, and a social hour enjoyed.

Newly elected officers, councillors, delegates and alternates: President, Charles L. McVey; vice-president, H. B. Mehrmann; secretary-treasurer, Pauline S. Nusbaumer; councillors, Stanley Berry, Daniel Crosby, E. A. DePuy, J. K. Hamilton, G. G. Reinle, C. A. Wills; delegates, W. L. Channell, W. S. Kuder, Gertrude Moore, George Rothganger; alternates, Eugene Barbera, F. W. Browning, Robert A. Glenn, C. Hall, W. E. Mitchell, A. C. Smith.

New Alameda Hospital—Incorporation papers have been issued to the Alameda Hospital Association. The trustees have plans well under way for the construction of a new four-story 100-bed hospital. The incorporators are Miss Kate Creedon, one of the proprietors of the sanatorium now in existence in Alameda; W. B. Stephens, M. D.; A. W. Porter, F. P. McLennan, and J. E. Hall.

KERN COUNTY

Kern County Medical Society (reported by P. J. Cuneo, secretary)—Following the custom of the past, the December meeting of the Kern County Medical Society was marked by the annual election of officers for the coming year.

The meeting was held at the Stockdale Clubhouse December 16, 1923, with Doctor Moore presiding. P. J. Cuneo was elected president; H. W. Hawkins, vice-president; H. W. Moore, secretary-treasurer; E. A. Shaper, censor; F. O. Hamlin, delegate; F. J. Gundry, alternate.

The business meeting was followed by a dinner-dance, arranged by Morris, Hamlin, and Moore. Members and guests were surprised by a splendid program consisting of entertainers from the Coast to Coast Theatrical Circuit, and a full-fledged orchestra to furnish the music for the dancing. Those attending were Dr. and Mrs. A. Moodie of Taft, Dr. and Mrs. Veon of Bakersfield, Dr. and Mrs. P. J. Cuneo, Dr. and Mrs. F. J. Gundry, Dr. and Mrs. Homer Rogers, Dr. and Mrs. Balnenburg, Dr. and Mrs. S. F. Smith, Dr. and Mrs. Joe Smith, Dr. and Mrs. Morris, Dr. and Mrs. E. A. Shaper, Dr. and Mrs. W. H. Moore, Dr. and Mrs. T. M. McNamara, Dr. and Mrs. O. P. Goodall, Dr. and Mrs. Fogg of Wasco, Dr. Yvall of McFarland, and Dr. Leland Ellis.

The Society will be the guest of the Taft members at Taft January 17, 1924.

The sympathy of the Society is extended to Dr. T. M. McNamara, who suffered the loss of his father.

Dr. Kathlyn Ellis has returned home, but is still in poor health.

The County General Hospital building is rapidly nearing completion. It is felt that it will mark a new era of co-operation and expansion of our Society in every useful way.

Manuel Salis has been appointed milk inspector for the newly created Bakersfield district by the Health Officer. Mr. Salis will devote his entire time to milk inspection.

The Mercy Hospital of Bakersfield, conducted by the Sisters of Mercy, contemplate adding a wing to their structure this coming spring, giving to Bakersfield the added facilities of twenty new rooms.

LAKE COUNTY

Lake County Hospital Annex—The new annex to the County Hospital has been completed. The annex comprises five new rooms, pantry, bath, and basement, the latter making a convenient and suitable quarters for the garage, woodroom, storeroom, and laundry. Two detention rooms are also located in the basement. There are now seven rooms for patients, which will accommodate approximately from 21 to 25 people.

LOS ANGELES COUNTY

Twentieth Annual Report of the Barlow Sanatorium, Los Angeles—The Barlow Sanatorium was founded in 1902 for the purpose of giving refined people of small means, who are suffering with pulmonary tuberculosis in the curable stages, an opportunity of receiving sanatorium treatment and care; and we feel that the results of twenty years' work have justified the undertaking. While there may be some who have not appeared to benefit by their stay in the sanatorium, the great majority of patients treated have made improvement, and a large percentage have been returned to their homes and work apparently cured.

In spite of the ever-increasing cost of maintenance, we have been able to keep the charge per patient down to $10 per week, which includes everything the patient needs; and because we have been able to handle more cases this past year, the cost per capita has not risen as high as might be expected. Our average number of patients has been 76.8 as compared with 70 the previous year, and the average cost per capita per week was $20.70. The endowment fund is $310,000.

In order to be admitted to the Barlow Sanatorium, patients must (1) have lived in Los Angeles County at least one year immediately before admission; (2) they shall secure $10 per week, which amount covers one-half the actual cost of care; (3) they must be in need of financial assistance; (4) they must be examined by one of the sanatorium staff; (5) they must be free from complication, such as tuberculosis of larynx, intestines, bones, etc.; (6) they must be in such condition that there is reasonable prospect of permanent benefit. In complying with the above conditions, it would naturally follow that many applications are received which cannot be accepted. The following table offers a better idea as to the number of applications received, accepted and rejected and the causes for rejection:

Total number of applicants	391
Applicants accepted	143
Applications deferred at the end of the year	136
Applications rejected	87
Withdrawn	25
No tuberculosis	11

Cottage Hospital, Burbank, Changes Hands—Miss Norma Short is now the sole owner of the Cottage Hospital. Recently the interest of Miss Beulah Newton was purchased by a third party, who in turn sold it to Miss Short, who will manage the hospital with a staff of six.

Murphy Memorial Hospital, Whittier—A recent number of the Whittier News contains an interesting illustrated article about the Murphy Memorial Hospital of which the community is justly very

proud. A new fifty-bed wing is nearing completion. It is one of the few smaller hospitals that is a completely equipped and organized general hospital.

New Glendale Sanitarium Nears Completion—This new health agency operated by the Seventh Day Adventist denomination has been planned to be the "Battle Creek of the West." The acreage at Wilson avenue and Sycamore Canyon road is ample and attractive. The site and improvements are valued at nearly $1,000,000. H. G. Westphal, M. D., is director, Mr. C. E. Kimlin, manager, and W. J. Johnson, resident physician of the medical plant.

MONTEREY COUNTY

Monterey County Medical Society (reported by T. C. Edwards, secretary)—Officers elected to serve the Monterey County Medical Society for 1924 are: President, William H. Bingaman, Gonzales; vice-president, William Gratiot, Pacific Grove; secretary, J. A. Beck, Salinas; treasurer, T. C. Edwards, Salinas; delegate, W. R. Reeves, Salinas; alternate, J. A. Beck, Salinas.

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement (reported by G. J. Hall, secretary)—The following officers have been elected for the year 1924: G. N. Drysdale, president; F. N. Scatena, vice-president; G. J. Hall, secretary-treasurer. Directors, G. N. Drysdale, F. N. Scatena, W. W. Cress, J. B. Harris, C. E. Schoff, G. P. Dillon.

Meetings of the Society will be held the third Tuesday of each month at the Sacramento Hotel, 8:30 p. m., with lunch after the meeting.

On January 15, W. R. Briggs read a paper on "Pathology of the Eye in Relation to General Pathology."

The Sutter Hospital Opened—The Sutter Hospital at Twenty-eighth and L streets, a modern institution for the treatment of the sick, was formally opened on December 2. Many floral pieces and notes of congratulation and wishes of success were sent to the hospital, which was open from 2 o'clock until 10 o'clock for public inspection. The stockholders were taken through the hospital in groups by physicians, who explained the systems which will be employed and the details of the equipment.

T. Binkley is house physician. Members of the board of directors of the hospital association are Drs. G. A. Spencer, president; W. A. Beattie, first vice-president; George A. Briggs, second vice-president; E. T. Rulison, treasurer; J. W. James, secretary. Dr. James, chief of hospital staff; Dr. F. N. Scatena, assistant. Miss E. Wolfinder, head nurse.

SAN BERNARDINO COUNTY

San Bernardino County Medical Society (reported by E. J. Eytinge, secretary)—The Society met January 8 at the San Bernardino County Hospital, with 30 members present, 50 absent, and 10 guests. The following program was given:

"Infections of the Hand and Forearm." By P. M. Savage. Discussion opened by E. J. Eytinge.

"Demonstrations and Discussions of Interesting Pathological Specimens." By R. B. Hill of Los Angeles. Discussion opened by N. G. Evans.

"Discussion of One Thousand Hysterectomies." Lantern slide demonstration of operative technic. By E. C. Moore of Los Angeles. Discussion opened by C. G. Hilliard.

There was a demonstration of the Spencer Delinearscope.

A. N. Kerr and V. L. Minehart of Arrowhead and Lenore Campbell of Loma Linda have been elected to membership in the Society.

The secretary again requests that the names of any eligible physicians who are not members of the county society at present be sent to him. It is just as important to get a former member back into the Sociey as it is to enroll a new one. The State Society is making a special point of this matter.

SAN DIEGO COUNTY

St. Joseph's Hospital—This splendid new hospital is now nearing completion. The seven-story modern building is located on a five-acre tract of land on quiet streets. The main building is 260 feet long by 44 feet wide. Provision is made for two additional wings when they are required.

The Sisters have taken an advanced but praiseworthy position in devoting nearly all of the space to single and double rooms.

The Sisters of Mercy opened their first hospital in San Diego in 1890, and progress in building and improvements in service have been constant since that time. The new hospital is a credit to the Sisters, to San Diego and to the physicians, who have heretofore been somewhat handicapped for lack of hospital beds for their patients.

The hospital will be equipped for radio connection in every private room. So a sick person at St. Joseph's can lie upon his bed and keep in close touch with a vast portion of the world in a practically uninterrupted series of programs.

La Jolla Sanitarium—The new addition is now under construction and when completed will enhance the beauty and usefulness of the hospital very much. The building will be of the monolithic reinforced construction and will be one of the most up-to-date hospitals on the coast. This new addition will almost double the capacity of the hospital.

SAN FRANCISCO COUNTY

San Francisco County Medical Society (reported by J. H. Woolsey, secretary)—During the month of December, 1923, the following meetings were held:

Tuesday, December 4—Committee on Medicine—Symposium on Treatment. (To be concluded next month.) What constitutes therapy?—Harold P. Hill. The psychology of sickness; the attitude of physician to patient—J. Wilson Shiels.

Tuesday, December 11—Annual Meeting—Reports of officers, committees, etc. Announcement of election (see below). Medical activities of the Veterans' Bureau—Herbert C. Watts, Chief Medical Division, Twelfth District. The principles and practice of case-rating—James G. Donnelly, Chief Rating Section, Medical Division, Twelfth District. The rehabilitation of a veteran suffering with a neuropsychiatric disability—Irving E. Charlesworth, Chief Neuropsychiatric Subsection, Medical Division, Twelfth District.

The following officers were declared elected for 1924: President, Emmet Rixford; first vice-president, Joseph Catton; second vice-president, Mary J. Mentzer; secretary-treasurer, J. H. Woolsey; librarian, Leo Eloesser; board of directors, Thomas Addis, Hans Barkan, L. H. Briggs, Edmund Butler, W. E. Chamberlain, E. C. Fleischner, M. R. Gibbons; delegates 1924-25, W. C. Alvarez; Edmund Butler, Joseph Catton, W. E. Chamberlain, E. C. Fleischner, M. R. Gibbons, J. H. Graves, Sol. Hyman, W. J. Kerr, A. R. Kilgore, J. C. Neel, H. A. L. Ryfkogel, William E. Stevens, V. G. Vecki.

Meeting of the Eye, Ear, Nose, and Throat Section of the San Francisco County Medical Society, October 23, 1923, E. F. Glaser, presiding (reported by F. C. Cordes, secretary)—Melanosis of the Conjunctiva—Louis C. Deane, in presenting the case, said that the most noticeable feature of an eye is its pigment. Its remarkable distribution, its normal variations in quantity and location, and again, its spectacular feature, lying there without apparent function, except as to curb or retain the light-rays, it can by some unknown process, fulminate into a growth so malignant as to claim at least an eye, if not a life. This is so of any part of the eye where pigment normally exists, whether choroid, ciliary processes, or iris. Pigment can creep into parts where it does not belong where it becomes a greater menace in that, with the tissue it has invaded, it may assume a tumor form and in most instances a malignant form.

Pigment is not present normally in the conjunc-

tiva or sclera. The limbus seems to be the connecting link between the pigment of the uveal tract and epibulbar region, for it is here that in the colored race we see a ring of pigment encircling the cornea, and it is in this region that the melanosarcoma of the conjunctiva is seen.

Mrs. H., middle-aged woman, always in good health, twenty-five years ago noticed in the right eye only some diffused brownish spots in the white of her eye, gradually increasing until they became coalescent. She states that the amount varied, increasing in quantity following excessive use of eyes or general fatigue.

I saw her first in February of this year. She consulted me not for the pigmentation, but for a small growth on the eye that had been increasing in size for nine months. The first thing noticed was a diffused brownish black pigmentation of her entire ocular and palpebral conjunctiva extending into the cornea for a couple of millimeters on its surface epithelium. A growth about 6x4x3 mm. was situated at the outer limbus on the horizontal meridian, deeply pigmented and movable, except for its proximity to the cornea.

The fundus showed no variation from normal, the iris was similar in color and appearance to the left eye and the cornea was normal except for the slight encroachment of pigment at its edge. Vision 20/20 and always the better eye of the two, so she states. The tumor looked malignant, and I extirpated it including surrounding conjunctiva and cauterized the underlying sclera, bringing the conjunctiva together with stitches. The wound healed as after a pterygium operation, and there has been no recurrence.

While cleansing the eye with cotton previous to the operation, I was astonished to find that I could wipe off the pigment from the conjunctiva, staining the cotton swab quite black. I repeated this on following days, and could always wipe off pigment.

Dr. Ophuls of Stanford University states that it is a non-malignant growth, with a diagnosis of melanosis of conjunctiva.

Since the operation, nine months later, the amount of pigment in the conjunctiva has markedly diminished, only appearing now in large circumscribed patches. She states that this diminution has occurred before.

The following thoughts seem to be of interest:

1. The varying intensity and quantity proving an active process of pigment proliferation.
2. Is the diminution of pigment due to absorption, or is it just wiped or washed off by the action of the lid, as I was able to remove some with a dry cotton swab.
3. It would seem that the activity of pigment production and recession has no bearing upon malignancy, as this tumor proved contrary to the rule.
4. Excluding congenital conjunctival nevi or moles or brown pigmented spots seen in dark people, any melanosis of the conjunctiva, no matter how mild, is very liable to develop into malignancy.

Fuchs states "that in most cases melanosarcoma develops." Weeks prefers to remove such spots surgically before waiting for further developments. Verhoeff and Loring say 80 per cent in favor of malignancy. Dean, with a cotton swab, then proceeded to demonstrate the wiping of the pigment from the conjunctiva.

Discussion—Pischel remarked that it was the first case of its type he had seen, especially interesting was the fact that the pigment could be brushed off so easily.

Obarrio interested in two points. The wiping off of the pigment is due to proliferation of pigment cells. Also there was 60 per cent more pigment present before operation, he having seen the case. He does not understand why removal of the tumor has stopped pigment proliferation unless due to the changing of vascular supply. The pigmentation has been receding ever since the operation. In 1903 he reported a case of marked pterygium and pointed out that if the blood vessels of the conjunctiva in healing turned upon themselves and did not ramify on the cornea there was no recurrence. In this case that has taken place and so thinks there will be no recurrence.

Franklin pointed out that melanosis is rare. We have naevi or circumscribed tumors of the iris that are considered congenital. Feels that subconjunctival injection might hasten absorption of this pigment.

Frederick feels that pigment must have broken through to allow wiping same off.

Deane in closing quoted Ophuls' report, "the upper layers of the epithelium are missing," and perhaps this accounts for the fact that the pigment can be wiped off.

Cataract Extraction Technic With Reference to Antisepsis and Iris Anesthesia—P. de Obarrio reviews cataract classification, observing that we should strive to determine two important factors—thickness of the capsule and size of the nucleus.

Slit lamp gives most valuable information, but its expense is prohibitive. Author uses the telescope of an ordinary ophthalmometer, and by projecting a strong light directly on anterior segment patient's eye and omitting entirely the mire-lights, a lot of valuable information can be obtained as to condition of iris, lens, capsule, etc. The double image produced by prisms is eliminated by removing same or by moving observer's eye to one side.

Reviews technic of preparation of instruments and patient. Makes a special point of the use of rubber gloves. Hands must be dry, glove-fingers short and well-fitting over tips. Avoid powder outside of gloves. When gloves on, wet with bichloride and just dry excess of liquid; this procedure gives necessary cohesion to instruments. Instrument handles should be preferably octagonal, as they give feeling of being "geared" to fingers. No appreciable loss of feeling with gloves.

Lays particular stress on use of mouth and nose cover for operator and assistants. Shows culture plates and tubes of result of experiments on exposure of operation field for five minutes under mouth and nose protection as well as without it, showing great increase in number of colonies as compared with check plate-cultures. Demonstrates that conjunctiva is never sterile, but principal organisms present are Xerosis bacilli from 80 to 94 per cent and staphylococcus albus from 70 to 85 per cent both of which are not necessarily pathogenic. Real danger of traumatized cornea is in the presence of pneumococcus, which cannot migrate through nasal duct of patient because of ciliated epithelium of same; hence, if present, must have been transplanted by hands, instruments, or by the action of speaking into the field of operation without nose and mouth protection. No excuse for avoiding all precautions, otherwise operator may be legally liable.

Absolute iris anesthesia produced by direct instillation of 4 per cent novocaine with adrenalin into anterior chamber immediately after corneal section.

Explains the mechanism of his method of lid traction to produce minus pressure on globe during operation. Claims lid traction to be the greatest factor of safety in ocular surgery and by far the most important advance in the technic of cataract extraction. Technic is based on clinical observation that eyes in which cornea collapses after section never produce vitreous loss. Author endeavors to produce this condition of minus tension artificially in all eyes to prevent vitreous loss as well as to assist in the replacement of the iris or the management of vitreous prolapse.

Very special stress is laid on the clinical fact that traction on the zonula can be exercised to a very great extent without producing reaction. On the other hand, compression in the neighborhood of the ciliary region to expel a lens produces considerable reaction. Intracapsular extractions by expressing

methods invariably produced irritable slow-healing eyes. Intracapsular extraction by traction produces considerably less reaction and frequently no reaction. Traction on zonula can be produced to an extent that may appear alarming without reaction and without vitreous loss if coupled with lid traction in accordance with author's technic.

Discussion—Franklin remarked that the paper had some very practical suggestions. The reason for so few infections in cases of poor technique is probably due to the washing away of the bacteria by the aqueous. We cannot use strong enough solutions to sterilize the conjunctival sac without injury. In the lavage it is really a mechanical cleansing. He has worn gloves in every case for the past ten years, and finds it does not interfere with the sense of touch, provided gloves are worn in every case. Feels that operation without a speculum is safer and easier on the patient.

Maghy pointed out the necessity of determining the type of cataract.

Frederick feels that a new knife is necessary in every case. He has seen Obarrio operate, using the iris anesthesia and saw that it worked well. However, the fewer instruments put into the anterior chamber the better the result and the less danger. Also feels that the advantage gained does not warrant the additional risk. He could not become accustomed to gloves and, inasmuch as the part of the instrument entering the eye is not touched, sees no necessity for same.

Pischel remarked that in Axenfeld's clinic, if the examination of the conjunctival smear showed staphylococcus aureous, the operation was postponed. The use of codein before the operation is a great help, as is also the paralysis of the orbicularis as described by Derby at the last A. M. A. Subconjunctival injection helps sufficiently so that intraocular instillation of cocain is not necessary.

Obarrio in closing wants to emphasize the holding up of the lids to produce a minus tension and also the wearing of gloves and a mask to guard against any outside infection.

Alveolar Fistulae With Reference to the Antrum—Merton J. Price presented a paper on this subject that will appear in full in the Journal.

Discussion—Sewell finds difficulty in closing the flaps; the making of flaps from the roof of the mouth is rather disappointing as they don't slip over, but are rather inelastic. The pressure of the blood supply is extremely important.

Deane remarked that he did not agree with Price that 80 per cent of antrum trouble came from teeth. He felt that many cases resulted from acute rhinitis, and that probably 80 per cent came from nose and throat and not teeth.

Graham was surprised to learn of the great number of fistulae, and thinks that this is due to the fact that radical dental surgery has been done so generally the last five or six years. He is rather certain that there are more now than formerly. The radical dental surgery permits more necrosis of the soft parts, and dentists should be warned to use the curette most carefully. He also feels that the nose and throat are responsible for more antrum infection than the teeth.

Price in closing stated that many failures of flap operations were probably due to the flap being too small, and there being too much tension. The failure of the dentist to recognize antrum infection and of the ear, nose, and throat man to recognize tooth infection is an important factor. Dentists still remove teeth for drainage of the antrum. The increase on the number of fistulae is probably due to the fact that many dentists with improper training attempt dental surgery.

Eye, Ear, Nose, and Throat Section of the San Francisco County Medical Society Met Tuesday, November 27, 1923, Edward F. Glaser presiding. (Reported by Frederick C. Cordes.)

Robert D. Cohn presented a paper on Halle's clinic with especial reference to his endonasal surgery. The full paper will appear in the January issue of this Journal.

Warren D. Horner presented a paper on the present aspect of post-graduate and clinic work in Vienna. The author reviews conditions in Vienna as he found them in an eight months' stay at the eye, ear, nose, and throat clinics from September, 1922, to June, 1923.

The importance of the American Medical Association of Vienna to the visiting physician is emphasized. This association, which is more than 12 years old, maintains clubrooms near the hospital. These serve both as a bureau for post-graduate courses and as a social center for all visiting English-speaking physicians. The membership runs from 100 in the winter months to about 250 in the summer.

The association is now up to its pre-war strength and effectiveness. The president, Bernard Kaufman of San Francisco, deserves to be congratulated for his excellent work during the reconstruction period. Courses of study are catalogued and announced by or through the association, which has arranged with the faculty for a standardized fee system. It also acts as financial agent for both student and instructor. The listing of available courses and the standardizing of their fees is of the utmost importance to the visiting physician. Practically all courses may be had in English, but a knowledge of German is naturally of great advantage. A wide variety of work may be had at the various hospitals, clinics, and institutes.

Prices for instruction run from $3 to $5 per hour for lectures or demonstrations, and from $15 to $50 per month for clinic work, depending upon the amount of individual instruction given. The fee is divided equally among the men taking the work, and all fees are quoted and paid in dollars.

Operative work on the cadaver is plentiful and good. Operations on the living are only obtained after months of work at the same clinic or perhaps in a few cases by private arrangement with some surgeon.

Owing to the low value of the kroner and the small fee obtainable for an office visit, teaching Americans for American dollars has become unusually popular among the faculty. Many of the Austrian faculty underrate American knowledge and methods in medicine. They are perhaps influenced in this view, because so many Americans go to Vienna for post-graduate instruction. However, those of the faculty who have been to America are enthusiastic over what they saw and give us the full credit that we deserve in the medical sciences. The Austrian cannot understand the common practice of so many of our best men devoting their entire time to private practice. The Austrian physician prefers the honor and title incident to a university clinic appointment more than a larger private practice. This makes for better post-graduate facilities there, and is one of the fundamental reasons why post-graduate work is better in Austria than in America.

Living conditions are good in Austria. Living costs are lower than in America; good pension board, room and service may be had, for example, at about $40 per month. Other items are proportionately low.

Austria's general political and financial conditions are improving steadily, due to her own efforts and the stabilizing effect of an allied loan.

Vienna offers many attractions to the visitor, outside of medicine, in the beauty of its public buildings, its parks, its operas, and its picturesque surroundings.

Polyclinic Opens New Clinic—A free diphtheria prevention clinic for children was opened recently at 1545 Jackson street as a branch of the San Francisco Polyclinic. Children between the ages of 6 months and 15 years will be given the Schick test

and the toxin-antitoxin permanent immunization injections.

Southern Pacific General Hospital (reported by W. T. Cummins, secretary)—The monthly staff meeting of the Southern Pacific General Hospital, San Francisco, was held on Monday, January 7. The following officers were elected for 1924: Chairman, F. K. Ainsworth; vice-chairman, W. B. Coffey; secretary, W. T. Cummins.

Brief talks were made by W. I. Terry, W. B. Coffey, P. K. Brown, W. F. Schaller, and R. J. Dowdall relative to the large number of interesting clinical cases which the hospital offers for study and treatment and to the importance of others than the staff participating by invitation in the scientific program.

St. Luke's Hospital Makes Staff Changes—A new professional staff for St. Luke's Hospital was appointed at a meeting of the board of directors held recently. This was the first meeting of the directors since the termination of the affiliation agreement with the University of California Medical School. The new staff is as follows:

Alanson Weeks, chief of division of surgery; Harld P. Hill, chief of division of medicine; A. J. Houston, chief of department of otorhinolaryngology; G. L. McChesney, chief of department of orthopedic surgery; W. P. Willard, chief of department of urology; Otto Barken, chief of department of ophthalmology; E. I. Leavett, chief of department of anesthesiology; Howard Morrow, chief of department of dermatology; E. V. Knapp, chief of department of pathology; J. M. Reyfisch, chief of department of X-ray; T. G. Inman, chief of department of neuropsychiatry; W. G. Moore, chief of division of gynecology and obsterics; R. K. Smith, chief of obstetrics; George Lyman, chief of division of pediatrics; William Ophuls and G. Y. Rusk, consultants in pathology.

In addition to these the following doctors were named as associate members of the staff: Philip Arnot, Rea Ashley, Hans Barkan, LeRoy Brooks, Z. E. Bolin, Paul Castelhun, E. Christianson, R. L. Dresel, A. C. Gibson, W. H. Hill, William Kenney, M. G. LaPlace, R. V. Lee, H. E. Miller, E. W. Parsons, G. Partridge, J. C. Parrott, J. M. Read, B. Stone, L. Taussig, J. C. W. Taylor, and G. S. Wrinkle.

Last June Howard H. Johnson assumed the management of the hospital. • The officers and the board of directors, under whose management the hospital has been conducted since May, 1920, are as follows: B. H. Dibblee, president; William H. Crocker, vice-president; Clifton H. Kroll, vice-president; Frederic M. Lee, secretary-treasurer; Frank P. Deering, Miss V. Newell Drown, A. B. McAllister, Louis F. Monteagle, Rt. Rev. William Ford Nichols, George A. Pope, and Dr. W. A. Phillips.

St. Joseph's Hospital Staff of San Francisco reviewed syphilitic therapy on January 9. Harry C. Coe of Stanford Medical School outlined the modern treatment of the disease, touching upon the old and new drugs and the criteria of cure. Howard W. Fleming of the University of California Medical Department illustrated operations upon the brain and spinal cord for luetic lesions. Ethan Smith, Harold Wright, C. Nixon, P. Collischonn, and W. T. Cummins discussed several features of the topic.

The program for the meeting of February 13 follows:

Particulars of syphilitic therapy in: (a) Obstetrics and Gynecology, A. B. Spalding of Stanford Medical School; (b) Pediatrics, M. L. Cohn, University of California Medical Dept., and (c) Neurology, J. M. Wolfsohn, Stanford Medical School.

SAN JOAQUIN COUNTY

Conference of State Hospital Officials—Superintendents of the State hospitals and institutions of California recently held a three days' conference at the Stockton State Hospital as the guests of Dr. Fred P. Clark, superintendent. The purpose of holding these conferences is to discuss plans for increasing the efficiency of the State institutions and make plans for the 1924 program. Members of the board of control and Governor Richardson attended the meeting. Those attending the conference were Mr. Walter Wagner, director of State institutions; Leonard Stocking, superintendent of the Agnew State Hospital; J. M. Scanland, superintendent of the Napa State Hospital; D. R. Smith, superintendent of the Mendocino State Hospital; O. S. Applegate, superintendent of the Norwalk State Hospital, F. O. Butler, superintendent of the Sonoma State Home; John A. Reily, superintendent of the Southern California State Hospital at Patton; Mr. Edward Twogood, secretary of the State department of institutions.

An elaborate entertainment and dance was given in the women's department of the hospital. Patients and attendants took part in the program, and moving pictures were shown.

San Joaquin County Medical Society Approves Health Unit—The Stockton Record says: "Endorsement of the San Joaquin health district's work was given by the San Joaquin County Medical Society directors last night, but approval of the district's plans for raising money was deferred until a vote can be taken at the February meeting of the Society. Fred Conzelman, who presided, stated that, despite their personal opinion that the cause is worthy, the directors felt that they did not have the power to act.

H. S. Chapman was appointed director of the clinic for another year, and was commended for his work during the time he has been in charge.

SANTA BARBARA

Santa Barbara County Medical Society (reported by A. C. Soper Jr., secretary)—The Society, to the number of 33 members, five internes as guests, and B. E. Merrill of Santa Paula, assembled at the Samarkand Hotel January 14. The annual banquet began at 7:30, and was presided over by President Means, the table being arranged in the form of a "T," with the officers and speakers at the head table. The banquet finished at 9.

H. J. Ullman, at the suggestion of the president, gave a humorous demonstration of the influence of thought-waves on an electrically controlled instrument, which flashed, wavered, or failed to shine, according to the intensity of thought in his "victims."

Mr. Edward F. Brown, prominently identified with the city improvement movement, by invitation gave an address on the necessity of development of the individual as a preface to that of the community, and touched upon many ideas for the betterment of the criminally inclined class.

William J. Melliner read a humorous description of California, with pithy comments on the rival cities, north and south.

Moses Thorner of Santa Maria spoke briefly on his appreciation of California, and claimed special supremacy for his own town.

The annual report of the secretary-treasurer was read and accepted.

Notice of application for membership by transfer of Irving Wills and W. H. Eaton met with approval, the matter to be referred to the censors in the usual manner.

Election of officers for 1924 resulted in Samuel Robinson being elected president; Franklin R. Nuzum, vice-president, and Moses Thorner and Edwin F. Smith, the first and second vice-presidents-at-large. The secretary-treasurer, by unanimous vote, was instructed to cast a ballot for himself for re-election.

Santa Barbara Cottage Hospital—The third Annual Clinic Day and banquet was held Monday, January 14, 1924, Franklin R. Nuzum, general chairman; Rexwald Brown, chairman surgical committee; Hugh Friedell, chairman medical committee; William J. Mellinger, chairman ear, nose, and throat committee. The following physicians took part in the clinics: Henry J. Profant, Phillip C. Means,

George S. Wells, William J. Mellinger, H. F. Pierce, Samuel Robinson, Rexwald Brown, H. L. Schurmeier, L. W. Hotchkiss, George W. Jean, Franklin R. Nuzum, Allen Williams, George R. Luton, H. J. Ullmann, W. D. Sansum, Ben Bakewell, Nathaniel Brush, H. O. Koefod, W. H. Campbell, H. E. Henderson, G. S. Loveren, and Hugh F. Freidell.

SANTA CLARA COUNTY

Santa Clara County Hospital—A new two-story wing to accommodate 50 patients and a central power plant have just been completed. The first floor of the new wing will be used for admission and emergency services. The second floor and solarium will be used for surgical patients. The large, airy basement will be utilized for physiotherapy. The additions cost about $220,000, including equipment.

The hospital occupies a forty-acre tract of land, and now has accommodations for 300 patients. Doxey R. Wilson, M. D., is director of the hospital. Frank Johnston is resident physician, with three young physician assistants. The visiting staff is made up of members of the Santa Clara County Medical Society.

Columbia Hospital Becomes Garden City Hospital—The Columbia Hospital was taken over by L. J. Belknap January 1, and will be conducted in future under its original name, Garden City Sanitarium. It will continue under the management of R. D. Brisbane, co-operating with Belknap until next summer, when the buildings will be removed to make way for the new junior high school, for which the land was recently purchased by the Board of Education. The concrete building and two cottages will be removed onto land owned by Belknap facing on Santa Clara street. The concrete building will be enlarged and equipped with modern appliances for a first-class hospital and will be conducted with one of the best equipped physiotherapy plants on the coast. This latter is already equipped and running. The wooden building will be wrecked.

SOLANO COUNTY

Solano County Medical Society (reported by A. V. Doran, secretary)—Edgar Peterson has been appointed assistant surgeon for the Southern Pacific Company for the Vallejo district.

Fred Heegler and George Thornton Sr. have been appointed members of the Board of Health.

B. J. Klotz died December 17, 1923, his death being caused by hemorrhage from the stomach—perforation of ulcer into blood vessel.

Mrs. B. J. Klotz has been appointed coroner and public administrator for the unexpired term of B. J. Klotz, deceased. J. Brownlie has been appointed deputy coroner.

SONOMA COUNTY

Sonoma County Medical Society (reported by N. Juell, secretary)—The Society met on January 10, with 14 present, 24 absent, and two visitors. The program was as follows:

"Fifty Years in Medicine," by N. Juell.

Discussion of "Professional Ethics," led by E. W. Bixby.

Sonoma County Hospital Improvements—Repairs and improvements have been carried out for the Sonoma County Hospital to the value of $10,000. About half of this money was spent for new furniture and equipment, and the balance was used in renovating the building.

Petaluma General Hospital—This hospital, located at Sixth and I streets, has recently been enlarged by the addition of a wing connecting the main hospital building and the maternity ward so that the entire group of buildings is now on one floor with the same elevation. The hospital has been improved and beautified, while there are additional conveniences for physicians, patients, and nurses. The new addition, designed by B. Jones, includes the new administration department, reception room and office, several large private rooms for patients, as well as sun rooms, corridors and convalescent quarters.

STANISLAUS COUNTY

Stanislaus County Medical Society (reported by R. E. Maxwell, secretary)—Society met at Hotel Modesto, December 14, the meeting beginning with a banquet. President E. R. McPheeters presided.

Members present were: B. F. Surrhyne, Walter Smith, C. E. Finney, Carl Benson, J. W. Morgan, E. F. Reamer, E. G. Allen, J. A. Young, J. L. Collins, F. W. McKibbon, C. E. Pearson, E. R. McPheeters, R. E. Maxwell, H. Smith, C. I. Bemis, J. L. Hennemuth, L. D. Mottram, F. R. De Lappe, and E. F. Hagadorn.

E. R. McPheeters explained the formation of the new association formed by the nurses in this county. Also that they had formed and stipulated a new official nurses' registry.

Owing to the irregular manner in which this had been accomplished, it was moved by B. F. Surrhyne and seconded by J. W. Morgan that the registry, formerly maintained by Mrs. Craddock on Hackberry street in Modesto, be recognized by our Society until the State Association of Nurses regularly organizes as such in this county, and their official announcements sets forth a definite registry as being official.

Officers for the year 1924 were then elected as follows: R. E. Maxwell, president; J. L. Hennemuth, vice-president; E. R. McPheeters, secretary-treasurer; C. I. Bemis, censor; E. R. McPheeters, State delegate.

P. N. Jacobson of Oakland read a paper on "Value of Cystoscopy and Pyelography in Abdominal Diagnosis," supplemented by X-rays.

Q. O. Gilbert, formerly instructor of medicine at the University of Michigan, gave a talk on "Perverted Physiology of Right Upper Abdomen," augmented by an excellent series of X-rays with a valuable explanation of same.

A vote of thanks was extended to the speakers for their interesting and instructive papers.

McPheeters Hospital Addition—A new addition to provide additional rooms, physicians' offices, a complete X-ray room, two treatment rooms and a laboratory to McPheeters Hospital, Modesto, is now under construction. Above the new addition will be constructed a pergola for convalescent patients. Improvements are being made on the nurses' home adjoining the main hospital. E. R. McPheeters plans to move his offices to the hospital when construction work is completed.

TULARE COUNTY

Tulare-Kings County Joint Tubercular Hospital to Have Addition—Contract has been awarded for the building of a children's ward as an annex to the present bi-county tubercular hospital at Springville. This annex is to cost $57,697, and will contain 40 beds for children.

YOLO COUNTY

Yolo County Medical Society (reported by Lela J. Beebe, secretary)—Two new members have been admitted to this Society: J. Edward Harbinson of Woodland and Thomas E. Cooper of Davis.

Woodland Clinic—Clinical meetings are held every two weeks at the Woodland Clinic (Fred R. Fairchild, M. D., director), open to all physicians and others especially interested. During December the following papers were read: "The Relation of the General Practitioner to Industrial Accident Cases," by W. J. Blevins. "Fractures of Long Bones," by Fred R. Fairchild, the latter being illustrated by lantern slides and clinical demonstrations. J. E. Harbinson read a paper on "A Presentation of Some Interesting Problems in Gall-Bladder Disease," and John D. Lawson on "The Diagnosis of Gall-Bladder Disease by use of the X-ray."

THE OPTOMETRISTS AND THE ELEVATION OF STANDARDS

In the present position of the optometrists in Minnesota, and their apparent efforts to build up their professional standards, we find and notice many of the steps followed some twenty years ago by the medical profession. Their attitude toward the medical profession deserves some analysis. It is quite apparent that their work is essentially the fitting of glasses. They have no desire to be classed with opticians—men who, in addition to the mechanical work of preparing and framing lenses, often advance into the position of commercial spectacle fitters and merchandisers. The optometrists, in a measure, frown upon the credentials of the opticians who invade their field of glass-fitting, and here we note the beginning of a spirit which aims to advance their own professional standing and secure recognition for their credentials.

The optometrist attests that his reason for the use of the term "doctor" is perfectly correct because he has the degree of "Doctor of Optometry"; that Columbia and some three or four other colleges offer courses of four years' duration, leading up to this degree, the entrance requirements for which are a four-year high school diploma, as it is for other departments. (They admit, however, that like other cults the course of four years may be considerably shortened by the use of summer courses.)

To all direct inquiries as to qualifications, the conscientious optometrist would, of course, disclaim any intention of being an M. D. Nevertheless, above all of this effort on his part to practice only on his merits, appears the very obvious fact that most of the public makes no distinction between him and the medical oculist, and he most certainly basks in the reflected distinction and standing of the medical profession as a whole. It may be quite safely predicted that, if conscientious students and practitioners of optometry hold faithfully to their promises and keep up both their entrance requirements and matriculation standards for licensure, soon the keenest men among them will see the great advantage of applying two or three further years of study, and entering the medical profession proper. This would leave those without such zeal and professional spirit to seek a short-cut to a good position and a livelihood by holding all the requirements down and thereby abandoning the professional for a trade spirit. No doubt this contest is on, at least to some degree, within the ranks of optometrists. It must be apparent to their good men that the broader knowledge of the human body is absolutely essential if they are to be more than skilled salesmen of glasses; certainly, if they are to rise above merchandising and be able to give their clients native instruction, education or direction—ideas good even for their souls as well as their bodies. They cannot attain this position of power without the very fullest knowledge that can be acquired at the particular period of their study.

Reasoning along this basis, the decisive opposition of the optometrists to our Basic Practice Act in the last legislature was ill-advised and illogical. It was the recoil of those fearful of their own position, yet firm in an appreciation of their own fitness. Among other assertions, they contended that they were willing to demand tests in basic sciences as "applied to the anatomy, physiology," etc., of the "head and neck!" They seemed to overlook entirely that there is nothing in the neck which begins to have the association with ocular disease that the kidney has, or (even more illustrative of the point) that nothing in medicine may quite so vitally influence the eye as syphilis—a disease with the most protean and universal bodily manifestations.

Admittedly, good optometrists do not locate in thinly settled country sections; in no way do they claim that they serve the public any cheaper than regular medical oculists. Therefore, they cannot be justified on a basis of country service or lessened community cost—arguments so often heard in favor of graduating doctors of inferior grade and less training. The optometrists do not even openly proclaim that there are insufficient regular medical oculists to properly fit glasses. In fact, like most irregular medical practitioners, they congregate chiefly in thickly settled centers of population where, it is agreed by everybody, are found the greatest number of good oculists.

How, therefore, does the careful optometrist justify his cult, aside from the obvious purpose of making a living? He does so chiefly in the good old-fashioned way of proclaiming the "inferiority of the other fellow"; "His lack of understanding of muscle balance"; "the fact that many medical doctors fit glasses who have had only a few weeks of preparation to do so." They further offer the free presumption that their minds, being unfettered by other claims for attention, encompass more fully the particular principles of physics and optics involved in their work. They assert that their long line of satisfied customers proclaim their general usefulness and community need. In the undoubted fact that many of these men do conscientious and satisfactory work, we can foresee that they are with us to stay. Present European conditions confirm an old financial law, that a strong and a weak currency cannot exist simultaneously: the strong is hoarded, and goes out of circulation. Seven-year and four-year trained "doctors" cannot exist together indefinitely. Either a flux of the latter will destroy the initiative of the former, or the lesser trained must be brought up to an average consistent for both, and parity result.

A recent attendant at the A. M. A. convention in San Francisco returned with much to say about the furore among the California profession over the increasing number and power of the quacks and cults in that State. One of the teachers in Harvard Medical School, when queried about the outcome, is quoted as having said in effect that they have taken an osteopath into the staff of one of their teaching hospitals. There they propose to give him a chance and see what he will be able to accomplish. We must remember, in this connection, that the qualified optometrists are by no means "quacks." It seems entirely logical that we should assist them where possible to a further realization and attainment of professional standards; discarding advertising and holding their members to the strictest ethical code. Then, as they improve, let no other group, without any standards, be allowed to take their place.—Editorial, Minnesota Medicine, October, 1923.

THE 1924 LANE LECTURES

The Stanford University Medical School has announced the forty-second course of popular medical lectures, to be given at Lane Hall, north side of Sacramento street, near Webster, on alternate Friday evenings, at 8 o'clock sharp. All interested are cordially invited to attend. The lectures already given were: January 4—"Active Principles Derived From the Glands of Internal Secretion," P. J. Hanzlik; January 18—"Thyroid Disease," Clement H. Arnold; Friday evening, February 1—"The Secretion of the Anterior Hypophysis," Herbert M. Evans.

Lectures to be given during February and March are: Friday evening, February 15—"Hypophyseal Disturbances in Man," E. B. Towne; Friday evening, February 29, "Insulin and Diabetes," D. E. Shepardson; Friday evening, March 14—"The Effect of the Sexual Cycle on Voluntary Activity in the White Rat," Professor J. R. Slonaker.

Are You Giving Yours?—"Every man owes some of his time to the upbuilding of the profession to which he belongs."—Theodore Roosevelt.

Nevada State Medical Association

HORACE J. BROWN, M. D., Reno.....President
CLAUDE E. PIERSALL, M. D., Reno.....
..Secretary-Treasurer and Associate Editor for Nevada

ABSTRACTS FROM NEVADA MEDICAL BULLETIN

(Editor, C. E. Piersall, Masonic Temple, Reno, Nev.)

At the last business session of the Nevada State Medical Association, after the new officers were elected, the newly elected secretary was asked if the Bulletin would be continued for the year 1924. The answer was given in the affirmative, with a provision that assistance would be rendered the secretary. Our veteran secretary, now our 1924 president, has kindly offered assistance, which will no doubt be used. Any suggestions or criticisms, constructive in type, sent in by the members of the State Medical Association will be appreciated very much, and will help to increase the value and interest of the Bulletin.

Like "Bobby Duff's" letter to Santa Claus, handed the postman on December 26, preparatory for next Christmas, we are now beginning to prepare for our next year's program; in fact, we have already a nucleus formed by two papers on "Amoebic Dysentery"—one on the clinical aspects and one on the laboratory findings. This will probably be enough papers on the above-named subject, so you authors may exclude that subject and begin to write on something else. Several other papers have been promised, and a number of honorary members and visitors have signified their intention of presenting papers or discussions, if we only send them a written invitation and notice of the date of our meetings. We intend to do this, and on time. If any member wishes such invitation to go to his friend, or friends, outside of Nevada, we will gladly welcome their names and addresses to add to our list.

Remember, if you want to receive the California State Journal of Medicine hereafter, you must have your dues paid in advance. Seven dollars a year is the amount for all except those members who also belong to the California Medical Association.

President Brown has announced the membership of committees for 1924 and, with officers and trustees, they are as follows: President, Horace J. Brown; first vice-president, William M. Edwards; second vice-president, A. C. Olmsted; secretary-treasurer, C. E. Piersall; trustees, A. C. Olmsted, W. A. Shaw, A. P. Lewis; delegate to A. M. A., Horace J. Brown; alternate, J. LaRue Robinson.

Committees—Membership, C. W. West, Hal. L. Hewetson, B. Brown; Judicial, M. A. Robison, Donald Maclean, R. A. Bowdle; Scientific Work and Program, J. L. Robinson, A. P. Lewis, E. E. Hamer; Necrology, V. A. Muller, S. R. Clark, G. L. Dembsey; Council, C. E. Swezy, A. J. Hood, R. R. Craig, O. Hovenden, J. West Smith, D. A. Smith, S. K. Morrison, C. C. Bullette, C. H. Lehners, C. C. Blake; Entertainment, S. K. Morrison, W. L. Samuels, J. L. Robison; Public Health and Education, Henry Albert, W. A. Shaw, M. R. Walker; Military Affairs, the President, Vice-Presidents and Secretary.

The military affairs work will be quite important and great in amount so each ex-service member in good standing will also be placed on this committee.

Keep this list on file for reference.

Nevada News Items

J. R. Eby, Elko, recently sustained an injury to his right eye in an automobile accident.

The following officers have been elected by the Elko County Society for 1924: President, A. C. Olmstead, Wells; vice-president, J. R. Eby, Elko; secretary-treasurer, John E. Warden, Elko; councillor, H. A. Paradis, Montello.

A. F. Adams, Reno, has been appointed County Physician in place of A. R. Da Costa, resigned. This consolidates the offices of County Physician and City Physician of Reno.

The State Department of Child Welfare, which functions under the Sheppard-Towner Act, is being reorganized and the Governor will shortly announce the appointment of a new board to administer the Act.

W. H. Hood, Reno, has returned from a vacation of a month spent on the Coast, and has resumed practice.

The Elko County Society voted at a recent meeting to invite the State Association to meet at Elko in 1924.

Utah State Medical Association

J. R. MORRELL, M. D., Ogden - - President
WILLIAM L. RICH, M. D., Salt Lake - Secretary
W. R. CALDERWOOD, M. D., Associate Editor for Utah

Salt Lake County Medical Society (reported by M. M. Critchlow, secretary)—The meeting of January 14 was called to order by President A. A. Kerr. Forty-five members and two visitors were present.

Judge Harold M. Stephens spoke in behalf of Mrs. Stephens, chairman of the Home Hursing Committee of the Civic Center Board, in regard to training girls to do simple home nursing. He recommended that a committee be appointed to cooperate and advise with the civic center in regard to this matter. J. F. Critchlow moved that the society endorse the proposal to co-operate and advise with the civic center in regard to training girls in home nursing, and that the society co-operate with the civic center in carrying out this idea. Seconded by Middleton and carried. Holbrook moved that the Community Clinic Committee be appointed to act in co-operation with the civic center in the home-nursing project. Seconded and carried.

George Roberts presented a pathological specimen and gave the history of a very interesting and unusual patient who died of spontaneous rupture of the heart. Holbrook presented a case of tuberculosis of the spine with paralysis following injury, with improvement following treatment. X-ray films of the pathological condition were demonstrated. The case was discussed by J. F. Critchlow, Middleton, and A. J. Hosmer.

F. J. Curtis read a paper on "Dementia Praecox," stressing the etiological factors and the type of patient the disease occurs in. The paper was discussed by Roberts, Llewellyn, and John Z. Brown. Major S. C. Guerney of the United States Army gave a paper on "Medicine in the Tropics," stressing the importance of the laboratory diagnosis. He discussed diseases caused by amoeba, helminthes, and bacteria, diseases with unknown etiology and diseases caused by the absence of vitamines in food. The paper was discussed by Steele and J. F. Critchlow.

Applications for membership from F. K. Root, C. W. Woodruff, and J. C. Bown were read and given to the Board of Censors for action. The application of W. T. Cannon was voted on, and he was elected to membership.

A letter requesting aid for German physicians and scientists, written by William T. Peterson, secretary of the American Aid for German Medical Science, was read. Motion by Scott that the letter be layed upon the table. Carried.

BOOK REVIEWS

"The Infant and Young Child." By John Lovett Morse, M. D., Edwin T. Wyman, M. D., and Lewis Webb Hill, M. D.

This is a book that should be of great value to the young mother. It ought to relieve her of many worries and aid her more effectively to care for her infant because it is full of good, sound advice with little to which exception may be taken by the most critical. Especially is the teaching of preventive measures effective against the common diseases, as well as smallpox, diphtheria and tuberculosis, sound and complete.

The book is very well arranged. It is particularly interesting that the advice given can readily be applied for use on the Pacific Coast with little modification.

The authors stress the fact that many fallacies, in fact many actually harmful practices, have been handed down through generations from mother to daughter and thus perpetuated. These fallacies are emphasized and illustrated, especially amongst the notes on the care of the mouth, washing and caring for diapers, the warning against rubber diapers, as well as in the very sensible paragraphs about the infant's clothing.

The chapter on breast feeding emphasizes to the mother how important breast milk is to the well-being of her child and it brings to her sensible directions about her own diet and, especially, it deprecates "stuffing." Here on the West Coast many pediatricians differ from the authors and recommend longer intervals between nursings than the Boston writers advise.

A fundamental which ought to be burned into the consciousness of every mother and every physician is brought out when the authors insist upon the prime necessity for thorough physical examination of wet nurses and all other servants who may be brought into contact with children, particularly the dangers from such attendants as may have incipient pulmonary tuberculosis, cannot be too often or too forcibly stated.

Every pediatrician has individual preference in the artificial feeding of infants. The group of men working in California no longer cling to the use of the percentage methods or of top milk and cream mixtures to any great extent. It is also the practice among them to use more concentrated formulas than these authorities of the Boston school find advisable. Apart from this divergence of opinion, there can be only admiration and support for the excellent advice contained in the chapter on the preparation of foods, advice which includes the care of materials and of utensils and to which is appended a number of recipes that will prove of value to mothers. For the feeding of older infants, the practice in the West is to begin the use of cereals and vegetable pulp quite early, a practice which does not find favor with the authors of this book, who defer the use of vegetables until the child is past two years of age. Bacon and sugar are taboo to these writers; as a result their diets call for much larger quantities of milk and are much more dilute than those in general use in this part of the world.

The need for training children to sound habits of eating is very wisely dealt with. Attention is called to the extreme suggestibility of children, and it is pointed out that this suggestibility is active in forming likes and dislikes of children for this or that food. The common aversions that children may exhibit towards essential articles of diet have often been brought about by some chance remark of a parent or friend. (The reviewer is of the opinion that for this chapter alone the book is well worth putting into the hands of every mother.) In dealing with this phase of child psychology, the authors write: "As so many people are weak-minded and soft-hearted, it is not advisable to have young children come to the table."

Every pediatrician must agree with the authors when they frown upon the indiscriminate diagnosis of malnutrition, and upon their insistence that to properly manage a case of malnutrition, intelligent investigation into particular family characteristics, as well as attention to the peculiar characteristics of the child, must be undertaken.

There are very satisfying, concise, interesting chapters which discuss the development, care and home training of the child.

The authors' insight into the problems of prevention of disease is well shown in the following quotation regarding the lack of medical supervision of Sunday schools: "Strange as it may seem to some, it apparently makes no difference in the severity of whooping cough, measles and other contagious diseases whether they are contracted at Sunday school or not." It is certainly a commentary on human fallibility that pediatrists, physicians and child welfare workers spend so much time in investigating evils and in recommending reforms, and yet so often miss the greatest evils of all.

On the whole, this is a book that can hardly be bettered as a handbook for young mothers interested in sound, modern nursery practice. C. G.

Infection and Resistance. By Hans Zinsser, M. D. 3rd ed. 666 pages. New York: The Macmillan Co. 1923.

A third edition of Zinsser's work within a period of ten years indicates rather forcibly the rapidly changing views on the biologic aspects of immunity. However, we are seeing in these few years, and ahead, a crystallization of vague and discordant hypothesis into fundamental facts and a sound system of rational deduction.

Probably no phase of immunity is more vexing, more fascinating, more bewildering and more essential than our understanding of anaphylaxis. Zinsser has entirely rewritten the chapters on this state with a more vigorous and confident approach. The effort, and success, of taking under wing and correlating pseudo-anaphylactic and anaphylactoid processes is gratifying.

Complement-fixation theories, and especially technical procedures, are not up to time, and might even be considered stale. These chapters have hardly more than an interesting historical value.

This volume embraces in a free and most readable style the broad field of infection and resistance. Much is contained that is of purely historic interest but essential in bringing into modern focus, pioneer and even prophetic conceptions. There is a pronounced effort at avoiding technical presentations. These could be entirely deleted. Isohemolysins and agglutinins, in their present broader application are fully discussed. Chapters on therapeutic immunization, active and passive, together with the phase of non-specific immunization, should aid considerably in the intelligent use of biologic agents. The chapter on colloids which appeared in previous editions has been rightly omitted.

In a previous review, I believe that I suggested a general reading of Zinsser's work. It is a book that can be read here and there—preferably for not too long a time. Written in good style, on a fascinating and absorbing subject, and makes you think a lot. E. A. V.

Cerebrospinal Fluid in Health and in Disease. By Abraham Levinson. 267 pages. 2nd ed. St. Louis: C. V. Mosby Co. 1923.

This volume of 267 pages represents a large amount of personal work done by the author which is always valuable in any monograph.

Of special interest to those who are not cognizant of the difficulties encountered in the development

of a study of the cerebrospinal fluid, the opening chapter on the history of the cerebrospinal fluid is replete with interesting data, and stimulating to one interested in this subject. One can understand then the difficulties in the field from pure clinical observation to the results found in the physical laboratory.

For the researcher with the cerebrospinal fluid this work is not so valuable as to the student and general practitioner, because there are not enough details explaining the data given. However, the bibliography is well chosen and sufficient.

One would expect to find adequate description for performing the different tests, such as Lange Colloidal Gold Test, with enough detail described to perform these tests, but in this the book is sadly lacking.

The author separates the cerebrospinal fluid into non-meningitic and non-luetic, rather than normal fluid. It would have been interesting if a further explanation of this classification could have been given.

The reviewer has found that the chloride content of normal cerebrospinal fluid varies between the narrow limits. (0.72 and 0.74 per 100 ccs.) The author finds other variations, which I believe should be rechecked on a large number of fluids, as it is well known that the chlorides of normal fluids vary much less than other constituents.

On the whole, the book is well worth owning and studying. J. M. W.

American Illustrated Medical Dictionary (Dorland)—A new and complete dictionary of terms used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Veterinary Science, Nursing, Biology, and kindred branches; with the pronunciation, derivation, and definition. Twelfth edition, revised and enlarged. Edited by W. A. Newman Dorland, M. D. 1296 pages with 338 illustrations, 141 in colors. Containing over 3000 new words. Philadelphia and London: W. B. Saunders Company, 1923. Flexible Leather, $7 net; thumb-index, $8 net.

A copy of this splendid dictionary ought to be on the desk of every physician. It is prized so highly in the editorial offices of the Journal that the copy furnished by the publishers for review is used as the desk copy for the editor of the Journal.

Heart Records, Their Interpretation and Preparation. By S. Calvin Smith, M. D. 313 pages. Illustrated. Philadelphia: F. A. Davis Company. 1923. Price, $7.

This well-bound and well-written book is full of beautifully illustrated records.

The author has evidently experienced many of the difficulties which a beginner generally encounters in trying to set up an electrocardiographic outfit, so his advice is very valuable.

It seems impossible to get a book which will clearly illustrate the different electrocardiograms and give a clear explanation of the causes of the abnormal curves and also full advice to the beginner, who most often has to "set up" his outfit.

Calvin Smith fills the want as to the latter difficulties, but has left plenty of room for the former. However, his book is called "Heart Records," and that is what it contains. H. S.

Happiness itself is sufficient excuse. Beautiful things are right and true, so beautiful actions are those pleasing to the gods. Wise men have an inward sense of what is beautiful, and the highest wisdom is to trust this intuition and be guided by it. The answer to the last appeal of what is right lies within a man's own breast. Trust thyself.—Ethics of Aristotle.

BOOKS RECEIVED

Annual Report of the Surgeon-General of the Public Health Service of the United States, for the Fiscal Year 1923. Washington: Government Printing Office, 1923.

American Illustrated Medical Dictionary (Dorland). A new and complete dictionary of terms used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Veterinary Science, Nursing, Biology, and kindred branches; with the pronunciation, derivation, and definition. Twelfth edition, revised and enlarged. Edited by W. A. Newman Dorland, M. D. Large octavo of 1296 pages with 338 illustrations, 141 in colors. Containing over 300 new words. Philadelphia and London: W. B. Saunders Company, 1923. Flexible leather, $7 net; thumb-index, $8 net.

Neurologic Diagnosis. By Loyal E. Davis, M. D., Associate Professor of Surgery, Northwestern University Medical School; Fellow of the National Research Council. 12mo of 173 pages with 49 illustrations. W. B. Saunders Company, Philadelphia and London: 1923. Cloth, $2 net.

Operative Surgery. Covering the operative technic involved in the operations of general and special surgery. By Warren Stone Bickham, M. D., F. A. C. S. Former surgeon in charge of general surgery, Manhattan State Hospital, New York; former visiting surgeon to Charity and to Touro Hospitals, New Orleans. In six octavo volumes totaling approximately 5400 pages with 6378 illustrations, mostly original, and separate Desk Index volume. Now ready—Volume I containing 850 pages with 921 illustrations; Volume II containing 877 pages with 1008 illustrations. Philadelphia and London: W. B. Saunders Company, 1924. Cloth, $10 per volume. Sold by subscription only. Index Volume free.

Medical and Veterinary Entomology, a text-book for use in schools and colleges, as well as a handbook for the use of physicians, veterinarians, and public health officials. By William B. Herms, Professor of Parasitology in the University of California. Second edition completely revised. New York: The Macmillan Company. 1923.

Pruritus of the Perineum (Pruritus Ani, Vulvae and Scroti). By Joseph Franklin Montague, M. D., of the Rectal Clinic, University and Bellevue Hospital Medical College. Foreword by George David Stewart, M. D., President New York Academy of Medicine. With 37 illustrations. Paul B. Hoeber, Inc., New York. 1924.

Children's Diseases for Nurses. By William Palmer Lucas, M. D., Professor of Pediatrics, University of California Medical School, San Francisco; Physician-in-Chief Children's Department, University of California Hospital, etc., New York: The Macmillan Company. 1923.

Medical Record Visiting List or Physicians' Diary, revised, New York: William Wood & Company, Medical Publishers.

International Clinics, a quarterly of illustrated clinical lectures and especially prepared original articles, by leading members of the medical profession throughout the world. Edited by Henry W. Cattell, M. D., Philadelphia, with the collaboration of a distinguished staff. Volume IV, 33d series. 1923. Philadelphia and London: J. B. Lippincott Company. 1923.

Medicine in the Public Press

With this number of the Journal is introduced a column of comment on medicine in the public press. The editor invites comment on the advisability of making this column permanent and of elaborating it to include practically all of the appropriate "news."

The editor also invites every member of our association to send in all press clippings considered appropriate for discussion in this column.

Doctors Face Diploma Quiz—Under this and similar display headings the press announces that the Governor of California has instructed the Board of Medical Examiners to conduct an investigation into "Eastern diploma mills." "It has come to my attention,' the Governor is quoted as saying, "that fake medical diplomas are being turned out by certain spurious medical colleges in Eastern cities, and I would suggest that your board use every precaution to prevent graduates of such colleges from practicing in this State."

Why "spurious medical colleges in Eastern cities"? There probably is no state that has as many alleged colleges purporting to prepare "doctors" as does California. Certainly there is no state that can offer less adequate laws governing the establishment and operation of "colleges" as "doctor" factories.

Again, we wonder why we are getting so excited about the hypothetical few M. D.'s who may be graduates of "spurious Eastern colleges." Why not clean the state of those hundreds and probably thousands of inadequately educated persons, many of whom are "graduates" of legally operating California "doctor" schools, and others who don't even trouble to get licenses of any sort and don't even claim to have spent the many dollars and few hours of time necessary to get a "diploma" from mushroom schools in our own state? Who are these people and where are they practicing, you ask? Walk along the prominent streets of your cities and look at the signs. Do this at night and look at the electric-lighted signs. Look in the telephone directories and at the advertising sections of the newspapers.

Then what about those that have been convicted of practicing medicine without a license and pardoned by the Governor? What about the suits that at one time were pending against some 300 of these gentry and were dismissed?

The real situation should not be limited to the sudden "probings" against the dangers from a few possible graduates of Eastern "spurious schools" while our own state is the home of far more serious conditions.

Adequate legislation to cover one phase of this problem was passed all but unanimously by the last Legislature and was vetoed by the Governor for reasons that we hope he now wishes he had never uttered.

Health Questions—The statement that a minister of a San Francisco church received and answered from 10 to 50 questions a day was considered of news value and the minister was considered the most "asked" man in the city.

If the Better Health Service conducted by the League for the Conservation of Public Health were to have its questions drop to only 10 to 50 a day, we would know that there was something wrong with the service. And our questions are all about Health. This service is growing constantly in interest and importance. That it is being more and more appreciated by the public is attested by scores of letters daily. Hundreds of correspondents endorse the method of conducting the service in the name of an organization without the mention of the names of doctors or other medical agencies.

Rendering the Right Service in the Wrong Way—According to news items, the San Francisco public school department is entering the field of the practice of dentistry. An appropriation for funds to equip dental offices has been requested and approved. Every child, and adult for that matter, should have all the prophylactic, diagnostic and dental treatment service he needs. Particular attention should be given to children's teeth—even the temporary teeth. However, we doubt the wisdom of the schools' attempting to render this service, nor do we believe it at all necessary. If any public tax-supported bureau is to practice either medicine or dentistry, it should be the Health Board. Even this is neither necessary nor advisable until it is shown that the dental profession either cannot or will not meet the situation.

There are nearly 1000 dentists in San Francisco. Each of these already has offices, office help, equipment and other fixed expenses. They also have the necessary X-ray, laboratory, anesthesia and other contacts. In other words, they are fully prepared to practice dentistry. Why duplicate the large item of fixed charges connected with good service, which must be paid for by someone? Our casual questioning reveals the fact that there are too many dentists with so little to do that they must accept small compensation wherever offered. In addition to the hundreds of dentists' offices where overhead expense goes on even for those with little to do, there are a considerable number of clinics equipped to serve school children and others. There is now in San Francisco enough dental equipment, well arranged in offices and clinics, and enough personnel to take care of a population much greater than we now have. Why duplicate these costs and place the practice of dentistry under a bureau that cannot render the service?

"Fake" Medical Colleges—The press publishes an interview with P. T. Phillips, president, and C. B. Pinkham, secretary, of the California Board of Medical Examiners, which says: Two Los Angeles medical colleges face cancellation of charters and more than 20 practicing physicians of the State have orders to appear before the California State Medical Examiners to defend their right to practice. One of the Los Angeles institutions, the Pacific Medical College, is alleged to have sold a diploma for $300 to one of the doctors now under arrest in St. Louis. The other institution, the American University, is charged with having offered its diplomas for an "inducement" to Italians in Venice, Italy, who desired to come to America as full-fledged American doctors. Dr. Pinkham is quoted as saying: "This 'university' is a fake, according to information we have received concerning it. Its 'campus,' as reported to us, consists of a small upstairs room in a Los Angeles suburb. This room is fitted with a dilapidated bed, an aged desk, a few broken chairs, and serves as eating, sleeping and 'working' quarters for the 'dean.'"

Assuming these statements to be true—and we have no reason to believe otherwise—what are the people of California going to do about it?

As we have repeatedly shown in articles and once in an address on the floor of the Senate in Sacramento, there is no adequate State law to control the situation. If physicians and physicians' organizations had not tried hard to remedy the situation, we could be criticized with justice. However, we have done all we could, and we will keep on trying.

What was known as the Medical College bill was prepared by and introduced into the Senate and Assembly of the Legislature in 1921 by the League for the Conservation of Public Health. It passed the Senate and died in a committee in the Assem-

bly. This bill did not raise in any way the question of secular medicine. It provided that any college or school purporting to teach the healing art should be incorporated. In order to be incorporated, it should come up to certain specified and reasonable standards, in finances, equipment, attainments of teachers, and other assets, and that it should require a certain minimum of real work in specified fundamental subjects by students who had had reasonable preparatory education.

Some such law must be placed on the statute books of the state for the protection of the good name of the state, as well as the health and even the lives of our citizens.

There are a score or more of "colleges" in California that profess to educate people to treat the sick that are no better, if indeed they are as good, as some of the "colleges" responsible for the present national scandal.

License to treat the sick in most states is based upon alleged education. The cure is to safeguard the education by making decent requirements for schools, faculties and students.

Serum Is Discovered Again—News dispatches quote a doctor A. R. Dochez of Columbia University as announcing a curative serum for scarlet fever. It may be so, but the method of announcement seems to have earmarks that make us skeptical. It is usual to see announcements of this character during the winter months when scarlet fever is prevalent, and sometimes the senegambian shows up when the "new serum" is marketed. Let us hope the report is true.

Are There Fake Doctors in State Hospitals?—Press dispatches announce that Mr. W. D. Wagner, director of the State Department of Institutions, is going to find out. He is going to conduct a "searching investigation" to find out if any of the "diploma mill" doctors have crept into his service. This is quite easy. One letter will give him the complete educational record of all of his doctors. However, it's not likely that any will be found, for the type of "doctors" who buy diplomas are not those who will be content with the "enormous" salaries that the State pays its doctors to treat its mentally sick citizens.

And They Call Them Specialists—Under this title George Ade (Cosmopolitan) treats specialists of many kinds in his usual humorous vein. We all laugh at what he says and some will see the implied moral. He refers to specialization in medicine by saying: "Doctor Gazarius says that your teeth do not look right, so he turns you over to Doctor Escatorius, in charge of the X-ray. You get the awful-looking prints of your teeth, which resemble twilight in the Sierras, and you ask Doctor Escatorius how about it, and he says that the radiograph must be submitted to Doctor Giggleheim. After days have elapsed Doctor Giggleheim reports that numbers 3, 18, 27 and 31 are indicated for extraction. So you tell him to go ahead and pull, but he says no, he does no extracting, but you had better go to Doctor Walzabus with your chart and let him keep on pulling until you tell him to stop.

"So you are passed along, like one of the parts of a flivver. You started out by consulting a dentist and you finish by being a dumb unit in a great system."

Discoveries Announced Too Quick—Many American doctors and scientific men are too quick in their announcements of discoveries, Doctor Arthur Biedl, professor of medicine at Prague, tells our newspapers.

This is a true statement, but we are sorry that the doctor spoiled it by saying that "European scientists are more careful and conservative in making known their findings." We won't forget Friedman of turtle fame; Coue of beaded string fame; Voronoff, Steinach, and a host of others who, to express it mildly, make premature announcements.

Senility—Now that "doctor" Frank Crane has spoken, we know all about senility. There is nothing to indicate that he is more careful of some of his other statements than he is in repeating the one time facetious remarks of the late Doctor Osler. He says: "Senility has nothing in particular to do with old age. . . . I have discovered that youth and senility are mere attitudes toward life." With this remarkable definition of senility and the equally remarkable "discovery," this much read and popular writer concludes with this remarkable statement: "Another recipe for a full and happy old age is found in the advice of Nietszche: 'Live dangerously. Build your house on the side of a volcano.' We have spent a good deal of sympathy upon destitute old age. Our sympathy should be extended to old people who are perfectly safe."

This is part of the education! the public is getting in medicine and health.

Counterfeit Doctors—Under this heading the Hanford (California) Journal says editorially: "In a profession given to quackery, quacks would attract little attention. The counterfeiting of medical diplomas is in itself a tribute to the medical profession. Counterfeiting implies that the established currency is sound. So it is with this great profession. All the more reason, therefore, why the profession itself should make every effort to eliminate the quacks, and why the public should help by informing itself of every doctor's medical pedigree and ostracizing the occasional pretender or crook."

When the legislation proposed by the League for the Conservation of Public Health becomes law it will solve this situation.

Is R. C. Cabot Being Misquoted?—One of the strong points being used against the medical profession by those who treat the sick by curious means is a statement credited to Doctor R. C. Cabot of Boston that "I know from my own certain knowledge that the vast majority of physicians in Massachusetts cannot make a diagnosis of early tuberculosis. I do not believe that one-tenth of the physicians in any state can tell incipient tuberculosis when they see it from physical signs."

If Doctor Cabot did not make this foolish statement, there would seem to be chances for him to increase his income and render the cause of better health a service at the same time. If he is correctly quoted he should apologize to his colleagues.

Some of our other prominent members, particularly Mayo and Crile, are also being extensively quoted as making statements easily interpreted as derogatory to their colleagues. Are there not enough forces trying to destroy public confidence in physicians and open the door wide for the unqualified without the assistance they can so frequently and readily cull from the careless remarks of prominent physicians and teachers of medicine?

Baby Gets Chance for Life—The press of the entire country feature the story of an eight-months-old baby who was "rushed" from St. Louis to Doctor Jackson of Philadelphia, who "was declared the only person in the country who could remove a tack from the infant's bronchial tubes." Wonderful publicity for Doctor Jackson, but we can't understand how such a splendid opportunity for publicity ever got by Rochester, Minnesota. The implied

reflection upon St. Louis physicians who are expert in the use of the bronchoscope is not at all serious.

Increasing the Goat Industry—Press clippings announce that "goat milk, on an average, sells in this country for 25 to 50 cents a quart. The ordinary milk goat will furnish about 1400 pounds of milk a season, although the high grades give from 2000 to 2400 pounds. Three-quarters of a ton of alfalfa hay and one-fourth of a ton of grain will feed a doe for a year. And goats are immune to tuberculosis. Get your goat."

If the increase in the use of goat milk and other edible portions of goats continues; and if one element in the propagating of goats continues to be exploited, to make the old young again, we are liable to find difficulty in maintaining goat herds. However, this danger may not be as imminent as it appears, because the Journal recently refused a display advertisement from a slaughter house offering to supply the rejuvenation glands to all physicians, as they are now supplying them to some. No wonder abscesses are sometimes reported to follow injections of alleged pure goat gland extract which was purchased from slaughter houses.

The Perils of Psychology—"The Spectator" (S. F. Examiner) in discussing this subject considers the danger "in this present fad is that people shall get to contemplating themselves until they lose their normal vigor which characterizes the healthy and become probably sickly and certainly a nuisance. . . . Freud's researches and conclusions are of great value to those who are equipped to use them for the benefit of the race. But Freud becomes a pest in the hands of those who are ignorant and unskilled to use his theories. The chief peril for the amateur Freudian lies in the fact that much is made of repressed sexual tendencies much better dealt with under the purifying influences of idealism and in the wholesome activities of normal social life than by continuous self-study, which easily leads to morbidity."

Public Health Lectures at University Hospital—A series of lectures on health topics is announced for the next four months by the University of California Medical School. These lectures, by well-known bay city physicians and surgeons, will be delievered in Toland Hall, University Hospital, Third and Parnassus avenues, San Francisco, at 2:15 p. m., on successive Sundays, the initial lecture having been January 20 on "What the Public Should Know About the Prevention of Diphtheria," by E. C. Fleischner, M. D.

Lectures for the following months, it is announced, cover a wide variety of subjects, including modern dentistry, goiter, asthma, bone and joint diseases, vaccines and antitoxins, life expectancy, anesthesia, prenatal care, indigestion, cancer, and other topics of vital popular interest.

The American Congress on Internal Medicine—The eighth annual clinical session of the American Congress on Internal Medicine will be held in the amphitheaters, wards and laboratories of the various institutions concerned with medical teaching, at St. Louis, Mo., beginning Monday, February 18, 1924. Practitioners and laboratory workers interested in the progress of scientific, clinical and research medicine are invited to take advantage of the opportunities afforded by this session.

Address inquiries to the Secretary-General.

Elsworth S. Smith, President,
St. Louis, Mo.

Frank Smithies, Secretary-General,

Chicago, Ill.

Correspondence

THE PHYSICIANS' CIVIC RESPONSIBILITIES

Letter from President Ray Lyman Wilbur of the A. M. A. to President T. C. Edwards of the California Medical Association, and Doctor Edward's reply:

President Wilbur: "If we of the medical profession are to play our proper part in public affairs we must work largely through existing organizations. This, it seems to me, means that every State medical association should have a well-organized committee on public welfare and legislation. Such a committee to be effective must deal in a practical way with men and with legislation. It seems to me desirable for it to make plans along three lines: (1) See that the best possible candidates are nominated, particularly for State offices; (2) See that of the candidates nominated the best possible are supported for election; (3) See that candidates before and after election are kept fully and accurately informed concerning matters pertaining to public health and the medical profession.

It is important to have this subject approached on a basis that will not seem purely selfish, but that will be for the good of the public in general, which, of course, means that it will be satisfactory to the medical profession.

It is of advantage if the chairman of the committee is one who has demonstrated his efficiency by past service and who can be induced to keep the position for some considerable period of time. His efficiency will depend upon the extent of his acquaintance, his knowledge of legislative procedure, and will naturally increase with each year's service.

In order to handle the administrative work of the committee, a good secretary is necessary. Either the chairman or the secretary should reside at the State capital and, if possible, they should reside so that they can have frequent personal conferences.

Some of the State associations are already effectively organized along these lines or others that have been proven by local experience to be equally satisfactory. In some States the arrangement is not so fortunate and it is particularly in these States that I urge prompt organization. If we are to present the uniform front that is necessary, effective organization in every State is essential. This applies both to State and National affairs. Organization should not wait until the Legislature meets or Congress convenes, but such action as may be necessary should be taken at once.

There has been set up at Association headquarters a Bureal of Legal Medicine and Legislation, which can be called upon freely by the legislative committee for suggestions and advice. I hope very much that the officers of your society will review their present plans in this regard or consider new ones, and that they will take particular note of the desire of the Association to be of service through the establishment of the Bureau of Legal Medicine and Legislation under Dr. Woodward."

President Edwards: "Your letter of October 31, 1923, which was sent to every State medical association, suggesting the need for 'a well-organized committee on public welfare and legislation,' was referred by me to the January meeting of the Executive Committee of the State Association. I said in my letter to you of November 15, that it was my impression that, as far as California is concerned, the proposed work of such a committee was being effectively covered by the League for the Conservation of Public Health.

I felt, however, that my judgment alone should not decide such an important question. The Execu-

tive Committee agrees thoroughly with you on the need for such work as you have alluded to and that, wherever possible, existing organizations should do the work.

The League for the Conservation of Public Health has been doing this work since 1918, and you are familiar with the successful record it has made. The American Medical Association and our State Medical Association have repeatedly complimented the League for its hospital betterment work, better health service, and for its legislative campaigns for the improvement of laws relating to preventive medicine and the prevention of legislation that would lower the standards of health and retard the practice of medicine.

The League is actively engaged in solving the problems that would come within the functions of a committee on public welfare and legislation and has accumulated a vast fund of information. As far as we are informed, we do not know of any organization in any State that has better trained personnel that is as vigilant in watching the tendencies and movements as our League. The League has more information on the factors behind various legislative measures, political groups, assemblymen and senators, the various welfare movements, the anti-medical forces and their sources of strength, the newspapers and other channels of publicity than any other organization of which we have any knowledge.

The life blood of every movement is publicity, and the executive secretary of the League is recognized throughout the country as a publicity director of outstanding character and ability.

Many of the present welfare and legislative problems come within the field of hospital betterment. The splendid committee of the League, consisting of Doctor W. E. Musgrave, Chairman, Doctors William Ophuls, Percy T. Nagan and John H. Graves, insures that this vital work is being ably handled.

The League pointed out, at its recent annual meeting, the civic duty of the members of the medical profession to select men of intelligence and integrity for legislators, men who recognize the value and need of scientific medicine and its essential agencies. The time to insure good legislation by selecting such men is at the primaries and not at the general election. If unfit tickets are selected at the primaries they cannot be defeated in November, and it makes legislative work at Sacramento desperately difficult. The League has had to fight some of its legislative battles under heavy handicaps. In one of the battles which it fought and won for the hospitals, the official public health forces were on the opposite side; in a battle on nursing education, won by the League, Union Labor was the opponent; in numberless contests all of the cults were combined against the League. The League has not lost a single legislative battle. In one contest, widely heralded by the press of the State, the administration tried to pass the so-called Professional Standards Bill. As it would have demoralized professional standards here, it was opposed and defeated by the League.

Medical men are composed of all shades of political belief and they seem to take less interest and have less information about the candidates they support and the issues they favor than any other group. In all important campaigns we find the members of the medical profession arrayed against one another. The League has done more to unify and solidify their efforts and thereby make them more effective than any other organization.

As the official personnel of the League is composed of leading members of our State Association, I can assure you that any request from you will be welcomed by the League and given hearty co-operation."

THE OWNERSHIP OF PATIENTS' RECORDS

F. W. Rinkenberger, M. D., of Los Angeles submits the following question:

"As a hypothetical problem, we will say that patient 'A' has been under the care of surgeon 'B,' and does not regain his health, and later consults surgeon 'C.' 'A' is unable to give 'C' definite information as to the surgical procedures he has undergone, or the conditions found at operation. 'C' goes to the hospital and asks for the chart of 'A,' but is refused permission to see the same without the permission of 'B.'

"It always seemed to me that this is a source of friction, inasmuch as it must be conceded that a patient has a right to change his medical or surgical attendants if he sees fit, provided there is nothing underhanded, or any influence brought to bear to cause the patient to change his or her mind, and it would seem to me that the right to the chart or record containing the laboratory reports, and all the other details which are really of value to the patient, should be subject to his or her order on the hospital without the permission of the previous attendant, who might, through selfish motives, or otherwise, object to a later attendant having the value of the previous findings. Yet it is for the benefit of the patient (as I see it) that we keep these records.

"I would greatly appreciate your ideas on the subject, and as it is a question that must often come up in different parts of the country, I believe it would be of value if you would print your opinions on the subject in the State Journal of Medicine."

Answer—Clinical records should be, and are in the majority of instances, prepared primarily in the interest and welfare of the patient; secondarily, they serve as an important guide to the physician. They enable the physician or physicians, as the case may be, to recall many details which at any time may become important, and the mere fact of writing the record necessitates a clear crystallization of the physician's ideas about the patient. This latter is a most important and much neglected qualification, and one that ought to be taught more than it is to young men and women just starting their professional careers.

In many countries and some States the law makes the patient's clinical record the property (privileged communication property) of the physician or the institution in which the record was prepared. So far as I know there is little law and few court decisions that bear directly upon the point as to whether, in case the patient is in a hospital, the record is the property of the physician who attended the patient or whether it is the property of the institution. Certainly, with any reasonable, fair and unselfish interpretation, it ought not to be necessary to decide this point. If the physician is the kind of a physician he ought to be, and if the hospital is the kind of a hospital it ought to be, the patient's record, regardless of who prepared it, obviously should be available to any subsequent physician holding the position of attending physician to that patient. Otherwise we defeat the primary and most important reason for preparing these records. No honest, conscientious, unselfish, fair-minded physician will ever, under any circumstances, refuse the written record or whatever personal opinion he may have regarding a former patient to another physician who may be at a later time attending this patient.

Many of the best hospitals in California have a rule that the record of any patient is available to that patient's physician at any time he wishes to consult it. Of course, it is extremely important that the data frequently contained in well-prepared records of patients be safeguarded against scrutiny by unauthorized and improper persons. In many States this is particularly and specifically protected by law. It should be better protected by law than it is in the State of California.

BOARD OF MEDICAL EXAMINERS, STATE OF CALIFORNIA

(Reported by C. B. Pinkham, Secretary)

"John of God": We have had many complaints against Juan de Dios Garay ("John of God") and have spent considerable time within the past two years trying to put him out of business. It has been almost impossible to convict him of violation of the State Medical Practice Act.

At each time I went through Garay's office with a search warrant, I found thousands of letters—letters from sick or afflicted; letters from the lonely or lovesick; letters from those who sought his occult powers for almost everything imaginable—and in each case carbon copies of his replies, showing him to be an artist in the art of extracting money from the credulous.

In one case a Mexican boy from Fresno sent $50 to gain the love of a 13-year-old Mexican girl, and "Juan de Dios" sent him a package of white powders with instructions to divide them into 14 equal parts and to burn one of such parts each night between 11 and 12 o'clock.

To some he sent bottles of his "Aztec Treatment," a concoction of herbs. He even had made some plaster medallions bearing a likeness of himself, which he sold to patients. Some of his patients regard him almost as a god.

Enclosed is a clipping from the Los Angeles Examiner of December 16, 1923, regarding the arrest of Garay by postoffice inspectors on a charge of using the mails to defraud. I furnished the postoffice inspectors with copies of circular letters mentioned in the clipping, and gave them sufficient information to secure his indictment by the United States Grand Jury, and I trust that this will be the "finish" of "John of God."

In commenting upon the above abstract of a report of the board's special agent, Doctor Pinkham says: "The enclosed letter shows the legal difficulties we experience in trying to prosecute 'fakirs' and 'quacks.' You will note that our special agent reports no success in prosecutions in local police courts, and it was not until the postoffice inspectors took action that we were able to accomplish anything.

The Los Angeles Examiner of December 16, 1923, in printing an article relating to the arrest of Juan de Dios ("John of God") Garay stated that 'Authorities state that Garay has obtained more than $300,000 from ignorant Mexicans and negroes during the past ten years in his operations in Los Angeles.'"

Letter Explaining Osteopathic Initiative—Under the provisions of the Osteopathic Initiative passed by the people of the State of California at the November, 1922, election, the Board of Osteopathic Examiners is given sole jurisdiction over graduates of osteopathic schools, and is empowered to carry out all the provisions of the Medical Practice Act in the instance of graduates of chiropractic schools. This means that the board of osteopathic examiners can license graduates of osteopathic schools as either drugless practitioners or physicians and surgeons; can collect the annual tax from all such individuals and otherwise perform the functions provided under the Medical Practice Act.

According to the 1923 directory published by the Osteopathic Board, Harold L. Jason holds a physician and surgeon certificate, which entitles him to unlimited practice in the State of California.

Naturopathy Legally Defined—Herewith we submit a copy of a communication from our chief counsel, Adolphus B. Bianchi, relative to a court decision establishing the limitation of the certificate to practice naturopathy, which many of the readers of the Journal know was validated in the State of California by special act of the Legislature in the year 1909, the enactment demanding that the Board of Medical Examiners endorse all certificates issued by the Naturopathic Association of the State of California that were presented to said Board within a certain period.

The Legislature failed to define what naturopathy was nor did the Legislature require that the holders of said certificate file with the Board of Medical Examiners any evidence of professional education.

For many years the holders of these validated naturopathic certificates have considered themselves as physicians and surgeons until the courts decided their limitation, stated by Chief Counsel Bianchi as follows:

"The recent appellate decision in the matter of Millsap vs. Alderson, et al, 42 Cal. App. Dec. 29, removes all the clouds from this situation. A naturopath is not a physician and surgeon, and under the license issued to him as such naturopath by the State Board of Medical Examiners, he cannot perform surgery. He is not authorized to practice medicine and surgery as a physician and surgeon so licensed by the Board may practice.

The decision further restricts the practice of any naturopath. 'Therefore, the substance employed by one practicing naturopathy in the treatment of the sick and afflicted would be light, air, water, etc., and a naturopath, or a doctor of naturopathy, would be a person who holds an unrevoked certificate from the Board of Medical Examiners authorizing him to treat the sick and afflicted by the use of the substances above enumerated.' That is to say, the substance enumerated in other parts of the decision as being contained and set forth in the Articles of Incorporation of the Association of Naturopathics of the State of California. The Gerber decision is no longer applicable. A nauropath is not entitled to hold himself out or designate himself or practice as a physician and surgeon."

Naturopathic Licentiates of the State of California—Attention of physicians is drawn to a decision, Civil No. 3951, Second Appellate District, Division No. 1, rendered August 25, 1923, in the case of Roy Millsap, petitioner and respondent, vs. Harry E. Alderson et al., constituting the Board of Medical Examiners, wherein the court holds that a naturopath is not a physician and surgeon, and the certificate to practice naturopathy does not constitute the right to practice medicine and surgery. Roy Millsap appealed to the Supreme Court for a rehearing, which was denied on October 23, 1923, hence the opinion above referred to is now the law in the State of California, and we are drawing it to your attention in order that you may be guided thereby.

United States Marine Hospitals Crowded—"Owing to the increased amount of shipping on the Pacific Coast, the Marine hospitals at San Francisco and Port Townsend, operated by the United States Public Health Service, are now overcrowded," Surgeon-General Hugh S. Cumming announced today. So great has been the influx of patients, due to the increased activity in American shipping in San Francisco, that the Public Health Service has found it necessary to place many patients in contract hospitals. To increase the capacity at San Francisco, the service now plans to remove attendants from their quarters to furnished lodgings in the downtown section of the city. By doing this, thirty-eight beds will be added to the capacity of this hospital. Surgeon-General Cumming also announced that "plans for the enlargement of the Marine hospital at San Francisco and for a new Marine hospital to be constructed at Seattle, Wash., are now receiving serious consideration, but that appropriations for these projects will be necessary before they can be undertaken."

O. G. Wicherski. M D.

Doctor Otto Gustav Wicherski

After an illness of only a few weeks and from the midst of a busy life of public service, Dr. O. G. Wicherski was called on January 2 to higher service for the Master.

Born in New Ulm, Minnesota, forty-seven years ago his has been a life filled to the brim with service for others. His first active work after careful preparation was that honored calling of teaching school. From this he graduated into the study of medicine, receiving his M. D. degree from Rush Medical College in 1904. After a hospital internship and a few years of general practice in South Dakota and Nevada he affiliated himself with Dr. D'Arcy Powers on the faculty of the Post-graduate Medical School of San Francisco. Of his work here Dr. Powers always expressed himself in the warmest terms.

Locating in San Diego in 1911, he rapidly became prominent; his unusual executive expressing itself in public health work for the county and city. For the past six years he has been Medical Director of the San Diego County General Hospital, to which office he applied his talents with energy and intelligence. His was a rule of heart as well as brain, which union is so essential in caring for the poor. During the trying times of hospital betterment he has enjoyed the whole-hearted support and co-operation alike of the county supervisors, the general public and the medical profession.

Of Dr. Wicherski's devotion to duty it may truly be said that he left the sphere of his efforts the richer by reason of his contact with it.

R. P.

With Our Advertisers

A well-defined movement is obvious among all classes of good journalism to so adjust the mechanism of their publications that their advertising columns shall be read with as much interest as other reading matter, because they are equally informative and attractive. It may not be out of place to repeat again what we have so often said, that the California State Journal of Medicine is enabled to be what it is more from the income derived from advertising than from any other source. Advertisers very properly scrutinize returns on their investments in advertising, just as they do on any other investments, and if the Journal is to go ahead and improve, we should see to it that those who invest with us get returns on their money.

Optical Companies—It is a pleasure to call the attention of our readers to the page advertisement of the Riggs Optical Company appearing in this issue of the Journal and to emphasize the high-class copy they include in that advertisement. The confusion that has existed in this important field of medicine has been a source of concern to physicians, patients and technicians in the optical field, but the situation seems to be clarifying itself to a certain extent, and the position taken by some of our good optical companies is helping in this clarification, to the interests of the people who need and must wear glasses.

We have been carrying for a very considerable time the advertisements of the Trainor-Parsons Optical Company and the John F. Wooster Company, both of San Francisco, who announce themselves as high-grade prescription opticians. Manufacturing and technical people who take the advanced stand required to securing advertising space in our Journal ought to be encouraged in that stand by the ophthalmologists who write prescriptions.

Medical Book Department of The Emporium—We are glad to call attention to the announcement of The Emporium, beginning in this issue, inviting you "to browse at your leisure" in their Medical Book Section and to use the department as a reference and reading room. Their stock of medical books is very complete, including a great many foreign importations, and they will order for you any book in print, even cabling to their foreign offices in all parts of the world. Orders from out of town will also have their prompt attention. This service, with that of J. W. Stacey, whose announcement has been carried in the Journal for the past few months, insures for San Francisco and California adequate supply departments for all sorts of medical and techincal literature, for physicians, dentists, and nurses.

Medical Illustrating—The Journal carries constantly the card of Mr. Ralph Sweet, who is devoting his entire time to medical illustrating. Now that the annual meeting of the California Medical Association is approaching, and also that of the American Medical Association, it seems appropriate to call attention to this service. We do not hesitate to endorse Mr. Sweet as a very competent medical illustrator, nor do we hesitate to say that illustrations that illustrate are an extremely valuable part of medical publications, as they are of other publications.

Our Iletin (Insulin, Lilly) Advertisement—In this number we carry perhaps the most extensive and carefully prepared color two-page advertisement ever produced in the Journal. This is the announcement of Eli Lilly and Company with reference to iletin. Eli Lilly and Company announcements are always of value and interest, and are found in our advertising columns constantly.

Address of the Retiring President, Los Angeles County Medical Association—"No man can serve this society for one year in the presidential chair without forming serious convictions as to its welfare," said William H. Gilbert, president of the Los Angeles County Medical Association during 1923, in his address as retiring president, (Bulletin Los Angeles County Medical Association, Jan. 17, 1924). "On all sides one hears the voices of the boosters and the knockers. The attitude of a leading newspaper, which for years has carried on propaganda against the medical profession has not only seriously influenced the minds of the people but has struck a terrible blow at the morale of the profession itself. . . .

It is surprising when one considers that this association numbers thirteen hundred members that its regular attendance is so small. One cannot say that the scientific papers have not been interesting or well prepared. As you know the prime motive of the county medical unit is education. In fact the county unit should be a post graduate medical school. One hears occasionally that the papers, no matter how well prepared, are poorly delivered, and I must confess that I have sat in this chair, and heard the most scholarly dissertations mumbled over and delivered in such a manner they could not be heard or understood beyond the first three or four rows. Essayists do not seem to realize that the man who listens is entitled to a square deal in the delivery of the paper, and that it should be read in such a manner as to be impressive and instructive. Without doubt most of the poor attendance of the parent body is due to the large number of meetings held by the subordinate branches, hospital staffs and various other medical organizations. In fact the time has arrived when the man that keeps up his attendance in the various branches of this society and the hospital staffs with which he is affiliated is spending more nights away from home than is justifiable."

DEATHS

Anderson, Ross R. Died at Los Angeles, January 17, 1924. Graduate of the College of Physicians and Surgeons, Baltimore, 1905. He was a member of the Los Angeles County Medical Society, the California Medical Association and the American Medical Association.

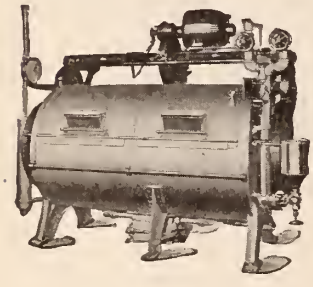
Dresel, Gustav. Died at San Francisco, January 1, 1924, age 67. Graduate of the University of Frankfort-on-the-Main, Germany, 1882. Licensed in California 1884. He was a member of the San Francisco County Medical Society, the California Medical Association and a fellow of the American Medical Association.

Wicherski, Otto Gustav. Died at San Diego, January 2, 1924, age 47. Graduate of Rush Medical College, Chicago, 1904. Licensed in California, 1910. He was a member of the San Diego County Medical Society, the California Medical Association and a fellow of the American Medical Association.

Wythe, Stephen. Died at Oakland, December 25, 1923, age 50. Graduate of Cooper Medical College, San Francisco, 1895. Licensed in California, 1896. He was a member of the Alameda County Medical Society, the California Medical Association and the American Medical Association.

A corner of the washroom U. S. Public Health Service Marine Hospital, San Francisco

A Modern Hospital Wash Room on the Pacific Coast



The Marines "follow the flag," and the United States Public Health Service follows the Marines.

To insure patients at the Marine Hospital in San Francisco an abundance of aseptically clean linens and wearing apparel the U. S. P. H. S. has installed a model hospital laundry.

The washroom, which is the foundation of good laundry service, is equipped with standard American Cascade Washers. These washers were adopted after careful investigation because they wash more thoroughly, with less labor, fewer supplies, and in shorter time —standard requirements in every laundry.

In addition, the Cascade exactly meets hospital requirements for all-metal washers in which linens can be washed aseptically clean, and gauze reclaimed as well.

Have us forward further details why The Cascade is the approved washer for every hospital laundry.

Hereditary Hemoptysis—For seven years Emanuel Libman and Reuben Ottenberg, New York (Journal A. M. A., December 15, 1923), have had under observation a family of bleeders. In this family, seven persons presented almost identical histories of repeated profuse hemoptyses beginning about puberty or in early adult life and occurring at intervals throughout life. The heredity of the disease in this family is not sex-limited. The disease occurs in and is transmitted by females as well as by males. The hemorrhages occur only at or after the age of puberty, the earliest hemorrhage recorded in any individual being at the age of 12 years. None of the hemorrhages have been fatal. Tuberculosis has been excluded as the cause of the hemorrhage. The only comparable disease is the "idiopathic family hematuria" described by Apert, which has been observed in two families. The condition seems not to skip generations.

Official Organ of the California, Nevada and Utah Medical Associations

Veterans' Notice

"THE INSURANCE DIVISION of the Veterans' Bureau is endeavoring to tell one hundred fifty odd thousand ex-service men in California that in their scramble to re-enter civilian life at the close of the late war, they left on the shelves of the Government about a billion dollars of life insurance that belongs to them and for which no one else may make claim," says Louis T. Grant, Manager Twelfth District. "Some of them have called for their share, but millions of dollars of the best and cheapest insurance on earth is still awaiting rightful owners who for the most part do not know about it.

"In disseminating this information we have heretofore confined our efforts to ex-soldiers' organizations such as the American Legion, Veterans of Foreign Wars, Disabled American Veterans, etc. Now we find that our most thorough endeavors through these channels do not reach the great body of men we are anxious to get in touch with, for the reason that the majority are not affiliated with these groups. We must try new measures or allow the insurance to remain where it is.

"The thought has occurred to us that with your kindly help and the cooperation of the editors of other house organs published by the larger commercial firms in San Francisco, we can reach thousands of men who have never heard our message. We know from experience that once a former soldier or sailor learns that the insurance policy which protected him during war is held in the archives of the Government and can again be taken up and continued during peace, he is quick to reclaim it."

INTESTINAL PROTOZOA—A REVIEW FROM THE STANFORD MEDICAL CLINIC *

By ALFRED C. REED, M. D., and HARRY A. WYCKOFF, M. D., of San Francisco

(From the Stanford University Medical School.)

During the past year there have come under our observation in the Stanford Clinic of Parasitology and Tropical Medicine ninety-five cases of intestinal protozoal infections. The varieties and frequency of these protozoa were as follows:

E. coli, 56; E. histolytica, 17; giardia, 18; iodameba, 5; chilomastix, 7; trichomonas, 3; E. nana, 6; balantidium, 1.

It is our desire at this time to give a very brief resumé of these cases and the conclusions we have reached, especially with regard to pathogenicity and treatment.

Of the 95 cases, 65 harbored a single intestinal parasite. Thirty had multiple infections. Several were complicated further by the presence of helminths, chiefly trichuris, Bothriocephalis, hookworm, and oxyuris. One Mexican boy of 15 years showed a mixed infection with E. coli, E. hystolytica, iodameba, giardia, and trichiuris. Of the 95 cases, 48 had never been outside the United States, and of these most had lived at least five years in California. The other 47 cases were drawn from twenty different foreign countries, Italy supplying the largest number of 7. Thirty-one cases were females and 64 males. The age incidence was not significant. Sixty-three cases, or 66 per cent, presented a history of gastro-intestinal disturbances. Of these 63, 36 had associated some other unrelated definite disease condition. Of the 32 in whom no history of gastro-intestinal abnormality was found, 1 each suffered from asthma, cancer, Detel's crisis, bronchitis, diabetes, venereal disease, malaria, and Addison's disease. In three each the outstanding difficulty was hypertension and psychosis. Eye, ear, and throat disorders claimed a total of 7; heart disease, 5; and Type II arthritis, 6. Thus 32, or 33 per cent of all the cases, were discovered in the course of a general complete examination for some condition not referred to the gastro-intestinal tract. In these 32 cases the relation of the parasite to the clinical condition present is of considerable interest. Twenty of these cases were cured of their protozoal infections by treatment. In each case where the protozoa were eradicated, a definite clinical improvement in the patient was noted. This was in the group where no gastro-intestinal disturbance was found, past or present. Only one inference can be drawn. There must have been some pathologic effect of the protozoa on their host. In only a few cases could one assume any direct relation between the protozoa and the pathology present. In most it seems that the presence of the protozoa tended to decrease the resistance of the host to the major disease condition present and the removal of this intestinal handicap improved the vitality and the reaction against whatever other pathologic factors were present.

Of the total 95 cases, 15 suffered from Type II hypertrophic arthritis. These have been discussed elsewhere. No characteristic or remarkable findings were noted in the blood counts. A blood count was made on each. So far as red cells and hemoglobin was concerned, 53 were normal and 42 anemic to some degree, none severe. In 14 cases the eosinophil count exceeded 3 per cent. In these 14 the average eosinophilia was 6.7 per cent.

The association of constipation or diarrhea with the parasites was interesting. Of the 95 cases, 46, or 48 per cent, reported normal regularity of bowel movements. Diarrhea was predominant in 13, or 13 per cent, and marked constipation was the rule in 36, or 41 per cent.

CONCLUSIONS

From the study of this series we have drawn three general conclusions:

1. In no case can it be said with safety that the presence of intestinal protozoa is not of pathogenic importance. This statement is made irrespective of the variety of protozoan. In nearly every

* Presented to the Section on Medicine at the Fifty-second annual session of the California Medical Association.

case there is present either pathology or symptoms which can be related logically in some connection with the protozoan infection. The presence of the protozoa seems to constitute an added handicap in the reaction of the host to other and unrelated disease conditions. With this handicap removed, a better fight is waged against other morbid factors. The corollary of this conclusion is that intestinal protozoa are at least potentially pathogenic. At another time we will discuss the detailed pathogenicity of E. coli including the so-called Councilmania type. The variation in pathogenicity between E. histolytica and the less dangerous flagellates, such as trichomonas, need not be any greater than the actual variation in pathogenicity of E. histolytica in different hosts and under varying circumstances.

2. The only pathognomonic or even seriously suspicious indication of the presence of a protozoan intestinal infection is furnished by the microscopic demonstration of the organisms in the stools. Calling to mind the occurrence in our series of such a marked disproportion between gastro-intestinal and diarrheic symptoms and the presence of protozoa, it is evident that no clinical observation of any sort will furnish the clue to the presence of protozoa. Every patient suffering from gastro-intestinal disturbance should be examined for protozoa. Every case of obscure or incomplete diagnosis should have an examination for protozoa. And to these we might add, every patient with chronic diseases which are resistant to treatment, should have an examination for protozoa. For clinical purposes, a patient cannot be said with reasonable certainty to be free of protozoa short of six stool examinations by a competent examiner on six different days, including specimens following epsom salts.

3. Our experience has gradually led us to a fairly routine and standard type of treatment. Many drugs and methods have been tried out. We are now engaged on the investigation of better methods for the treatment of flagellates. At present they are ordinarily almost incurable except by persistent and severe measures. In our series among those patients who received a full course of treatment and where at least two months have elapsed with cyst-free stools, we find the eradication of E. coli in 12 cases, E. histolytica in 9 cases, E. coli (Councilmania type) in 11 cases, giardia in 8 cases, and chilomastix in 1 case. For amebas we feel that cure can be considered established if the stools remain cyst-free for two months following the termination of treatment. In the case of flagellates this limit is not sufficient. In one of our cases of giardia, cysts reappeared after an absence of five months. The criterion of cure in flagellate infections is still indefinite.

Our standard treatment for all intestinal protozoa is as follows: Ten daily hypodermics of emetin hydrochloride, 1 grain each. These are followed by pills or powder of bismuth emetin iodide, 3 grains daily, to a total of 40 grains. At the same time three full doses of neosalvarsan are administered at weekly intervals. In the case of flagellates as well as in long-standing cases of E. histolytica infections, massive colon irrigations are frequently added, using 1:2000 thymol or quinin, and later, oil enemas containing camphor, aristol, and similar anti-parasiticides.

Carbon tetrachloride has been carefully employed in moderate as well as large dosage, and has proved useless for protozoa and cestodes. We have found its only value to be against nematodes. Incidentally, we have found that 15 cc. of carbon tetrachloride given in an iced diluted emulsion is quite safe when the liver and kidneys are fairly normal. Two types of reaction occur with this drug. First, that associated with direct irritation of the stomach. Second, that which is characteristic of chloroform poisoning, either immediate or delayed. One man, a Spaniard with hookworm, inadvertently received 35 cc. of carbon tetrachloride. Within two hours he suffered a severe chill, an epilepti form seizure, severe vomiting, and then somnolence. His recovery was complete, but the hookworms were not removed.

Following the standard treatment outlined above, a certain number of patients will develop mild symptoms of emetin poisoning, and the course of treatment must be modified accordingly. The commonest symptoms of this sort are weakness, especially of the lower extremities, breathlessness, and undue tiring. Some patients are intolerant of bismuth emetin iodide, and vomiting can only be prevented by varying the method of administration.

Considering the wide prevalence in California of protozoan infections of man, the wide dissemination of cysts by persons who act as carriers, and the pathologic importance of the parasite for clinical medicine, we believe more detailed attention to them by the physician in general would be justifiable.

350 Post St.

DISCUSSION

Roy W. Hammack, Pacific Mutual Building, Los Angeles—The growing interest in the subject of intestinal protozoa is well reflected in this paper. It is my experience in the laboratory that the demand for stool examinations is rapidly increasing. Yet our knowledge of the pathogenicity of the intestinal protozoa has not grown so rapidly as our knowledge of the occurrence and character of the organisms themselves. We hear every variety of opinion regarding the effect of the protozoa on the host from the one extreme view that only E. histolytica is pathogenic, to the other, that all protozoa are pathogenic. Some enthusiasts even claim to be able to predict from the symptoms of a patient the finding of flagellates in the stool. Studies in pathologic anatomy, while sometimes suggestive, have proven little except in amebiasis. Experimental investigation of the manner of action of these organisms is greatly needed, but unfortunately the problem is a very difficult one.

Such a study and critical review of a large number of infections as presented in this paper is a real contribution to our knowledge of protozoan infections. The authors' conclusions are, I believe, sound and conservative; yet one cannot help wishing for more detailed evidence in their support. Particularly is this true of the statement that "In nearly every case there is present either pathology or symptoms which can be related logically in some connection with the protozoan infection."

Alfred C. Reed (closing)—Hammack's point is well taken. In an earlier paper we had discussed this in more detail, and at this time, for the sake of brevity, merely state our conclusions. It is our belief that the lines needing special investigation are chiefly two: First, improved treatment of all the

intestinal protozoa. Second, definite information as to their individual pathogenicity. Our ideas on this subject have been elaborated elsewhere.

Harry A. Wyckoff (closing)—It is indeed true that our knowledge relating to the pathogenicity of intestinal protozoa is very imperfect.

We have endeavored, in another place, to collect some facts in this connection, with a view to establishing a nucleus around which the results of further observation might be grouped. The present paper is the record of an attempt to utilize clinical material in carrying out this plan.

EFFECT OF STRUCTURAL CHANGES IN THE LUMBAR AND PELVIC REGIONS ON THE SCIATIC NERVE *

By HALBERT W. CHAPPEL, M. D., Los Angeles

Malformation, disease, or trauma of the lumbar spine or pelvis, may cause motor or sensory symptoms along the entire course of the sciatic nerve, or in a very limited area supplied by it. The lumbar vertebrae, five in number, are the largest of the movable vertebrae, the body having a greater diameter transversely than from before backward, with short thick laminae, a spinous process which projects horizontally backward, and slender transverse processes extending directly outward. The articular processes are thick and strong, and their articular surfaces are vertical, the superior, concave, look backward and inward, while the inferior, convex, look forward and outward. The movable vertebrae are joined together by elastic discs between the bodies, by synovial joints between the articular processes, and by strong ligaments. The fifth lumbar vertebra is joined to the first sacral vertebra by anterior and posterior ligaments of the bodies, capsular ligaments of the articular processes, the ligamenta subflava of the arches, supraspinous and interspinous ligaments, and by an intervertebral disc. The lateral lumbo-sacral ligament, and the ilio-lumbar ligament also add to the stability of the lumbo-sacral synchondrosis.

The sacrum, situated just below the last lumbar vertebra and articulating with it, in the adult is the union of five vertebrae. It also articulates laterally with the ilii, forming a complete joint with cartilage, synovial membrane ligaments, and supporting muscles and having slight but real motion of a sliding type. Inferiorly, the sacrum articulates with the coccyx. The ilium, together with the os pubis and ischium form the innominate bone and with its neighbor of the opposite side complete the bony formation of the pelvis.

The line of weight bearing, which passes to the innominate bones through the lumbar vertebrae and sacrum, is not a vertical one, and in the erect posture there is a constant tendency for the fifth lumbar vertebra to sag forward and downward on the sacrum, being prevented normally by muscular and ligamentous action, and by maintaining the normal curves of the spinal column.

The sciatic nerve, the longest and most widely distributed in the human body, originates in the fourth and fifth lumbar roots and the first, second, and third sacral roots, the branches from which form the lumbo-sacral cord, uniting at the level of the sciatic notch. Passing around the ischial spine, it descends in the posterior part of the buttocks between the ischium and great trochanter, to and down the posterior aspect of the thigh, becoming superficial at the upper end of the popliteal space, where it divides into the external popliteal and internal popliteal nerves which supply the motor and sensory regions below the knee. The sacral plexus and its branches before uniting to form the sciatic nerve, lie very close to the lower lumbar spine, the lumbo-sacral articulation and the sacro-iliac synchondrosis.

Congenital variations of the sacrum and fifth lumbar vertebra are quite common. A fifth lumbar vertebra or a first sacral vertebra, normal on one side, may closely resemble the normal first sacral vertebra or fifth lumbar vertebra on the opposite side or the same development variations may be present on both sides, making it difficult to differentiate between the lumbar and sacral types of vertebrae.

Changes of the articular surface in the lumbo-sacral joint or joints, from the normal vertical to a horizontal axis, cause a chronic inflammation, and thus a thickening of the structures supporting those joints.

Occasionally the coalescence of the laminae is not completed, leaving a cleft in the arches of the vertebrae through which there may be a protrusion of the whole or a part of the spinal cord. This malformation is known as spina bifida, and is considered by many to be the most common of all congenital abnormalities of the vertebral column. A very important form is spina bifida occulta, where the laminae have just failed to meet and the membrane over the opening is strong enough to resist the intraspinal pressure. Frequently this form never gives symptoms, but troublesome claw feet, weakness of the lower extremities, and trophic disturbances developed after a few years and are believed to be directly caused by it.

A fifth lumbar vertebra situated abnormally low, especially when one of its transverse processes impinges on the ilium, a wedge-shaped fifth lumbar vertebra causing an abrupt lateral deviation of the lumbar spine with marked rotation or a congenital absence of the sacrum are sources of irritation to the lumbo-sacral cord.

Ryerson reported a case of recurrent spondylolisthesis with paralysis of the spastic type. He says: "It is quite true that it is not easy to constrict the spinal canal at the level of the fifth lumbar vertebra, but it can be done, and I can think of no other method by which this little girl's paraplegia could have been caused." From this it would seem possible to have a forward and downward displacement of the fifth lumbar vertebra on the sacrum sufficient to give pressure symptoms of the sciatic nerve. In nearly every case of true spondylolisthesis, there is a congenital malformation of the fifth lumbar vertebra, usually a non-fusion of the laminae, which makes it more prone to dislocation than that of a normally formed vertebra.

* Presented to Section on Anatomy at the Fifty-second Annual Session of the California Medical Association, San Francisco, June, 1923.

Structural changes of the lumbar spine due to necrosis of the bones and collapse of the bodies of the vertebrae in Pott's disease are rarely the cause of the nerve symptoms. Pressure on the cord and nerve roots from the inflammatory material, mostly granulation tissue and thickened spinal membranes, slowly produces sensory and motor symptoms along the entire course of the sciatic nerve. An abscess, which usually follows the course of the psoas muscle, not only relieves the pressure symptoms, but removes the broken-down granulation tissue and carious bone from the diseased area.

Tumors of the lumbar spine and pelvic region rarely exist without producing symptoms of the sciatic nerve. When the bone is involved structural changes are marked, and nerve tissue is destroyed very rapidly.

Osteoarthritis involving the lower lumbar vertebrae, the lumbo-sacral articulation, or the sacro-iliac joints, is a very common cause of sciatic nerve symptoms. Although the Roentgen ray usually reveals osteophytes varying in size from the minutest roughening to well-developed spurs, or even bony fusion of two or more vertebrae, it occasionally fails to show any abnormality which can be demonstrated by means of the Roentgen ray. Recent literature has reported the presence of osteophytes on the bodies of lumbar vertebrae at autopsy that did not show in clear roentgenograms of the same region taken shortly before death. It is not only the pressure from the osteophytes, but the inflammation which stimulates their growth that irritates the nerve roots. Very minute structural changes may be responsible for severe nerve symptoms.

Traumatic separation of the symphysis pubis, as from a forceps delivery, gives a corresponding twist at one or both sacro-iliac joints, with pressure symptoms of the sciatic nerve. The inflammation resulting from subluxation of the sacro-iliac synchondrosis frequently irritates the sciatic nerve, although all the symptoms may be confined to the region of that joint.

Fracture of the bodies of the lumbar vertebra usually does not affect the sciatic nerve. Rarely an excess of callous impinges on the nerve roots. When the neural arch has been fractured, motor and sensory disturbances of the lower extremities are quite common.

Because of the close proximity of the lumbo-sacral cord to the transverse process of the fifth lumbar vertebra or to the lateral lumbo-sacro articulation, fracture of either usually produces enough callous to cause marked irritation to the sciatic nerve, and occasionally partial or total paralysis. Again, there may be no effect on the sciatic nerve when there was not only complete destruction of the fifth lumbar vertebra, but the transverse processes of all the lumbar vertebrae on one side were fractured and widely separated from the bodies, and the lumbar vertebrae sharply rotated. One month after the accident this patient was allowed to walk without spinal support. Nerve symptoms developed, which disappeared soon after rest in the recumbent position was resumed. Later a Hibbs' spinal fusion bridged the space between the fourth lumbar vertebra and the sacrum and completely stabilized the lumbo-sacral articulation.

As injury to the sciatic nerve from direct pressure or irritation from inflammation near it may produce paralytic, neuritic, neuralgic, and causaligic syndromes, a thorough clinical and X-ray search for structural changes in the lumbar spine and pelvic region should be a routine in every case of sciatic nerve symptoms.

134 South Norton Avenue.

DISCUSSION

Harold H. Hitchcock, M. D. (1906 Franklin Street, Oakland, Calif.)—The vicious habit of standing, as so many people do, with their pelvis tilted forward, their abdominal and gluteal muscles relaxed, and their lumbar lordosis greatly increased, together with anomalies of the articulations between the last lumbar vertebra and the sacrum, as pointed out by Goldthwait, I believe are great factors in making low backs less stable. It has not been my experience to see failure of union of the posterior laminae in spondylolisthesis. The failure of the laminae of the last lumbar vertebra to unite is a very common anomaly, and I believe it a coincidence when seen in spondylolisthesis. The variations in the articular facets are of more importance as a factor predisposing spondylolisthesis.

As in hip disease, referred pain is often felt in the knee, so I believe that much of the sciatic pain seen in patients with low back trouble is referred pain from either a lumbo-sacral or sacro-iliac lesion, and that the sciatic pain is not often caused by direct pressure on the sciatic or the nerve roots composing it.

Henry H. Lissner, M. D. (Brockman Building, Los Angeles)—It is not my intention to belittle the more recent advances made in the study of the causes of backache and sciatic pain, but it is my purpose to call attention to the usual psychological stimulus attendant upon all of the newer developments, in either medicine or surgery, and to warn against an ultra enthusiasm which leads the medical mind into a blind alley. Of course, not every backache, following trauma or otherwise noted, is due to spondylolisthesis; and not every pain in the region of the sciatic nerve or referred along its anatomical distribution is due to disease or inflammation of the nerve itself.

From the diagnostic standpoint we must consider conditions within the nerve, the effects of toxic absorption, and conditions without the nerve, which may cause pressure upon it to produce symptoms referable to it.

Sciatica per se is too well known to discuss in extenso. One point must be considered, namely, if there is localized atrophy of a group of muscles, it is suggestive that there is something more than a simple sciatica or neuritis at work. One must also be satisfied that there is no disease in the hip-joint, pelvis or spinal column which could give rise to symptoms.

Rectal and vaginal examinations should be made to be sure that no pelvic inflammatory or malignant mass is pressing, or that a retroverted uterus is not causing the trouble. Tuberculosis, gumma or malignant disease of the lumbo-sacral vertebra may produce pains resembling sciatica. A careful study of the urine and blood should be made for sugar, since double sciatica is not at all uncommon in diabetes.

Every man should investigate the action of the sphincters and palpate carefully the pelvis and spine, make rectal and vaginal examinations in all patients whose symptoms conform to a sciatic involvement and should have X-ray studies made, both antero-posterior and lateral views, after all other conditions have been excluded from the diagnostic standpoint.

Finally, don't let the X-ray examination be the

first step toward the diagnosis of conditions involving the lumbar and pelvic regions.

Maynard C. Harding, M. D. (Timken Building, San Diego)—Doctor Chappel has given us a surprising amount of information in a very condensed and understandable form. I wish to comment on only two points. The first is, why should injuries to the lumbo-sacral and sacro-iliac joints give pain in the sciatic distribution? In the first place, the typical radiation of sacro-iliac pain is down the back of the thigh to the popliteal space. This is the skin distribution of the small sciatic nerve, not of the great. It is inconceivable to me that the very slight gross movement which takes place in the ordinary sacro-iliac subluxation can cause actual damage by pressure or stretch. We must look for the origin of the nerve supply for explanation.

The sacro-iliac joint is supplied by twigs from the superior gluteal nerve, which arises from the fourth and fifth lumbar and first sacral nerves. Also by unnamed twigs of the sacral plexus arising at the same level. It receives another innervation from the primary posterior branches of the first and second sacral nerves. The skin covering this area is usually a seat of pain in sacro-iliac conditions, and is also supplied by the same primary posterior branches. The small sciatic arises from the posterior cords of the second and third sacral nerves. I believe it is this close segmental relation of these nerves which accounts for the distribution of pain.

My other point concerns the differential diagnosis between sciatic pain from sacro-iliac injury, and from toxemia, and inflammation.

In sacro-iliac slip the pain comes suddenly, it may go suddenly, or persist as a soreness a day or more after relief of the cause. There is rarely localized tenderness along the nerve, and never severe. There may or may not be a positive Kernig. In toxic pain, the pain comes more gradually. It pains in all postures. It is not relieved suddenly. Tenderness is moderate. There is usually a Kernig. In true inflammation the onset is gradual, and the relief is gradual. There is pain in all postures. Tenderness is marked, and the Kernig is marked and very painful.

Doctor Chappel (closing)—Since a discussion of all the causes for low back pains and sciatica would open up the whole realm of medicine and surgery, and as I fully appreciated that many conditions, aside from structural changes in the lumbar spine and pelvic region, may cause irritation to the sciatic nerve, I purposely limited the contents of this paper to causes which are frequently overlooked when determining the etiology and outlining the treatment for sciatica.

Standardizing Reform—We should say that the trouble with the hygienists is that they are obsessed with the idea of standardizing the people with respect to keeping well.

It is one thing to reform rigorously our spelling and set up correct and fixed orthographic standards, but when it comes to reforming human beings it should be borne in mind that some folk ought to be beguiled into what would be sinful and damaging for others.

But alas! the professional reformer can never be induced to see problems from such an angle.

We are today so much in the hands of narrow propagandists of all kinds that there is absolutely no chance of rational procedure. Therefore, any further material reduction of our mortality rate, much as we should wish to see it, is hardly to be looked forward to with any assurance. If it does come about, it will be because of more or less fortuitous determinants.—Editorial, The Medical Times, November, 1923.

TRAUMATIC SYNOVITIS OF THE KNEE, ACUTE AND CHRONIC*

(A Review of the Literature.)

By RUDOLPH L. DRESEL, M. D., San Francisco

In this paper I have tried to limit myself to the purely traumatic affections of the knee-joint, not those due to disease such as tuberculosis, hemophilia, or infectious arthritis, or those due to strain, such as so-called villous arthritis, which might influence the existing lesion.

Anatomy—The knee-joint is a hinge-joint, with some slight degree of ant-posterior motion as well as some slight rotation. It depends for its strength on its ligaments and on its muscles. It has two articulations, femoral-tibial and femoral-patellar. There is a capsule thickest behind and thin at the lateral aspects of the patella. There is an external and internal lateral ligament and two crucial ligaments. The tendon of the biceps strengthens the outside of the joint and reinforces the external lateral ligament. The ligament is separate from the capsule except behind, and it is separate from the external semi-lunar cartilage by the tendon of the popliteus muscle, and a bursa. The capsule mingles with the periosteum, reaches in front as the quadriceps pouch around as high as the lateral tuberosities, and in back one cm. above the cartilage covering the condyles, attached around the articular surface of the patella and down slightly on the sides of the tibia. On each side there are strong bands running from the condyles to the patella, the vasti and the fascia lata. The heads of the gastrocnemius, and some fibers of the tendon of the semimembranosus help to strengthen the capsule. The internal lateral ligament is very closely attached to the capsule and only artificially separated from it. The vastus internus fibers are inserted low enough on the internal capsule to cause in certain positions of the knee-joint, and under certain conditions of muscular contraction, a distortion of the internal capsule and the semi-lunar cartilage attached to it.

In traumatic affections of the knee-joint it is important to keep in mind the difference between the internal lateral ligament and the external, and the difference between the internal semi-lunar and the external, which maks considerable difference in the susceptibility for injury to the joint.

The external semi-lunar joins at its posterior horn to the posterior crucial ligament. There is no more than one centimeter between the two horns. The coronary ligament connects the cartilage to the tibia, it is not very strong and allows some motion, that on the outer semi-lunar being 2 centimeters in front and 2.5 centimeters in the back, thus allowing fairly free motion. The popliteus muscle separates the cartilage from the external lateral ligament.

The internal semi-lunar is C-shaped and has no definite attachment in front. It is sometimes free and at other times it is attached to the rough sides of the tibia at no particular point. The peripheral border of the internal semi-lunar is attached to the internal lateral ligament, the posterior horn is at-

* Presented to the Section on Orthopedic Surgery at the Fifty-second Annual Meeting of the California Medical Association, San Francisco, June, 1923.

tached to the tibial facet of the spine, the coronary ligament is short, not more than 0.5 cm. long (Piersol).

The crucial ligaments are the strongest in the knee, the anterior arises just in front of the spine close to the external semi-lunar, running backward, upward and outward to the back of the inner side of the external condyle. The posterior crucial is the stronger, arises from the back of the groove of the tibia at the posterior aspect and passes forward and upward to the inner side of the internal condyle. This leaves the spine free and covered by synovial membrane.

The posterior ligament of the ligament of Winslow is an especially thickened portion of the capsule which helps only preventing hyperextension of the joint. It is directed upward and outward to the inner border of the external condyle, and is joined by an expansion from the insertion of the semi-membranosus.

The synovial membrane is closely connected with the capsule, separated only by a layer of fat or fat-pads. Of these the most important are: The subpatella, extrasynovial but intracapsular, about the front and top of the tibia. This pad stretches out on either side as the alar ligaments reaching to the semi-lunar cartilages. The ligamentum mucosum, of small importance, runs from the patella to the top of the intracondylar notch. The joint is freely connected with the quadriceps-pouch and less freely with the popliteal-pouch because of the crucials and the fat-pads.

There is a bursa under the patella tendon, which practically never communicates with the joint. Laterally, there is a bursa between the external lateral ligament and the tendon of the popliteus, and another between the ligament and the tendon of the biceps. This bursa generally connects with the joint. In back there is a large bursa beneath the inner head of the gastrocnemius, and this sometimes connects with the joint later in life.

Mechanism—The tibia normally is rotated outward to a slight extent in extension. Further rotation outward is resisted by the internal lateral ligament, probably not the crucials to any extent. Inward rotation is resisted by the external lateral ligament and the anterior crucial. Adduction is limited by the external lateral ligament and the posterior crucial. Abduction is limited in the fully extended position by the internal lateral ligament; in flexion by the internal lateral ligament and the anterior crucial. The anterior crucial is quite tense in extension; the posterior in flexion. In other words, the posterior crucial prevents displacement of the femur on the tibia, when as in alighting from a leap, the whole weight is carried forward, the knee being flexed. The greatest help in the stability of the knee, and over which we have more or less control, is the tone of the quadriceps muscle and its expansions. Thus, there may be injury to the internal lateral ligament, and in further abduction the anterior crucial may be torn. A displacement of the internal semi-lunar cannot be unless the internal lateral ligament is stretched or ruptured. If the internal lateral ligament is torn above the joint the cartilage remains intact on the tibia; if the ligament is torn below the level of the joint, the cartilage will be torn upward and will follow the rotatory motion of the femur. The cartilage becomes displaced, and as the articular surfaces of the joint become separated the cartilage will slip inward and become nipped as the separated bones come together again. It is for this reason that Jones makes the statement that the strength of the knee-joint is proportionate to the strength of the internal lateral ligament. To quote from Edwards of Glasgow, "medial rotation of the tibia on the femur is limited by the tortion of the crucial ligaments, and at its limit by the tensity of the lateral ligament; whereas, external rotation is not opposed by the crucial ligaments, thus supporting the view suggested that the lateral ligaments are the most important group in maintaining stability of the knee.

Pathology—Effusion may occur as a result of a sprain of the internal lateral ligament with or without cartilage displacement. It may be due to damage to the synovial membrane by direct violence with or without ligamentous damage. But the external, lateral ligament is rarely torn, and external cartilage displacement is rare because of its freedom and because of the separation of the ligament by the popliteus muscle.

E. Nichols, in his report on football injuries (1915), had many cases of synovitis of the knee mostly due to twist when legs were caught in a pile. He says, "In many cases it is an index of serious joint injury; in other cases it seems to result from a simple twist. In the cases of simple synovitis, in no cases since 1910 has the knee been fixed in plaster or on a ham-splint. First he uses a long, hot soak and then a compression bandage, this is removed at bedtime, and the knee soaked again and the bandage reapplied. Baking the joint is begun the next day and as soon as the effusion has reached its maximum massage is begun. Most cases of simple effusion without ligamentous damage are able to begin practice on the tenth day. A persistence of the effusion in almost every case is an indication of serious joint trouble.

In cases of semi-lunar cartilage there is invariably a pretty violent acute synovitis. Many, although not all, show an immediate locking of the joint. The subsequent disability varies a great deal, depending apparently upon the position of the torn end of the cartilage. Some players after such an injury may play half a season before there is a recurrence. Other men directly after the injury are troubled with constantly recurring locking of the joint. The semi-lunars were reduced after the Jones method, and fixed by a single strapping over a pad at the internal anterior portion of the joint. This was found better than any apparatus or cross-strapping.

A man with a semi-lunar cartilage displacement was often allowed to play, but he never was a reliable player thereafter. Nichols found ten semi-lunars in 145 knee injuries due to football.

Major Harding, U. S. A., studied seventy cases of acute synovitis of the knee, traumatic, at a camp in the State of Washington. He grouped them as follows: (a) General strain, 40 per cent; (b) In-

ternal lateral ligament, 43 per cent; (c) Internal semi-lunar, 32 per cent; (d) External lateral ligament, 1 case; (e) Periosteal tear, femur, 3 cases; (f) Cracks in the patella, 3 cases.

Internal lateral ligament and semi-lunar cartilage injuries were the most common combinations. Twenty per cent gave a history of previous injury. All cases had effusion and all cases were aspirated. Eighty-seven per cent had bloody fluid, ranging from blood-stained to bloody fluid clotting on exposure. The amount obtained was from 20 to 120 cc., averaging 63 cc. All were cultured and all cultures were negative. All X-rays except three were negative. These three showed cracks in the patella, and three showed what he interpreted as thickened alar ligaments.

In this connection Salmond, in the British Journal of Surgery, 1919, speaks of the occasional unrecognized fractures of the patella border, mostly situated at the outer border of the bone. Generally due to slight trauma, such as a twist from overstepping the curb, very probably due to muscle action. Mostly, the injury was so slight that the patient overlooked it at the time, and came later with the diagnosis of chronic synovitis or arthritis.

In Harding's cases those aspirated had pain averaging one and one-half days; those not aspirated eleven days. He believes the stretching due to the fluid which causes the stretching of the capsule to be a prominent cause of disability and cause of slow recovery. All the cases were baked and when the soreness was gone, massaged, and gotten on their feet and ordered to wear a flannel bandage for about three months. Before they were discharged they were ordered out on walks increasingly long, and if at the end of that time they could walk five miles without recurrence they were discharged.

Mauk (Virginia Medical Journal), in speaking of chronic knee-strain, says that the usual treatment of bandage and bed is the cause of most of the trouble. He believes that in any synovitis the internal lateral ligament is always injured. He uses a tight bandage and a posterior cast for three or four weeks, with a daily massage after three or four days. Later a knee-cage, not a compression bandage.

In a paper in the 1921 Surgery, Gyn. and Ob., Metcalfe, speaking from his army experience at Fort Sam Houston, says he has given up the old approved method of treatment; i. e., rest in bed, compression bandage, heat, and massage.

This method resulted in three to six weeks' treatment with ofttimes recurrence of the effusion as soon as the soldier was returned to duty. Often their complaint was bitter enough that it was necessary to discharge them from the service. Starting in 1916, he aspirated all knee-joints and put the knees up in traction and in extension. During 1916 he aspirated 150 knees and extended them, and with few exceptions the joints became normal and the men ready for work in less than two weeks. It was observed that a knee aspirated immediately showed practically free blood, and in six days bloody serum and in ten days straw-colored serum. In one patient only did he open the knee-joint and express more than twenty loose bodies resembling cartilage and varying in size from a dime to a silver dollar. Examination showed this substance to be fibrin. This patient made a complete recovery after the removal of the particles. Since a knee aspirated immediately showed almost free blood, it was his practice to aspirate after forty-eight hours.

In more than 300 cases treated he withdrew 60 to 100 cc. of bright blood or bloody fluid. Extension was removed after ten days, and the patient was allowed up and allowed to start walking. Return to duty usually occurred after three weeks, and was rarely followed by recurrence. These conclusions are very similar to those obtained by Major Harding. Metcalfe lays great stress on the damage done by the stretching by the fluid and the deposit of fibrin. "Continuous stretching makes for chronic effusion."

Bennett analyzed 750 cases of synovitis of the knee, and found them in the following proportions: Internal derangements, 428; bodies, 24; genu valgum, 4. The rest were due to disease. Bennett agrees that the semi-lunar cartilage, if fractured, is generally torn longitudinally near its attachment to the internal lateral ligament in the middle three-fifths, is left attached at the anterior and posterior one-fifth and the loop thus formed lies in the intercondylar notch. He calls this the bucket-handle type, and claims this to be the most common type of injury.

C. F. Painter, in the U. S. Navy Bulletin, says that the most severe injuries occur in early and in late adolescence. Of these the following are the most common: Internal semi-lunar cartilage; hypertrophied alar ligaments; occasional traumatic bursitis (under biceps tendon). He classes the semi-lunar injuries into two groups—those in which the ligamentous attachments between the tibia and the face of the semi-lunar is torn away and the cartilage becomes mobile enough to permit of catching in the joint, but seldom locking. Second, those, besides having the ligament torn away, the cartilage is fractured. The result is that the free edge of the cartilage flaps in and out of the normal position, and may be detached from its anterior ligamentous attachment for an inch or an inch and one-half. Mostly, the break is at the same place of the junction of the inner and outer third. Continued long enough, this also causes thickening of the synovia and the alar ligaments.

Fractures of the epicondyles may give, clinically, the picture of a ruptured ligament, lateral. There is apt to be sharp synovitis. Good results, except in the formation of joint mice as pointed out by Codman, and these may produce and maintain chronic synovitis.

Diagnosis of hypertrophied alar ligaments is made if after a trauma to the front of the knee there is continuous local swelling on either side of the patella and slightly below it. There is considerable pain or ache in the joint, especially after standing or walking a while.

J. Dubs, in the British Medical Journal, calls attention to the X-ray shadow between the patella and the tibia-femoral joint, found very often in this condition. There is usually marked atrophy of the

quadriceps, with slight grating in the joint on active or passive motion. When the trouble is marked there is often a sensation of pinching in the joint, but the carrying out of the motions is not prevented. In chronic cases there may be an inability to fully extend the joint, but there is no locking or pain. Operative treatment indicated in the chronically irritated ones.

Bicipital bursitis is rare and is purely a traumatic affair. It is due to a strain on the biceps muscle combined with the fact that there is a minute communication between this bursa and the knee-joint. Usually presents as a small tumor beneath the biceps about one-half inch above its insertion into the fibula. Symptoms are pain and tenderness, patients usually limp a good bit. Operative removal indicated as a rule.

FRACTURE OF THE TIBIAL SPINE AND RUPTURE OF THE CRUCIAL LIGAMENTS

Rupture of the Crucial Ligaments—This is a relatively rare condition, always due to an injury of a grave and spectacular nature, caused by a severe direct injury, knee flexed, tibia markedly abducted and rotated inward. The fibers of the internal, lateral ligament are practically always ruptured also. And if the twist is beyond a certain point the spine of the tibia may be fractured either entire or the internal tubercle. The posterior crucial always invariably escapes except in such injuries which are connected with dislocation of the knee. In this connection, one must keep in mind the connection between the internal lateral ligament and the internal semi-lunar cartilage; for instance, should the forces which rupture the cartilage continue to produce further abduction of the knee, the entire strain is borne by the anterior crucial ligament, and later the strain falls on the tibial spine which in its turn may become fractured. Often after operations on the semi-lunar, as Sir Robert Jones has pointed out, the result is not satisfactory probably because there was an injury to the internal lateral ligament and the crucial ligament as well. There has been much discussion and a variety of opinion as to the treatment of this condition. Hey Groves advocates operative intervention in all cases. He has devised a special "tunneling" operation described in the British Surgical Journal 7:505, 1915. But most writers on this subject, especially more recently, do not agree with him. Cotton, Kurlander, Sever, F. Jones, Mayo-Robsen, and Bennet all agree that rupture of the crucial ligament is not so serious as at one time it was credited with being. Very serviceable joints may be expected after injuries of this kind, and the operative methods employed may be counted upon to restabilize the joints with very little surgical risk. It does not seem to them that in the majority of instances the tunneling operations and the transference of muscles or transplants of fascia are necessary. Cotton has operated several cases of this sort in ex-soldiers and has devoted his attention to the repair of the lateral ligaments, especially the internal lateral ligament. Sir Robert Jones, speaking of the Hey-Groves operation, says: "From the mechanical standpoint I think the Hey-Groves operation is incomplete, in that it does not attempt to strengthen the internal lateral ligament. The new fascial ligament has to bear the entire strain in both abduction of the knee and in anterior sliding of the tibia, as well as in the internal rotation of the tibia on the femur. He has modified the operation and reconstructs the internal lateral ligament as well.

All the recent writers agree that a ruptured crucial ligament, when so diagnosed, should be treated by immobilization for a period of at least two months, and this is considered preferable to primary suture. It is best to immobilize in about thirty degrees flexion (thus keeping all torn structures relaxed during healing). Later, they can either be fitted with a knee-cage or, if found necessary, some stabilizing operation can be attempted.

Henderson in the last number of the Archives of Surgery sums up his experience with ruptured crucial ligaments as follows: "In my experience ruptured crucial ligaments have never been the cause of significant chronic mechanical trouble in the knee-joint. Probably the ligament unite and afford stability, or patients are able to get along without them."

In cases of fracture of the tibial spine conservative treatment with the knee in extension or nearly complete extension is indicated; operative treatment is not indicated. Sir Robert Jones recommends that the knee be kept immobilized for at least ten weeks. If later, or in older cases, there is trouble because of excessive callus, this can be removed at operation. Sir Robert Jones cites several such cases in detail.

Posterior crucial ligament tears are exceedingly rare, and the treatment is along the same lines as the anterior crucial tears.

Fractures into the joint give generally fair, sharp synovitis. They are generally caused by direct trauma and involve either the femoral condyles or the internal or external tuberosities of the tibia. If there is much displacement, these patients generally have much arthritic pain afterward; it is, therefore, usually best to cut down upon, and replace the fracture. If there is slight displacement, on the other hand, the results without operation are good, especially if a Thomas splint with a knee flexion bar is used at the end of two or three weeks so as to mobilize the knee. Fractures of the patella and dislocation of the patella, although causing synovitis, does not come under the scope of this paper.

Other causes of purely traumatic synovitis are few in number. They are caused either by trauma or by trauma plus some constitutional disease or from disease alone thought to have been caused by trauma. The most common of these are the loose bodies, i. e., osteochondritis dissecans; hypertrophic arthritis with fracture of hypertrophic spurs and osteochondromatosis. Osteochondritis may or may not be due to trauma; there seems to be considerable divergence of opinion as to that. The articular surfaces of the knee are peculiarly brittle in this affection, and it has been noticed that very frequently the condition is found in both knees. Further, Henderson, Freiburg, and others have called attention to the fact that, in practically all cases the loose body or bodies, seldom more than two or

three, arise from the internal condyle of the femur, always practically in the same place. These facts make it very improbable that the condition is due to trauma. But, of course, the knee-joint is so exposed and so subject to trauma that a history of trauma is almost always given, no matter what the condition.

Fracture of hypertrophic spurs usually give little trouble in diagnosis, and it is only necessary to remember that a hypertrophic joint is very apt to flare up after operative interference, and is also easily infected if opened. So that often, unless there is very definite locking, it is wiser to leave the joint alone and not attempt to remove the loose bodies.

Osteochondromatosis is a condition little understood. There is usually no definite history of trauma. The number of loose bodies are usually quite large, twenty or thirty, or even sixty or seventy. According to Whitelock and Henderson, this condition is probably a developmental aberration due to a misplacement of some of the original cells of the meso-derm, which take on properties later in life not familiar to the normal cells in that situation, but produce cartilage and bone. At any rate, such a knee is subject to frequent recurrent synovitis at the least provocation, and such loose bodies should be removed. It is well to remember that these bodies often lodge posteriorly in the joint, and cannot be reached by the ordinary incision. In approaching the posterior compartment of the joint there are two incisions of choice—the posterior incision devised by Osgood (inner side of vessels above popliteus muscle), and the anterior-posterior incision of Henderson (S G O 33-698, 1921).

Congenital syphilis may give a chronic or recurrent synovitis of the knee-joint, but this is usually symmetrical and in practically all proven cases associated with eye, bone or other pathology. This condition ought not to be a cause of mistaken diagnosis. In the acquired form there is seldom synovitis; if so there may be some synovitis due as far as can be ascertained to syphilitic bone infection at or near the joint, and if these things are not present ought not to affect a traumatic synovitis.

I have carefully read the literature on endocrinology to see if there was any mention of an acute or chronic synovitis of the knee, which might in some way obscure the diagnosis, but can find no mention of any such condition. Bennet of Johns Hopkins and some German writers speak of having observed that occasionally menstrual derangements, if irregular, and especially if delayed at onset, may cause passive effusion into the joint. This is obviously not due to trauma nor ought it to materially affect the course of a traumatic synovitis.

SUMMARY

It is important to bear in mind the intimate relation of the internal semi-lunar cartilage and the internal lateral ligament; also, the relation of both of these structures to the internal crucial ligament.

Furthermore, it is important to remember that the tone of the quadriceps muscle has much to do with the stability of the joint. It is very necessary, as far as it is possible, to keep up the tone of this muscle during treatment.

There seems to be some difference of opinion as to the treatment of acute synovitis. Most writers are dissatisfied with the ordinary methods used, and advise more active treatment such as early aspiration of all cases of severe synovitis, as well as better fixation during the first period while recumbent and more prolonged treatment afterward during convalescence, as well as early and increasing massage and motion without undue strain.

It is very probable, also, that in such cases of knee injury with considerable internal damage accompanied by marked synovitis, the continuation of the synovitis is due to the original severe capsular stretching and not to any latent syphilitic infection or other chronic systemic disease as is so often thought. We are often prone to attribute the cause of these persistent synovitis to a syphilitic infection, even in the presence of a negative Wassermann and the absence of all other signs of syphilis.

It would appear that crucial ligament injuries are not as disabling as has been thought heretofore, and that the damage to the lateral ligaments, especially the internal lateral ligament is the most important thing in this type of injury.

In all cases of fracture into the knee-joint it is important to start early knee motion while the fracture is uniting. This is best done by the use of the Thomas splint with a knee flexion bar.

(177 Post Street.)

DISCUSSION

George Rothganger, 4501 San Pablo Avenue, Oakland—I regard the views of Harding and of Metcalfe on traumataic effusions into the knee-joint as valuable. The practice of early aspiration in such effusions has been his for a number of years. Whatever contributes to the dissemination of this measure, as Dr. Dresel's abstract, aids that much in reducing the number of knee-joints that are permanently injured by the distension of fluid.

The separation of injuries of the semi-lunar cartilage into those with tibial attachments torn and those with fracture of the cartilage is sound for therapeutic reasons. In the latter, removal of the cartilage is the one solution of the injury.

Statements belittling the seriousness of rupture of a crucial ligament are not to be taken too literally. As it is always associated with other injuries because of the extreme violence producing it, and as these injuries when alone may have a satisfactory recovery, the disability must be due to the ruptured crucial ligament.

Ellis Jones, Brockman Building, Los Angeles—Dresel has admirably reviewed the etiology and treatment of traumatic synovitis of the knee-joint. The need of early aspiration of the acute knee-joint cannot be overemphasized; relief of symptoms is usually immediate.

We have not found it necessary to apply fixation apparatus following a simple strain of the internal lateral ligament. A canton flannel bandage or a compression bandage has seemed sufficient, and the heel of the shoe is raised three-eighths of an inch on the inner side to deflect the strain to the uninjured external lateral ligament.

A common sequel to a simple traumatic synovitis is a relaxed and mechanically inefficient quadriceps. Treatment with the Bristow coil will restore the muscle tone more quickly than any other device.

Whereas formerly we were content with massage and relative fixation to produce a capable quadriceps in from four to six weeks after injury, we now find the quadriceps restored within ten days of treatment with the Bristow coil.

The knee-joint is as secretive as the abdomen and it is wise not to be too positive in our diagnosis at a single examination. A badly swollen knee does not permit of the most accurate diagnosis, and our first duty is to relieve the patient, get rid of the effusion by aspiration, and a subsequent examination after aspiration may often give us very reliable information impossible to obtain previously. It is well to remember that, while injuries to the external semi-lunar cartilage are rare, yet when they do occur they may refer the symptoms to the internal aspect of the joint. We have removed two external semi-lunar cartilages, almost entirely detached, in a patient whose subjective symptoms were referred entirely to the inner aspect of the joint.

A common, unrecognized injury is a pinched retropatellar pad. Examination of both knees in a flexed position will show a thickened retropatellar pad and a simple synovitis. Extension exaggerates symptoms and it is often impossible for the patient to voluntarily extend the knee. This inability to extend the knee is often wrongly interpreted as "locking," due to an injury to the meniscus. In the presence of considerable effusion aspiration is indicated and the knee-joint should be fixed in a walking cast in twenty degrees of flexion and with a one-half inch lift in the heel of the shoe. The cast is worn for ten days, at which time the pad is usually found of normal size and the knee-joint symptomless. It is this type of injury which is most common in patients with a mild hypertrophic osteoarthritis, in which the retropatellar pad is always somewhat enlarged and, therefore, subject to injury. Untreated or improperly treated, a simple injury of this type, especially in the presence of a low grade infectious arthritis, leads to synovial hypertrophy, which in turn becomes aggravated by further minor trauma.

A bad twist to the knee may also produce a mild but definite posterior subluxation, hardly apparent to the examining eye. Pain on forced extension referred indefinitely to the hamstrings and instability in walking, a mild effusion without a definite area of tenderness should make us suspicious. Lateral radiographs of both knees confirm the diagnosis. Reduction is best accomplished by forced flexion and counter-attraction under an anesthetic followed by plaster fixation in 30 degrees of flexion.

Beriberi and Rice Neuritis—I think it is proper to conclude that beriberi must be distinguished from rice disease, while a condition which is similar to rice disease may also be found in human beings in Chichiko dyspepsia.

I dare not, however, say that beriberi has nothing to do with a rice diet or with vitamin deficiency in food. It is quite probable that the eating of rice as the main diet may in itself contribute a factor to the occurrence of beriberi, and administering vitamin B may produce good results in preventing or curing beriberi. Therefore, the close connection between beriberi and rice-eating or vitamin deficiency is beyond doubt, and it is evident that rice disease is in itself an avitaminosis; but I wish to emphasize that I cannot agree with the opinion that human beriberi is altogether one and the same with rice disease, as observed in experimental animals.

The real cause of beriberi can probably be explained by admitting one or more factors to the etiologic agents of rice disease in animals. And the determination of this factor will be the most important subject of further investigations in the problems of beriberi.—Mataro Nagayo, M. D., Journal A. M. A., October 27, 1923.

REPORT OF A CASE OF TORULA INFECTION *

By MONA E. BETTIN, M. D., Los Angeles

The torula is a wild yeast and differs from the saccharomyces or tame yeast, in that it neither forms spores nor ferments sugars. It does not produce mycelium either in cultures or tissues. It seems to have a predilection for the central nervous system and does not cause a generalized infection. It destroys tissue by its growth and does not cause a marked inflammatory reaction as is caused by the blastomyces and coccidioides. The coccidioides immitis is much larger than the torula, reproduces by sporulation and on culture shows mycelium, usually affecting joints first and then becoming generalized, with abscess formation in all lesions, usually resulting fatally. The blastomyces reproduces by budding, but on culture also shows mycelium. This organism causes a generalized infection or may affect the skin alone, but there is usually typical tubercle formation, and patients may recover.

The first cases of torula infection in human beings were reported by Stoddard and Cutler of the Rockefeller Institute in 1916. They had two cases, and found four others in the literature. Since then Pierson of San Francisco reported one in 1917, and Evans of Loma Linda reported two in 1922. The patient whose case is now being reported was ill over a period of several months with symptoms resembling those of encephalitis. The spinal fluid, however, showed numerous yeast-like organisms which proved to belong to the torula group. A chronic meningitis was found at autopsy with lesions in the optic thalami and an abscess at the base of the right lung.

The case report of George G. Hunter follows:

This woman was a nurse, about 40 years of age, single, with a history of previous general good health except for gall-bladder infection with operation about one and one-half years previously. The family history is excellent. Father died at 90; the mother at 70 of pernicious anemia. The patient was the fifth of eight children, one having died of tuberculosis at 50, one after an appendix operation; the others are in good health.

The patient was first seen December 18, 1922, and at that time was complaining of excruciating generalized headaches which had been constant and increasing in intensity for a month or six weeks. Of late there has been some nausea and vomiting, but no other subjective neurological symptoms. During the summer of 1922 she went from Los Angeles to her home in Canada, where for several months she experienced periodic recurring severe headaches, something new for her, and also during that time had for a while a discharging ear. Her family noticed during this period that she was very nervous, whereas she had previously been a very placid woman. In October, 1922, she returned to California in fairly good health, the headaches having abated, but shortly thereafter they recurred and were continuous. During the latter part of November and early December she had been under the observation of a careful physician, who had found in her blood, urine, cardio-vascular-renal system, and in the examination of her sinuses nothing to account for her headaches. There had been no temperature during this time and no increase in her

* Presented to the Section on Pathology and Bacteriology at the Fifty-second Annual Session of the California Medical Association, San Francisco.

Brain.

leucocytes. Up until a few days prior to my visit of December 18 she had been caring for herself, was up and about, and did not look upon her condition as a serious one.

Examination at this time revealed a very stiff neck, painful upon rotation or attempted flexion. There was a moderately developed Kernig sign. The deep and superficial reflexes were slightly increased; pupils were midwide, active to light and distance; skin slightly hypersensitive, and the extremity muscles were tender to firm pressure. There was no clonus and no Babinski and no history of sphincter disturbances or cranial nerve involvement. There was a temperature of 99.4, pulse of 88, this being the first record of a temperature above normal. Her mental condition was entirely normal except that she seemed a little drowsy and dull. An examination of the fundi was negative except for perhaps an unusual fullness in the veins.

On December 19 a lumbar puncture was made which revealed a clear fluid under considerable pressure. There were no acid-fast organisms; the Wassermann test was negative.

Upon the findings to date we were of the opinion that the case was either an encephalitis or a tuberculous meningitis, with the former diagnosis the most probable.

The patient was removed to a sanitarium, where for a few days her condition grew distinctly worse. The headaches became more intense, there was considerable nausea and vomiting, and the temperature ranged between 98 and 102. There was very extreme sensitiveness of the skin and in the body generally to movement. About the 25th there appeared to be a remission, temperature returned to normal, she became more comfortable and mentally clear, and it seemed as though convalescence was beginning. This condition continued for a few days, but soon a relapse with recurrence of all her previous troubles occurred, with a good deal of mental confusion and clouding, and at times a very active delirium. At this time she could be roused out of her mental condition and her intelligent attention held for quite a period of time. Her temperature was very irregular, often being higher in the morning than in the afternoon, but never exceeding 101 during this time.

On January 10 she complained of a cloud obstructing her vision, and a moderate neuro-retinitis was observed. The visual difficulty fluctuated for a few days, but very soon she became entirely unable to distinguish light, without, however, any marked change in the fundus of either eye. After the 10th of January her mental condition was such that very little co-operation was obtainable. Lumbar puncture was attempted on two occasions, but due to the intense spasm of the lumbar muscles and the hyperextension of the spine, both were unsuccessful. A general condition of extreme sensitiveness persisted until about a week before her death, which occurred on January 24. At this time her stupor had developed to the degree where complete relaxation with loss of reflexes made it possible to do a successful lumbar puncture, and it was at this time that the true nature of her infection was revealed. Her physical examination so far as the heart and lungs were concerned had been entirely negative throughout until late in the disease, when there appeared dulness with many crepitant rales at both bases posteriorly, which we assumed to be a secondary hypostasis. She had complained of an unusual amount of pain in her lower left chest about the middle of January just before continuous mental stupor developed. There had at no time been any evidence of distinct localization in her neurological symptoms, but rather one of a generalized irritative nature. The fluid drawn just before her death was distinctly opaque, rather whitish in color, with evidence of marked suspension of some foreign substance which proved on examination to be yeast. Fortunately a complete autopsy was obtained.

Although the findings were quite in accord with those found in other cases of yeast infection, the true diagnosis might easily have escaped notice except for the discovery of the torula in the spinal fluid late in the course of her illness.

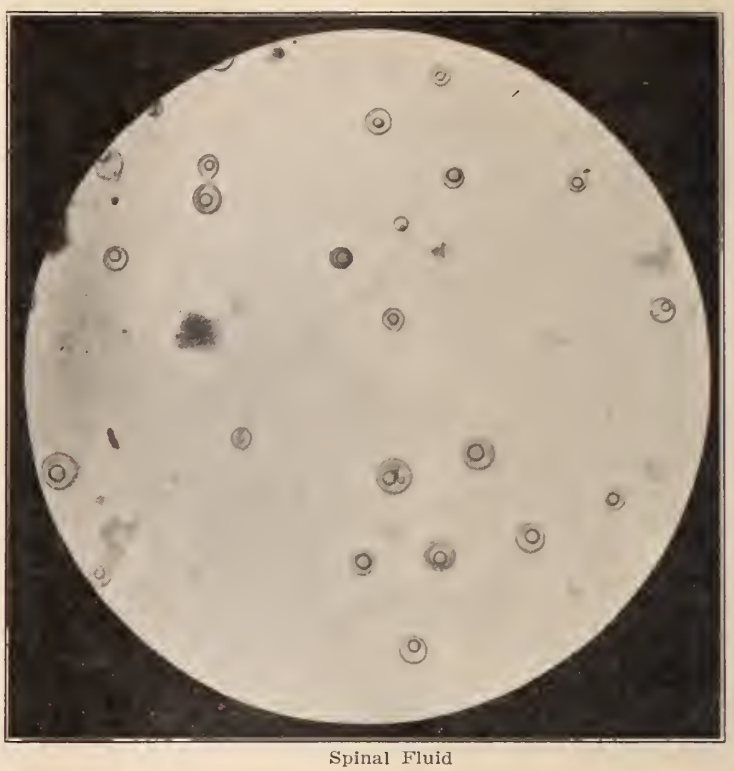
LABORATORY FINDINGS

Examination of the spinal fluid obtained from lumbar puncture December 19 showed 146 cells per cmm.—practically all small mononuclears; globulin test positive; Wassermann test negative, with 1 cc. fluid. No organisms were found in smears, and cultures were negative. The blood count was practically normal. Urinalysis was negative. The second specimen of spinal fluid was obtained January 17, about a week before the patient died. This fluid was cloudy, with a whitish granular precipitate. There was no web formation and no tendency to any agglutination of the particles. Examination showed 64 cells per cmm., with 960 torulae per cmm.; globulin test positive. Cultures on glucose agar showed heavy whitish growth at end of 48 hours; this turned a distinct yellow as it became older. There was no mycelial growth such as occurs in cultures of coccidioides and blastomyces. Intraperitoneal inoculation of guinea pigs was made with this fluid, and the torulae were recovered from fine pin-point blisters on the peritoneal surface. No lesions were found in their brains.

AUTOPSY FINDINGS

Embalmed body of fairly well-nourished woman. Skin surface negative; subcutaneous and retroperitoneal fat abundant—this seemed remarkable in such a prolonged illness. The peritoneal cavity showed no excess of fluid; the peritoneum was smooth. The liver, spleen, pancreas, suprarenals,

and gastro-intestinal tract were negative; kidneys showed cloudy swelling. There was a small nodule on the anterior wall of the uterus, which on microscopic examination proved to be a fibromyoma. Otherwise, the uterus was negative. Tubes and ovaries negative. Pericardium negative. Heart negative, with exception of mitral value, which showed slight thickening along edge of leaflets. Microscopic examination showed this to be made up of a deposit of leucocytes and fibrin. No torulae were found in these sections. Left pleural cavity negative; right obliterated at base. The lower lobes of both lungs showed hypostatic pneumonia. There were dense adhesions between the base of the right lung and the diaphragm. The lung was inadvertently ruptured in trying to get it out, and showed a cavity about 7½ cm. in diameter. This was filled with a gelatinous-like sticky substance. There was no marked zone of inflammatory reaction around this lesion. No other nodules were found in the lungs.



Spinal Fluid

Culture.

The brain was of normal size. The dura was markedly adherent. All convolutions were flattened and the pia was markedly thickened, especially in the sulci. When the meninges were pulled off the brain, numerous shallow pits of pin-head size and smaller were noticed over the surface of the convolutions. The lateral ventricles were not dilated. The ependyma and choroid plexus appeared negative. The ventricular fluid was cloudy and on microscopic examination showed numerous yeast-like organisms. Serial sections of the brain were made in the frontal plane after it had been thoroughly hardened, and showed nothing until the region of the optic thalamus was reached. Here the grey matter of the thalami seemed to be replaced by gelatinous masses made up of spaces connected by delicate threads, giving a honeycombed appearance. There was no inflammatory reaction and no caseation. The fourth ventricle was almost filled by an exudate which seemed to extend into the brain substance. This was especially marked over the roof in the region of the corpora quadrigemina, where there was dense fibrous tissue with calcareous deposits.

Microscopic examination of sections made from the lung lesions showed the alveoli near edge of cavity filled with yeast organisms, some of which showed budding. These organisms were about the size of red blood cells, some of them larger; many of them had a brownish precipitate in the center arranged in a stellate form. Some showed an outer zone, separating them from other organisms. Here and there in the interstitial tissue were collections of round cells. No giant cells were seen. No distinct tubercles were found and there were no areas of caseation. Sections of the lung away from the cavity showed alveoli filled with leucocytes and red blood cells, but no organisms were found there.

Microscopic examination of sections from the meninges showed numerous yeast organisms lying

in vacuoles between the endothelial cells, which were spread far apart. In between were scattered a good many round cells. Some of the blood vessels showed a marked perivascular infiltration of round cells.

Microscopic examination of sections of the brain in the region of the optic thalamus showed the tissue replaced by numerous collections of these same highly refractive spherical organisms. Most of them were surrounded by an outer zone which separated them from each other, but there were very fine threads running between, apparently holding them together. The organisms seemed to have replaced the brain tissue, with no inflammatory reaction whatever. There were a few round cells scattered here and there, but no giant cells were found. Sections in the region of the corpora quadrigemina and cerebellum showed areas containing calcareous deposits, and occasional giant cells with marked increase in fibrous tissue. It was difficult to find any organisms in these sections. Evidently these were healed lesions. The accompanying photographs show the organisms as they appear in the brain tissue, in the spinal fluid, and in the cultures.

ANATOMICAL DIAGNOSIS

Chronic meningo-encephalitis with foci of infection in optic thalami and corpora quadrigemina. Hypostatic pneumonia of lower lobes of both lungs with pleuritic adhesions at right base, and cavity formation in right lower lobe caused by torula. Acute mitral endocarditis; cloudy swelling of kidneys; small fibromyoma of uterus.

The initial lesion in this case was probably in the lung, and the disease was evidently of long duration, as evidenced by the efforts at healing found in the region of the roof of the fourth ventricle. We want to call your attention again to the fact that the diagnosis of such infections may be very easily overlooked and that this disease may be much more common than is generally supposed.

516 Auditorium Building.

DISCUSSION

Philip H. Pierson, M. D. (516 Sutter Street, San Francisco)—I have read with considerable interest the excellent manner in which Bettin has presented this case of torula infection. I would like to emphasize the following points: It is of a great deal of importance to report in as much detail as possible even a single case of this type, for by their accumulation we get very valuable data. The finding of so many torula organisms in the spinal fluid is not common and was probably due to the breaking down of one of these small areas. In any case of questionable meningeal involvement it is advisable to make cultures on glucose agar, as in this case, for when the organisms are present their growth is best watched on such media. I am interested in the fact that old calcified lesions in a healed state were found, for this is further evidence, as I suggested in my report of a case, that the disease may be much more frequent than expected and escape notice. While the pathology of this infection does not bear any direct similarity to that of Virchow's disease, may there not be a stimulation from these calcified meningeal lesions for the overgrowth of the bony structure in Virchow's disease? Perhaps Bettin will answer this in her closing discussion. In one of Cutler and Stoddard's cases which I had the opportunity to see, the portal of entry was the ear in all probability. The same is possibly true in this case, although it may have been directly through the respiratory system. Another point of considerable interest is the difficulty in distinguishing this infection from tuberculosis before death. The meningeal and pulmonary findings could clinically have very well passed for a tuberculous infection. Finally, I want to compliment Bettin on her very thorough presentation of this interesting case.

Newton Evans, M. D. (Loma Linda)—In reading Bettin's paper some points of interest have presented themselves. It is very fortunate in the development of our knowledge of this interesting but little known disease, that in this case it was possible to secure so complete a clinical history of the progress of the disease and a satisfactory autopsy.

All of Bettin's findings are in remarkable conformity to the clinical and pathological findings in the few cases previously reported. One is much impressed by the apparent parallelism, between the clinical history and pathological findings, and by the possible explanation which is afforded for the period of amelioration of symptoms, by the partial healing of the lesion in the region of the fourth ventricle, and later for the recrudescence of the symptom, by the development of the lesions of the optic thalamus.

One cannot escape the impression that possibly if more careful microscopic observation of the fresh spinal fluid had been made at the time of the first spinal puncture reported, the organisms might have been detected at that time, even though the efforts at culture were without results. Experience has shown that a cursory microscopic observation may easily mistake the organisms for lymphocytes.

I am gratified to see this report of an additional type case, which emphasizes the conclusion that we have in the torula infection a clinical entity which is of the nature of meningeal-encephalitis and is of great interest and importance.

Gentian Violet in Staphylococcus Septicemia—Churchman found that gentian violet in 1:1,000,000 dilution will inhibit the growth of staphylococci. A dilution of 1:50,000 has no deleterious effect on white blood cells that have been exposed to it for two hours. A 1:20,000 dilution has no effect on growing tissues. David T. Smith and Horton Casparis, Baltimore (Journal A. M. A., December 29, 1923), have given 10 mg. per kilogram of body weight intravenously to rabbits (calculated dilution in the body fluids of 1:70,000), with no effect except instant staining of the mucous membranes and sclerae. The staining later disappeared. They, therefore, felt justified in injecting gentian violet intravenously into an infant, age 15 months, suffering from staphylococcus septicemia. Staphylococcus aureus had been demonstrated in two blood cultures made during the three days preceding the first injection. There were about ten colonies per cubic centimeter of blood. Three injections of a 0.25 per cent aqueous solution of gentian violet were given at 24-hour intervals. The first dose was 5 mg. per kilogram of body weight. The calculated resulting concentration of the dye in the body fluid was 1:140,000, assuming the fluid content of the body to be 70 per cent of the body weight. The white blood cell count, which was 22,000 at the time of injection, was reduced to 10,000 12 hours later, but returned almost to the original count during the next 12 hours. Because of the possibility that the reduction in the white blood cell count was due to the effect of the dye in that concentration, the amount was reduced, and the second and third doses consisted of 4 mg. per kilogram of body weight. Blood cultures made immediately preceding the second and third injection were sterile. After the third injection the patient's appearance had improved, his fever was reduced, and the white blood count had decreased.

CANCER OF THE ESOPHAGUS IN GENERAL PRACTICE

By GORDON F. HELSLEY, M. D., San Francisco

There is a general conception that carcinoma of the esophagus is a rather rare condition. That this is not exactly true is shown by practically all extensive autopsy series, five of which give 413 cases in 39, 312 post-mortems or one case in 95 deaths. The actual frequency is doubtless somewhat less than this, but certainly esophageal cancer is by no means an unusual disease.

Since at least nine-tenths of the cases are in men, we should expect it to rank fairly high among the tumors of the male sex. It is quite beyond one's expectation, however, to find from an overwhelming list of statistics that in men cancer of the esophagus is exceeded in frequency only by cancer of the stomach.

This being the case it is eminently desirable that every physician be able to recognize a case of this disease. Usually the diagnosis is easy. An adult over 40 years, usually a man, complains of difficulty in swallowing of comparatively short duration. The trouble possibly began quite acutely when he was swallowing a poorly masticated piece of bread or meat. Semi-solids or liquids could be taken as usual, however. Later, even with thorough mastication, solids could no longer be swallowed. Finally, liquids go down with difficulty.

There are several important variations from this history. The complaint may be of vomiting, sometimes quite a while after eating. This regurgitation can be easily distinguished from true vomiting, but often the distinction is not made until after a course of treatment for stomach trouble. The difficulty in swallowing is not always progressive. It may have been but a passing incident, casually mentioned by the patient, or it may have been very severe for several weeks or months, and then disappeared. Although such intermittence is not common, it must be borne in mind. The typical cases are self-diagnostic; it is the diagnosis of the atypical ones which deserves attention.

There are quite a few cases in which there is *no* history of dysphagia. It is not at all unusual for a well-developed cancer of the esophagus to be found at autopsy entirely unexpectedly. Personally, I feel that this is usually due to lack of care in the anamensis, but it goes to show how little evidence there may be from a stenosing tumor.

There are other symptoms of variable importance. Hoarseness may be of definite diagnostic value. The regurgitation of food and saliva mixed with blood and sometimes purulent material is a very ominous, almost pathognomonic symptom. Pain in the chest or epigastrium may be complained of, and rapid loss of weight is commonly mentioned.

Examination notes a gaunt, hungry-looking man without cachexia. Some claim that the appearance is so characteristic that they can make a diagnosis at first sight. The salivary glands often show visible and palpable hypertrophy compensatory to the excessive mastication. The breath is foul, and food remnants may be present in the pharynx. Auscultation over, the cardia shows delay in the esophageal emptying sound. Examination with the laryngeal mirror sometimes reveals paralysis of one or even both vocal chords. Metastasis formation may be found in the cervical lymph glands.

Before a definite diagnosis can be registered, some other conditions must be differentiated. A benign stricture from a corrosive is to be considered, but the history usually decides that. However, I have seen several cases of stricture following corrosion in which no history was obtainable of the patient's having swallowed any corrosive substance. Sometimes this is due to reluctance to acknowledge a suicidal attempt. If the patient is of unsound mind a history is commonly unobtainable. In addition there are cases of corrosive stricture in intelligent patients where there is no knowledge of ever having swallowed anything injurious.

Stricture of the esophagus may be caused by tuberculosis or more frequently by syphilis. Both these relatively rare etiological factors can be partly substantiated or ruled out by a complete history and thorough examination with the appropriate tests, but the only way one can be certain is by microscopic examination of an excised specimen.

Pressure from some extrinsic source, aortic aneurism or mediastinal tumor must be considered and judged by a careful examination. Also a goiter may cause dysphagia, but it must be remembered that the presence of a goiter does not rule out an esophageal cancer. I know of a case in which strumectomy was done to relieve difficulty in swallowing. The operation brought no relief, and a short time later autopsy revealed a cancer of the esophagus.

Cardiospasm, hysterical dysphagia, and esophageal diverticula all have a characteristic history, but are often very hard to differentiate from a neoplasm.

In all these cases of dysphagia it must be strictly borne in mind that carcinoma is the most frequent disease of the esophagus. So Chauffard reports that of 1700 esophageal cases, 1020 were cancers. If the patient is over 40, more particularly if a man, and has symptoms or signs in the least suggestive of cancer of the esophagus, this should be considered the presumptive diagnosis, to be ruled out only with the greatest caution.

It is worth while in every case of chronic disease to ascertain whether or not the esophagus has always properly functionated. The knowledge of a pre-existing, though transitory, attack of dysphagia may give the correct explanation for a putrid bronchitis due to an esophago-bronchial fistula, a diabetes due to pancreatic metastases, or ascites and jaundice due to secondary growths at the liver hilus.

Far more important than accurate diagnosis, from the patient's viewpoint, is the possibility of curative treatment, and this depends on early diagnosis. To this end the same attention must be directed to the esophagus of every patient as is given to the other organs of the body.

If anything indicates esophageal disease one's full diagnostic powers should be brought into play. But whatever opinion one has, it should at once be put to the test of an X-ray examination, both screen

and film, and this before use is made either of a sound or of an esophagoscope. The former has no place in the diagnosis of cancer of the esophagus; the latter should always be preceded by X-ray examination. For all practical purposes the Roentgenological evidence is conclusive. If desired, an esophagoscopic examination can be made for confirmation, and to finally clinch the diagnosis a bit of the tumor can be excised for microscopic examination. This latter procedure is, however, somewhat dangerous in itself and is probably conducive to metastasis formation, so if done at all it should be only as the first stage to a radical operation.

Let us suppose now that the case has been referred back by the Roentgenologist with the diagnosis of probable carcinoma of the esophagus. The patient looks to his physician for treatment.

The proper treatment of any disease is curative, if possible. In a cancer that means removal or destruction of the growth. An authoritative medical system of recent date says: "As carcinoma of the esophagus is a fatal disease surgical intervention with the idea of cure is contra-indicated." The same nihilistic attitude is commonly present throughout the profession, and it makes frequent appearance in the literature. The facts of the matter give considerable justification for such a standpoint. Sauerbruch, with the skill and experience that marks him as pre-eminent in thoracic surgery, has operated 200 cases of cancer of the esophagus without curing a single one. (Personal communication.)

But there is another side to this. There are on record many cases of successful resection of carcinomas of the cervical portion of the esophagus. There have been at least five successful operations on the thoracic portion, but only the case of Torek has stood the test of time and can be considered as a cure. Still, it has been clearly shown that the operation is technically possible.

The chances of finding a tumor which is not too large for resection and which has not metastasized are, or at least should be, better here than in most internal cancers, for it presumably gives its symptoms early and to a remarkable degree is a benignant neoplasm. It has been described as the most benign cancer. At the time when the first symptoms are well established, at the time when the diagnosis should be made, a very large proportion are operable—surely, over half.

Of course, if there is definite evidence of metastasis formation or extensive infiltration, radical operation is not to be considered. The X-ray may show the growth to be so extensive that resection is clearly impossible. If the growth is situated immediately above the aortic arch, it is inaccessible to present surgical technique. The age and physical condition of many patients absolutely forbid a formidable operation.

If none of these contra-indications are present, these cases should be considered proper subjects for operation, providing the work can be done by a surgeon skilled in the necessary technique. The true facts of the case should be explained to the patient and his family; the rapidly fatal course of the disease, the impossibility of cure by any method other than surgery, and finally the faint hope offered by radical operation. There will be found many patients who desire to take this chance.

Then the case should, without delay, be put in the hands of a surgeon. It is important that gastrostomy should *not* be done before the case is referred to the surgeon who will attempt the radical operation, since such a procedure may seriously interfere with his operative plan. With what the surgeon may do and should do we are not here concerned. That interesting chapter is too long to even touch on.

Since the results from operative treatment have been quite discouraging, physicians have grasped at everything else that offered hope for either cure or palliation. Most important of these is radium. There have been many reports of favorable results, particularly from the French, and one case of apparent cure. The general unsatisfactory results and the difficulty of rational application, however, indicate that radium is as little suited to treatment of cancer of the esophagus as it is for other cancers of the alimentary canal. When the final judgment of Forbes, who has had extensive experience with radium treatment, is that, on the whole, the results were nil and that death was hastened, so that he has abandoned its use in these cases, we may well feel that, as a substitute for surgery on operable cases, radium is decidedly unsuitable.

With respect to purely palliative treatment, we have radium and deep X-ray therapy, which seem to be very useful in some cases, useless or injurious in others. Dilatation may be carried on by means of fusiform bougies preferably introduced over a guide-wire, or by laminaria pencils. Other methods of treatment are the installation of inlying canulae, cauterization, and treatment with astringent medication. Except for radiotherapy, these procedures are so unsatisfactory and also dangerous that they do not merit serious consideration. All these local methods of treatment have the disadvantage of accelerating local infiltration and the formation of metastases. Something can be done in the choice of smooth, non-irritating food. It must be borne in mind that the dysphagia is caused in many cases by a spastic contracture more than by tumor obstruction.

When swallowing finally becomes too difficult, we still have left gastrostomy to prevent death by starvation. It is noteworthy how often this procedure fails to prolong life. Forty-two cases which I reported lived an average of twenty-eight days after gastrostomy. This is quite in accord with general statistics on the subject, and would indicate that this is practically a useless operation for these cases. The truth is, however, that, if the gastrostomy were done a few weeks earlier, while the metabolic balance was better maintained and before the patient was thoroughly dehydrated, the statistics would be greatly improved.

It is often necessary to make a prognosis in these cases, and that is very difficult. Every cancer is a law unto itself, and there are most remarkable variations in malignancy. The average duration of life after the first symptoms of carcinoma of the esophagus is reckoned to be about six months. The

careful use of radium and X-ray and a fairly early gastrostomy will probably lengthen this period somewhat. The prognosis must always be guarded. I know of a patient with undoubted cancer of the esophagus for whom nothing whatever was done, but yet eighteen months after his discharge from the hospital he was in apparent good health, with only slight dysphagia. Such cases also force us to accept with reservation reports of apparent cures, by radium for example.

SUMMARY

Cancer of the esophagus is an important disease of the adult male. Careful anamensis regarding dysphagia is important in all cases of chronic disease. If suspicion of esophageal carcinoma arises, the sound should not be used, but the case sent for X-ray. With Roentgen diagnosis of cancer, the question of operability should be considered; if there are no contra-indications and the patient so desires, the case should be put in the hands of a competent surgeon. The lapse of time for all this to be carried through should number days, not weeks or months. If the case is inoperable or declines operation, treatment by radium and X-ray, with eventual gastrostomy, comes into view. The average expectancy of life after the first symptoms is six months.

The success of curative surgery for cancer of the esophagus depends on the co-operation of the medical practitioners, who first see these cases, with the surgeons. As Sauerbruch has said, the delay in having the surgeon see the case is not usually the result of a late diagnosis, but is due to the ruling opinion that the condition is absolutely inoperable. The greatest danger from sounds, radium, etc., is not the direct injury they may cause the patient, but is that patients who should be sent for operation, who would be glad to have operation, are treated by these temporizing methods until the golden hour of operability has passed.

291 Geary street.

DISCUSSION

Edwin I. Bartlett (291 Geary Street, San Francisco)—Carcinoma of the esophagus is indeed a gloomy subject. It would seem that nature has failed to provide any way of escape for the victim. The symptoms appear only in the late stages of the disease: the carcinomatous cells have a tendency to invade longitudinally ofttimes for several inches so that removal of the growth with a fair margin may mean extensive resection: the technical difficulties in the removal of the thoracic lesion, no matter how small, are insurmountable: the disease generally appears in a man who is the only bread-winner of the family, and he has only a few months to live after the disease is discovered.

Discussions of such a subject can have little practical value. There is a phase of this subject, however, as pointed out by Helsley, which is of practical importance, viz., the type of treatment for palliative effect. This should consist of the simplest procedure for supplying food and fluid to the stomach, and in the majority of instances, simple gastrostomy gives the best results. Any attempts at treatment of the local lesion either augment the disagreeable or distressing symptoms or result in death. Radium, which promises so much in the treatment of malignant disease, has failed to destroy the local lesion, has made the patient more miserable, and has brought death more quickly. Radical surgery has no cures to its credit, and nearly every case so treated has died from the operation.

Improper treatment through mistaken diagnosis is such a common error that its mention in this paper bears emphasizing. The danger is not from the fatal delay or from stimulation to growth of the neoplasm. It involves a waste of money and effort, and possibly may result in unnecessary surgery and greater suffering. Carcinoma of the esophagus must always be borne in mind in the presence of symptoms referable to the mediastinum or stomach, and in all instances of disturbance of deglutition and phonation. Any occasion which requires an examination of the larynx or bismuth studies of the gastro-intestinal tract demands careful consideration and close observation relative to esophageal neoplasm.

Dr. Helsley (closing)—It is gratifying to have Bartlett confirm and emphasize some of the most important points of my paper. Particularly, his recognition of the fact that carcinoma of the esophagus is not always self-diagnostic and the reasons he gives why accurate diagnosis is important are worthy of thought.

We occupy irreconcilably opposed positions as to the applicability of radical surgery to this condition. I have seen the case which Torek cured and I know that there could be no more unfavorable location for the tumor than this one, which was successfully removed. Therefore, I feel that the outlook is not without hope and that progress can be made only as medical practitioners displace from their minds the nihilistic attitude which has so long ruled this field.

THE RELATION OF GROWTH TO RICKETS *

By SIDNEY BOWERS, M. D., Los Angeles
(From the Department of Pediatrics, University of Minnesota Medical School.)

Many observers have noted the influence of growth upon the development of rickets. Czerny and Keller state that overfeeding must be avoided as prophylaxis against rickets, even with breast-fed infants. They have not observed florid rickets in underfed infants. Esser believes rickets is due to overfeeding. Mellanby observed that some elements of diet increase growth and allow calcification processes to lag behind. The greater the growth the more necessary it is to have in the diet and absorbed substances which aid in calcifying bone, namely, calcium, phosphorus and anti-rachitic vitamine. When these latter substances are relatively deficient or defective in their action, rickets results. Hess found that those infants were most likely to develop rickets who, in a poorly nourished condition, subsequently thrived and gained in weight. McClendon observed that, during loss of weight, a small amount of phosphorus prevented rickets in rats, while during normal growth a much larger amount was necessary. "Every growth-promoting substance has a rachitic influence when it promotes growth; therefore, every anti-rachitic substance that promotes growth may have two opposing actions." In rats, remaining at stationary

* Read before the Southwestern Pediatric Society, September 5, 1923.

weight over a long period, the phosphorus requirement for building up new tissue is greatly reduced. Under such conditions, the small addition of phosphorus to a standard rickets-producing diet suffices to enable the bone to recalcify, and a spontaneous cure of rickets results.

It was noticed in rats that when strontium replaced calcium in an otherwise satisfactory diet, it stimulated growth and caused the bones to develop the picture of "strontium" rickets. Jundell has treated cases of rickets with relative inanition, and claims excellent results. From the observations and experimental work of numerous investigators discussed above, it would seem as if there was a definite relationship between certain factors of growth and the development of rickets. In an attempt to determine this, the following study was conducted:

PROBLEM

Infants between the ages of six months and eighteen months inclusive were examined. There was no selection of cases except as regards age. The examinations were carried on during the months of August to December, inclusive, 1922. In all 223 cases were examined.

The examination data consisted of the following:

Age, sex, birth weight, present weight, body length, feeding history, when first sat up, when first walked, dentition, presence or absence of craniotabes, size of the fontanel, measurement of any zone of softening in the region of the fontanel, head and chest circumference; the presence or absence of a square type head, of rosary, of Harrison's groove, of chest deformities, of protuberant abdomen, of palpable spleen, or of enlarged epiphyses; the condition of the musculature and the diagnosis. In some cases roentgenograms of the epiphyses of the wrists and ankles were obtained.

The birth weight was gotten from the parents who, in most cases, seemed to have fairly accurate information regarding this. Feeding data was procured from the parents and from the clinic record. Past weight records, as well as the present weight of the infants, was obtained from the clinic records, having been determined by nurses trained in this work. The length was accurately measured with a board especially constructed for measuring the length of infants. Measurements of the fontanel were taken from a traced outline of it, according to Elsässer's method. This consists of measuring the two diameters from the four points midway between the angles, these being added and divided by two. The chest circumference was taken at the nipple-line. The condition of the musculature was graded good, fair, and poor. The positive signs were graded one, two, and three plus, as was also the diagnosis of rickets. This was carefully considered in every case. At this time it would be well to mention a few important points in consideration of the diagnosis of rickets.

Hess and Unger place beading of the ribs as the most reliable of the immediate clinical signs in the diagnosis of rickets, with the disadvantage that it does not differentiate between the active and inactive phases of the disorder. A negative roentgenogram does not rule out early rickets. The inorganic phosphate of the blood is generally diminished in the early stages of rickets, but this is not pathognomonic. Schwarz concluded, from a study of craniotabes in infants, that at least during the first six months, rickets could not be diagnosed on the basis of this sign. Park has reported the types of costo-chondral junction, which may occur in rickets. Numerous investigators, among whom are Baetjer, Jacobson, Albert-Weil, and Giles have contributed data on the Roentgen-ray diagnosis of rickets.

In the present study, roentgenograms were taken of the epiphyses of the wrists and ankles in 94 cases. Of these cases, 32 were rachitic, although the roentgenogram was only definitely positive in 17 of these. Of the 223 infants examined, there were 69 cases of rickets, or 30.94 per cent. There were 103 female infants with 32 cases of rickets, or 31.6 per cent, and 120 males, with 37 cases of rickets, or 30.83 per cent. A classification of the cases according to age in months and sex, with the number of cases of rickets in each, is shown in Table I.

TABLE I

Age in Months	Males		Females		Total	
	No. of Cases	Cases of Rickets	No. of Cases	Cases of Rickets	No. of Cases	Cases of Rickets
6	21	9	14	5	35	14
7	29	6	11	1	40	7
8	10	4	14	4	24	8
9	11	5	11	2	22	7
10	8	2	10	1	18	3
11	5	0	5	2	10	2
12	4	0	8	3	12	3
13	9	4	5	1	14	5
14	4	1	8	4	12	5
15	5	3	6	3	11	6
16	3	0	5	2	8	2
17	6	2	2	2	8	4
18	5	1	4	2	9	3

Feeding—The feeding history was obtained in 219 cases. Of these 170 were entirely breast-fed for six months or more, except for the addition of cereal in the fourth or fifth month in a few cases. There were 52 of these with rickets, or 30.58 per cent. There were 34 infants that were breast-fed less than six months, most of these having had a subsequent feeding of a cow's milk mixture. There were 15 infants partially breast-fed for more than six months, 13 having had complemental feeding, and 2 supplemental feeding, consisting of a cow's milk mixture. This made a total of 49 cases based partially or entirely upon artificial feeding. There were 17 cases of rickets among these, or 34.69 per cent.

Most of the 219 cases when six months old had cereal added to the diet, vegetable when seven months, and orange juice in a large number of the cases by the third or fourth month. All cases in which rickets was diagnosed, with the rosary as the only definite sign, had received some anti-scorbutic in the diet for some time previous. Most of the breast-fed infants were entirely weaned by the

tenth or eleventh month. An outline of the feeding is shown in Table II.

TABLE II

219 Cases with Feeding Data
170 Entirely Breast-fed 6 Months or More—52 of These Rachitic, or 30.58 per cent

Breast-fed Less Than Six Months

Time B. F.	No. of Cases	Cases of Rickets	Later Feeding: No. of Cases	Feeding	Cases of Rickets
			9	Cow's milk mixture	0
1 mo. or less	10	0	1	Protein milk	0
			5	Cow's milk mixture	1
2 mos.	6	2	1	Malted milk	1
			9	Cow's milk mixture	5

December	12	4	33.33	11	5	45.45	23	9	39.13

GROWTH

The factors considered under growth were weight, length, ponderal index and rate of growth. Curves were plotted from Baldwin's figures on the growth in weight and length of normal infants, both male and female. These are shown in Charts 1, 2, 3, and 4. Ponderal indices were computed from Baldwin's figures according to the formula

$$\text{(ponderal index) PI} = \frac{\text{(weight) W} \times 1000}{\text{(length) L}^3}$$

Curves were plotted for the same.

Figures of normal deviation were then computed from the normal curves by the semi-quartile method. This allows a 12½ per cent deviation above and also below the normal curve for normal deviation. These curves were plotted on each chart.

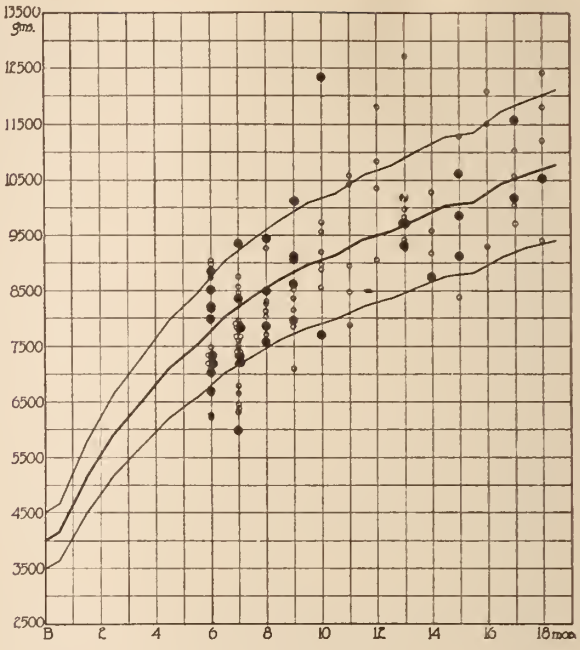

Chart I—Weight, Males

The figures of the cases included in this study were then entered about these normal curves, respectively, according to sex and the factor considered.

It will be noticed in Charts 1 and 2 that the cases in general compared well with Baldwin's normals in weight. Charts 3 and 4 show that, in length, they fell somewhat below those of Baldwin, while regarding ponderal index, Charts 5 and 6 show that they were somewhat above his, although, in general, were within the limits of normal deviation.

The cases were then grouped according to whether they were above normal, or below normal in weight, length and ponderal index with the sex given for each. The percentage of rickets in each group was computed. These figures are shown in Table IV.

TABLE IV

Condition	Males: No. of Cases	Males: Cases of Rickets	Males: Per cent Rickets	Females: No. of Cases	Females: Cases of Rickets	Females: Per cent Rickets	Total: No. of Cases	Total: Cases of Rickets	Total: Per cent Rickets
Overweight	13	4	30.76	9	4	44.44	22	8	36.36
Normal weight	94	30	31.91	77	22	28.57	171	52	30.40
Underweight	13	3	23.07	17	6	35.29	30	9	30.0
Overlength	..	..	.....	..	..	.....	..	..	.....
Normal length	117	36	30.76	102	31	30.39	219	67	30.59
Underlength	2	..	.....	..	..	.....	2	..	.....
High ponderal index	29	9	31.03	31	10	32.25	60	19	31.66
Normal ponderal index	89	27	30.33	70	21	30.0	159	48	30.18
Low ponderal index	1	..	.....	1	..	.....	2	..	.....
Extra rapid growth in weight	15	4	26.66	9	4	44.44	24	8	33.33
Normal or below normal growth in weight	105	33	31.42	94	28	29.78	199	61	30.65

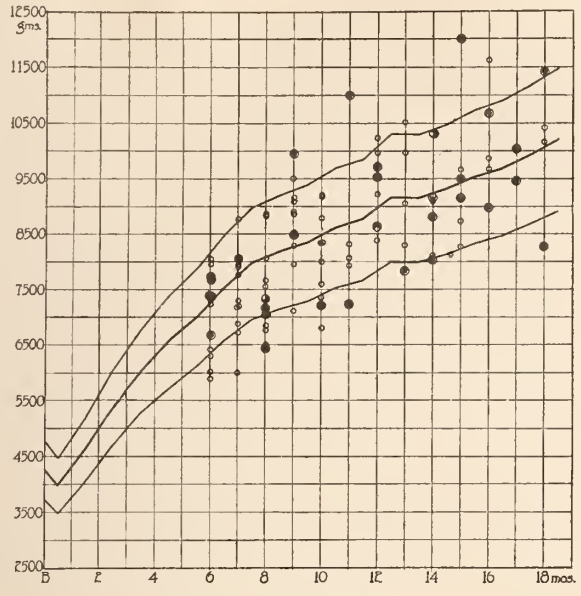

Chart II—Weight, Females

Weight—In total, these were 22 overweight infants, with 8 cases of rickets, or 36.36 per cent; 171 normal weight, with 52 rachitic, or 30.40 per cent; and 30 underweight, with 9 rachitic, or 30 per cent. Thus, a definite increase is seen in the percentage of rickets in overweight infants.

Length—In the case of 2 of the 223 infants, one female and one male with rickets, the length was not obtained. There were no overlength infants. The normal length infants number 219, with 67 rachitic, or 30.59 per cent. There were 2 underlength infants, with no rachitic.

Ponderal Index—There were two of the 223 infants, one male and one female with rickets, in which the ponderal index could not be determined on account of not having the length. Of 60 infants with a high ponderal index, there were 19 cases of rickets, or 31.66 per cent; 159 with a normal ponderal index, with 48 rachitic, or 30.18 per cent; and 2 with a low ponderal index with no rachitic.

It is plainly seen in the ponderal index charts that the majority of cases of rickets not only occur in the upper normal deviation level, but that the closer the upper normal limit is approached the more cases of rickets are seen. Therefore, had the normal deviation limits been placed closer to Baldwin's normal curve, there would have been a much larger percentage of rachitic cases in the high ponderal index group than as it now stands.

Rate of Growth—From the previous weight records, which in many cases contained monthly weight observations, curves were plotted of all the cases considered in this study.

The curves were then compared with those of the normal according to the sex considered, and any extending above the normal deviation limit were classified as cases of extra-rapid growth.

In this group there were 24 cases of extra-rapid growth in weight, with 8 cases of rickets, or 33.33 per cent. The other cases were either normal or below normal growth in weight and totaled 199, with 61 cases of rickets, or 30.65 per cent.

Thus, it is easily seen, that there is an increase in the number of cases of rickets among infants with extra-rapid growth in weight.

SUMMARY

In this study 223 infants were examined. Among these there were 69 cases of rickets, which made a percentage of rickets of 30.94. The percentage of rickets was 30.58 among the infants that had been

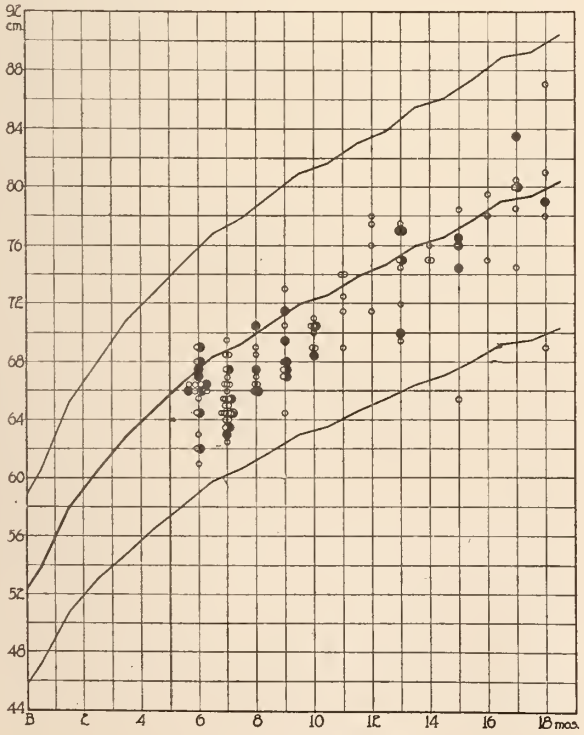

Chart III—Length, Males

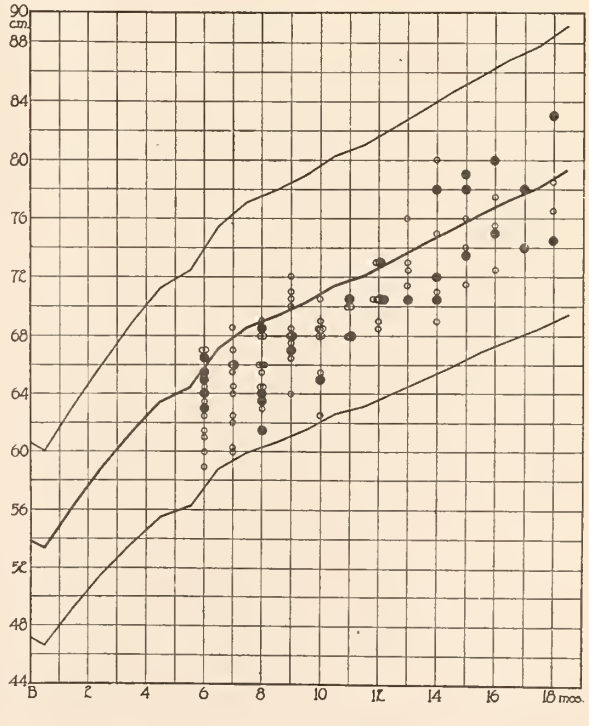

Chart IV—Length, Females

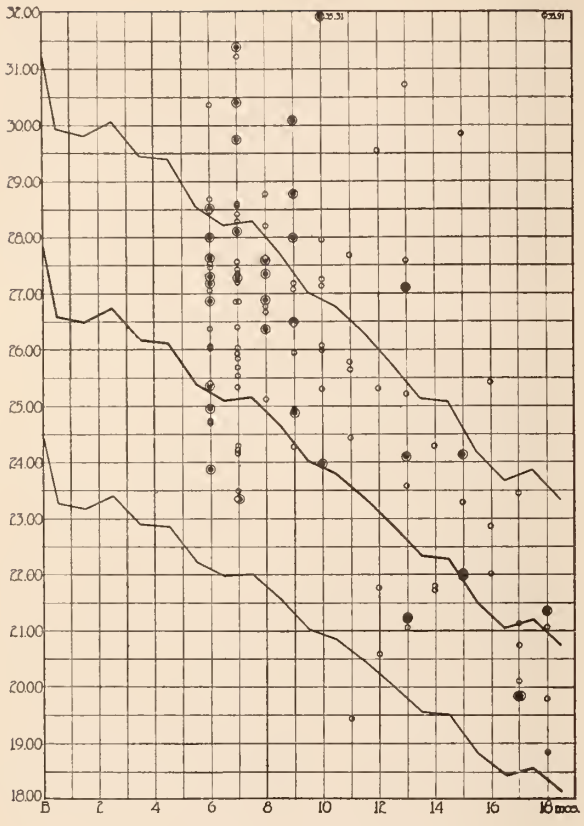

Chart V—Ponderal Index, Males

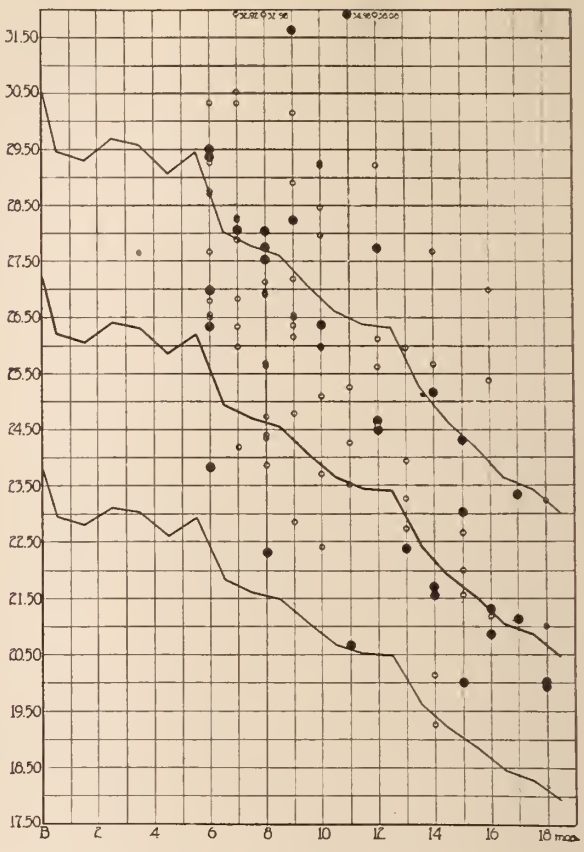

Chart VI—Ponderal Index, Females

Note—White center, non-rachitic; black center, rachitic.

breast-fed for six months or more, as compared to 34.69 per cent among those that were partially or entirely upon artificial feeding during the first six months. The percentage of rickets among the cases examined in August was 24.24, while in December it was 39.13.

There was 36.36 per cent rickets among the overweight infants, as compared to 30.40 per cent among the normal weight, and 30 per cent among the underweight.

There were no overlength infants. Among the normal length infants, the percentage of rickets was 30.59. Only two infants were in the underlength group and neither of these had rickets.

Of the infants with a high ponderal index, 31.66 per cent had rickets, and of those with a normal ponderal index 30.18 per cent had rickets. There were only two infants with a low ponderal index and neither of these had rickets.

The percentage of rickets among the infants with extra-rapid growth in weight was 33.33, as compared to 30.65 per cent among those infants with either normal or below normal growth in weight.

CONCLUSIONS

1. There seems to be a definite relation between growth in weight and the development of rickets.

2. Probably overweight infants are more susceptible to the development of rickets.

3. Also, an increased susceptibility to rickets probably occurs in infants with extra-rapid growth in weight.

4. The factor of the seasonal incidence of rickets is again borne out.

5. An increased incidence of rickets among artificially fed infants is again demonstrated.

I wish to express my appreciation to Rood Taylor, assistant professor of pediatrics, University of Minnesota, for suggesting this study and for valuable advice. I also wish to thank R. E. Scammon, professor of anatomy, University of Minnesota, for valuable suggestions.

Proceedings of the Annual Congress on Education, Licensure, Public Health and Hospitals—A report, a copy of which, no doubt, has been received by officers of all State boards, is so distinctive that it deserves more than passing comment. Issued in a comprehensive form, it constitutes an innovation, and the press of the American Medical Association is to be commended for this interesting and valuable publication.

These proceedings are expressive of the close inter-relationship that has been developed between the allied subjects of medical education, licensure, hospitals, and public health in this country, and at the same time each annual congress forms an index of the progress of American medicine, particularly as it relates to the betterment of human welfare.

A review of the discussions presented further emphasizes the wisdom and foresight that led to the establishment of these annual conferences, and the stimulating contact of the allied interests represented by the several organizations comprising the congress.—(Federation Bulletin, October, 1923.)

EDITORIALS

CHANGE IN THE NAME OF THE JOURNAL

At its last meeting the Council of the California Medical Association passed a resolution authorizing the work previously conducted under the name of *Medical Society of the State of California* to be carried on under the name of *California Medical Association*. Among other matters considered and decided was that of appropriate change in the name of the Journal, and by resolution the Council instructed the editor to change the name of the Journal in some appropriate manner. Carrying out these instructions, with the approval of the Executive Committee, the name of the Journal has been changed, effective with this issue, to CALIFORNIA AND WESTERN MEDICINE.

This change at the same time complies with previous action of the House of Delegates and of the Council endorsing co-operation with the states of Utah and Nevada in making this Journal their official organ. Part of the agreement was, that at an appropriate time a more inclusive title would be given to the Journal.

ABOUT THE 1924 SESSION OF THE CALIFORNIA MEDICAL ASSOCIATION

The annual session of the California Medical Association will commence this year on *Monday*, May 12, instead of Tuesday, as heretofore, in order that Northern members may motor down with their families on Saturday or Sunday, and that those going South by train may take advantage of the $19 rate given on a 16-day round trip ticket starting Friday, Saturday or Sunday.

Headquarters are to be at the Los Angeles Biltmore hotel, Fifth and Olive streets, Los Angeles. The schedule of hotel rates, and Southern Pacific rates and time-table are appended.

All members who expect to attend the 1924 meeting should make their hotel reservations early with Mr. James H. McCabe, office manager of the Los Angeles Biltmore, who will confirm such reservations direct with the physician. The State office handles no reservations whatever.

The Committee of Arrangements report that they are providing for the visiting ladies golf and other entertainment. The scientific program will appear in a later issue.

Many section programs are full, and secretaries have been compelled to refuse good papers. Members who desire to have such papers published in the Journal can submit them to the editor after presenting them to some county or other medical society.

Hotel reservations for the State meeting this year are being handled through Mr. James H. McCabe, office manager of the Los Angeles Biltmore, Fifth and Olive streets, Los Angeles. The rates are as follows: (Each and every room has its own bath.)

Single Rooms—$5 to $10 per day.

Double Rooms—Double bed, $7, $8, $9, and $10 per day; twin beds, $10 and $12 per day.

Connecting Rooms—Three persons, $14 to $22 per day; four persons, $18 to $24 per day.

We would suggest that members make their reservations **now** direct with Mr. McCabe, that there may be no disappointment later.

SOUTHERN PACIFIC RATES FOR STATE MEETING

Leaving Friday, Saturday, Sunday, 16-day ticket, round trip, $19.

Leaving Monday, 30-day ticket, round trip, $22.

Lower berth, $4.50; upper berth, $3.60.

Drawing-room, $16.50; compartment, $12.75—two tickets.

OPTIONAL MEDICAL DEFENSE

LETTER NO. 4

February 6, 1924.

To All Members of the California Medical Association:

Dear Doctor:

The Indemnity Defense Fund was terminated as of November 30, 1923, and Medical Defense terminates as of June 30, 1924.

For those desiring it, Optional Medical Defense has been provided by the Council, effective July 1, 1924. Under this plan those not desiring Medical Defense are relieved from any financial obligation for the same, and Medical Defense is provided for the many members that have stated they wanted it.

This Optional Medical Defense by the Society's legal staff will be conducted in conjunction with the member's insurance carrier. All indemnity, including court costs, will be borne by the insurance carrier. For example, a member having Optional Medical Defense will be defended not only by the attorneys of his insurance company, but also by the Society's attorneys acting with the insurance company's attorneys for him; the Society's attorneys as his counsel being particularly concerned with all features of the member's defense touching him professionally and personally. Such arrangement is entirely acceptable to the insurance companies writing physicians' defense. This defense will be of the same character as that heretofore maintained by the State Association, except that it will only be available to those who apply and pay for same.

Members interested in the eradication of unwarranted malpractice claims and cases, and in Medical Defense against the same, can do so by applying for membership in the Medical Society of the State of California. This body was organized by the Council in June, 1923, immediately after the name of the

State organization, at the request of the American Medical Association, was changed to the "California Medical Association."

Any member of the California Medical Association in good standing, who has and maintains in force a standard physician's defense policy for $5000 or more, is eligible.

Dues for the first half year, from July 1, 1924, to January 1, 1925, are $5 (the dues for the first year having been fixed on the basis of $10 per annum). Dues are payable to the secretary, Balboa Building, San Francisco, California.

The management and conduct of this Optional Medical Defense is in the hands of a board of seven trustees. Those first elected are James H. Parkinson, Saxton T. Pope, William T. McArthur, George H. Kress, T. C. Edwards, Rene Bine and Charles L. Curtiss. The executive committee is James H. Parkinson, chairman; T. C. Edwards, Rene Bine, and Emma W. Pope, secretary.

Any member of the California Medical Association desiring to secure this Optional Medical Defense and to maintain the Society's present legal department should fill out, sign and mail to the secretary, Balboa Building, San Francisco,. the following application.

Very truly yours,
EMMA W. POPE, Secretary.

Application for Membership in the Medical Society of the State of California.—The undersigned, a member of the California Medical Association in good standing, hereby applies for membership in the Medical Society of the State of California, and agrees to comply with and be governed by its constitution, by-laws, and the rulings of its Board of Trustees and Executive Committee.

The undersigned understands that membership dues are payable annually, first half year's dues, July 1, 1924, to January 1, 1925, being fixed at $5, and that membership can be terminated by the member at any time by resignation or failure to pay annual dues.

The undersigned holds physician's indemnity policy in the amount of $..... issued by..... Company, which indemnity insurance for at least $5000 with any licensed company must be kept in force to entitle undersigned to defense by the Society.

.....

Address .....

AMERICAN MEDICAL ASSOCIATION BULLETIN

The A. M. A. took a fine long step forward when the house of delegates voted to supply the Bulletin to every Fellow of the Association free or as part of the service to members.

Are you reading your Bulletin regularly and carefully? we recently asked ten members as we met them in the day's work. Three of the ten never looked at it; six read it carefully, and one did not remember ever to have seen a copy. This editorial note is to call attention to the importance of the Bulletin as a source of interesting and important information and to urge its more careful perusal by a larger number of Fellows.

LINGUAL ABSORPTION OF NITROGLYCERINE

The application of nitroglycerine to the tongue for the production of its ordinary systemic effects appears to be a fairly common method of administering the drug. However, the reason for the great efficiency and promptness of action has not been understood. According to some, the effects of the drug could only take place after swallowing, and, hence, after absorption from the stomach or intestine. Therefore, the effects would be no better than from the ordinary oral administration. That the tongue is superior to other regions of the alimentary tract for absorption of nitroglycerine has been demonstrated recently by Grossmann and Sandor of the medical clinic at Zagreb.

From observations of the changes in the blood pressure and pulse rate in a considerable number of patients, Grossmann and Sandor found that qualitatively these changes were the same, but quantitatively different, depending on the method of administration of the nitroglycerine. The actions were found to be strongest with lingual application or by rinsing of the mouth with fluid containing nitroglycerine. The effects from ordinary oral administration were slower and weaker. Direct administration through a tube into the stomach produced no effects whatsoever, and direct duodenal administration (also through a tube) gave only weak effects. The results in patients with hypertension were the same as in normal subjects. The dosage used was eight drops of the spirits of nitroglycerine in 10 to 15 cc. of water for rinsing the mouth. In tablet form on the tongue, the nitroglycerine was just as effective as in the form of spirits, indicating that the tongue has a good absorbing surface.

These simple observations of the Jugoslavian clinicians indicate something of the mechanism responsible for the conversion of nitroglycerine (chemically, glyceryl trinitrate) into nitrite, since it is the latter group which is responsible for the pharmacological action. This conversion is currently attributed to the influence of alkalinity in the intestine, and of the tissues in part, at least, a deduction based on the old experiments of Hay, who showed that the treatment of nitroglycerine by alkali liberated the nitrite radical. However, Grossmann and Sandor found that the degree of alkalinity necessary for the liberation is greater than the alkalinity present in the mouth or in the tissues. Acids were found to lessen the liberation of nitrite, and this agreed with the diminished efficiency of action from direct gastric administration of the nitroglycerine. The greater efficiency from direct duodenal administration agreed with the liberating influence of alkalies. However, the acidity of gastric and alkalinity of the intestinal juices are variable factors, and so far as the mouth is concerned, the degree of alkalinity would be insufficient in any case. Hence, the authors conclude that ferments, which are known to liberate nitrite from nitroglycerine, are important factors, but they attach a still greater importance to lipoid solubility in the case of lingual absorption.

Thus, it is seen how simple it may be to obtain definite, accurate and critical evidence of the action of a drug under clinical conditions. After pharmacological analysis, this is the method of choice

for clinical therapeutics, rather than the empirical method as ordinarily practiced, and which amounts to nothing more than guessing and carelessness. By the same token, the pharmacological analysis is confirmed or corrected, and in any case benefited. But, the greater benefit, no doubt, eventually goes to the patient.

Grossmann, M., and Sandor, J.: Klin. Wochn. 1923, 2:1833, "Zur klinischen Pharmakologie des Nitroglycerins."
Hay: Deutsch. med. Woch., 1884, p. 440, "Ueber die Wirkung der Nitrite und des Nitroglycerin bei Angina Pectoris."

THE NEW CONTROL OF SURGEONS

If the recent article under this title by Mr. William G. Shepherd (Harper's Magazine) were only the usual stupid and in part untrue attack upon the medical profession of our country, it might be ignored, as such articles usually are. There are two phases to this new attack upon the 140,000 odd of the total of some 150,000 educated physicians of the United States that make it demand some attention by all friends of better medicine everywhere.

One of these points is the editorial commendatory note italicized and published at the top of the article, which, whether or not so intended, will not produce a pleasing reaction in the minds and hearts of readers who still believe in medicine as a humanitarian profession and who still believe the body of educated physicians are just as honest, and thousands of them just as capable, as are the handful that the author exempts in his diatribe.

The other important point in the article is, the implication that a special medical organization with only some 6000 members stands sponsor for the alleged information which the writer attempts to impart to the world. Unless careful readings of the article have misled us as to the author's intentions, some of his statements about the American College of Surgeons are fabricated; we hope with greater care than are some of his other statements that have no basis whatever in fact. It is hard to believe that the astute leaders of the American College of Surgeons, even if they thought as Shepherd implies they do, would be so stupid as to put such a very thin veil over the obvious propaganda which appears to run like a thread through the article. Nor is it conceivable that the authorities of the College of Surgeons, a private and unofficial organization, would endorse a tirade against their fellow physicians—a public confidence-destroying criticism which has its appeal in an invidious comparison between a few thousand physicians, members of a limited organization of one specialty of medicine, and the probably more than 75,000 other physicians who are also doing surgery in the country, and for the most part doing it honestly and well. They graduated from the same schools as did members of the College of Surgeons and are honorable members of the official medical organizations of the country.

Even should a few—and they are probably only a few—members of the College of Surgeons believe that their new and, in Shepherd's eyes, important obligation to their self-selected standards entitles them to assume such a holier-than-thou attitude, they would surely not be so dense as to deal the blow to their own organization that the article is sure to cause. There can be little doubt that, whatever else this essay may do, it will prove first a severe blow to the College of Surgeons, and secondarily of course, to the cause of better medicine and all medical agencies. Already reports are coming to this editor of the chortlings of glee among the enemies of medical progress. They are saying that there are only some 6000 honest physicians among 150,000, and that these honest ones have banded themselves together with a hidebound oath "on the honor of gentlemen" to save medicine.

As to the article itself, most of it is the usual line of stupid propaganda that physicians have grown accustomed to see in certain kinds of journals prepared by publicity agents. A few particularly choice bits with comment, which of course is unnecessary to physician readers, may help the article on its way. The author says:

"To put it coldly, it is not entirely unlikely that some day you or I or some one we love may be wheeled into an operating-room, put to sleep under an anesthetic and be helplessly subjected to a surgeon's knife, at the risk of having life leave the body then and there, or being physically weakened for life, for no other motive than to put money into the pocket of a surgeon or a doctor."

This is a wholesale indictment of the integrity not only of physicians, but of hospitals, which of course is true only in those rare instances that indicate the untruth of the proposition. The author must have had some qualms himself, because he hastens to assure the reader that he received his information from "the men of the white aprons and rubber gloves—the surgeons themselves." We, of course, don't know who his "rubber-gloved" advisors were, but all of the other 140,000 surely will not allow such uses of their names and bartering of their principles to go unchallenged. We shall be surprised if many of the members of the College of Surgeons do not repudiate some of the author's statements.

As an apology for not giving the names of the physicians who gave him the misinformation about their colleagues, Shepherd makes the statement that:

". . . my readers will please remember that doctors and physicians are under an oath, sacred to their profession, against publicity, so that I cannot use their names."

Physicians will, of course, smile when they read that statement, which to the unsuspecting general reader appears plausible. Surely a casual glance at the newspapers almost any day will convince any reader that all sorts of physicians, both in and out of the College of Surgeons, are being interviewed and are writing for public reading.

We assume that the author is being facetious when he discusses "cutting the greed glands out of surgery." He mentions that some of the handful of surgeons he endorses because they are "controlled" have become so greedless that they refuse to operate on the Chicago newly rich who have the operation habit.

He talks easily and freely about "fee splitting" and "division of fees" as if they were the same

thing. He condemns the physician for his part in splitting fees, but seems to feel certain that the surgeon is protected from blame for his part in a nefarious contract that requires two people to make, by the oath that some surgeons take "on their honor as a gentleman" that they won't split fees. It would be interesting to know if Mr. Shepherd believes that an oath changes a man's heart or even his conduct. If he does, he must feel lonesome in this workaday world.

Methods for the honorable division of fees where more than one physician has contributed service in earning the fee are provided for in the principles of ethics of the American Medical Association. Obviously, each physician is entitled to just the proportion of the fee he has earned, and this division must have the patient's approval. Obviously, any portion of any fee going to anyone who has not earned it is dishonest and forbidden by medical ethics—this is so-called "fee splitting" as distinguished from honorable and honest "division of fees." Of course, anyone who believes this dishonest "fee splitting" can be controlled by an oath made "on the honor of a gentleman" is inadequately advised of the methods of dishonest people.

One of the most obviously deceptive statements in this article is, "medical schools are recommending their students for internship in the minimum-standard hospitals." It would have been easy for the great surgeons the author says he consulted, as well as those the editorial note says have read and approved the article, to have told the truth, that the ratings of hospitals for internships were made and controlled by the Council on Medical Education and Hospitals of the American Medical Association and not by the American College of Surgeons, as implied in the article.

But why go on? Most physicians must have read Shepherd's article, because the editor of the Journal has never before received so many protests from angry men about any other article denouncing physicians unfairly, unjustly and, in part, untruthfully.

Of course there are instances of unnecessary surgery; of "fee splitting"; of physicians attempting more than they should with or without the knife; of over-charging, but they are not the rule, and such an onslaught upon the honor, honesty and integrity of a great profession shall not go unchallenged.

If reports to official medical organizations from their own members are true, dishonest methods occur proportionately among the 6000 odd surgeons who have pledged themselves "on the honor of gentlemen" that they would refrain from these nefarious practices as they do among the other 100,000 odd who have not taken the oath.

BROADENING OUR MEDICAL HORIZON

Elsewhere in this issue of the Journal is published a teaching innovation by the Department of Medicine of the University of California Medical School. In a letter William J. Kerr, head of the department, says that the object of this new method of teaching is to better prepare the student in the art of medicine, economics, ethics, and citizenship responsibilities.

Certainly, no one should know better than successful alumni the importance of this step, and they will know what to teach and how to teach it.

Let us hope that somewhere in their curriculum, as well as that of other schools, provision will be made to teach medicine as a service-loving vocation where wealth cannot be expected and where all service is consecrated.

"THE GORGAS IDEA"

Physicians everywhere are much interested in having the splendid services rendered to humanity by the late Dr. Gorgas recognized by some fitting monument to his memory. Franklin Martin of Chicago, who has been asked by some of those interested to canvass sentiment, was recently in California on that mission. He was entertained and spoke in Los Angeles and San Francisco.

On Wednesday evening, January 13, local fellow members of the College of Surgeons entertained the visitor at dinner at the Bohemian Club. After dinner Martin presented his tentative program for the development of the "Gorgas Idea" to a large audience of physicians at the San Francisco County Medical Society hall.

The subjects of "Standardization of Hospitals" and the proposal to extend "standardization" to all other agencies of medicine, including medical books and what not, was explained and commended. After indicating also the necessity of more and better organizations of physicians who would assume leadership in medical and public health matters, the speaker struck a responsive chord when he proposed a "Gorgas Foundation" as a living monument to the memory of our departed colleague, rather than the usual monument of brass and stone. It was pleasing and gratifying to physicians to hear reviewed the splendid work of Gorgas and the analysis of the great service he rendered in so many fields, but particularly in holding the medical services to our men during the war in the hands of those adequately educated and trained to give the best that medicine had to offer.

The fundamental idea of the development of the "Gorgas Idea," Martin stated, is to give to every individual the heritage to which he is entitled—Good Health—by means of:

Scientific research into the cause, prevention and cure of disease;

The application of such preventive and curative measures as may be necessary under the supervision of the leaders in scientific medicine;

Save to the world the present economic loss in human resources from preventable disease;

Prevent the stupendous economic loss resulting from sickness, ill-health and preventable deaths;

By transforming disease-infested localities into fertile and productive areas, increase the wealth of the individual and the nation.

President Wilbur, W. E. Musgrave and Celestine J. Sullivan were called upon by Wallace I. Terry, chairman of the meeting, and in speaking informally expressed the fullest endorsement of California med-

ical men in any wise movement to honor the memory of Gorgas.

President Wilbur obviously expressed the sentiments of the audience when he disagreed with Martin as to the alleged value of "Standardization" of hospitals and other medical agencies. He endorsed the position of the growing number of thinkers and writers who are not only pointing out the blighting effect "Standardization" has had and is having upon many movements that should be progressive, but that it is an important factor in forwarding the molding into common standards of mediocrity of vast throngs of people.

President Wilbur said that it was not "standardization" that the world and worldly things needed, but a return to individual initiative, activity and purpose fostered by education and sharpened by competition.

Musgrave agreed with Martin that medical leadership in all things medical was much to be desired, but that multiplying organizations was not the way to get it. Nationally and otherwise we are overorganized now and what we need most are "mergers" and not more new organizations. It is utterly futile to talk of national medical leadership with some two score national organizations of medical agencies and each one pulling in a somewhat different direction. It is equally futile to talk of State or more local medical leadership with dozens of organizations pulling at different angles and in which the election of new leaders annually changes the direction of force even in the same organization.

We are not headed toward medical leadership, but toward several medical professions and with mixed policies calculated to produce a slowing up of medical progress. "Standardization" of this or that medical agency for this or that purpose by this or that minority group is the best illustration of how that much desired leadership has gotten all in motion, but not the motion that means progress.

Celestine J. Sullivan, executive secretary of the League for the Conservation of Public Health, said: "One idea expressed by Gorgas could and should be applied effectively for the solution of our present diploma mill and quackery problem. When the question of admitting chiropractors, osteopaths and other members of the countless cults to the Medical Corps of the Army came before Surgeon-General Gorgas, he diagnosed and treated the problem in the same able way that he handled an epidemic. Although there was great political pressure brought to bear upon Gorgas, he did not compromise. He said: "A scientifically educated physician is at liberty, and it is his duty to employ any method of treatment whatever which he believes will benefit his patient. The best safeguard against preventable deaths is a good medical education, and we will require that any man coming into the Medical Corps shall have the degree of M. D. The admission of chiropractors, osteopaths and similar cultists would be regarded, and justly so, as lowering the standards, education and professional, of our Medical Corps."

The League for the Conservation of Public Health, in its Hospital Betterment work, has put this important Gorgas idea into practical effect in all representative hospitals of California. No hospital today worthy of the name will admit to its staff any of the cult representatives which Gorgas excluded from the Army Medical Corps for the good of the service. The present newspaper discussion of diploma mills and their quackish products, and the spectacular prosecution of a few itinerant quacks, will have no more effect upon solving the quack problem than would Gorgas have had in cleaning up yellow fever if he went to Havana and Panama with a fly swatter and killed a few pestiferous mosquitoes.

Gorgas diagnosed the problem of quackery correctly when he said it was an educational problem. And, it is obvious, that the prevention and cure of disease will have a heavy handicap until all those who are licensed to treat the sick are qualified to do so by education.

ADMISSION OF PATIENTS TO HOSPITALS

The latest of the periodic attacks upon the San Francisco Hospital again calls attention to an important problem in hospital management, namely, that of who should be responsible for the prompt admission of patients and who should have authority to refuse any but first-care service as a charge against the city and county.

San Francisco formerly had a very unenviable reputation for excessive red tape and prolonged delay in the admission of sick people to her hospitals. This reputation was carried by seafaring people to the far corners of the earth. Some of it was unwarranted at that time, and most hospitals in this city, and elsewhere in California for that matter, have long since solved their problem, fixed responsibility for admission in the hands of one person, in such a way as to insure the prompt first care of every sick person who applies.

We are not informed as to the details of the present San Francisco City and County Hospital situation, but we do say most positively that, if authority for admission to that hospital of patients whom physicians believe should have hospital care and who are unable to pay for it is not limited to the social-economic diagnostician, subject to review by the director of the hospital and no one else, there is something wrong with the admitting system. It is, of course, entirely within the province of the Board of Health, as the governing body of the hospital, to lay down policies and general rules and regulations and designate an executive to see that they are carried out. Beyond this point neither the board nor any officer of the board should go.

The importance of a careful selection of the right social and economic diagnostician cannot be overemphasized. Neither can we overemphasize the full co-operation and support she should have in her work so long as she is right, and when she is wrong too often, the position should be vacated and another appointment made.

We are not disposed to believe much of the current comment to the effect that political favor has to do with the admission or rejection of sick people by this great hospital, as it does in some other county institutions.

Two points, and two points only, should govern the admission or rejection of patients by the hospi-

tal: One is, that the patient should be competently decided to be unable to pay the cost of hospital care, and the other is, that the patient should be suffering from conditions that the examining physician believes may be best cared for either temporarily or permanently in a hospital. The obsolete, unfair rule which requires that the patient shall be a resident within the political unit for six months or a year before being eligible to admission to most county hospitals ought to be abrogated. From the standpoint of public health and the protection of other citizens of the city and county, the mere fact that the patient is within the political jurisdiction should be all the evidence of citizenship required. We, of course, are fully advised of the complaint that some of these people are loafers who migrate from one county or State to another with the changes of climate. Nevertheless, they are human beings and we are not prepared to endorse rules and regulations which cause neglect or delay in their treatment, this not only in the interest of the wanderers' health, but as a protection of the public health against the various infections these patients so often carry.

TAXING PHYSICIANS UNFAIRLY

There are Federal, State and municipal taxes upon physicians that are unfair and discriminatory.

The Harrison Narcotic Law—Every physician who dispenses certain narcotics must pay a special tax of $3 toward the support of a bureau charged with the duty of checking up on the doctor's honesty. Actually, the bureau goes much further: It provides a complicated and frequently changing system of reports that require a great deal of the physician's time to render and which are needlessly inquisitorial. The whole government machinery for the administration of this law has become as complex and expensive as the average government bureau becomes when given time and plenty of money. The autocratic attitude of some of the enforcement officers is not calculated to make better citizens of physicians. A bill reducing this tax was introduced in the last Congress by Congressman (doctor) J. J. Kindred of New York. We are informed that similar legislation will be proposed in the Sixty-eighth Congress.

State Taxation—California has for several years had a law which requires all physicians to pay to the Board of Medical Examiners a $2 registration tax. The original law provides that this fund shall be used by the board for its expenses in enforcing the provisions of the Medical Practice Act. This law has always been considered by practically all physicians as unjust and unconstitutionally discriminatory. However, so long as the money was used in safeguarding the public health no concerted action looking to repeal of the law was taken. Now that, under the "efficiency and economy" program of the State Government, these funds are turned in to the State treasury and used, at least in part, for the general purposes of government, it is about time for concerted action. Legal action against the payment of this tax bringing out diversion of the funds from the use provided in the original law would probably meet with public approval and might attain a favorable verdict in court. In any event, the subject may well be considered by the California Medical Association with a view to asking the League for the Conservation of Public Health to promote repeal legislation.

Municipal Taxes—An ever-increasing number of municipalities are placing a special privilege tax against physicians. Usually these are flat rate assessments and some of them are very high. This form of special taxation is almost universally resented, the reasons being that the physicians always have given their time free in the medical care of the poor of the municipality. They object to rendering free service and being taxed at the same time. In any municipality or other government unit the amount of service given freely to wards of the unit is many hundred times the amount of the tax. That the government unit should either pay for the physicians' time given to them or relieve the physicians from special license taxes will be endorsed by all right-minded people.

It is irritating, unjust proceedings of this character that may some day force physicians into strong organizations.

TREATMENT BY NEGLECT

Theodore Diller, Pittsburgh (Journal A. M. A., December 22, 1923), is of the opinion that there are patients who are examined far too much. The self-centered psychoneurotic delights in examinations, re-examinations and more examinations. And in these days of many clinical procedures and manifold laboratory tests there is great risk of over-examining certain of these psychoneurotics. There is a judicious neglect which the physician makes in his visits. It is extremely important and necessary that enough time be given to hear the patient's story; but it is a mistake to spend time in hearing undue repetitions of this story. While the first visit may be of an hour's duration, the next one may be half an hour; and other visits of a minute and a half may be most appropriate. There are times when the patient is much better visited once a week or once in two weeks rather than every other day. There is a type of psychasthenic patient that leans on drugs, on appliances or members of his family, and on his physician. He does the maximum leaning instead of the minimum leaning, and does not look forward to the time when he will not lean at all. The job of the physician is to lead him to lean less and less and, if possible, to walk alone and not lean at all.

Diller's remarks will crystallize one important truth in the hearts and minds of true physicians. The author makes no claim that he is advancing anything "new" and he no doubt realizes that most good physicians are practicing what he preaches. More should do so and some undoubtedly will be recruited to more effective service by the able presentation of the subject.

Thoughtful minds in running around and behind the article will readily see many applications not mentioned in the article, one of the most important being that many communities are doing in a wholesale way just what Diller cautions against, by creating so much machinery of such wide variety for the examination and treatment of the sick that active competitive methods must be utilized to get "business" for them. Almost any "progressive" community is now so well supplied with medical "mills," usually operated by non-medical people, that "grist" must be reground in order that they can all make a showing.

Whatever else the growing system does, it insures plenty of just what Diller's article cautions against.

Medicine in the Public Press

Why Not Build Highland Hospital?—One of the most curious and certainly the most expensive method yet reported in financing and building a hospital is that now dragging its weary way along in Alameda County. Periodically, for the last several years, newspapers have given much space to what is planned to be done. Too much of the publicity deals in futures.

Several years ago a site was purchased and plans approved for a new County Hospital to cost some $3,000,000. A hospital was much needed then and is more needed now. Whether the county needs or will support a $3,000,000, over 500-bed hospital, if or when it is built, remains to be seen. It will cost easily $900,000 a year to operate a real hospital of that size if it is completed now. The longer the delay, the more it will cost, if the accounting system takes cognizance of the interest on the various sums that have already been spent, together with the interest on tax-collected money or interest and amortization charges on bonds, if any are to be sold.

Can you imagine any business man starting out to make a three-million-dollar investment by putting in some one-third or one-half million dollars a year with no hope of receiving any returns either in money or service until after the last installment had been paid? Why tie up hundreds of thousands of dollars a year for year after year with no return in service or money and no hope of any for years to come? If installment methods had to be followed, why were installment funds not allowed to accumulate and draw interest until enough was on hand to build? Or at least complete each unit and put it into service as finished? The interest on these installments over the years already gone by and those apparently yet to come would have been a pretty penny. With funds available, less than two years would be ample time to build from the ground up. Why not give the long-suffering taxpayers something for their money if not by giving better care to more people who need it, then at least by accumulating interest on tax money until it is needed?

Distinguishing Between Facts and Propaganda in Health Work—When Pearl published that interesting book upon the Biology of Death, in popular parlance he started something. Particularly when, to prove that other elements than the work of health agencies have been instrumental in reducing the death rate from a considerable number of causes, he submits the following argument: He compares the decline in the mortality between 1900 and 1918 in two groups of diseases—A and B. The first group, A, are the so-called "controllable" diseases and include: (1) tuberculosis of the lungs, (2) typhoid fever, (3) diphtheria and croup, (4) dysentery. For them, the claims of the health people have been made. The second group, B, include four so-called "non-controllable" causes of death, namely: (1) bronchitis (acute and chronic), (2) paralysis without specified cause, (3) purulent infection and septicemia, (4) softening of the brain. No one, he says, would claim that the public health program has in any way been responsible for the decline in these death rates. He then shows that the rate of decline from year to year in both groups A and B has been about the same during this period of eighteen years.

The conclusion is, therefore, obvious that if conditions can decline without the intervention of public health work, then public health work cannot assume credit for the decline in those conditions with which it does deal.

To clinch the argument still further, Professor Pearl then compares the decline in the mortality from two diseases—namely, typhoid fever and diphtheria—in two groups of countries, A and B, A having a highly developed public health and sanitation program and B not having such program. Under the first head are included Australia, Austria, England and Wales, and Germany; under the second head are included Italy, Jamaica and Rumania. Again, the writer indicates that the rate of decline in the death rate from typhoid fever and diphtheria has been about the same in the two groups of countries.

We are not at this moment discussing the merits or demerits of Pearl's statements, but rather want to point out the sudden and emotional outbursts of protest that come from so many sources. It is interesting to glance over a collection of the criticisms and to note how closely their authors are connected with one or more of the numerous organizations who have been termed "job initiating" and "job protecting" in their primary purposes.

Louis I. Dublin (The Survey) says: "Dr. Pearl has a real complaint with those who claim the 'entire decline in the death rate which has occurred has been due to the efforts of health officials, whether conscious or unconscious, as is often asserted and still more often implied in the impassioned outpourings of zealous propagandists. The open-minded student of the natural history of diseases knows perfectly well that a large part of the improvement in the rate of mortality cannot possibly have been due to any such efforts.' And in elaborating this complaint he is inclined to belittle the value of activities which health workers consider unquestionably effective and even to imply that some, which, like the tuberculosis campaign, are sacrosanct, are of little if any value."

Pearl is only one of the many who are beginning to speak forcibly of the all but negative value of the so-called statistics that are in reality propaganda by half-baked so-called health organizations. If health work is not put back into the hands of persons educated and trained in medicine there is real danger that legitimate, well-directed efforts may suffer because of the uncontrolled vaporings of this or that incompetent "uplift" or public health or anti-something organization.

Who is a Child, Medically Speaking?—The problem raised by the query is one of some magnitude in medical school faculties. Attempts at its solution cause more controversies and heartburnings among medical teachers than the public realizes, or, for that matter, more than either the public or the medical profession are particularly interested in. Nevertheless, it is to a degree everyone's problem, because as the young medical student is taught, so is the physician likely to practice.

The first phase of the problem is its lower register, as it were—the boundary line where the obstetrician leaves off and the pediatrician picks up the problem of the infant's health and medical care. Many obstetricians consider the child in their field from conception until one or more years old. Many pediatricians expect the infant to be handed to them at birth, and some of them are following the welfare group in claiming the child's care before its birth, leaving the mother detached, as it were, to the obstetrician.

Silly you say, and so it is; but if you think it isn't a live question, go to almost any medical school and get the various reactions.

Then there is the upper register, or when does a child cease to be a child, medically speaking, and pass from the field of pediatrics to that of adult medicine. Pediatricians have not, as a rule, been staying put on the answer. They have moved the age of childhood, or, more correctly, the pediatrics age, up until they now claim it extends to 16 years, and some even to 18 years of age.

Silly you say again, and again you are right; but so long as medical students are turned out to practice with these and a dozen other more or less unimportant controversies ringing in their ears, just so long will there be discord.

These and dozens of other problems have grown and continue to grow out of the ridiculous lengths

to which "specialization" in medical teaching and practice is being carried.

What a splendid service medical schools would render both to physicians and the public by agreeing upon and teaching along some more or less similar lines.

The Second Coming of Coué—The pitiful spectacle of this propagandist's second coming to our country and his recent first visit to California is well summed up by the San Francisco Bulletin when it says editorially:

"The second coming of Emile Coué to America is in marked contrast against the blare of trumpets and the front-page spreads with which he was greeted on his first arrival.

It was scarcely known that he was in America until there was word of his arrival in San Francisco.

Less than two years has sufficed for an almost complete slump in the reputation of one who, for a time, was declared to be one of the world's great thinkers and benefactors.

From comparative obscurity as an apothecary in Nancy he was suddenly raised to a notoriety that was mistaken for the beginning of enduring fame.

Miraculous cures of all manner of diseases and ailments were said to have been wrought by the mere repetition of his supposedly magic words.

Nor is there reason for doubting that in many cases cures were actually effected. Many complaints real enough to the victims themselves are no more than the result of a disordered imagination, and when there is actually nothing the matter with a patient Coueism and similar isms are very often effective.

Their weakness is that the cures do not often last. The patient comes to realize not that his ailment was imaginary, but that there was self-deception in the cure. The old abracadabra will not work, and a new one must be found.

Coué gave the world a new one when he devised the formula, 'Every day in every way I am getting better and better.' It was so catchy, so simple to remember, that everybody in forty or fifty languages was repeating it.

But there was a catch in it. Very soon the thing was seen to be very much like trying to lift oneself up by pulling at one's bootstraps.

Of course, all this says nothing of the personal magnetism of M. Coué. That is a force admitting of no disputes, but personal magnetism of his kind must be personally or directly applied, and such a man cannot treat because he cannot reach all mankind.

If there is anything serious the matter there is nothing like calling in the regular physician."

Prayer as a Therapeutic Agent—An article on this subject (Christian Advocate) has been sent in for comment in this column. The minister who wrote it feels that the ministers are working in a complementary manner with the doctors in the treatment of physical diseases, but feels that the doctors do not assist the ministers as they should in the ministers' field of healing in mental and soul sickness.

There are two classes of exceptions to this general conclusion suggests the minister. One class is the psychologists, whom the author considers followers of the most popular science of healing. He cites as most brilliant studies of the subject particularly the books called "Outwitting Our Nerves" by Josephine Jackson and Winbigler's book on "Suggestions." He is particularly pleased with the statement in the latter book that "the day of belief in the healing power of drugs is passed." Thus we have the master key to the author's mind.

The author praises one group of physicians, among whom he classes Hyslop of England and R. C. Cabot of Boston as great representative leaders. The author quotes Cabot as saying:

"Healing comes to some individuals directly through prayer, I am sure. I use it in my practice and rely upon it more often than medicine. . . . If I had no material means at hand I should use prayer alone, with confidence that it would work the cure."

So that's that.

Intellectual Giants Disagree About Diet—The ideal health-insuring breakfast discussion recently so warmly championed by so many people, each with his own ideas upon the subject, is now being heatedly argued in England. Recent Associated Press dispatches of a controversy between two eminent men of letters show how we agree about what to eat:

Bernard Shaw and G. K. Chesterton have locked horns in another controversy—whether Great Britain ought to brighten its breakfast tables with importations from America, such as grapefruit, orange cocktails or other fruit dishes.

Shaw, a vegetarian, says the suggestion of fruit dishes makes his mouth water, but the roast-beef-eating Chesterton contends that if there is one thing that would justify armed assault on the United States it is "this attempt to introduce the American diet on the British breakfast table."

Their controversy was inspired by a little piece sent to the newspapers by Peggy O'Neil, the American actress, who is playing in London, in which she said the English breakfast was a terribly dull and depressing thing, and begged for the brightening influence of fruits.

Rushing to the defense of his homeland fare, Chesterton declared Americans should never raise the subject of breakfast in the presence of Englishmen.

"The Americans sleep in hothouses," he said, "and wake up so thirsty that they are obliged to devour quantities of fresh fruit and drink gallons of ice water and alcohol, but it isn't breakfast. If there is one glorious thing in England which must never die it is the breakfast of bacon and eggs."

"Why bacon," Shaw inquired. "Do the Jews never enjoy their breakfasts?"

"Mr. Shaw would have been a very intelligent man," rejoined Chesterton, "if only he had always had boiled elephant or tiger for his morning meal."

"Pardon me," Shaw retaliated, "Mr. Shaw is a very intelligent man. Methuselah could hardly have been expected to go on eating pigs and pullets every morning for 969 years. Manna will be the food of the future. Must we always be condemned to slops and marmalade? Now, if Chesterton had attacked buckwheat cakes and molasses I should have sympathized, but fresh fruit! My mouth waters."

Lunatics of Literature—"Psychiatry, or morbid psychology, is the most popular branch of medicine today with the layman, and the most unpopular with the physician," says Joseph Collins in a discussion of Lunatics in Literature (North American Review). "Yet most of the stories of the past ten years would testify that their writers had never set foot in an institution for the insane nor made the acquaintance of any of the inmates.

"No one has ever been able to define insanity satisfactorily. There is no reason for believing that it will ever be accomplished. Nevertheless, the term will continue to be used derogatively and diagnostically. Insanity results in, or is the result of, disorder of personality. It is manifest in thought or in conduct, or in both. The individual whose personality disorder is confined to thought is not considered a lunatic by the law or by his neighbors, although he may be the victim of definite mental disease. He does become a lunatic when his conduct is at variance with that which we recognize as normal, proper, good, safe, legitimate."

After a further most interesting and enlightening analysis of some of the old and recent lunatics of fiction, Collins says: "It is desirable that we should become saner both as individuals and as nations. That we are becoming less so as individuals the statistics of institutions for the insane would seem to prove; that we are becoming less so as nations needs no proof, but if it did I could readily supply

it. We get the Laocoon grasp on disease when we know whence and how it comes. We await this information in regard to insanity. Meanwhile it only throws sand in the gearbox of the available machinery for finding out about it to create literature in which established facts are misrepresented. If we are going to have insanity in fiction, let us have the real thing."

Chiropractic Fountain Head Addresses Sciots—"Early to bed and early to rise,
"Work like mad and advertise,
"And you will be healthy, wealthy and wise,"
was the keynote of B. J. Palmer's address recently to the Sciots of San Diego. His address ranged from a forceful exposition of American business methods of firm, community and national advertising, and concluded with a brief but stirring discourse on the aims and purposes of Masonry. He emphasized and re-emphasized the importance of honesty in propaganda and advertising. Some said that indeed he did "protest too much."

Plastic Surgery Enters Beauty Specialty Field—An international clinic composed of British, French, and American surgeons has been opened in London. In addition to doing the recognized plastic surgery, this clinic proposes to frankly enter the field now pre-empted by beauty specialists.

Public Health Nurse's Report—In a recently published and otherwise commendable monthly report of a public health nurse, we find these illuminating items: "Pupils found defective, 84; defective corrections, 39; minor treatments, 97."

Definite practice of medicine is being more and more engaged in by nurses and other unlicensed and inadequately educated persons. It does not augur well for the future of nursing, and surely nurses have enough to do in the field they have been trained and educated to fill and in which their services are needed.

Shall Clerics Practice Medicine?—The Church of England has had a distinguished committee of church authorities and physicians working on this problem for some three years. The committee draws some interesting conclusions, some of which are:

1. It is not the function of the Church to apply its means of restoration to no higher end than the recovery of bodily health. . . .
2. No "sick person must look to a clergyman to do what is a physician's or surgeon's work to do."
3. The committee recognizes the duty of the Church to combat disease, and declares that it has a certain field in which it can act properly and advantageously.
4. The report, as it is summarized in the New York press, recommends, in effect, that methods hitherto confined to the Church of Christ, Scientist, or to psychoanalysts, should be established as part of the Anglican practice, with this distinction, that, while the majority of the faith-healing cults disdain the medical profession, the Church of England committee is fully mindful of medical science, and proposes that the direct power of moral and spiritual suggestion be allied with scientific knowledge. No separate or distinct ministry of healing is planned, nor is licensing of individual healers or official recognition of healing societies recommended.
5. The report severely scores the amateur healers practicing psychology as a treatment for disease, declaring that the committee "cannot be blind to the fact that the exponents of some of these methods have departed from legitimate fields of scientific investigation and have propagated views that are subversive both of moral and religious principles."
6. No case of the cure of organic disease was found by the committee.

The Better Health and Longevity Association—Under this name there has recently been launched an association with headquarters in Chicago for the promotion of periodic medical examinations of all adults.

"Americans have the best teeth in the world," said Edward H. Ochsner, president of the Illinois State Medical Society and one of the organizers. "They have them because they have the best dentists and have been taught to have their teeth examined at regular intervals.

"Our new association will sponsor physical and dental examinations for every adult in Illinois, at least once a year. Sickness and contagion will be greatly decreased, we believe, and millions of dollars will be saved to the laboring man, the employers and casualty companies," he declared.

"If we can reduce the average day's illness three, two or even one year, millions of dollars will be saved," said Ochsner.

Periodic medical examinations, if wisely done and adequately followed up with carefully prepared reports of findings and treatment, would do as much for the health and happiness of all people as any other health-improving service yet suggested.

The real reasons as to why children are not included in the scope of the various organizations and the thousands of independent physicians engaged in this work ought not to be left out of consideration. Actually, children need the examinations as much as do adults.

Many physicians are missing some wonderful opportunities in this field of medicine, opportunities to render a fine service for their communities and increase their own income at the same time. When the work gets into the hands of a comparatively few clinics, health centers and other groups controlled by non-medical people, we may wake up and begin to call for action.

The opportunities are good to promote this service in California as it should be promoted in the best interests of physicians as well as other citizens. But that opportunity is not going to last long—not over another year or two—if we can read the signs of the times aright.

Is this Class of Inadequate Medical Practice Necessary?—Items similar to the following are a feature in all news-clipping services:

"The school nurses are at present performing most valuable services to the community, in examining school children periodically and suggesting treatment. They can be called in by inexperienced school teachers in case of illness among pupils, and thus by a quick diagnosis are a force in combating against epidemics. In the rural districts these nurses go directly into the homes where they are often able to find the direct causes of the child's ill health."

It is perfectly obvious that a systematic attempt to limit the practice of medicine to the treatment by drugs of disease is being made. It will then be possible to assign the more important services of physicians in preventing, diagnosing, and even the treating of disease by any method except poisons, to any group of nurses, teachers or others who are trained for their own legitimate work but not to practice medicine, which many of them are now doing.

Yes, We Have No Oranges—Since the comparatively recent dawning of the day when everyone is a "doctor" and the kind that talks at that, we are "larning" a lot we did not before know. Thus, during the last few weeks, we have seen the spectacle of the nutrition "experts" of a great commercial organization asserting that candy is not fattening.

About the same time other groups of specialists have "discovered" that oranges may produce as beneficial results as milk in food for school children.

These are only two small samples of what we may expect when everyone is "educated in medicine."

This So-called Health Education—A paid employe of the department of education uses your taxes to pay her salary while she broadcasts this erudite medical wisdom. "Health is coming to be generally

recognized as an essential and primary objective of education. What can schools do to produce healthy children? They can provide healthful surroundings that will promote, not menace, the health of children. They can give instruction in matters of health, and recognize the fact that instruction is of little value unless it functions in habit of healthy behavior."

If you can beat that, we would like to hear from you.

Physical Examination of School Children — We were surprised the other day to see the broadcasted news-story that the director of physical education was going to have some 50,000 school children examined before they entered school this year. That was a bold statement for a government employe to make in California. Sure enough, next day the statement was modified to mean only those children whose parents wanted the examination made. At the same time the papers published an interview with the chairman of the Christian Science publicity committee endorsing the educator's "modified" statement.

If it were intended that the examination of school children should be carefully made by educated physicians and their findings given to parents as permanent records for the information of physicians who might be called upon to treat these children in the years to come, it would have been a good thing to encourage. But if the examination was to be the usual one, made by nurses, teachers or other technicians, then for once in our lives we thank the Christian Scientists for stopping the mockery of scientific medicine.

Minute Men of Medicine—What appears to be a worthwhile movement for the improvement of public health had its origin recently in Philadelphia. The movement consists essentially in the mobilization for epidemic and other medicine emergencies of the physicians of the city as associate health officers. By co-operation and co-ordinated action between the medical society and the city health officer, some thousands of the members of the county society now belong to the organization.

The health officer naturally feels more comfortable with the people protected against lack of medical service during any emergency. It is a striking situation for a health officer and executive officers of a county medical society to be provided with such a reserve army of health—each member always ready to answer the mobilization call.

Good as Far as It Goes—Under a subheading of, "Doctors Practicing Under Bogus Licenses are More Treacherous Than Bandits," the Palo Alto Times says editorially:

"May success attend the crusade launched in this State and elsewhere over the country to discover, expose, and discredit practitioners in medicine and other lines of healing who are practicing under licenses fraudulently secured. The highway bandit is not nearly so dangerous as grafters of this sort. The bandit's victims are fewer, for one thing. Moreover, they are conscious of the fact of being mistreated and robbed, whereas the deluded clients of the healing quack are lured through false promises, either expressed or implied, and place themselves completely at the disposal of a combination of ignorance and crookery.

"The most eminent and skilled physicians are ready to admit the limitation of their science. The quack, however, is usually known to make the most extravagant guarantees. Gullible individuals with no standards of personal judgment are found in large numbers being robbed of the money they pay over in fees for treatments supposed to represent wisdom and skill secured through adequate study and legitimate practice. The law must protect people against this sort of treachery, just as it must protect them against burglars and thugs."

This is as good as far as it goes, but it only scratches the surface. There are several licensing boards in this State, and under the law they **must** license persons inadequately educated or trained to practice the healing art. It is the license requirements fixed by law that are at fault.

Then, too, there is that largest group of all among quacks—those who do not even bother to secure the license that is too easy to get. If you wish to find these, look at the signs and advertisements.

The medical profession has introduced two bills into previous legislatures that would correct the whole situation: One, known as the Medical College bill, passed the Senate and died in a committee of the lower house unfriendly to scientific progress. The "Doctor" protection bill passed both houses of the last Legislature all but unanimously and was vetoed by the Governor.

Both bills will be introduced again.

Voluntary Health Insurance — The California and Hawaiian Mutual Benefit Association consisting of the employes of the California and Hawaiian Sugar Refining Corporation is undertaking, with the co-operation and assistance of the employers, to establish a mutual fund for the payment of wages lost during sickness.

The corporation carries, and will continue to carry, the expense of securing the benefits of the Industrial Accident law to all employes. This, however, does not take care of sickness not coming under the provisions of the accident law. The old employes' hospital association which has existed for some time among the employes will be merged with the new association.

There is a chance of much helpfulness growing out of voluntary organizations of this kind, but there are many more chances that it will be found to be impracticable. It takes more than a slogan to run a hospital, and it takes more money and better organization than has yet been provided to operate successfully an adequate and complete medical service under the name of a hospital association.

Recovery From Mental Sickness — Mr. Walter D. Wagner, director of State hospitals, according to press dispatches, announces, "Permanent recoveries are effected in the cases of 40 per cent of all patients sent to California's various institutions for the insane." It is further stated that these figures have been arrived at "following exhaustive investigation of conditions in the hospitals."

Forty per cent and any other per cent of cures is not enough, so long as well known and approved methods of treatment are not utilized. The percentage of cures can be further increased by removing many of the associated physical diseases so important both in causing and aggravating mental sickness.

Focal infections from bad teeth, tonsils, chronic inflammatory processes in other places; old ruptures; gall-bladders full of stones and inflamed; metabolism diseases; chronic heart, kidney and circulation disturbances, and many other conditions which undoubtedly exist, can be, and should be, diagnosed and ameliorated.

Scientific dietetic, good surgery and good medicine, including various forms of physical therapeutics, has markedly increased the cures in other places, and there is not the slightest question of doubt but what they would increase Mr. Wagner's percentage of cures most decidedly.

Of course, to do these things requires more laboratory, X-ray, medical, nursing, and other minimum requirements of **any** hospital for any class of patients anywhere, both to increase the accuracy of diagnosis and the quality of treatment, than is now part of the services of most state hospitals. But this cannot be had at a cost of 62 cents a day per patient. More money wisely spent will increase the number of "cured" patients—not cases—that will go back home to usefulness.

Three Aids — Under this headline the San Diego Tribune says editorially:

"Where stock swindlers rob men and women of

scanty savings, 'fake' medical practitioners rob them of something inestimably more important—health, happiness, peace of mind, and sometimes of life itself.

"The contemptible nature of the 'fake' healer is inherent in his business. The stock swindler appeals to human greed. The quack doctor preys upon pitiful and appealing human necessities. Ignorant people who are sick are vastly more helpless than intelligent people who are sick, and it is upon the helpless class that the diploma-mills and the irresponsible "doctors" depend for existence.

"The public is not without blame, both in the case of the swindler and that of the spurious 'doctor.' People who have sense enough to make use of banks and legitimate investment houses don't waste their savings with 'wildcat' concerns. People who have sense enough to investigate the healing agencies available to them can easily determine whom to trust —can easily learn which practitioners have built themselves up into professional competence through long study and successful practice, and which are merely fly-by-night money-grubbers.

"It is true, too, that the medical profession itself must come forward and help protect the ignorant against themselves. It is as important to prevent people from becoming the prey of irresponsible quacks as it is to prevent them from contracting avoidable diseases. Now as never before, the honest doctor must insist upon the very highest ideals within the profession, the very fairest, and most honest and most enlightened policies toward the general public. Part of the craze for irresponsible healing methods is due to public ignorance; but part of it—and this fact ought to be faced squarely—is due to outworn policies of secrecy and 'hokum' within the medical profession.

"Education of the public, education of the healing professions and rigid requirements under the law, will—all three together—do much to protect ignorant and ailing people from those who would make money from human suffering."

Mergers in Health and Welfare Agencies—"Mergers" in health agencies now have the center of the stage, very much as unmerging had a few years ago. We are a restless people who are continually making governmental changes in policies in this or that class of services because, whatever the plan in vogue, it is not successful. We continually refuse to recognize the fact that more serious, energetic work by government personnel, with more loyal support of effective agencies, is the important element in efficiency, but not necessarily in popularity.

There is no doubt in the mind of any thinking student but what overorganization, with too much organizational independence, classification of government agencies from the standpoint of political expediency, and the enactment of too many silly restrictive laws, are responsible for much government inefficiency in many fields. The health field probably heads the list, nationally by states and locally, in carrying political subdivisions of indivisible services to a ridiculous extreme.

Several legislatures are as usual battling with the ever-present problem of "merging" or "unmerging" their health services. Governor Smith of New York recently sent a special message to the legislature, which contains matter that should interest the people of all states. Among other things he said:

"The last Legislature was willing to place Raybrook Hospital under the Department of Health, but was unwilling to place the independent and unco-ordinated Hospital for Crippled and Deformed Children and the Institute for Malignant Diseases in the same department." . . . "I must again call your attention," the Governor continued, "to an important group of State activities which today are administered by a confusing, duplicating series of agencies—namely, those dealing with the welfare and institutional activities of the State. State welfare and institutional activities are hopelessly scattered and are subject to so many overlapping inspectional and supervisory agencies that when anything goes wrong it takes a special investigator, under the Moreland Act, several months to fix any measure of responsibility. Any planning of a positive, humane and forward-looking character is entirely impossible under present conditions."

The trouble with all these much-to-be-desired mergers of health agencies in whatever State they are undertaken is, that they are made from the standpoint of political expediency, usually by people who know political values, but little of service values. Some day, let us hope, some State will really merge its health agencies from the primary viewpoint of effectiveness of service by persons who know the various angles; and when this is done, other States will follow.

Trapping the Nerve-Impulse — Under this attractive catch-phrase title, Professor E. Newton Harvey of Princeton writes interestingly (Scribner's) about a subject not sufficiently studied by physicians or others. The story of facts and theory is so well told that only the advanced student of physiology will recognize where the one leaves off and the other begins. It is well worth any physician's time to review his neurology by a careful perusal of the article.

Red Cross Clinics in Marin County—It is reported that the Red Cross of Marin County will re-establish the pay dental clinic at 214 Fifth avenue, San Rafael.

"Well Baby" clinics are also scheduled for San Rafael, Larkspur, Corte Madera, Mill Valley, and Fairfax. Babies are weighed and measured and all sorts of free advice given to mothers about the care and feeding of their babies.

It is said that some income for the doctor in these clinics has been arranged for, but that both rich and poor will be prescribed for free.

Is Civilization Self-Destructive? — Most of us accept as a fact, and without question or further seeking of knowledge, the oft-repeated statement that civilization is advancing and that democracy in government and other activities is the outstanding basis of progress.

Some years ago (1910) a Canadian statesman caused quite a stir by defining democracy in government as interim government between monarchies, and otherwise challenged what we call progress as retrograde movement. He cited history to show that no democracy nor democratic civilization had ever lived more than a few hundred years; that these periods were wedged in between periods of more centralized government, and that but few countries had ever repeated the experiment of democracy.

The controversy caused at that time is being repeated over the charge of Mr. Wiggam (Strength, Philadelphia) that civilization as we understand and practice it is self-destructive. He quotes and endorses Stanley Hall's statement that "Man has not yet demonstrated that he can remain permanently civilized." He calls to mind the well-known fact that, in order to maintain a vigorous strain of large fine potatoes, they must be passed ever so often through periods of growth in difficult soil.

"Now, in their breeding qualities men and potatoes are exactly alike. Human beings in a state of savagery are in the same situation as the potatoes that were planted in hard, sterile soil. Every potato in such soil has to fight for its life. The weaklings never get above the ground, or if they do they are killed off. But in the rich soil all sorts of potatoes survive, and they also rear offspring. The strong are in time crossed with the weak. Thus weakness is spread. Feebleness and disease perpetuate themselves.

"Just so, when men are in savagery and barbarism they progress constantly in their physical, mental, and moral qualities. Barbarism is the only process by which men have ever progressed in their natural inborn strength of body and mind; and civilization is the only process by which mankind has ever grown

organically weaker. Civilization is thus the most dangerous enterprise upon which man has ever set out. In the days of his savage state, nature was looking day and night for the weak spot in every man's armor, and without mercy took her toll.

"But what happens when men become civilized? I can best answer this question in the words of Professor Karl Pearson, who said to the British Medical Association: 'You are enabling the deformed to live, the blind to see, the weakling to survive. In our institutions we provide for the deaf-mute, the blind, the cripple, and render it relatively easy for the degenerate to mate and leave their like. In the old days, the hand of nature fell heavily on the unfit. There were no doctors to enable them to limp through life, no charities to take their offspring or provide for their own necessities.

"'To the honor of the medical profession, to the credit of our social instincts, be it said, we have largely stopped all this. We have held out a helping hand to the weak; but at the same time we have, to a large extent, suspended the automatic action whereby a race progressed mentally and physically.

"'What will happen if, by increased medical skill and by increased State support and private charity, we enable the weaklings to survive and propagate their kind? Why, undoubtedly we shall have a weaker race.'

"We are anti-Burbanking the human race at every point."

PUBLIC HEALTH SUMMER INSTITUTES

The United States Public Health Service takes pleasure in announcing that, in response to an extensive demand for summer school work in public health, it has arranged with Columbia University, the University of California, the University of Michigan, and the University of Iowa to conduct public health summer schools this year.

The faculties of these various summer schools will include many leading "specialists" of the United States.

The tentative schedule of the courses to be given at the University of California, Berkeley, June 23 to August 2, is as follows:

Epidemiology; Clinics in Preventive Medicine; Elementary Bacteriology; Protozoology (lecture course); Protozoology (laboratory); General Biology; Public Health Laboratory; Public Health Administration Laboratory; The Health Center; Public Health Administration; Physiology (four courses); An Introduction to Psychology; Social Psychology; Problems of Social Mal-Adjustment; Medical and Psychological Problems (in Criminology); The Abnormal Mind; Mind and the Organism; History of Experimental Psychology; Mental Hygiene; The Elements of Nutrition; The Nutrition of Development; The Physiology of Nutrition; Seminar in Nutrition; Advanced Biochemistry; Child Hygiene; School Hygiene; Physical Education (thirty-four courses); Social Hygiene in Public Schools; Principles and Practice of Public Health Nursing; Home Care of the Sick; Health Education; Statistics; Control of Poverty; The Logic of Argument; Public Speaking.

For additional information address the Surgeon-General U. S. Public Health Service, Washington, D. C.

Faraday had but to will it to raise his income in 1832 to five thousand pounds a year. In 1836 the sum might have been doubled. Yet this son of a blacksmith, this journeyman bookbinder, with his proud and sensitive soul, rejecting the splendid opportunities open to him—refusing even to think them splendid in presence of his higher aims—cheerfully accepted from the Trinity House a pittance of two hundred pounds a year.

COUNTY NEWS

ALAMEDA COUNTY

Alameda County Medical Association (reported by Pauline S. Nusbaumer, secretary)—The monthly meeting of the Alameda County Medical Association was held at the Ethel Moore Memorial building, Monday evening, January 21, President Charles L. McVey in the chair; Clarence DePuy, acting secretary. Interesting patients and case histories were presented by Clifford Sweet, Clarence DePuy, Kate Gompertz, and J. L. Lohse.

The regular program was arranged by N. A. Cary.

Observations on the effect of posture in some types of low back pain.—H. H. Hitchcock. Discussion opened by Kate Gompertz.

Osteoarthritis.—F. J. Carlson. Discussion opened by George Rothganger.

Spastic paralysis. Operative and conservative methods of treatment.—O. P. Stowe. Discussion opened by Arthur Fibush.

Vasomotor lesions of the extremities. Demonstration of cases.—N. A. Cary. General discussion.

The president made an appeal to the members for the development of a closer fraternalism, and presentation of case histories and case reports previous to the regular evening's program. J. L. Lohse addressed the meeting briefly on the Doctors' Golf Association. All members of the association are invited to participate in future tournaments. Refreshments were served, and the usual sociability enjoyed.

The annual banquet was held Tuesday evening, February 5, at the Hotel Oakland. After a good repast and an enjoyable program of story-telling, vocal and instrumental music, W. W. Campbell, president of the University of California, the guest of honor, gave a most instructive and interesting address on "Where Do We Live?" illustrated with lantern slides. It was voted a delightful evening by all present.

The regular monthly meeting of the resident and visiting staff of the Alameda County Hospital was held Monday evening, February 4, at the Ethel Moore Memorial building. The program of the evening included:

Importance of Diagnosis in Oral Infection.—S. B. Fontaine.

Acid Base Balance in Metabolism.—H. Rogers. Discussion by Gertrude Moore and Q. O. Gilbert.

Case Reports—Adeno-Carcinoma of Colon with Perforation.—D. N. Richards.

Case of Laryngeal Diphtheria with Obstruction of Bronchi.—Q. O. Gilbert.

The Fabiola Hospital staff held its annual meeting at Fabiola Hospital, January 29. After disposing of the unfinished business of the preceding year, the election of officers for the ensuing year took place with the following result: E. G. Simons, chairman of the staff; H. D. Bell, vice-chairman, and Claire Rasor, secretary-treasurer. Owing to the amount of business and election of officers, there was no scientific program presented.

The Merritt Hospital staff meeting was held Monday, February 4, at Merritt Hospital, with President George Rothganger in the chair.

Tumors of the Breast.—W. E. Mitchell.

Discussion on the subject of "State Medicine."

After a general discussion of these subjects, light refreshments were served.

The staff of Providence Hospital held its annual meeting February 12. The following members were elected as officers for the ensuing year: President, O. D. Hamlin; vice-president, J. R. Fearn; secretary-treasurer, Frank S. Baxter; executive committee, G. G. Reinle, C. T. Devine, H. B. Mehrmann, H. W. Harding, E. H. Barbera, and N. A. Cary. Case reports were given by E. H. Barbera, W. B. Palamountain, C. A. Wills, and J. R. Fearn. This being

the annual meeting no regular scientific program was presented.

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary)—The regular monthly meeting was held at the residence of C. R. Leech at Walnut Creek, Hall Vestal presiding. The minutes of the previous meeting were read and approved, notifying the society of the election of the officers for the present year.

Discussions were held in regard to insurance. Letters were read from the Fort Wayne and other insurance companies, the consensus of opinion being that the "Group Insurance" was in the nature of an experiment, and as insurance is a matter of life and death, we had better stay with the ship that carries us safely over.

Cases of stomach trouble in children were discussed by the members, discussion being opened by McKenzie.

Members present were: C. R. Leech, Hall Vestal, George McKenzie, F. L. Horne, E. C. Love, J. Edward Clark.

J. Emmet Clark and William A. Rowell were elected to membership.

FRESNO COUNTY

Fresno County Medical Society (reported by T. Floyd Bell, secretary)—At the meeting held January 8, at the General Hospital of Fresno County, forty members were present.

Grant Selfridge of San Francisco gave a paper on "Cosmetic Surgery," which was illustrated by lantern slides.

H. E. Alderson, also of San Francisco, read a paper on "Occupational Dermatoses."

The following officers were elected for the ensuing year, and were duly installed: President, John D. Morgan; first vice-president, Paul S. Barrett; second vice-president, J. A. Montgomery; secretary, T. Floyd Bell; assistant secretary, Charles A. James; treasurer, United Bank and Trust Co.; board of governors, Frank Tillman; delegates, Guy Manson, J. R. Walker; alternates, Thomas F. Madden, L. R. Willson; board of censors, C. P. H. Kjaerbye, B. B. Lamkin, W. F. Stein; committee on ethics, J. L. Maupin, J. H. Pettis, A. B. McConnell; committee on program, A. H. Konigmacher, D. I. Aller, E. A. Larson.

The February meeting of the Fresno County Medical Society was held February 5 at the nurses' home of the General Hospital of Fresno County, with the following members present: Cross, Couey, Miller, Ingram, Stein, Wilson, Kjaerbye, Dixon, Jamgotchian, J. R. Walker, Wiese, Vanderburg, G. W. Walker, Sheldon, Montgomery, Lamkin, Webster, Weddle, C. A. Robinson, Ransom, Pettis, Scarboro, Ellsworth, Wheeler, Schottstaedt, Milholland, Broemser, Craycroft, Tillman, Bell, Morgan, Newton, C. D. Collins, Jorgensen, Wahrhaftig, Anderson, Aller, and Robbins.

Visitors present were H. O. Collins, director of the hospital; L. Seligman of Dinuba, and G. C. Nedry, recent arrival in Fresno.

The usual routine business was transacted.

A. B. Spalding, Professor of Obstetrics and Gynecology at the Stanford Medical School, presented a very interesting and instructive lecture on "Problems in the Repair of the Pelvic Floor." His lecture was illustrated throughout by lantern slides. He spoke of the anatomy of the pelvis, especially the muscles and fascia, and showed how damage was done to these structures and means of preventing such damage. He also dwelt upon the operative repair, especially emphasizing the use of the pelvic fascia.

S. M. Long was unanimously elected a member of the society.

General Hospital of Fresno County—A. C. Spalding was the guest of the staff of the hospital at luncheon February 5, and gave a very interesting and practical talk on "Eclampsia," dealing with various phases of the subject, but especially the treatment and particularly the non-surgical treatment.

On Tuesday evening, February 12, the staff of the hospital will hold its annual dinner and meeting at the California Hotel.

GLENN COUNTY

Glenn County Medical Society (reported by C. L. Terrill, secretary—The Glenn County Medical Society met at the Willows Sanitorium January 22, and elected the following officers for 1924: J. D. Edmundson of Orland, president; C. L. Terrill, secretary.

KERN COUNTY

Kern County Medical Society (reported by William H. Moore, secretary)—The regular meeting of the society was held at the Petroleum Club, Taft, January 15. The West Side branch of the society were hosts, and had prepared an entertaining program.

M. W. Pascoe was toastmaster at a very excellent dinner. The principal speaker of the evening was Granville MacGowan of Los Angeles, who spoke on "Skin Diseases," emphasizing careful observation for diagnosis and treatment. Charles L. Hawkins of Taft presented a clinic in kidney disturbances. He showed numerous interesting pyelograms. William Duffield of Los Angeles was a guest and proved an eloquent speaker.

Members present: H. W. Hawkins, Charles Hawkins, D. E. Edgerton, Homer Rogers, M. W. Pascoe, P. T. Page, T. M. McNamara, C. S. Compton, L. W. Ellis, O. W. Young, Joe K. Smith, Keith S. McKee, A. R. Moodie, F. A. Hamlin, F. J. Gundry, C. W. Kellogg, P. J. Cuneo, C. A. Morris, F. G. Linde, W H. Moore, E. A. Shafer.

LOS ANGELES COUNTY

Hollywood Hospital Stock Changed to Non-Dividend Basis—All friends of good hospital service will read with pleasure that the Hollywood Hospital Corporation has changed their organization to a non-dividend-paying basis. It will be remembered that the Hospital Betterment Service urged an organization of this class when the proposition first began to take shape.

Hollywood needs a good hospital, and some of the physicians and other good citizens deserve commendation for their persistence in making progress, in spite of many difficulties.

MERCED COUNTY

Merced County Medical Society (reported by Brett Davis, secretary)—The January meeting of the Merced County Medical Society was held January 17 at the office of the secretary. Members present: W. C. Catton, Brett Davis, J. L. Mudd, E. R. Fountain, J. L. McDaniel, and A. S. Parker. Visitors: F. W. Yocom of Livingston, C. F. Harrar, a newcomer in Merced; J. D. Dameron of Stockton, and J. C. Robertson of Modesto.

The society officers of 1923 were re-elected to serve during 1924, and F. W. Yocom, who joined the society, expecting to get a dimit from San Francisco County Medical Society, was elected delegate to the State society with J. L. Mudd as alternate. Claude Henry Church of Yosemite was also elected a member of the society, subject to approval by the State society officials.

Dameron then read a paper on "Private Hospital Management." Robertson talked on the same subject, and a general discussion by all present followed.

An epidemic of measles has been prevalent in and near Merced.

B. H. Bush is now a patient in the Burnett Sanitarium, Fresno, with laryngeal diphtheria.

MARIN COUNTY

Marin County Medical Society (reported by J. H. Kuser, secretary)—Clark, Dufficy, De Lancey, Hund,

Howitt, W. F. Jones, Kuser, Landrock, Larson, Mays, Newman, and Stanley were present at the January meeting, which was called to order by the newly elected president, R. G. Dufficy. The other officers are: Vice-president, Landrock; secretary and treasurer, J. H. Kuser; trustees, Larson, De Lancey, and Mays.

Mr. Gallagher of the Aetna Insurance Co. addressed the meeting on group insurance. The committee on the hospital reported the necessity for a new modern hospital of at least sixty beds. A committee was appointed to interest the residents of the county in financing the project.

Hospital Resolution

"Whereas, The city of San Rafael and county of Marin has hospital facilities inadequate and unsatisfactory for present and future needs, and

"Whereas, There is a definite requirement for better hospital care available to the citizens of the community, and

"Whereas, The establishment of a suitable hospital would be a valuable asset to the city and surrounding country, and

"Whereas, Such a proposed hospital would not only aid in the growth of the city, but would tend to conserve the health of the citizens, be it, therefore,

"Resolved, That the Marin County Medical Society sponsor such a proposed adequate hospital, and is ready and willing to help in any way; be it further

"Resolved, That a hospital building committee be appointed by the president of the Marin County Medical Society, with the sanction of its members, to devise ways and means to promote such a hospital; and it is further

"Recommended to have a committee of twelve citizens who have the general interest at heart to talk up this proposition and also submit a number of names of citizens to confer with said committee."

A motion was passed requesting our representatives in Congress to use their efforts to reduce the narcotic tax. The war being over, it was considered a rank injustice to tax the medical man in order to enable him to relieve pain.

MODOC COUNTY

Babies All Right Now—Under this heading, the Cedarville Record says editorially:

"Well, the babies of Surprise Valley and Modoc County ain't agoin' to have any more sickness now, because Dr. ——— was around last week and told the babies all about how to tell their mothers when they didn't feel well. Miss ———, supervisor of nurses, also came along, probably to nurse the doctor. Miss ——— was also in the party to tell the kiddies when they had the toothache. We don't know why Mrs. ——— came along, unless it afforded her an excuse to draw her salary. Their visit here was highly gratifying to the taxpayers, as it makes a big dent in the tax budget. The taxpayers are, of course, tickled plumb to death to have the ladies visit the county, as it resulted in so much good being done—especially in providing them with a pleasant junketing trip."

The editor is wrong in thinking that local and State taxpayers pay all this bill. Under the Sheppard-Towner law our beneficent Washington government pays half back to the State. Of that Washington money, some was also collected locally.

President Coolidge has announced his unequivocal opposition to Federal subsidies to State governments, and so we don't have any expansion of this particular fad for at least two more years.

PLACER COUNTY

Placer County Medical Society (reported by Robert A. Peers, secretary)—The society held its regular meeting at the Placer County Hospital in Auburn on the evening of February 9, President Miner presiding. The following members were present: H. N. Miner, C. J. Durand, R. J. Nicholls, G. H. Fay, H. N. Kanner, R. A. Peers, J. A. Russell, J. G. Mackay, F. L. Fanning, L. B. Barnes, F. E. McCullough

Visitors: Richard W. Harvey, Ernest H. Falconer, Cyril E. Lewis.

Fred Harrison of Georgetown and Cyril E. Lewis of Auburn were elected members of the society.

Dr. Mackay, chairman of the Committee on Fee Schedule, made his report. The final decision on the report was withheld until the matter could be further discussed at the next meeting.

The literary program of the evening consisted of two very interesting addresses, which were quite generally discussed. Richard W. Harvey of San Francisco gave an address on the "Personality of the Patient." Ernest H. Falconer, also of San Francisco, discussed the significance of blood pressure.

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement (reported by G. J. Hall, secretary)—At the January meeting of the society, G. N. Drysdale, the newly elected president, presided. Wallace R. Briggs read a paper on "The Pathology of the Eye in Relation to General Pathology." Interest in the subject was enhanced by the use of original lantern slides and beautifully prepared sections of the eye, showing pathological conditions.

The society is having its programs presented by the local members, and finds this a very excellent plan. It has been definitely proved that with the clinical material available the Sacramento physicians are writing and presenting papers and discussions on a par with those that were presented by other plans. During the last few years there has been frequent discussion, in an effort to determine the advisability of inviting speakers from other centers or urging local men to present their ideas in discussions. After having tried both plans for several years, the directors have definitely established the policy of having all papers presented by local physicians, with the exception of the paper at the annual banquet. And also, of course, we will gladly urge the acceptance of an invitation to speak here by any physician from any place who has some special work to report that would be of general interest. The society feels that Sacramento is very rapidly being recognized as a medical center, and that this recognition is justly deserved.

In reference to the post-graduate clinic plan proposed by the State Association, the Sacramento Society does not feel any need for such work here, and as a consequence has voted to answer the question in the main negatively. The reason for this action is in accord with the plan referred to above, and not an expression of sentiment against a plan that obviously will probably be very valuable to smaller societies.

Our annual meeting and banquet will again be held, as always before, on March 17, that being the date of the first meeting of this the oldest medical society now existing in the State.

SAN BERNARDINO COUNTY

San Bernardino Medical Society (reported by E. J. Eytinge, secretary)—The society met February 5 at San Bernardino County Hospital, with fifteen members present, sixty-six absent, and thirty-five guests.

Nelson W. Janney of Los Angeles presented what, he said, has proved to be rather a practical adaptation of the insulin treatment of diabetes. The talk was illustrated by lantern slides, as the society now has a Spencer delinearscope, and is prepared to show slides, cards, photographs, and small objects at its meetings.

Phillip J. Tunnell of Loma Linda was elected to membership.

SAN DIEGO COUNTY

San Diego County Notes (reported by Robert Pollock)—The new La Jolla hospital, a modern fireproof structure of fifty beds, is rapidly assuming an outline on the Prospect avenue skyline. Situated in this delightful suburb with its outlook on the Pacific, this hospital will furnish a most attractive place

for the treatment of nervous and chronic, as well as post-operative cases. However, it will be adequately equipped in every way, containing a modern operating room, X-ray and clinical laboratories, diet kitchen, sun parlors, and the best of nursing service. Attached to it by covered corridors will be a well-planned metabolic clinic and hospital of fifteen beds, bringing the total capacity of the two buildings to about sixty-five beds. The metabolic department will have its own director—applications for which position are now in order—who will be allowed opportunity for and will be encouraged to do research work along metabolic lines. No movement better calculated to arrest the attention of those who watch closely the development of the times has been started in Southern California in recent years.

The County Medical Society went to Camp Kearney Hospital Tuesday, February 12, to participate in an intensive study of the problems involved in the treatment of tuberculosis. Papers were presented by members of the medical staff of the hospital as follows:

"Tuberculin Therapy." D. O. N. Lindberg.
"Helio Therapy." Bryant R. Simpson.
"Artificial Pneumothorax." W. A. Cashion.
"Tuberculosis of Larynx." John H. Mallery.

After general discussion of these papers, a luncheon and smoker was enjoyed through the hospitality of the medical commandant and his staff.

G. R. Stevenson, M. D., has recently been appointed by the county supervisors to the office made vacant by the death of O. G. Wicherski. This appointment of county physician and medical director of the San Diego County General Hospital meets with the approval of the County Medical Society and the community at large. A splendid field is here offered for the expression of those professional, executive, and social qualities of which Stevenson has shown himself to be possessed.

Sheppard-Towner Clinic for Escondido — The Sheppard-Towner law enforcement machinery is starting a baby clinic in Escondido, according to press dispatches. Mrs. Rose Crise is chairman of the standing committee that will conduct the clinic.

SAN FRANCISCO COUNTY

Eye, Ear, Nose, and Throat Section of the San Francisco County Medical Society (F. C. Cordes, secretary)—At the meeting of January 22, Kaspar Pischel gave an extract of Karl Hamburger's paper, "Experimental Glaucoma Therapy." Hamburger injected synthetic suprarenin sub-conjunctivally near the cornea as much as ½ cc. A few minutes afterward the pupil dilates to extreme mydriasis; synechiae which withstood action of atropin are sometimes torn.

This observation induced Pischel to add to the atropin cocain sub-conjunctival injections in cases of stubborn iritis an equal amount of adrenalin, with good results. The intraocular tension is reduced by adrenalin injections considerably from 20 to 50 mm., and even the other not injected eye often becomes softer. The healthy eye sometimes becomes soft (10 to even 6 mm.). In the chronic glaucomatous eyes, pressure went down 20 to 50 mm.; even the other not injected eye often becomes softer. Several cases in which eserin had had no effect, after the suprarenin injections, reacted promptly on eserin. Hamburger's explanation is: "Glaucoma is caused by atony of the blood vessels, on account of the atony of the sympathetic nerve. Therefore, he says, the uveal corpus cavernosum is filled with blood and increases the pressure in the interior of the eye. The essentials of the therapy of glaucoma consist in stimulating the sympathetic nerve and thus stimulate the vascular tonus."

Doctor Pischel tried adrenalin injections in a few cases; the dilatation of the pupils was quite striking; the lowering of the pressure was not uniform. He asked the members to try it and report their experiences.

Charles Edward Locke Jr. presented a paper on "Three Cases Pulsating Exophthalmos or Intracranial Arterio-Venous Communication"—Three cases which had had unilateral pulsating exophthalmos were presented. One of these patients had been treated only by simple digital compression of the carotid, the second by digital compression and ligation of the internal carotid artery, and the third by digital compression and by both ligation of the internal carotid artery and the orbital veins. The first patient responded quickly to compression of the carotid and now, three years later, shows nothing except slight enlargement of scleral and episcleral vessels and atrophy of the disc on the affected side. The second case did not improve under digital compression of carotid, but did show marked improvement after Locke ligated the internal carotid. The exophthalmos decreased, the bruit ceased, and the extra ocular muscles palsies became much less marked. The third patient's became worse during the preliminary course of digital compression, but ligation of the internal carotid decreased the exophthalmos, and relieved entirely the diplopia and strabismus. Later, however, a marked pulsating swelling appeared above the inner angle of the eye. Locke and Cordes performed a ligation of the superior ophthalmic vein and its branches. This did away with the pulsating swelling; but some months later the veins of the temporal region became engorged and tortuous. There still remains a certain degree of exophthalmos. In reviewing the literature, Locke concluded that digital compression of the carotid should be used always as the initial therapeutic procedure. If unsuccessful, internal carotid ligation should then be used. Since de Schweinitz and Holloway's analysis of the 313 cases in the literature up to 1907, Locke was able to collect 285 additional cases, making a total of 598. The pathology of the condition is usually arterio-venous communication between the internal carotid artery and cavernous sinus. Less often simple aneurism of either the internal carotid or ophthalmic artery, or tumor of the orbit is the cause.

Discussion—Otto Barkan—The visual field defect in one of Locke's cases shows that the line of fracture must have involved the bony optic canal. In the optic canal, the periosteum constitutes the sheath of the optic nerve. The septa of the optic nerve are formed by extensions from the periosteum: thus the fracture of the bone and consequent laceration of its periosteum in this situation frequently involves a laceration of the substance of the optic nerve with hemorrhage and edema and consequent segment defect in the visual field as is seen in this case.

E. B. Towne presented a paper on "The Value of Positive Signs in the Localization of Brain Tumors." The improved results in the field of neurological surgery, though partly due to the technical proficiency of the operator who is accustomed to this work, are to be largely attributed to the fact that every effort is now made to diagnose and localize tumors in an early stage. With the lesion accurately localized, extirpation of Roentgen ray therapy, depending on the situation and on the pathological character of the tumor, may be undertaken. Nothing can displace the usual methods of diagnosis—careful history, neurological examination, eye and ear examinations, and Roentgen rays of the skull—as a basis of diagnosis. But a considerable proportion of tumors cannot be accurately placed without further evidence, and we have other methods which are of value. These factors may be taken up under four headings, with illustrative case reports and lantern slides. In each case the practical diagnostic value of the various findings will be discussed, with special reference to the facts contributed by examination of the eyes, nose, and ear. (1) Roentgen-ray demonstration of calcification in brain tumors is a positive and conclusive finding. Newell found that 40 per cent of the verified brain tumors examined by the department of roentgenology at Stanford University Hospital during 1922 were visualized and accurately localized by the skull films. One patient, who had a calcified glioma of the

frontal lobe, gave entirely negative findings otherwise. (2) Proliferation of the skull over meningeal tumors (dural endotheliomas) is a positive and conclusive finding, which is of especial importance when these tumors, as frequently happens, compress a frontal lobe. (3) Changes in the percussion note of the skull (McEwen's sign), is a corroborative finding which requires confirmation by other localizing signs. (4) Cerebral pneumograms (Dandy) mark the greatest advance of recent years. Deformity of the air-filled ventricles gives positive localization of the lesion. The danger has probably been overestimated; there have been no bad results in the Stanford Clinic. Cases were reported in which the pneumograms showed the situation of the tumor. This is to be considered the final and certain method, to be used when all other means fail.

Discussions — Howard Naffziger — I agree with Towne, in regard to the superiority of quantitative perimetry with 1 mm. discs as compared to other methods. I would like to ask a question of the ophthalmologists present in regard to two cases of probable cerebrallar tumor with choked discs of six diopters I have recently seen. Decompression was done in each, resulting in reduction of the swelling of the discs and appearance of slight atrophy. After one and a half years, intracranial pressure was again much increased, but with very little associated edema or choking of the discs. I wonder has this been observed before and might it be explained by blocking of the lymph channels as result of the first choking? I have received a great deal of benefit from otological examination in two cases that I recall. Ventriculograms are of great aid. We have had no fatalities from the method as yet, and only one or two moderately severe reactions. In regard to calcifications, and with due regard to the improved X-ray technique and the excellent work of Chamberlain and Newell, I do not feel that 40 per cent could show calcification. Many calcifications, possibly the result of old infective processes, cannot be interpreted as meaning brain tumor.

Doctor Newell—I would like to lay stress upon the importance of ocular findings. Although some are not localizing, just as in X-ray scalloping of the skull or erosion of the sella may not be localizing, other eye-signs are distinctly localizing and have their counterparts in X-ray findings such as destruction of the floor of the sella or calcifications. I agree with Naffziger that the series of 40 per cent calcifications is extraordinary and cannot be expected to be repeated; there happens to be a large proportion of calcified gliomata in this series. X-ray localization of the tumor is disappointing on the whole. Yet one or two cases with absolutely no other findings except convulsions in which X-ray showed tumor due to the accident that it was calcified make one feel the importance of X-ray study of the suspected tumor.

Walter Schaller — A choked disc is an indirect symptom most frequent in brain tumor, and this makes the responsibility of the eyeman a very great one. I have seen a number of examples of choked discs going on to blindness without having had the benefit of these modern methods of diagnosis. I have seen such cases ascribed to sinus disease. Any case which is not frankly due to a sinus should have the benefit of these tests. I should like to ask of the ophthalmologists whether it is possible to differentiate between a toxic optic neuritis and a papilloedema due to brain tumor by mere inspection. Without the benefit of careful perimetric examination and neurological examination, I believe one cannot differentiate between the two.

Kaspar Pischel—I would not venture to make a differential diagnosis from the ophthalmoscopic appearance alone. I recall from my own experiences cases of pronounced papillitis caused by albuminuria, while I have fresh in my mind a case of brain tumor who showed when first seen by me only a haziness of the outlines of the disc.

Southern Pacific Hospital — The monthly staff meeting of the Southern Pacific General Hospital was held on Wednesday, February 6, at 8:30 p. m.

Program—"My Lady Gout," J. Wilson Shiels; Informal Talks by D. A. Beattie (San Jose), M. W. Brown and W. O. Smith (Alameda) and A. H. McFarlane (Mountain View), Company district surgeons; Report of a Case of Myelogenous Leukemia, Philip King Brown; Report of Two Cases of Lymphogenous Leukemia, W. T. Cummins; Roentgen Demonstration, L. B. Crow.

St. Joseph's Hospital Staff Meetings—St. Joseph's Hospital staff, San Francisco, on February 13 concluded "Modern Treatment of Syphilis" by having physicians point out particulars of the subject in their respective lines.

Ludwig A. Emge stated that proper treatment prevents many of the remote effects of syphilis, including ectopic pregnancy. The new conception of heredity permits the mother to nurse her baby. Wassermann reaction in the new-born is unreliable until after twenty days. Placental diagnosis, though difficult, is better. X-ray of foetus is useful where autopsy is refused. Neosalvarsan and mercurial rubs, with appropriate rests, are best in pregnant mothers and result in the birth of three-fourths of the babies, as against one-fourth where no treatment had been given.

M. L. Cohn considers mercury and arsenic most important when treating hereditary syphilis. Infants under one year should be given inunctions and mercurial injections. After the first year, calomel and chalk powder, according to weight, 1 per cent bichloride injections with massage of site, are used. Eight weekly mercurial injections, followed by eight weekly arsphenamine injections, are used. Injection into the longitudinal sinus is resorted to in infants under one year, if necessary. Intramuscular injections of arsphenamine are not advised. Iodides and the bismuth preparations are not used.

J. M. Wolfsohn spoke on neurosyphilitic therapy, which may be necessary even nine months after the primary lesion. There may be arterial, meningitic or parenchymatous lesions, only the first existing alone, although all occur in combination. Tabes is most common and is treated systemically, like any other lesion. Inunctions with oleate of mercury or blue ointment, thirty-six rubs of a dram each, followed by benzin washing, is used. After the first week, start with neoarsphenamine. Watch the kidneys. If patient cannot stand Hg or As, try the bismuth preparations. Hectine "A," "B" and "C" hectargyre can also be used and will cure, especially early cases. The Burn's method of injecting mercurialized serum intraspinally is used only where there are lancinating pains. Dercum's spinal drainage and intravenous salvarsan is best in other cases. Regenerative educational movements are useful. Give three courses of treatment a year and treat three years. In general paralysis of the insane, start with only .10 of neosalvarsan; in five days .15 and repeat and increase gradually. Salicylate of Hg and calomel injections cause pain. K I is useful in arterial lesions (thrombosis and embolism)—not in parenchymatous or tabetic cases. In G. P. I. use in small amounts, gtts. XX t. i. d. Be careful of the teeth in all cases.

Election of officers for 1924 resulted in the reelection of A. S. Musante as head of staff; Frank Lowe as vice-president; Louis Overstreet as secretary; R. F. Grant as financial secretary; F. C. Keck as treasurer, and William Quinn, W. T. Cummins, L. B. Crow, P. Collischonn, C. E. French, T. J. Janes, J. M. Stowell, and D. E. Stafford as executive board.

The program for March 12 will consist in "Medical Improvements Noted in the Old World," by Alex Keenan, and "X-ray as an Aid to Early Diagnosis," by F. H. Rodenbaugh.

The Franklin Hospital Staff met on February 4, 1924, Otto Westerfeld presiding.

The officers elected for the ensuing year are as follows: Chairman, J. Wilson Shiels; vice-chairman, W. H. Heinzman; secretary, Ewald H. Angerman.

J. Wilson Shiels read an interesting paper on "Gout," and Harry E. Alderson gave a talk on "Oc-

cupational Skin Diseases" to an appreciative audience.

The popularity of the morning clinics prompted a number of those present to pledge their aid in furthering this work by showing their unusual or timely cases.

S. J. Hunkin conducted the morning clinic on February 4, 1924, and presented several instructive orthopedic cases.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by Alex C. Soper Jr.,secretary)—Meeting called to order Monday, February 11, at the Cottage Hospital, President Robinson in the chair. Present: Twenty-one members, four internes, and the following guests: Mr. Curtis, superintendent of the hospital; Dr. Blatherwick of the metabolism wing; Dr. Allen, president of the dental society.

Irving Wills and W. H. Eaton were unanimously elected to membership.

Moved, seconded, and passed with one dissenting vote that the dues of the society for 1924 be $12.

Correspondence from the U. S. Veterans' Bureau in re the proper reports on cases of ex-service men ill reportable diseases, and from Mr. J. C. Thorpe, in re mechanical therapy, read.

Hill Hastings, M. D., of Los Angeles gave a very interesting talk on "The Tonsils as a Source of Joint Infection, with Subsequent Reports from One Hundred Patients." Discussion was lengthy and thorough, and participated in by Allen Williams, Nuzum, Profant, Means, Mellinger, Allen, Stevens, and Brush.

SANTA CLARA COUNTY

Medical Luncheon Club (reported by George L. B. Barry)—The Santa Clara County Medical Luncheon Club recently held its semi-annual election of officers. Alson A. Shufelt was elected president; P. A. Jordan, vice-president; and George Long Barry, secretary-treasurer.

The club includes in its membership only those doctors who are members of the County Medical Society. Meetings are held every Friday at noon, at which time a program consisting of a speaker from out of town or from within the club is heard. Many local, as well as general, subjects of medical interest are reviewed. It has been the pleasure of the club recently to hear from several of its members who have been abroad or East; also from two local attorneys at law—attorney Ernest E. Williams, on a medico-legal subject, and attorney Edwin A. Wilcox, on his recent visit through Spain.

J. I. Beattie and Doxey Wilson recently returned from an Eastern trip, and each discussed the work being accomplished at Chicago and Rochester medical centers.

Jay C. Elder, George Hall, L. M. Rose, and Donald Davy have recently returned from European medical centers and spoke about their personal experiences, each having gone to a different clinic.

H. C. Brown, city health officer, reviewed the milk situation and said that San Jose's milk supply was scoring high and ranking first as to quality among the cities in California.

At a round-table discussion of interesting patients, John Hunt Shephard elucidated the technique of the operation for the removal of thyro-glossal duct cyst. Bert E. Lochr reported a case of malignancy of the uterus treated with X-ray, but followed by multiple metastatic nodules of the skin. D. E. Tiffany discussed a case of frontal sinusitis with medical treatment. An unusual instance of multiple subperiosteal abscesses was reported by Fred S. Ryan. Cultures made by F. Proescher in the San Jose Hospital laboratory have repeatedly shown a pure growth of trichomycete.

Los Gatos has Diphtheria Clinic—The Board of Trustees of Los Gatos grammar school offers to the pupils free treatment in the prevention of diphtheria. Parents of the school children have been circularized and asked to give their consent to have the toxin-antitoxin immunization given.

California Medical Association

Abstract of the Minutes of the 142nd Meeting of the Council of the California Medical Association—Held in Los Angeles Biltmore, Los Angeles, Calif., January 26, 1924. Present: Edwards, MacGowan, Parkinson, Carrington, Kiger, Stover, De Lappe, Beattie, Bine, Kress, McArthur, Curtiss, Emma W. Pope, and General Counsel Peart. Absent: Strietmann, Coffey, Ewer, McLeod, Hamlin, and Saxton Pope.

Seal: Whereas, The name of this society was changed on the adoption of the amended constitution by the House of Delegates at the annual meeting held at San Francisco, June, 1923, from "Medical Society of the State of California" to "California Medical Association"; and

Whereas, The seal of the society is now inscribed as follows: "The Medical Society of the State of California, 1856 and 1902"; now, therefore, be it

Resolved, That the inscription on the seal of this association be amended and changed to read "California Medical Association, 1856 and 1902."

Appointment of Indemnity Defense Fund Trustee—William Ellery Briggs of Sacramento, whose term as trustee of the Indemnity Defense Fund expired January 1, 1924, was elected to succeed himself for the ensuing three years.

Bank Accounts of Indemnity Defense Fund—The following resolution was unanimously passed:

Whereas, The name of the society was changed by amendment of its constitution at the annual meeting of the House of Delegates held at San Francisco, June, 1923, from "Medical Society of the State of California" to "California Medical Association"; and whereas, certain moneys of the Indemnity Defense Fund are on deposit in various banks, and the Board of Trustees thereof is named in said accounts and otherwise as "The Board of Trustees of the Indemnity Defense Fund of the Medical Society of the State of California"; now, therefore, be it

Resolved, That the title of the said board and of the said bank accounts, wherever same appear, be changed to read and appear as "The Board of Trustees of the Indemnity Defense Fund of the California Medical Association."

Model Constitution and By-Laws for County Medical Societies—The general counsel submitted the Constitution and By-Laws of the San Francisco County Medical Society, stating that this constitution was prepared to meet the particular needs of that county society, but that he believed it might serve as a model form for other county societies.

After discussion, it was the sense of the council that a copy of the Constitution and By-Laws of the San Francisco County Medical Society be furnished each member of the council for his consideration; and that the question be placed on the docket for the next council meeting as to the desirability of approving such constitution and offering it to county societies as a model form.

Professional License Tax—Resolved, That a committee of three be appointed by the Chair to take up the matter of professional license tax in conjunction with the committee of the American Society of Civil Engineers or any other agencies.

Bulpit vs. Fullerton Ordinances—The secretary read correspondence just received from the secretary of the Orange County Medical Society regarding the charges preferred against J. Muncey Bulpit of Santa Ana for practicing in the town of Fullerton without a license, although licensed to practice in the State of California and answering an emergency call at the time of his arrest. The question of municipal license tax was then discussed by all present.

Action by the Council—Resolved, That the gen-

eral counsel be empowered to take up, investigate and defend, if necessary, the case of Dr. Bulpit vs. the town of Fullerton.

Physicians' Income Tax—Wire sent by the chairman of the council to the A. M. A. regarding income tax and reply thereto were read, and the present ruling whereby convention expenses are not deductible from physicians' income taxes, together with the possibility of securing a reversal of such ruling was thoroughly discussed.

Action by the Council—Resolved, That letter be written to all senators and representatives in California regarding the re-establishment of the ruling exempting physicians' traveling expenses to medical conventions from their income tax; and that it is the sense of the council that such expenses are deductible by members of the association.

Tax on Earned Incomes—The general counsel discussed the present tax on earned incomes, and recommended that the A. M. A. be requested to circularize all State societies regarding a tax reduction on earned incomes as against unearned incomes.

Action by the Council—Resolved, That the A. M. A. be requested to take up the question of a tax reduction on earned incomes as against unearned incomes with all State units and all other professional groups, with a view to making this national action; and that all California physicians be requested to get in touch with all California senators and representatives.

Gorgas Memorial — The secretary read a letter from Franklin Martin, chairman of the board of directors of the Gorgas Memorial, requesting the secretary to accept membership on the State governing committee and subscribe $100 to the Endowment Fund as such a member; this money to be used for advertising purposes only.

Action by the Council — Resolved, That the communication be received and placed on file; that the editor be instructed to furnish the necessary publicity in the form of an editorial in the Journal; and that the whole question be laid on the table.

Question of Dividing United States into Territorial Districts—The secretary read the report of the Committee on the Division of the United States into Territorial Districts and also extracts from the minutes of the House of Delegates of A. M. A. as adopted in June, 1923, which states that this plan is neither desirable nor feasible.

Action by the Council—It was the sense of the council that no action be taken at this time; and that the committee be discharged, with thanks.

Woman's Auxiliary — The secretary read a letter from ex-President Brainerd embodying the report of his personal representatives to the annual meeting of the Woman's Auxiliary of the A. M. A.

Action by the Council—The communication was received and placed on file.

Bunnell Memorial — The secretary read a report from the committee on the Bunnell Memorial. It was the sense of the council that the report be received and placed on file, and the committee be requested to furnish further data to the council.

Keene Committee—Report of the committee appointed to investigate the condition of the grave of the first president of the Society, J. B. Keene, was read and considered.

Action by the Council—Resolved, That the committee's report be accepted with the understanding that the work shall be properly done for a sum not to exceed $175; and that the matter of inscription be referred to the chairman with power to act; and that the committee report back to the council.

Drug Addiction — The secretary presented a request from the Bureau of Drug Addiction for the co-operation of the California Medical Association, together with a report from the League for the Conservation of Public Health on the same subject, which was fully considered by the council.

Action by the Council—Resolved, That the council having heard the report from the League for the Conservation of Public Health, the communication from the Bureau of Drug Addiction be received and placed on file.

Audits for 1923—The secretary read audits of the accounts of the association and the fund as prepared by Lester Herrick and Herrick, public accountants, for the year 1923.

Action by the Council—Resolved, That the reports of the auditors, Lester Herrick and Herrick be received and placed on file.

Recommendation of Physicians—Question of policy, with reference to the compilation of an alphabetical list of all members of the association by specialties, was considered and thoroughly discussed, inasmuch as many requests are received by the State office for such information.

Action by the Council—Resolved, That, when an inquiry comes into the State office for a physician or surgeon in any particular specialty, the secretary refer those requesting such information to the proper officials of the county society where the services are to be rendered; and that the county society be notified of such inquiry. Dr. Bine voted "No," and desired his vote so recorded.

Tentative Program for 1924 Meeting—The secretary presented a tentative program for the 1924 meeting commencing with a council meeting on Sunday evening, May 11, and continuing through Thursday, May 15.

Action by the Council—Resolved, That the program, as presented by the Committee on Scientific Program, be adopted.

Graduate Work for Physicians in General Practice—Progress report from the committee on graduate instruction for physicians in general practice was read and considered.

Action by the Council—Resolved, That the partial report of the committee on graduate instruction for physicians in general practice be received; and that the chairman of the committee be instructed that, if any county society desires to hold a meeting along the lines of their report, they be allowed to do so; and that the committee report back to the council.

Optional Medical Defense — The general counsel presented a revised form of announcement of "Optional Medical Defense," as requested by the council.

Action by the Council—Resolved, That the form and contents of the anouncement of Optional Medical Defense as this day submitted to the council by the legal department be and the same is hereby approved; and that a copy of such announcement be mailed to each member of the association; and that such other notice thereof be given as the executive committee may determine.

Commercial Exhibits—The question of commercial exhibits for the 1924 meeting was brought up and discussed, in view of a request for definite instructions from William Duffield, chairman of the committee on commercial exhibits.

Action by the Council—Resolved, That William Duffield be instructed that commercial exhibits at the 1924 State meeting shall comprise only such articles as are approved by the Council on Pharmacy and Chemistry of the A. M. A., or that are of strictly ethical character.

Change in Name of Journal—Resolved, That the editor be requested to change the title of the association's Journal at such time as he thinks appropriate to conform with the present name of the association.

Illness of ex-President Brainerd — Dr. McArthur advised the council of the serious illness of ex-President H. G. Brainerd.

Action by the Council—On motion of McArthur, seconded by Kiger, the council, having heard with regret of the serious illness of former President H. G. Brainerd, extends its sympathy and hope for his speedy recovery.

Publicity for the 1924 State Meeting—The question of publicity for the 1924 State meeting was considered.

Action by the Council—On motion of Kress, seconded by De Lappe, it was the sense of the council that Mr. Celestine J. Sullivan of San Francisco, ex-

ecutive secretary of the League for the Conservation of Public Health, be requested to take charge of publicity matters in connection with the annual meeting of the association.

Industrial Medicine—All members of the council discussed the various problems and points brought out at the open meeting held in the evening, to which meeting all members interested in industrial medicine and surgery were invited.

Action by the Council—Resolved, That the various matters under discussion at the open meeting, together with those matters included in correspondence before the council, be embodied in the form of specific queries and submitted to every member of the Industrial Medicine and Surgery Section of the State Association, with a request for recommendation and suggestions; and further that this questionnaire be submitted to the executive committee for approval before transmittal of said section.

Utah State Medical Association

J. R. MORRELL, M. D., Ogden - - President
WILLIAM L. RICH, M. D., Salt Lake - Secretary
W. R. CALDERWOOD, M. D., Associate Editor for Utah

Salt Lake County Medical Society (reported by M. M. Critchlow, secretary)—A regular meeting of the Salt Lake County Medical Society was held at the Commercial Club, Salt Lake City, Monday evening, January 28, 1924, with sixty-seven members and seven visitors present; President A. A. Kerr presiding.

Minutes of the previous meeting were read and accepted without correction.

F. F. Hatch presented a very interesting case from whom he had removed a hypernephroma, and pathological specimen was demonstrated.

L. N. Ossman presented a case of arthritis of the spine, with abdominal symptoms showing improvement after application of the body-cast. He also presented interesting X-ray films of the spine.

A. J. Hosmer presented a case of fracture of the eleventh and twelfth dorsal vertebrae on which he had done a Hibbs operation.

The program for the evening was a symposium on backs. J. F. Critchlow presented the subject of "Railway Spine," illustrating very clearly how the condition was brought about by many examinations in a patient susceptible to suggestion.

A. J. Hosmer presented the subject of "Fractures and Dislocations," discussing symptoms and methods of relief by fixation. To illustrate his points, there were X-ray films shown by J. P. Kerby.

S. C. Baldwin presented the subject of "Arthritis of the Spine," stressing physical examinations, X-rays, and history. He dwelled especially on infectious and traumatic arthritis and treatment by immobilization. These papers were discussed by Tyree, Ossman, Holbrook, Morrell of Ogden, Ezra Rich of Ogden, and J. P. Kerby, who exhibited some films showing anomalies.

The proposed amendment to the By-laws, providing for a permanent medico legal committee, was read. Raley moved it be accepted.

Kerby moved that the amendment be amended so that the three members would be appointed to serve a term of three years, three members a term of two years, and three members a term of one year. Seconded and carried as amended. This was discussed briefly by J. F. Critchlow, Colonge, and Beer.

The applications for membership from J. Clinton Bown, F. K. Root, and Charles W. Woodruff were voted upon. These men were elected to membership.

A letter from Carl L. Sandberg, expressing appreciation for the floral offering sent by the society to Mrs. Sandberg's funeral, was read.

Minutes of the Salt Lake County Medical Society February 11, 1924

Sixty-seven members and three visitors were present at the regular meeting of the Salt Lake County Medical Society held at the Commercial Club, Salt Lake City, Monday evening, February 11. President Kerr presided.

Minutes of the previous meeting were read and accepted without correction.

Judge Harold M. Stevens spoke on the purpose of the Community Clinic and gave a report of the work done and cost of operating clinic. He also gave some examples of the cases treated, giving brief clinical history and results.

No clinical cases were presented.

The first paper of the scientific program was enentitled "Goitre in the Great Basin," given by George W. Middleton. He discussed the distribution, probable cause, treatment and results in the goitre cases he has treated. He also discussed the technique of operation, post-operative treatment and medical treatment. This excellent paper was discussed by L. J. Paul, W. L. Lindsay, Skidmore, Hampton, Hosmer, and Ralph Richards.

E. S. Pomeroy gave a paper on "Newer Methods in the Treatment of Syphilis." He discussed the variout methods of treatment with the older and newer drugs giving their uses and dangers. Discussion by Schulte, Estes, and Rich.

B. W. Black read a brief outline of the life of our late member, L. B. Laker of Eureka, Utah. He read a resolution and moved that it be spread upon the minutes and a copy sent to the family of the deceased. Seconded and carried.

W. R. Tyndale reported for the Library Committee, putting forth the idea of having a loan library. He moved that the Library Committee should be enlarged so as to include one member of all the various specialties. Seconded and carried.

M. M. Nielson reported that the committee appointed to investigate institutions caring for charity cases was not ready to give a final report.

Nevada State Medical Association

HORACE J. BROWN, M. D., Reno.....President
CLAUDE E. PIERSALL, M. D., Reno.....
..Secretary-Treasurer and Associate Editor for Nevada

Annual Meeting—Great enthusiasm is being manifested in the arrangements and program for the next annual meeting of the State Association. Offers of papers are being received in an encouraging number, but we expect more from other members.

Both the Elko County Society and the Eureka "bunch" are 100 per cent in membership and dues, and the Eureka men are 100 per cent in offers for papers.

Our Journal of Medicine goes to print on the 20th of each month. Only our members who have paid before that date may expect their Journal that month. Dues are now due. All members are urged to send in items of interest for publication in the Journal. Either send them to your associate editor for Nevada, or to the editor of the California State Journal of Medicine direct. The California State Journal of Medicine will be glad to give more space to Nevada if material is sent to the editor.

Medical School News

Teaching Therapeutics and the Art of Medicine—With a desire to improve the teaching in practical therapeutics and the art of medicine, the department of medicine at the University of California Hospital has selected fourteen alumni of the school to devote a week of their time to this instruction during the spring semester (January 15 to May 15). Such instruction will be given to senior students and interns at the University Hospital. Each alumni instructor will spend his entire time at the hospital, taking part in ward rounds, assisting in the instruction of students, holding seminars and giving one talk to the entire student body and house staff during the week.

If the plan works to the mutual advantage of students, alumni, and faculty, it probably will be repeated each year. The schedule is as follows:

January 28-February 2, Walter C. Alvarez, 177 Post street, San Francisco.

February 4-9, J. W. Shiels, 516 Sutter street, San Francisco.

February 11-16, Henry Chesley Bush, Arroyo Sanitarium, Livermore, Cal.

February 18-23, James W. Seawell, 117 North street, Healdsburg, Cal.

February 25-March 1, Dewey R. Powell, Farmers and Merchants' building, Stockton, Cal.

March 3-8, Ruby L. Cunningham, Infirmary, Berkeley, Cal.

March 10-15, Elmer W. Bingaman, Gonzales, Cal.

March 17-22, Daniel I. Aller, 908 Mattei building, Fresno, Cal.

March 24-29, John N. Chain, Fourth and E streets, Eureka, Cal.

March 31-April 5, A. A. Alexander, 1307 Broadway, Oakland, Cal.

April, 7-12, Irvin H. Betts, Visalia, Cal.

April 14-19, Otto T. Schulze, Napa, Cal.

April 21-26, Ergo A. Majors, 532 Fifteenth street, Oakland, Cal.

April 28-May 3, Dan H. Moulton, Chico, Cal.

University of California Medical School—Several conferences have been held by members of the faculties of the Stanford University Medical School and the University of California Medical School for the purpose of discussing questions of medical education which have arisen. At a recent conference a committee, composed of William Ophuls, Frank M. McFarland, Emmet Rixford of Stanford University and W. P. Lucas, C. L. A. Schmidt, and L. S. Schmitt of the University of California Medical School reported the results of a study of the present premedical requirements.

By action of the Graduate Council of the University of California, medical students may offer advanced work in the medical curriculum toward the master's degree. Work in the clinical departments may also be offered toward the degree of Doctor of Philosophy.

A joint conference between representatives of the Graduate Council and the Medical School has recommended that the proposed degree of Doctor of Public Health be not granted unless the candidate has previously received the degree of Doctor of Medicine.

A committee of the faculty is now at work studying a revision of the undergraduate medical curriculum, with a view to making such changes as are desirable under the present Medical Practice Act.

In order that medical students may appreciate the value of carrying out the resolution of the Medical Society of California relative to a health center, the advisory board of the Medical School authorized the establishment of an adult health center in connection with the University of California out-patient department.

By mutual agreement the affiliation between the University of California Medical School at St. Luke's Hospital has been canceled.

A course of public lectures has been established. These lectures are held on Sunday afternoons at 2:15 p. m. in Toland Hall, University of California Hospital.

A committee of the faculty is now working on a plan to offer courses in graduate instruction during the summer months.

L. S. Schmitt, acting dean, has been delegated to attend the meeting of the Association of American Medical Colleges to be held in Omaha, February 28 and 29, 1924, and the Conference on Medical Education to be held in Chicago on March 3, 4, and 5, 1924.

The following changes and additions to the faculty have recently been made: Arthur D. Houghton appointed as associate in Anatomy, vice Katharine Scott Bishop, resigned; William S. Kiskadden appointed as assistant in Surgery; John J. Sampson appointed as assistant in Medicine; Frances A. Torrey appointed as assistant in Dermatology.

The following gifts have been received:

The gift of $1200 from Dr. Ferdinand Stabel for the establishment of the Ferdinand Stabel Research Fellowship in Bacteriology, for the study of chemotherapy, particularly basic Fuchsin in Tuberculosis and related problems, effective January 1, 1924, and ending December 31, 1924, with the understanding that Stabel reserves the right to continue this work after that date by making further financial provisions.

The gift of $717.64 from Dr. Norman T. Bridge, being his annual contribution to the Edith Claypole Memorial Research Fellowship in Pathology.

The gift of $1500 from the National Research Council, representing an advance from the appropriation "Sex Research Fund, 1924," to be used by H. M. Evans, in connection with his investigations of the physiology of reproduction.

The gift of $200 from the Alexander Ector Orr Foundation to be used for the furtherance of educational and medical work along charitable lines in the University hospitals, with particular attention to the work among destitute children.

The gift from Dr. Albert H. Rowe to the department of Biochemistry and Pharmacology amounting to $300, to be paid over a period of six months for use in connection with the studies in carbohydrate metabolism.

Stanford University School of Medicine (William Ophuls, dean; Albion Walter Hewlett, secretary of the medical faculty) — Summer Quarter, 1924 — Between June 15 and September 1, 1924, while there is no routine teaching of under-graduate students at the Medical School, properly qualified graduates in medicine and medical students of this and of other schools are invited to avail themselves of the opportunities for clinical and laboratory work as special workers. The workers are expected to assist in the practical work of the various departments. Their work will be supervised, but no set courses will be given. Opportunity to make special studies of clinical and laboratory problems will also be offered. There will be a registration fee of $3, and in some departments an additional fee for special instruction varying from $50 to $100 will be charged.

The minimum period of attendance will be four weeks. Participants are urged to devote their full time to one subject.

Applications, which should give an outline of the medical experience of the applicant, should be sent to the dean, Stanford University Medical School, 2398 Sacramento street, San Francisco.

Special workers will be received in the following departments:

Pharmacology—Research. P. J. Hanzlik. Charges will cover cost of animals and supplies only.

Pathology—Research in morbid anatomy and ex-

perimental pathology. W. Ophuls and J. R. Oliver. Charges will cover cost of animals and supplies only.

Pediatrics—H. K. Faber. Work in in and out-patient departments. Fee, $50 a month.

Neuro-Psychiatry—H. G. Mehrtens. Fee, $100 a month.

Skin and Syphilis—H. E. Alderson and staff. Fee, $50 a month.

Metabolism Laboratory — Research. Dr. Addis. Charges will cover cost of animals and supplies only.

Radiology—W. E. Chamberlain and R. R. Newell. Fee, $100 first month; $50 for each succeeding month.

Physiotherapy—H. L. Langnecker. Fee $50 for two and one-half months.

General Surgery—S. Stillman. Work in in and out-patient department. No fee.

Orthopedic Surgery—L. W. Ely. (1) Work in the out-patient department. No fee. (2) Special course. Fee, $100 for four weeks.

Genito-Urinary Surgery—J. R. Dillon. (1) Work in the out-patient department. No fee. (2) Special course for four weeks. Fee, $100.

Ophthalmology — A. B. McKee. Work in out-patient department. No fee.

Otorhino-laryngology—J. A. Bacher. Not less than three months, July 1 to October 1. Limited to three workers. Fee, $50 a month.

Surgical Pathology—F. E. Blaisdell. August and September. Fee depends on character of work desired. Blaisdell will give a special course on fractures and dislocations on the cadaver during August and September. Fee to be determined.

Obstetrics and Gynecology—A. B. Spalding, L. A. Emge, A. V. Pettit, and H. von Geldern. Clinical work limited to six workers. No fee.

Gynecological Laboratory—Research. A. B. Spalding and L. A. Emge. Charges will cover cost of animals and supplies only.

Obstetrics, San Francisco Hospital—K. L. Schaupp. Limited to four workers. No fee.

Female Urology—W. E. Stevens and L. Michelson. Limited to two workers. Fee, $200 for six weeks.

The 1924 Lane Lectures—William Ophuls, dean of Stanford Medical School, announces that Ludwig Aschoff, professor of pathology of the University of Freiberg, Germany, has accepted the invitation of Stanford University to deliver the Lane medical lectures for the year 1924. The probable date of the lectures will be from Monday, May 26, to Friday, May 30, inclusive, at 8 p. m., in Lane Hall of the Stanford University Medical School, San Francisco.

The subjects of the lectures will be: The Place of Origin of the Biliary Pigment; Atherosclerosis; Ovulation and Menstruation; Inflammation; Fatty Changes in Disease.

Examination for the United States Public Health Service — Examinations of candidates for entrance into the regular corps of the United States Public Health Service will be held at San Francisco, Cal., April 7, 1924.

Candidates must be not less than 23 nor more than 32 years of age, and they must have been graduated in medicine at some reputable medical college, and have had one year's hospital experience or two years' professional practice. They must pass satisfactorily, oral, written and clinical tests before a board of medical officers and undergo a physical examination.

Successful candidates will be recommended for appointment by the President, with the advice and consent of the Senate.

Requests for information or permission to take this examination should be addressed to the Surgeon-General, United States Public Health Service, Washington, D. C.

H. S. CUMMING,
Surgeon-General.

AMERICAN MEDICAL ASSOCIATION NEWS

The Chicago Session

Reduced Railroad Rates—The passenger associations of various sections of the United States have established a rate of one and one-half fare for the benefit of those who will attend the Seventy-fifth Annual Session of the American Medical Association. The benefit of this rate will be extended to members of the association and to members of their families who accompany them to Chicago. It will be necessary to purchase tickets to Chicago, paying the regular fare. At the time tickets are purchased, certificates must be secured from the railroad agents. These certificates must be validated by the secretary of the association and by railroad representatives at Chicago. After validation, the certificates will entitle holders to a rate of one-half fare for the return trip to their homes. Tickets for the occasion will be placed on sale in the extreme Far Western States not later than June 3; in territory nearer to Chicago, the dates of sale will be adjusted in accordance with distances to be traveled.

Hotel Reservations for Delegates—The House of Delegates instructed the secretary of the association to arrange for hotel accommodations for all delegates during the Seventy-fifth Annual Session of the American Medical Association, to be held in Chicago, June 9-13. In compliance with these instructions, tentative reservations have been made at the Drake Hotel, Chicago, so that each member of the House of Delegates may be assured of a room at that hotel. The names of all delegates, as far as they are known at the present time, have been sent to the management of the hotel, and letters have gone out to all delegates requesting them to write direct to the Drake Hotel asking for the reservation of such accommodation as may be desired. In writing the hotel, delegates should be careful to specify that the accommodations desired are to be provided from the allotment of rooms tentatively reserved for members of the House of Delegates. Reservations should be made at the earliest possible time. If, for any reason, a delegate does not wish to have accommodations at the Drake Hotel, he should notify the secretary of the association as soon as possible in order that reservations tentatively made and not required may be released for the accommodation of other members of the association.

Announcement by Committee on Hotels — The Committee on Hotels of the local Committee of Arrangements has arranged with the Hotel Men's Association in Chicago for the provision of satisfactory accommodations for all who expect to attend the Seventy-fifth Annual Session of the American Medical Association, June 9-13. This committee has the active co-operation of the Bureau of Conventions of the Chicago Association of Commerce. Members of the association who expect to attend the session should write direct to the hotels of their choice for reservations. If the preferred hotel is unable to provide accommodations as desired, the request will be turned over to the Committee on Hotels of the Local Committee of Arrangements, and accommodations at another hotel will be secured. Duplicate reservations should not be made. In the initial request for reservations, the date of arrival in Chicago, as well as the length of time the applicant expects to remain and the number and kind of rooms desired, should be clearly stated. It is also desirable that second and third choice of hotels be stated. The Committee on Hotels will make every effort to secure accommodations in keeping with expressions of preference. Dr. Frank R. Morton is chairman of the Committee on Hotels of the Local Committee of Arrangements. If satisfactory arrangements for hotel reservations cannot be made through communications addressed directly to hotels, the Committee on Hotels may be addressed at the office of the Local Committee of Arrangements, Room 1522, 25 East Washington Street, Chicago.

A complete list of Chicago's leading hotels and rates to be charged will appear in the Journal in the near future.

BOOK REVIEWS

Diseases of the Skin. Including the acute eruptive fevers. By Frank Crozer Knowles, M. D. Second edition. Philadelphia and New York: Lea & Febiger. 1923.

Every book has its own special excellencies, and the high point in this one lies in its illustrations and plates. For instance, there is an impressive photograph of erythema multiforme, and a speaking likeness of the cutaneous lesions of dermatitis herpetiformis, even to the tottering attitude of the patient. It is entirely fitting that this malady should be well illustrated here, as Duhring, who first described the disease as a separate entity, was the author's honored teacher.

Another interesting portrayal is of a belladonna eruption with the plasters in place, from which the eruption arose. It must always be remembered that severe constitutional poisoning may arise from this source, and, by the way, this bears witness to the efficacy of these plasters, which are now admirably prepared by our best drug houses.

Everyone conversant with skin disease is aware of the difficult problems presented by lesions of the hands, both those which are incurable and those which may be cured. A good photograph is given of epidermolysis bullosa of the hands, which is a congenital affection enduring throughout the entire life of the patient, and for which, as being incurable, only ameliorative remedies should be prescribed. As a contrast, there is an example of dermatitis from packing quinine, a most striking photograph, for which the remedy, a change of work, is obvious. Another good point brought out in the illustrations is of a kind of eczema which yields especially well to X-ray treatment. In fact, the hands are well pictured, and a list of these and the other illustrations would have been a decided advantage to this book.

There is yet another good point in the book, a chapter entitled: "Regional Distribution of Diseases of the Skin." As certain diseases do occur most commonly in certain regions, such an arrangement should be helpful in arriving at a diagnosis. In fact, Sabouraud has written a book, with the diseases arranged according to this plan. D. W. M.

Sexual Problems of Today. By William J. Robinson, M. D. Twelfth Edition.

Many of those who believe the sordid story of sex, as seen by the physician, should be made public property will endorse Dr. Robinson's book. Those who believe that much of the information given should remain privileged information of educated physicians will condemn the book in unmeasured terms.

Surgical and Mechanical Treatment of Peripheral Nerves. By Byron Stookey. With a chapter on Nerve Degeneration and Regeneration. By G. Carl Huber. 475 pages. Illustrated. Philadelphia and London: W. B. Saunders Co. 1922. Price $10.

A well written book of nearly 500 pages, containing over 200 drawings, diagrams, and photomicrographs. The book has value, largely in giving the experiences and opinions of the writer.

The title indicates the contents only in part. Perhaps one-quarter of the book is given over to a consideration of anatomy, gross and microscopic, nerve degeneration and regeneration, and a critical consideration of the earlier methods of nerve repair.

The principal nerves of the extremities, the principal motor cranial nerves, and the plexuses are taken up in individual chapters. Bibliographies appended to each chapter are excellent and well selected. While in certain portions of the book the reader could wish for more detailed consideration of certain points, it has been obviously impossible to follow all the by-paths into which one's interest might be led.

This reviewer wishes that more consideration might have been given to the details and possibilities of direct examination of individual muscle function. In the chapter on mechanical treatment, however, the exceptional experimental work of McLeod and his associates on the value of massage and electrical treatment has been omitted. The frequency with which cable grafts are featured seems to give undue emphasis to their practical value and the comparatively rare need of them.

The book is most readable and should be a valuable addition to the library of those interested in this branch of surgery. H. C. N.

Management of the Sick Infant. By Langley Porter, M. D. and William E. Carter, M. D. Second revised edition, illustrated. St. Louis: C. V. Mosby Co., 1924.

It is gratifying to students and colleagues of the authors that their book has reached a second edition in such a short time. Editors, as other physicians, must keep constantly available revised editions of good books to assist them in their work. We cannot say more for Doctor Porter's and Doctor Carter's book than that it is used as the editor's desk copy.

Blood Chemistry. Colorimetric methods for the general practitioner, with clinical comments and dietary suggestions. By Willard J. Stone. 75 pages. New York: Paul Hoeber. 1923. Price, $2.25.

A small book (75 pages) embracing laboratory methods of blood chemistry, and its clinical application, renal function determination, food lists for the dietetic control of disturbances of metabolism and test and maintenance diets for the control of diabetes.

It is a compilation of tests and dietary methods found, and more comprehensively presented, in the usual text-books on these subjects.

The obvious purpose of the book is to encourage blood chemistry in the "small" laboratory. The tests are given with fractional portions of the normal amounts called for in the original methods; but the contraction of methods already microscopical renders more difficult and less accurate tests that demand the utmost exactness in their performance.

E. A. V.

An Introduction to the Study of Mental Disorders. By Francis M. Barnes. Second edition. 295 pages. St. Louis: C. V. Mosby Company. 1923. Price, $3.75.

A second edition means that there has been a demand for the book, and examination explains it. It is short. There are less than 300 pages. The style is good and it makes easy reading. It has given a concise history of psychiatry from the ancients to the present, and bridges the gap between the somatic school of Kraepelin and the newer work of the psychological school without belittling or exalting either, although it is apparent that the author does not rave over Freud. None of the arch-Freudians are mentioned in the bibliography.

As an introduction to psychiatry for medical students, it serves its purpose excellently. E. W. T.

Intravenous Therapy. Its application in the modern practice of medicine. By Walton Forest Dutton, M. D. 542 pages. Illustrated. Philadelphia: F. A. Davis Company. 1924.

Much heterogeneous information is gathered between the two covers of this book. The chapters on transfusion are complete and historically interesting. They make up about a sixth of the whole book. Besides them is an encyclopedia of diseases, listed alphabetically, most of which might well have been omitted. L. E.

BOOKS RECEIVED

Hernia: Its Anatomy, Etiology, Symptoms, Diagnosis, Differential Diagnosis, Prognosis, and Operative Treatment. By Leigh F. Watson, M. D., Associate in Surgery, Rush Medical College, Chicago. Two hundred and thirty-two original illustrations by W. C. Shepard. St. Louis: C. V. Mosby Company. 1924.

Practical Chemical Analysis of Blood. A book designed as a Brief Survey of this Subject for Physicians and Laboratory Workers. By Victor Caryl Myers, Ph. D., Professor and Director of the Department of Biochemistry, New York Post-Graduate Medical School and Hospital. Second Revised Edition. Illustrated. St. Louis: C. V. Mosby Company. 1924.

Management of the Sick Infant. By Langley Porter, M. D., Professor of Clinical Pediatrics, University of California Medical School; Visiting Physician San Francisco Children's Hospital; Consulting Pediatrician, Baby Hospital, Oakland; Mary's Help Hospital, San Francisco; and William E. Carter, M. D., Assistant in Pediatrics and Chief of Out-Patient Department, University of California Medical School; Attending Physician San Francisco Hospital, San Francisco. Second Revised Edition. Illustrated. St. Louis: C. V. Mosby Company. 1924.

Geriatrics: A Treatise on the Prevention and Treatment of Diseases of Old Age and the Care of the Aged. By Malford W. Thewlis, M. D., Editor Medical Review of Reviews, The Therapeutic and Dietetic Age. With Introduction by A. Jacobi, M. D., and I. L. Nascher, M. D. Second Edition, Revised and Enlarged. St. Louis: C. V. Mosby Company. 1924.

Lectures on Endocrinology. By Walter Timme, M. D., Attending Neurologist, Neurological Institute, New York; Professor of Endocrinology, Broad Street Hospital; Professor of Nervous and Mental Diseases, Polyclinic Medical School and Hospital. With 27 illustrations. Paul B. Hoeber, Inc., New York. 1924.

Intranasal Surgery. By Fred J. Pratt, M. D., Assistant Professor, Eye, Ear, Nose and Throat, Medical School, University of Minnesota, and John A. Pratt, M. D., Assistant Professor as above. Illustrated with 195 half-tone engravings. Philadelphia: F. A. Davis Company. 1924.

Intravenous Therapy: Its Application in the Modern Practice of Medicine. By Walton Forest Dutton, M. D., Medical Director Polyclinic and Medico-Chirurgical Hospitals, Graduate School of Medicine, University of Pennsylvania. With 59 illustrations. Philadelphia: F. A. Davis Company. 1924.

Fighting Foes too Small to See. By Joseph McFarland, M. D., Professor of Pathology in the Medical Department of the University of Pennsylvania. With 64 engravings. Philadelhpia: F. A. Davis Company, Publishers. 1924.

Report From the Department of Pathology and the Department of Clinical Psychiatry, Central Indiana Hospital for the Insane, 1917-1918 and 1918-1919. Vol. VIII. Indianapolis: William B. Burfod, Contractor for State Printing and Binding. 1923.

Sexual Problems of Today. By William J. Robinson, M. D., President American Society of Medical Sociology, etc. Twelfth Edition. The Critic and Guide Company, 12 Mt. Morris Park West, New York. 1923.

Genito-urinary Diseases and Syphilis. By Henry H. Morton, M. D., Professor of Genito-urinary Diseases and Syphilis, in the Long Island College Hospital, and Genito-urinary Surgeon to the Long Island College Hospital and Polhemus Memorial Clinic, etc. Fifth Edition, Revised and Enlarged. With 328 illustrations and 38 full-page colored plates. New York: Physicians and Surgeons' Book Company, 352 West Fifty-ninth Street. 1924.

Surgical Pathology. By Joseph McFarland, M. D., Professor of Pathology in the Medical Department of the University of Pennsylvania. With 435 illustrations. Philadelphia: P. Blakiston's Son & Co., 1012 Walnut Street. 1924.

Practical Electrotherapeutics and Diathermy. By G. Betton Massey, M. D., Fellow and Former President American Electrotherapeutic Association; Former Surgeon to the American Oncologic Hospital, etc. New York: The Macmillan Company. 1924.

Reapportionment of Delegates to American Medical Association (Secretary West of the A. M. A. to Secretary Emma W. Pope of the California Medical Association)—"The last reapportionment of delegates was effected at the Seventy-second Annual Session, held at Boston in 1921. Another reapportionment will, therefore, be made at the Seventy-fifth Annual Session of the Association to be held in Chicago, June 9-13, 1924. As the reapportionment will be made on the basis of the membership in constituent associations, as that membership has been reported and recorded on the membership records of the American Medical Association on April 1, 1924, it is important that this office shall have complete reports of the membership of your association so that the names of all members may be duly recorded in this office before April 1, 1924.

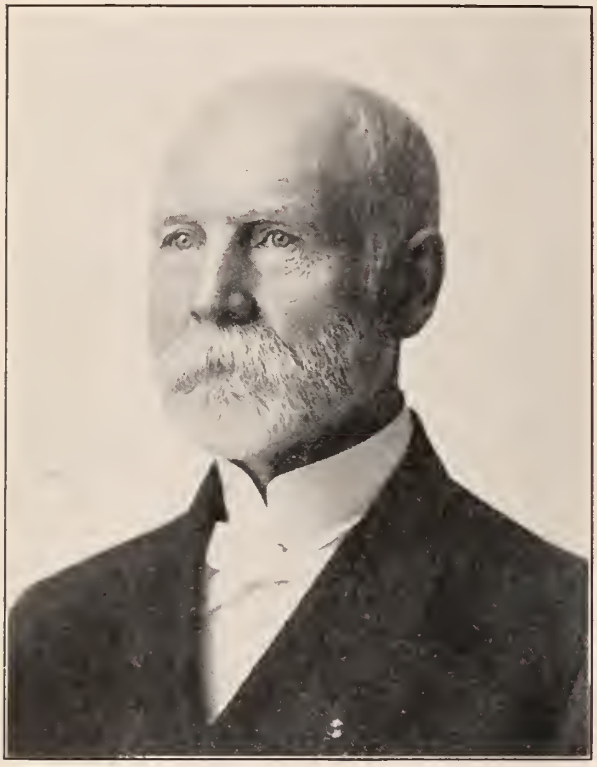
This matter is brought to your attention now in order that you may remind the secretaries of your component county medical societies of the need of the fullest possible reports of membership in their respective organizations.

Delegates already elected or to be elected for service in the House of Delegates for the Seventy-fifth Annual Session of the American Medical Association in June, 1924, will be in no way affected by the reapportionment to be made in Chicago.

On January 1, 1924, the membership of the American Medical Association, which, of course, is the combined membership of the constituent State and territorial associations, was 89,835. It is sincerely hoped that this splendid membership will be maintained and even increased by the affiliation of desirable and eligible physicians, and that the membership in your State will be maintained at a figure that will insure that there will be no reduction of representation in the House of Delegates."

Physiotherapists Meet—Some forty physiotherapists of Northern California attended a luncheon-meeting at the Clift Hotel in San Francisco recently. Miss Hazel Furscott, president of the association, presided and the meeting was addressed by James T. Watkins and W. E. Musgrave. Those present were: Florence Atkinson, Ethel Johnson, Beulah Rader, L. B. Bryan, Mrs. P. Rowe, Dorothy Vockel, Hilda Knausenberger, Hazel E. Furscott, Charlotte Ballard, Hilda Rodway, Elizabeth R. Stoner, Lou Kindall, Sarah R. Davis, Gus Hanson, Ruth Hassell, Ethel McDonald, Evelyn Lewis, Alice Hampton, Carol Alunes, Dagmar Magnisen, Mary L. Schaaf, Alice Peterson, Bertha Monroe, Mabel Penfield, Helen Boucher, Rose Swantelson, Miss Münsing.

Obituary



W. FLETCHER McNUTT
1839-1924

By C. F. Buckley, M. D.

Dr. McNutt was born in Nova Scotia in 1839 and graduated in medicine from Harvard. As he grew in years, he grew more ambitious and thought that he must go to other spheres where erudition was supposed to be greater and the courses more finished. So he betook himself to Europe and took a degree in Edinborough and then returned to this country and devoted all his energy to alleviating the sufferings of the Northern battalions who were devoting their lives to the cause of the Union. He served then in the Civil War for three years and retired with honor. As to the number of engagements and such things, it is unnecessary to go into details; he did his duty loyally and nobly. He was in some of the severest engagements, particularly around Vicksburg, and did some remarkable surgical work during the siege of that city.

If he had any characteristic more commendable than another it was his poise. I don't think his closest friends ever saw him lose his temper or get excited about any important thing he was engaged in. To young men of the medical profession, he was undoubtedly an outstanding example of the understanding physician.

He came to San Francisco in 1869 and became one of the city's leading medical authorities. He also filled two public posts, with great credit to himself and the community: he was prison director and also police commissioner, and introduced several innovations that are an outstanding benefit to the community.

I do not think that if Dr. McNutt were in the flesh and the storms and strife around and about us he would care for any long eulogy from me or anyone else. Whatever faults he possessed were his own; nobody ever suffered from them. The charm of his life was his sincerity and devotion.

May God reward a very worthy friend and an excellent doctor.

NEW MEMBERS

Los Angeles—Joseph M. Harris, Harry S. Fist, John P. Gilmer, William G. Raber, Clinton Roath, Leonard C. Sloane, Edson H. Steele, Matsuta Takahashi, Henry M. Thompson, Giuseppe Vercellini, Earl W. Wells, Harold R. Witherbee, Madison J. Keeney,

DEATHS

Dirks, Charles B. Died at Los Angeles, January 20, 1924. Graduate of Rush Medical College, Chicago, 1903. Licensed in California, 1914. He was a member of the Los Angeles County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Harrison, Samuel Ingelby. Died at San Francisco, January 6, 1924, age 66. Graduate of Rush Medical College, 1887. Licensed in California, 1898. He was a member of the San Francisco County Medical Society, the California Medical Association, and the American Medical Association.

Hodkinson, William Austin. Died at Santa Monica, January 28, 1924, age 54. Graduate of University of Pittsburgh School of Medicine, 1894. Licensed in California, 1910. He was a member of the Los Angeles County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Kaull, Lee Perry. Died at San Bernardino, December 19, 1923, age 51. Graduate of Kansas City Medical College, 1898. Licensed in California, 1908. He was a member of the Los Angeles County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Koltz, Bernard J. Died at San Francisco, December 17, 1924, age 45. Graduate of the University of California Medical School, San Francisco, 1900. He was a member of the Solano County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

McNutt, William Fletcher, Sr. Died at San Francisco, January 28, 1924, age 85. Graduate of Royal College of Surgeons, Scotland, 1865, and the Medical Department of the University of Vermont, 1867. He was formerly a member of the San Francisco County Medical Society and the California Medical Association.

Reed, Elgar. Died at Chino, February 13, 1924, age 58. Graduate of the Cincinnati College of Medicine and Surgery, 1893. He was a member of the San Bernardino County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Stallard, Samuel Lawrence. Died at Greenwood, New York, February 8, 1924, age 38. Graduate of the Kentucky School of Medicine, 1907. Licensed in California, 1922. He was a member of the New York State Medical Association.

The Great American Prim Press

Two of the "Machines that Reduce Labor Turnover" in the University of California Hospital.

An Ironing Machine That Goes to School

The two Prim Presses pictured here passed the "entrance exams" at the University of California Hospital Laundry with high grades, and the work they are doing is most satisfactory to the faculty.

Prim Presses encourage head work by eliminating foot work. They are electrically operated and have no foot-treadles. The press operator is relieved of the tiring manual labor which formerly sapped her energy, and she devotes all of her thought and effort to turning out better work and more work.

They are used for ironing wearing apparel of all kinds: Patients' gowns and pajamas, attendants' uniforms, surgeons' gowns and aprons, and nurses' gowns. Two of these presses enable one operator to do the work of three or four hand-ironers with less effort than hand-ironing calls for.

You will find Prim Presses especially suited to your institutional laundry for these reasons. Have us submit additional details which will convince you.

THE AMERICAN LAUNDRY MACHINERY CO.
Norwood Station, Cincinnati, Ohio
Los Angeles San Francisco Seattle

Over 300%

MORE than three times as much S.M.A. was prescribed in 1923 as in 1922. We believe that the physician who has used it will understand the reason, for he is already aware of the assistance which S.M.A. has given him in his own practice, and he will see in this increase convincing evidence that many other physicians are also obtaining exceptional nutritional results with S. M. A.

From 1915 to 1920 S. M. A. was used only in The Babies' Dispensary and Hospital of Cleveland. In January, 1920 it was made available to all Cleveland physicians. In November, 1921, its distribution was extended so that every physician in the country might obtain it for his little patients. From the time that S. M. A. was first offered to the medical profession, there has been a steady increase in the number of physicians using it, and in the volume prescribed by them.

S. M. A. is a food for infants deprived of breast milk, or who require nourishment in addition to what the mother can supply.

Requires only the addition of boiled water to prepare. Needs no modification or change for normal infants.

Prevents rickets and spasmophilia. Promotes normal growth and development.

Formula by permission of The Babies' Dispensary and Hospital of Cleveland. For sale by druggists on the order of physicians.

Literature and samples to physicians on request. The Laboratory Products Company, Cleveland, Ohio.

SOME PRACTICAL SUGGESTIONS IN THE TREATMENT OF FRACTURES *

By FRED R. FAIRCHILD, M. D.
(From the Woodland Clinic)

So commonplace a discussion as that suggested by the title of this paper would almost seem to be out of place in an assembly of highly trained scientific men. Yet I do not feel that an apology is necessary. It has been my observation that, in the effort to keep abreast of all that is new and often spectacular in surgical diagnosis and treatment, the good old-fashioned fundamental to success is often crowded out. I refer to plain common sense—to the balance that enables one man to do exactly the right thing at the right time while another is confused by theories. Certainly in no branch of our profession are the practical qualities of the surgeon taxed to a greater extent than in the treatment of fractures, and certainly in no department do we oftener see the fruits of bad judgment. This is true, because fractures are treated by surgeons of all grades of distinction and, of necessity, in the rural communities, by medical men who make no claim to surgical ability. It is also true that fractures are the most common of all surgical problems and, as "familiarity breeds contempt," we fall into the habit of a too casual consideration of the case. We do not think. We treat the fracture as other seemingly similar cases are treated, and often we go wrong, where a few minutes of careful consideration of the case as a separate problem would put us right.

The first practical general suggestion then, is to consider each fracture by itself. It is not enough to know that we are dealing with a Colles or a Potts or any other type fracture and then to proceed according to rule. Any of the classical breaks may have modifying factors of such nature as to make the routine treatment not right, but wrong. For example, even in a type fracture, the wrong relation of a small fragment to an articulating surface, or the apposition of two fragments of certain contiguous bones may mean a permanently deficient and painful joint. It may mean the loss of the rotating function of the forearm. Exact knowledge of the size and position of every fragment and its relation to the anatomical structures is fundamental. To state that this information can be had from proper radiographs and should never be neglected is academic. Yet the statement is not out of place, for we all know that the facts are that this information is often not so obtained, nor is it always considered indispensable. The wise surgeon never neglects so to safeguard his patient's happiness and his own reputation. He gets exact data and the factors of the problem all before him. Then is the time for some plain thinking, for the case is reduced to a more or less complicated problem in mechanics. There may be several possible solutions, but there is only one best way. Common sense, straight thinking, these alone enable one to select the proper course. These applied to each fracture case as an individual problem are the best guarantees for satisfactory results.

The next general suggestion is a warning against overenthusiasm for any one method. The young surgeon, particularly, is in danger of being carried away by the brilliant results of certain brilliant operators who are exponents of certain types of procedure. Fifteen years ago I was convinced that the application of metal plates and screws was the proper method for most open reductions. Then came gradual concession as to bands and other mechanical internal supports as deserving of consideration. Later the bone graft was the method of choice. Then came a time of open operation with replacement of fragments and no application of foreign material. Now we know that no method is the best; that all are good, providing there is judgment behind the choice and skill in its application. But more significant is this fact: that not one open

* Presented to the Section on Surgery at the Fifty-second Annual Session of the California Medical Association, San Francisco, June, 1923.

reduction is now found necessary where five were done some years ago and yet the number of fractures seen is many times greater, all of which means that we are now thoughtfully fitting the method to the case and not the case to the method. And it is worthwhile to note in passing that failure to do this constitutes the most common-source error in fracture work.

So much for the general practical consideration of our subject. It may be worthwhile to be more specific. The Thomas splint, it seems to me, should stand at the top of the list of practical things in fracture work. It is a most remarkable fact that this splint should have been almost unused from the time of the Civil War to the recent great war, for this splint combines the ideal attributes of a splint as no other one does for the management of fractures of the long bones. The qualities of securing extension and fixation of the fragments with freedom of the body, exposure of the limb and fracture site, giving perfect ocular and X-ray observation enable us to handle with assurance those cases that formerly caused us much worry. And yet with the absolute proven and undisputed value of this simple contrivance, the Thomas splint is even now all too infrequently used. If our own experience may serve as a basis of judgment, we must conclude that the majority of those men who are treating fractures do not know the Thomas splint, or knowing of it, from lack of experience do not appreciate its values. If this splint is as generally valuable as we believe it to be, and if it is as little appreciated as we are led from experience to suppose, no more practical thing can be done than to discuss it from the standpoint of personal experience.

We may assume that the general principles of the splint are familiar to all—a ring adapted to receive counter-extension against the trunk, two long arms extending along the sides of the limb and united well beyond the extremity, from which point extension is effected. Now what are the practical points in its use? There are several that only experience will teach, for, as we before pointed out, each case constitutes an individual problem because of probable variation from the classical, and our text-books seem to have a habit of discussing just the conditions that do not fit our individual case.

Unless one is so situated as to be able to make selection from a large number of Thomas splints, it will be found better to have an ordinary blacksmith make the splint desired. This because satisfaction will be had only by a properly fitting splint, and the splint will be made to fit properly only when many factors in its construction are taken into consideration. For example, assume a thigh fracture, at or above the middle. We desire extension, abduction, and fixation. We must know the two angles the plane of the ring is to have in relation to the axis of the thigh. We will probably have to bring the upper part of the ring forward to avoid impingement on the crest of the ilium. We must have the diameter and shape of the ring such as to give us the greatest bearing surface in relation to the trunk; otherwise there is danger of pressure sores. The ring must be so padded as to insure comfort and covered with a non-absorbing washable substance so that it can be kept sanitary without removal. The angle must be such in the shafts as to afford the desired flexion of the knee. The length of the thigh must be known to place this angle at the proper distance from the ring. Here, then, are many details to be considered and they are prosaic details, but very vital to the patient's comfort and to the ultimate result. An hour spent by the surgeon in knowing that all of these factors have been considered will be repayed a hundredfold. In considering them it is perfectly obvious that the custom-made splint will probably not serve the purpose. Usually these factors will be properly met only when the splint is constructed to meet the known conditions of the particular patient.

The splint having been modeled to serve the purpose, what does experience teach as to its application? The splint is placed over the limb, which is held in a cradle made by strips of unbleached muslin of width corresponding to necessity, which are pinned under the limb from one shaft of the splint to the other. Extension is secured by wide moleskin strips placed longitudinally on either side of the leg from the knee down. To these tapes are attached. No immediate effort is made to reduce the fracture, but as much extension as can be easily tolerated is made continuously for from three to five days. At the end of this time, it will be found that full, and often, overextension has been secured and that also by reason of this factor, the soft tissue will generally have been drawn, by tension, from between the fragments. The X-ray now comes into play and, by its aid, the fragments are so manipulated as to secure satisfactory position. This can usually be done with little pain and without anesthesia, because of the very satisfactory extension which is still in force while the final reduction is being accomplished. Reposition being secured, the position is so held by wide muslin bands about the limb—above or below the fracture around the internal or external rod, under or over the limb according to the mechanics of the situation. As proof of the efficacy of the procedure is the fact that we have found it necessary to do no open operation on a fractured femur since the war, and we have no case the results of which cause us embarrassment. (We are not, of course, referring to old fractures, or fractures seen after partial union in malposition.)

All that has been said of the type of fracture taken as an example is applicable, with proper modification, to the treatment of fractures of the other long bones. In the lesions of the tibia and fibula, if not too low, a properly fitted and padded upper of a shoe makes an excellent attachment for the tape. In the ulna and radius—perhaps the most troublesome bones to hold in position after fractures—the method is ideal, for, in addition to extension, we can secure supination or pronation and maintain the position. Since the use of the Thomas splint in this type of fracture, we have found open reduction necessary in one case only.

It will be worthwhile to speak more specifically of some of the details mentioned in a general way in the preceding paragraph. A description of the splint was given, but of what material should it be

made? This would seem not to be a material factor, but, on the contrary, it is of very great importance. By experience, we have found that most of the commercial splints are constructed of unsatisfactory material. The rods for the long lateral portions are generally too heavy or made of iron that is not sufficiently malleable. These pieces must be strong enough to retain their shape under the strain of the extension, but not so stiff as to make bending while in position a hard task. It will often be found necessary to increase or decrease the joint angle to place the axes of the main fragments in proper alignment. This may easily be accomplished without removing or seriously disturbing the adjustment of the splint by the use of two wrenches placed above and below the point to be angulated if the shafts are made of three-eighths inch Norway iron. This material and size affords ample strength with easy moulding qualities. If, as so often happens, one-quarter inch iron or iron of poor quality is used, we will find it impossible to alter the shape without removal, a most unfortunate proceeding.

Mole-skin was suggested as the material to use for attaching the extension tapes. We have found it so much more satisfactory than any of the common adhesive tapes that they are now never considered. Under long extension other adhesive substances slowly but surely slip from the canvas, and extension is gradually lost. This in itself destroys its value. In addition, irritation of the skin is common. Mole-skin plaster has neither of these undesirable features.

When the Thomas splint is used on the lower extremity, suspension of the limb may or may not be found advisable. If suspension is desired, we use for this purpose a very simple home-made frame that may be attached to any hospital bed in five minutes. The frame is placed on the side of the bed desired. Suspension is secured by a pulley attached to the frame, and counter-weights just sufficient to balance the limb are used. The pulley is so placed as to make a downward pull on the entire splint, reducing, by just this much, the pressure of the padded ring on the trunk. This little point is worth noting, as it adds materially to the patient's comfort. Another minor but worthwhile point is to suggest that tapes of certain length be attached to the end of the splint in such manner that elevation and lowering of the limb will be limited to certain desired points only.

Compound fractures form the subject of another discussion. For lack of time we must pass the subject with the observation that these fractures, controlled by this method, are treated with a far greater degree of satisfaction than by any method of casts or encircling splints. The wound can be always under observation, and the danger and disagreeable features from secondary contamination very largely avoided.

Before leaving the discussion of the virtues of the Thomas splint, I cannot fail to mention another type of case in which it has proven invaluable to us. I refer to its use in the post-operative care of open operations on the long bones, the femur in particular. I think most of you will agree that the post-operative mechanics, as applied to open reductions of thigh fractures, is quite as important and much more difficult than the original operation. How many times have we seen results that, judged from the immediate post-operative indications, should have been 100 per cent perfect, gradually change to failure or at least to conditions cosmetically or functionally less than satisfactory. The reason under old, though not obsolete methods—for they are still quite generally used—are obvious. Given a fleshy, well-muscled thigh that has been properly reduced by operation, a cast is applied in the most approved manner. What are the factors that endanger the final result? Strong, constant muscular tension which makes for bowing; a thick, soft muscular pad at the site of the point where angulation is possible; gradual atrophy of this pad from pressure; shrinking of all of the soft tissues within the encircling tube, giving more play than is desired; gradual angulation at the site of the fracture, and, not too infrequently, a fracture of the graft or plate or pulling out of screws, if one of these methods have been employed. Result unsatisfactory. If, on the other hand, the same plan as above discussed for closed fractures is followed, these unhappy results may be entirely eliminated; at least this has been our experience in some rather difficult cases.

The discussion would not be complete without some remarks relative to open-fracture reduction. The subject is so large and important that only those factors which personal experience has taught us is of value will be mentioned.

First let us consider the elements in any given case that should decide for or against an open reduction of any type. We have stated that good radiographs give us the details that enable us to form a correct judgment. But, just as the X-ray enables us to know when operative procedure is necessary, so this very diagnostic aid, if not backed by sound surgical judgment, surely leads to many unnecessary operations. The shadow picture has a bad habit of exaggerating deformities. Also an approximation of fragments that casts anything but a seemingly satisfactory shadow may, after all, be of such relation as to guarantee a cosmetically and functionally perfect result. There is no justification for an operation in the fact that a radiograph is not beautiful, nor in the knowledge of the fact that by an operation we could secure a much more satisfactory one. If we have proper length and proper axial alignment with only partial approximation of the two main fragments in deeply covered bones, we should be satisfied, for there will be no deformity nor deficiency of function. The X-ray plate should be used as a basis of judgment. Too often it is the deciding factor for open operation without the mixture of horse sense earlier mentioned.

Given a fracture that must be reduced by the open method, what is the best procedure? In an earlier paragraph, we stated that no method was the best, that each case must be decided by its individual modifying factors. Certainly, the avoidance of any foreign material as applied to a bone is to be desired. By the use of the splint that we have been discussing, this is possible in an astonishingly

large number of cases. We formerly felt—and correctly felt—under old methods that internal support was generally necessary. We now find that, with the post-operative aid of the Thomas splint, reposition of fragments with removal of interposed soft tissues is usually all that is necessary.

As to ununited fractures: our personal experience aligns us with the rather generally accepted belief that, where the osteogenetic function is shown to be deficient, internal supports of foreign material had best be avoided. We have had the best results with inlays, either sliding or, preferably, of the massive graft type. Where non-union is due to malposition or interposing soft tissue, preventing the meeting of the osteoblasts from the distal and proximal fragments, our experience has not led us to feel that metal plates or other foreign materials are in themselves objectionable.

Finally, we feel that there is one type of fracture that too often results in deformity or functional deficiency. Fractures of the lower end of the humerus, badly comminuted, involving the joint, and often complicated by some form of elbow dislocation, are very common in children. I know of no radiographic plate that is more discouraging. Nor do I know of any seemingly bad fracture that can more certainly be satisfactorily corrected. Manipulation under anesthesia will sometimes be all that is required. If under anesthesia passive motion allows full smooth extension and flexion, and the X-ray is satisfactory, dressing the arm in the Jones position will be all that is necessary, together with patience in restoration of function after the arm is taken down. If passive motion cannot be made satisfactory under anesthesia, under free exposure the fragments should be replaced until this test is satisfactory. With no foreign material applied to the fragments, the arm should then be dressed in the Jones position, and post-operative attention be given as above suggested. Our experience by this method has been most satisfactory, and this type of fracture has lost its terrors.

DISCUSSION

Harlan Shoemaker, M. D. (Bank of Italy Building, Los Angeles)—I am impressed by the wonderful practicability and applicability in the use of the Thomas splint as presented by Fairchild. I am also of the opinion that Fairchild will get better results than the average individual using this device. One thing that occurs to me in the early application of the Thomas splint is the reduction of hemorrhage in the soft tissues. The Thomas splint is undoubtedly the greatest transportation splint that has ever been devised. The doctor speaks of the use of a padded shoe as an attachment for the tape in the reduction of a fracture in the tibia or the fibula. This I believe to be very dangerous. The Sinclair skate has some advantages as a traction anchor. Any substance on the plantar surface is always safe. Where there is continuous extension or any traction on the tarsal bones, it is more liable to produce necrosis and would be very dangerous. The Thomas splint, of course, has its limitations in the practice of surgery. The ring of the splint is very poorly adapted for the female. On the other hand, some prefer the use of casts. The cast should be applied, in most cases, loosely for bone alinement, and snugly for bone correction. It has been my experience with the Thomas splint that the patient is forced into a recumbent position during the entire time of extension, while with a cast he may be turned at will and thus receive a great deal of rest and comfort from this manipulation. Personally, I prefer open reduction with a cast where there is practically no injury to the soft tissues. In very extensive injury to the soft tissues the open splint, with traction, is invariably used.

J. F. Cowan, M. D. (Lane Hospital, San Francisco)—In his excellent paper, Fairchild has brought out a number of valuable practical points in the treatment of fractures of long bones.

In the treatment of any fracture, common sense or straight thinking is of paramount importance, and it is just this that enables the bone-setter with crude apparatus to secure better end-results than are often obtained by a graduate in medicine with the latest improved splints and modern methods.

Another point which should be emphasized is that each fracture should be considered by itself, and that we should not become overenthusiastic about any one method, for no one method is applicable to the successful treatment of all types of fractures.

We have witnessed the advent and the partial or complete disappearance of Buck's extension, the double inclined plane, the Hodgen's splint, the Lane plate, bands, and various types of bone grafts, all of which have had and still have a limited application.

The late war has given added enthusiasm for the Thomas splint, largely because of its simplicity and the facility for transportation it affords; yet this splint has its limitations. The advantages of the Thomas splint are its extreme simplicity, its easy application, the little need of readjustment after reposition of the fragments has been accomplished, the fixation of the fragments in alignment, the ease with which compound fractures may be dressed, and above all the comfort it affords to the patient after proper adjustment. But it has its limitations as all other splints have. In fractures of the neck of the femur and fractures of the leg, while the Thomas splint may be used, other methods, I believe, are equally simple and more efficient.

In supra-condylar fracture of the femur, it is not possible to obtain adjustment and fixation of the fragments for permanent treatment by this or any other method in which traction is applied below the knee for the gastrocnemius, and plantaris muscles maintain the posterior displacement of the proximal end of the distal fragment.

Traction on the leg will only increase this displacement.

In these cases I have used caliper traction on the condyles with the leg flexed, the points of the calipers being engaged well toward the front of the condyles, never toward the back, for traction with calipers in the latter position tends to increase the displacement, while traction in the former position tends to correct it.

Dr. Fairchild's remarks concerning the application of the splint to the individual case are important.

Unfortunately, the village blacksmith has largely disappeared from our large cities, and we are, therefore, dependent upon commercial splints which, while adjustable, cannot be made to fit all cases.

The adjustment of the ring so that pressure is brought upon the tuberosity of the ischium and not on the pubis, and the position of the foot to prevent permanent shortening of the tendo Achillis and a stiff ankle-joint are important factors.

For fracture of the midportion of the thigh, there is no plan of treatment that causes as little discomfort to the patient as the use of this splint, when properly adjusted, and with the use of the Balkan frame with suspension and traction the results obtained surpass those of other methods.

E. W. Cleary, M. D. (177 Post Street, San Francisco)—Dr. Fairchild's paper is both valuable and

timely. Such discussions help us to remember and to give to others the results of the great war experience.

With modern methods of traction splinting at his command, the efficient fracture surgeon is operating on an increasingly smaller percentage of fractures.

I regard the Thomas leg splint as perhaps the single most valuable special appliance in the fracture surgeons' armamentarium. In my experience and observation, the standard United States Army Thomas splint may be efficiently applied to most cases of leg fracture in adult men of average stature. A splint specially made for each individual case, though desirable, is rarely necessary. In using the standard splint, where the size of the ring does not insure the maintenance of contact beneath the ischial tuberosity, such contact is maintained constant by suspension of the ring to a Balkan frame or other overhead suspension apparatus.

In fractures of the lower leg, especially compound fractures near the ankle-joint, traction from the sole of the foot has rendered obsolete the use of the Finochetto stirrup, the pin through the os calcis and the always precarious and unsatisfactory methods of traction from one or another appliance encircling the ankle or foot. The tremendous and enduring adhesive capacity of celluloid-acetone solution has rendered traction from the sole of the foot both simple and sure of application.

I have found direct bone traction through caliper tongs applied to the femoral condyles, as mentioned by Cowan, of great value in cases of supracondylar fracture, fractures of the lower one-third of the femoral shaft and in some old non-unions of upper shaft fractures where much overlapping and shortening demanded very heavy traction. A particularly valuable feature of the caliper tongs is, that their use permits the knee-joint to be moved and frees this joint from the injurious effects of long continued traction strain.

Adjustable pressure pads clamped to the side-bar of the Thomas splint assist in reducing lateral displacements.

In my own practice, I have discarded the Spanish windlass except in emergencies. I now use a thumbscrew or turnbuckle for adjusting traction with a Thomas splint. By incorporating a small spring balance and keeping the balance registering a given number of pounds, I am assured of uniform tension upon the limb.

Any traction splint requires frequent adjustment. Eternal vigilance is the price of good results by conservative methods. Perhaps this is the reason some surgeons still seem to prefer other methods less efficient but more spectacular, and making a lesser tax upon the surgeon's time and energy.

Dr. Fairchild (closing)—The complimentary expressions of the gentlemen kind enough to discuss the paper are fully appreciated; the criticisms are accepted in the same spirit.

Dr. Shoemaker objects to the padded shoe as an attachment for extension as very dangerous. In trying to briefly conclude a paper which was growing too long, my brevity led to my being misunderstood. The padded shoe as a support for any case when heavy traction is required is dangerous and painful to the patient. It should never be used. I have made use of it in very low fractures of tibia and fibula where only moderate traction is required. Traction from the sole of the foot would be better.

Dr. Cowan's point in regard to the use of caliper traction on the condyles is of importance. I have, in low femur fractures, used it with great satisfaction. The principle is the same as the making of traction from a pin through the anterior portions of the condyles, but the trauma is less.

CONGENITAL HYPERTROPHIC PYLORIC STENOSIS IN INFANTS *

WITH REPORT OF FORTY-SEVEN CASES

By GUY COCHRAN, M. D.
(From The Children's Hospital, Los Angeles.)

The earliest record of an example of this disease was unearthed by Osler, and is contained in "Cases and Observations by the Medical Society of New Haven," in the State of Connecticut, 1718, by Hezekiah Beardsley. The following history of the case is given:

"A child of Mr. Joel Grannis, a respectable farmer in the town of Southington, in the first week of its infancy was attacked with a puking, or ejection of the milk, and of every other substance it received into its stomach almost instantaneously, and very little changed.

"The feces were in small quantity and of ash color, which continued with very little variation till its death. For these complaints a physician was consulted, who treated it as a common case arising from acidity in the proma via the testaceous powders and other absorbents and correctors of acid acrimony were used for a long time without any apparent benefit. I was at first inclined to attribute the disorder to a deficiency of bile and gastric juices, so necessary to digestion and chylification, joined with a morbid relaxation of the stomach, the action of which seemed wholly owing to the weight and pressure of its contents, as aliment taken in small quantities would often remain on it, till by the addition of small quantities, the whole, or nearly all, was ejected; but his thirst, or some other cause, most commonly occasioned his swallowing such large draughts as to cause an immediate ejection, and oftentimes before the cup was taken from the mouth.

"A number of the most respectable medical character were consulted and a variety of medicines were used to little or no effect. His death, though long expected, was sudden, which I did not learn till the second day after it took place. This late period, the almost intolerable stench and the impatience of the people who had collected for the funeral prevented so thorough an examination of the body as might otherwise have been made.

"I next examined the stomach, which was unusually large, the coats were about the thickness of a hog's bladder when fresh and distended with air; it contained about a wine pint of fluid exactly resembling that found in the vesicles before mentioned, and which I supposed to have been received just before its death. The pylorus was invested with a hard, compact substance, or scirrhosity, which so completely obstructed the passage into the duodenum as to admit with the greatest difficulty the finest fluid; whether this was the original disorder, or only a consequence, may perhaps be a question. In justice to myself I ought to mention that I had pronounced a scirrhosity in that part before the child's death."

In 1904, Holt wrote that, "without surgical in-

tervention, the chances for recovery are small. With well-proved symptoms, laparotomy is justifiable, and in at least one instance has been successful." Then followed an increase of interest, and an occasional gastro-enterostomy was performed. But the mortality was high. In 1908, Fredet devised a much simpler and better procedure. In 1910, Weber, and in 1912, Rammsted, announced modifications of Fredet's technique. Now the one of general choice is called the Fredet-Rammsted operation.

Pathology—"The lesion of hypertrophic stenosis of the pylorus is hyperplasia of the unstriped muscle cells of the circular coat, while the connective tissue is not increased." A pyloric tumor is always present. It is usually about the size of an olive, though it increases with duration of symptoms. There are no adhesions about it. It is smooth, firm, ivory colored, and cuts like cheese. It encroaches upon the lumen of the canal, and produces an edema of the mucosa by pressure. Following operation by gastro-enterostomy the tumor remains: following the Fredet-Rammsted operation it disappears.

Etiology—There are many theories: it is probably a congenital overgrowth of muscle tissue. There is a case reported by Dent of one in a seven months' old foetus, and several have been seen in babies who died at birth. They are frequently associated with enlarged thymus glands, or other congenital defects—such as imperforate annus or club-foot.

Diagnosis—It is the history of mechanical obstruction—vomiting, which becomes projectile: this is followed by constipation, mucous stools and a rapid loss of weight. There is a visible active peristalsis from left to right. There is a palpable tumor at the region of the pylorus. This tumor can usually be felt, unless the pylorus lies too close to the liver edge. In the great majority of cases, the diagnosis should not be difficult, but in obscure cases aid may be given by fluoroscopic examination, especially when a tumor cannot be felt, and to distinguish between pylorospasm and stenosis, for we cannot believe with Haas that both are the same, and that it is a matter only of degree of spasm. We know that with hypertrophy we have spasm, but frequently, from various cases, we have spasm without hypertrophy.

Treatment—The treatment is logically medical, for there are all degrees of severity of symptoms in this, as in other pathologic conditions. Observation and medical effort is justifiable so long as the baby does well, or has lost not more than 20 per cent of its body weight, but the greatest number of these cases are not seen until late, and many almost moribund, when surgery is the only hope. That is why the mortality is so high, for many of these babies die of starvation—not of the simple surgical procedure.

Operation—There is a great variance of opinion regarding the anaesthesia. Many prefer to operate these cases under local, but it is not our experience—the babies squirm and cry—the intestines and stomach push out of the wound, and cause much annoyance and delay, and increase the shock to the patient. These little patients require little ether. The entire operation should occupy only fifteen to twenty minutes, and we have seen no untoward effects from the general anesthetic.

The incision is upper right rectus. It should not be over two inches in length. The tumor is felt, and by the aid of a blunt, rubber-covered hook the pylorus is brought out through the wound. The tumor is incised longitudinally, along the bloodless area. This incision should be only deep enough to spread sufficiently so that a blunt instrument—preferably a straight forceps—can be inserted and blunt dissection carried on. The tumor tissue tears easily, and soon the gray mucosa is seen bulging upward. This dissection extends the entire length of the tumor, for if any bands are left the result is not accomplished. Sufficient width of muscle layer must be removed to allow the mucosa to bulge into the entire length of the wound. This is easy at the thickened gastric end, but care must be taken, for the duodenal end thins out quickly and is easily torn. We have never sutured any omentum, or done any plastic work to cover the mucosa. The abdominal wound is closed in tiers, and also with silkworm retention sutures, for these wounds need support for about ten days or two weeks.

In post-operative care, the babies are given glucose or salt solution by drip, or under the skin. Feeding is begun one hour after operation—a teaspoonful of warm water alternating with diluted breast milk every two hours. This is increased gradually until by the fourth or fifth day the child is receiving full feedings. Throughout the entire care of these cases the heartiest co-operation is required between pediatrician and surgeon.

Since 1914, we have had forty-seven patients at the Children's Hospital who fall into this group, thirty-three of whom were operated upon. Twelve of those operated upon died; twenty-one recovered; three of the operations were gastro-enterostomies. Of the fourteen others treated medically, two died.

Of the forty-seven patients, there were forty-two boys and five girls. The ages varied from five weeks to four months. Twenty-three were artificially fed; twenty-four were breast fed. Duration of symptoms varied from seven days to ten weeks. Those operated upon had all lost 20 per cent or over of body weight.

Our mortality is too high, and to assign the reason is one of the objects of this paper. Most of our cases are charity ones, and are brought to the hospital nearly moribund. In these we have operated as the only possible thing we could offer. None has died on the table, but several have gone on to death from starvation in a short time. The earlier cases were treated expectantly with atropine and feedings, and became surgical when such treatment failed. We have only lost one of this group with peritonitis due to faulty technique. The diagnosis is usually not difficult if physicians are on the watch. We have used no plates, and only occasionally the fluoroscope for aid in diagnosis. We would recognize more of these cases and save more of these babies if we would watch all sick babies with projectile vomiting, constipation, visible peristalsis, rapid loss of weight, and other usual symptoms of

obstruction. We should keep it in mind from the beginning that these cases may become surgical.

SUMMARY

We have the greatest admiration for the work of Downes, who gave such a stimulus to the study of the subject of Congenital Hypertrophic Pyloric Stenosis. His experiences have been corroborated in our work in many ways:

1. Ether anaesthesia is preferable to local.

2. The Fredet-Rammsted operation is much simpler and more quickly performed than gastro-enterostomy, and therefore the best technique to follow in all cases.

3. In most cases the differentiation between pylorospasm and stenosis is clear, and only in questionable cases should fluoroscopic aid be resorted to. These little patients are too sick to be loaded up with barium unless it is absolutely necessary.

4. Cases under observation should not be allowed to lose too much weight before resorting to surgery; after loss of 20 per cent of body weight these cases become poor risks instead of good. Many come to us so late that we cannot avoid operation, but this is the chief cause of our high mortality. We lost most of our cases during the early years while we were doing gastro-enterostomies or working under local anaesthesia. There will be deaths under the most skillful care, but with the present simpler technique we hope for much better results in the future.

1136 West Sixth Street

DISCUSSION

Emmet Rixford (Stanford Medical School, San Francisco)—In his virile short sentences the author has well epitomized the salient points in the modern management of cases of congenital hypertrophic stenosis of the pylorus. I can only emphasize his statement that thorough co-operation of pediatrician and surgeon is essential, that operation should not be delayed if the condition is not soon ameliorated by the feeding of semi-solid food. The author's experience duplicates that of most surgeons, in that in many of his cases, more particularly the earlier ones, operation was too long delayed.

An important part of the operative technique should be swathing the child's limbs with cotton to lessen the loss of body heat, for these tiny mites are half-starved and chill easily, especially when ether anaesthesia is used. Many surgeons prefer chloroform if they happen to have anaesthetists who are experienced in using that drug. I would also add some emphasis to the point that, in the Fredet-Rammsted operation, it is very easy to open the mucous membrane of the duodenum. Any modification of technique which will save time is desirable, such as closing the abdominal wound with through-and-through sutures. For this I prefer silk, for it is less irritating to the child than silkworm gut unless it be very fine.

E. C. Fleischner, M. D. (350 Post Street, San Francisco)—The importance of an article which calls attention to the salient points in the management of hypertrophic pyloric stenosis in infants cannot be overestimated. There is no condition in infancy in which the successful outcome depends so much upon careful observation and logical treatment as in this disease. From the standpoint of the pediatrist it is unquestionably true that, in the hands of a skillful surgeon, early surgical interference is associated with more satisfactory results than indefinite procrastination and late surgery, even though the latter procedure may spare certain infants the necessity and risk of a laparotomy. This is particularly true in infants who are receiving breast milk, so much so that when a diagnosis of true stenosis has been made in a nursing infant, who, up to the onset of the disease, has been receiving an excellent mother's milk it is better to operate early and conserve the human milk supply than to temporize with various artificial foods, as a result of which the breast milk is lost and frequently operative interference required at a later date. There is one point in connection with the management of these cases to which particular attention should be called and upon which the greatest stress should be laid. Next to the importance of early operative interference in the successful treatment of these cases no one single procedure is as valuable as the plentiful supply of fluid to the tissues of these infants before operation. This is strikingly true in those cases that come to late surgery, but equally important before all laparotomies. These infants suffer as much from dehydration and perhaps even more so than from starvation, and it is possible to obviate the harmful effects of water privation by hypodermoclysis before operation, and in this manner improve tremendously the chances that the child has of recovery. It may be a dangerous generalization because of the difficulty in determining who is a good surgeon and who a mediocre one, but, in the hands of a capable man, early surgery will be productive of better results with less danger than temporizing and late surgical interference.

Edward S. Ruth, M. D. (6548½ Hollywood Boulevard, Los Angeles)—In discussing this paper I would like to confine my remarks to a possible etiological cause of hypertrophic pyloric stenosis.

In all series of hypertrophic pyloric stenosis cases, two factors stand out above all other symptoms and observations. First an overwhelming majority of cases occur in the male infant. In all series from 83 per cent to 95 per cent are in the male. Second, it is a disease which has its onset of symptoms from birth or soon after. These two factors it seems to me are significant from an etiological standpoint. Heretofore the etiological cause has been attributed to some nerve entity that, in some way, was responsible for the enormous overproduction of smooth muscle fibers about the pyloric end of the stomach. A great deal of experimental work has been done by Strouss, Trumpeer, and Bernstein by mechanically obstructing the pylorus, but nothing has been accomplished except for reproducing the classical symptoms of hypertrophic pyloric stenosis.

Scammond, in some of his weight and growth curves of the various organs of the foetus and postnatal life, showed rapid and enormous growth of the uterus up to the time of birth. After birth there is a rapid subinvolution and decrease in the size of the uterus, and its growth that was attained at the time of birth is not again reached until much later in life. This apparently indicates that we have something that stimulates smooth muscle growth during pregnancy. This I have termed a smooth muscle activator.

If the hypothesis is correct that the prenatal growth of the uterus is due to smooth muscle activator, then we may have the same muscle activator at work in the wall of the uterus of the mother, producing the enormous hypertrophy and the hyperplasia that takes place during the period of gestation. Now, assuming that we have a smooth muscle activator at work during pregnancy, I believe that this same activator may also produce hypertrophy and hyperplasia in the smooth muscle in the pylorus and stomach. This is the only place in the human body where we have a large accumulation of smooth muscle fibres. For some time it has been pretty definitely known that the hypertrophy of the pylorus is a prenatal growth, inasmuch as several have been reported in foetuses of seven months of age. Also Kerley reports one in an infant three

days of age. Again, surgeons who have operated upon infants with pyloric stenosis have also suggested that this enormous hypertrophy must begin in prenatal life, because it seemed impossible that such a growth could take place in a few weeks or a few days' time.

This explanation is, of course, hypothetical, but I believe that it has merit.

Chemical Foundation Wins (Propaganda for Reform)—During the late war, our Government seized many German patents on synthetic drugs. Later the Alien Property Custodian, on executive order of President Wilson, sold 4700 German chemical patents to the Chemical Foundation, Inc. This corporation agreed in turn to license any American firm that could present evidence of reliability in chemical manufacture to manufacture under these patents. As a result of this action, physicians may today obtain different brands of arsphenamin instead of one proprietary "salvarsan"—and at competitive prices. The same is true of other useful synthetics. About a year and a half ago, President Harding instructed the Alien Property Custodian to take steps to secure the return of all patents sold to the Chemical Foundation, Inc., on the ground that the price paid was inadequate and the transaction illegal. Suit was instituted by the Government against the Chemical Foundation, Inc., for the recovery of the patents. The suit was won by the Chemical Foundation, Inc. In the decision of the court, it was held that the price was adequate, for the reason that many of the patents were non-workable and that, therefore, because of the financial risk and hazard, the value of the patents "was too slight and problematical to warrant the payment by American citizens of a sum even remotely approximating what they might have been worth to the German owners for their monopolistic purposes." Hence, the bill of complaints filed by the Government was set aside. (Journal A. M. A., January 12, 1924, p. 130.)

A Medical History Society—An organization meeting of medical men and others interested in Medical History was held on Saturday, March 15, at 8 p. m. The meeting was called to order by Doctor Ophuls in the new quarters of the historical section of the Lane Medical Library, on the third floor in the library building.

Emmet Rixford was elected temporary chairman and Henry Mehrtens secretary. Doctor Ophuls outlined the origin of the historical library, calling attention to the latest large addition of books. These were procured by the efforts of Adolph Barkan from Prof. E. Seidel in Meisen, and include 5000 old manuscripts and rare medical books. Continual additions of old and rare medical books are being made to this collection.

It was the opinion of those present that such a society should consist not only of medical men interested in the history of medicine, but that specialists in the allied sciences would also find interest and profit in this collection.

A committee, consisting of Doctors Ophuls (chairman), Evans, P. K. Brown, Hyman and Kerr were appointed to formulate a draft of the organic laws of the society and to get in touch with members of the profession and others who are interested in its ends.

Voltaire's and Frank Crane's Estimate of Physicians Compared—Voltaire once said that "Doctors were men who crammed medicine, about which they knew little, into bodies about which they knew less, to cure diseases about which they knew nothing." Dr. Frank Crane says that regular physicians have done, and are doing more for the human race than all the cults, fads, quacks and pathies put together.—Boston Medical and Surgical Journal, March 6, 1924.

PERFORATIVE APPENDICITIS—APPENDICECTOMY VERSUS DRAINAGE *

By S. M. SPROAT, M. D., Portola, Calif.

In acute perforative appendicitis, with definite abscess formation, there is great temptation to remove the offending member, too often to the detriment of the patient. With a well-walled-off appendiceal abscess, the appendix lying at any portion of its length outside the wall, it is far better surgery to drain the cavity and leave undisturbed the appendix. In the free cases, where nature has made no attempt at limitation of the infection, it is better to remove the offending member, where this can be easily accomplished, but, where protecting walls must be broken down, tissues traumatized with extensive handling, and the infected material disseminated widely, such a procedure is not to the best interests of the patient.

In the cases reported, the following technique was generally employed. The abdomen and anterior rectus sheath was opened over a mid-rectus incision, and the intact muscle freed from its sheath and pulled toward the mid-line. Then, without injury to the muscle, the posterior sheath was opened in the same line as the anterior, and the peritoneum in the same location. When the abdomen is later closed, the intact muscle serves as a support to the abdomen and tends to prevent the herniae, which are so common in these cases. On entering the abdomen, when the omentum was encountered, it was always kept to the left, and the exploration was conducted as low down to the right as possible. Gauze-packs were not employed within the abdomen unless absolutely necessary, but only served to keep the omentum pressed well to the left side of the incision, and thus saved the tissues additional trauma. On encountering an abscess wall, a stitch or two was often placed in the omentum to hold it temporarily to the abdominal wall. The abscess cavity was then entered from its lowest possible point on the right-hand side of the abdomen.

The cavity was carefully explored with the gloved finger and the appendix located from within the abscess cavity itself. Should it lie without the walls in any part, it is in nowise disturbed. The walls of the abscess are also not disturbed in any way. The cavity is thoroughly and carefully explored to determine the presence of any concretion or foreign material that may have been extruded from the appendix. If any such is found, it is removed. There is no irrigation attempted, and it has been my unfailing experience that the more thorough the attempts at cleaning the peritoneum and the more extensive the operative measures in these cases, the poorer the prognosis for the patient.

We all are aware that infection and localized abscess not infrequently follows difficult clean cases that require long and tedious removal of a non-perforative appendix. It is my firm belief that the handling and disturbing of the bowels, omentum, and abdominal contents that is necessary to remove an appendix in abscess cases very often leads to the

* Read before the Twentieth Annual Meeting of the Nevada State Medical Association, Reno, September, 1923.

death of the patient a few days later. In inserting drainage, several points must be noted. First, to drain through a stab wound at the lowest possible point of the cavity. Second, to institute drainage to the portion of the appendix lying within the cavity. The closer to the right the drainage is placed and the freer the initial drainage, the shorter the convalescence.

The disadvantages that are given to this conservative method are, first, that about 20 per cent require secondary operation for the removal of the appendix, as, in this number, further appendiceal trouble is noted after recovery. Second, convalescence is retarded. In regard to the first objection, the removal at an opportune moment may be accomplished at slight surgical risk to the patient, and Murphy has demonstrated that such appendices are usually little more than fibrous cords. Convalescence is usually much more rapid in such cases, if the surgeon is prepared promptly and properly to open up any new abscess cavities, which occasionally develop. The tubes are preferably soft cigarette drains, a large one to the abscess proper and a smaller one contiguous to the appendix, and another through the stab wound to the lowest point of the cavity. Drainage is usually favored by lying on the right side in a semi-Fowler position. It is very important to overcome tissue dehydration by interrupted proctoclysis, hypodermoclysis, and intravenoclysis, and this is forced to tissue saturation during the first forty-eight hours.

Haggard had to reoperate such cases and remove appendix at a later date in about 20 per cent, and this percentage has almost coincided with mine. In other words, such an appendix, when properly treated and drained, will give no further trouble in 80 per cent of the cases. The fact that so many of these cases so treated recover after stormy convalescence convinces one that even a small amount of added operative trauma would have caused death. This added trauma is given when the appendix is removed. Better a safe secondary operation in 20 per cent than a dead patient. The method of Petit, in allowing the right lateral abdominal wall to form one side if possible, has been f llowed. The risk of post-operative hernia, which runs from 12 per cent to 15 per cent in these cases, is minimized as follows: There is no drainage made through the operative wound that is not carried through the split fibres of the rectus muscle. This, I believe, is the great advantage of this incision over the outer rectus incision, and it has been described by Eliot, Ellsworth, and Pickhardt.

I recently operated upon under this method, by local anaesthesia, a man 72 years of age, with a systolic blood pressure of 180 and glycosuria, with recovery. I am convinced that, had adhesions which were present been torn or seriously disturbed, death would have resulted instead of recovery within four weeks. To have removed the appendix, it would have been necessary to seriously disturb these adhesions.

The following is a list of cases operated in the past four years by this method, with time of hospitalization. In these cases, the appendix was allowed to remain and drainage only was instituted.

Mrs. S. B., 18 days; V. K., 17 days; J. L., 25 days; Mrs. W. L., 46 days; C. A., 19 days; F. F., 46 days; W. S., 21 days; M. F., still in hospital; G. T., 27 days; J. H., 47 days; T. A., still in hospital; C. J., 36 days; H. R., 33 days; L. A., 48 days.

Upon three of the above, the appendix was later removed. In one, there was a post-operative hernia, which was repaired. One, after being passed for life insurance, was later operated upon in another hospital for secondary abscess, and the appendix was removed, with death. Average length of hospitalization, 31 days; mortality, none died; 12 operated upon under ether anaesthesia and two under local; one had a fecal fistula, which closed spontaneously.

CONCLUSION

In definite well-walled-off abscess cases of perforative appendicitis, with the appendix lying outside of the abscess walls, the mortality will be lower and it is safer not to remove the appendix.

DISCUSSION

Horace J. Brown (Thoma-Bigelow Building, Reno, Nev.)—Whether to remove the appendix in these cases, or not, seems to be a question open to much discussion. In my own experience, it has been a puzzle whether to leave the appendix and drain, or remove the appendix and drain, with drainage being the only part of the procedure that I feel sure of. I have broken up adhesions in order to remove necrotic appendices, put in generous drains, and had so many good results that I felt confident that that was the method of choice until disaster overtook me and two or three such patients were lost in succession; then I would change to drainage only and feel very secure as long as all got well, but when disaster again overtook me I would change back again. Just at present I am on the "removal" side of the fence, but cannot say that I feel real secure there. Seriously, I believe that the whole problem depends upon the nature and severity of the infection. If we have an abscess, perforated or necrotic appendix that is caused by staphylococci, or colon bacilli as the predominating organism, then I think we can either remove the appendix, breaking up many adhesions in order to do so, or we can simply drain, with the accent on the "drain," and our patients will have a good chance of recovery; but if we have a streptococcic infection to deal with, and it is of the virulent type, I believe that a large percentage of such cases will die, regardless of the treatment used. I have become thoroughly convinced of the value of adequate drainage and believe that too many of us are prone to use drains that are more ornamental than useful. I believe that our patients will fare better if we use large, loosely packed, cigarette drains, and plenty of them, in all pus cases, and I know that I can sleep better when I know that I have an ample drain in any doubtful case.

R. A. Bowdle, M. D. (East Ely, Nev.)—So far as I can recall I have never operated for acute appendicitis without removing the appendix. I see a great many ruptured appendices. It seems to me that, with careful attention to the operative technique, you can remove the appendix with no greater trouble than that incurred in thoroughly exploring the abscess cavity with the glove-finger. I believe that every appendicular abscess should be walled off from the general peritoneal cavity by means of gauze strips. For this purpose I use a gauze packing about one inch wide and twelve inches long; these are moistened, and can be so arranged that, with a minimum of trauma, they will protect the remainder of the abdominal cavity. I think that the rough handling of tissues and the lack of knowledge in knowing

how to reach the caecum is responsible for many deaths that could otherwise be avoided. In the matter of drainage I firmly believe that it is better to drain a case that is questionable than to close one up that subsequently develops an abscess. In addition to the sites of drainage which Sproat uses, I invariably place a cigarette drain down into the right pelvis; this is particularly necessary where you are using the Fowler position following operation. Another very important point in the handling of these cases is the saturation of the patient's system with fluid. As has been so well shown by Crile, this can best be accomplished through hypodermoclysis. My routine is to give the patient at least 3000 cc. during the first twenty-four hours—he is kept well morphinized and in a Fowler position. I use practically the same incision which Sproat describes; occasionally in clean cases in children or young males I will use the muscle-splitting incision of McBurney.

Robert R. Craig, M. D., (Tonopah, Nev.)—More than half of my acute appendicitis cases are ruptured. I have never operated without removing the appendix, and so far have had no catastrophies traceable to this procedure. By gentle, careful technique most appendices can be located, isolated and removed without evisceration or contamination of the whole abdominal cavity. I see no advantage in the right rectus abdominis incision and often the disadvantage of opening into the free peritoneal cavity, instead of into the main objective, for one can to better advantage explore the abscess from the inside than from the outside. I prefer the right external incision, as far out as possible, sometimes opening directly into the abscess extraperitoneally. Through this incision one follows the leads, edematous peritoneum, omentum, and inflamed bowel, and by palpation reaches the abscess cavity, which is evacuated; and explored with the gloved finger, the appendix located and isolated with as little disturbance of protective walls as possible; often when the caecum is adherent the appendix is removed without drawing it into the incision. Three drains are used, one at least a cigarette or rubber tube, placing one in the pelvis, one to the stump of the appendix, and one high to upper limit of infection among the coils of inflamed intestine and omentum. If any part of the appendix lies without the abscess wall, the abscess is usually a very small one and at no point adherent to anterior parietes.

Dr. Sproat (closing)—I believe that conservatism, in not breaking down protective barriers to remove the appendix in acute cases where such barriers exist, is coming into more general usage. The more virulent the infection the greater the need for the absence of tissue trauma, and breaking down natural protective walls. In the majority of these cases the appendix extends outside of these walls, and they are notoriously difficult of removal, even with the greatest possible care.

Lower and Jones of Cleveland, in their paper read before the Section on Surgery, general and abdominal, at the American Medical Association meeting last June, state as follows: "The high operative mortality in cases of acute appendicitis and the postoperative morbidity in cases of chronic appendicitis are, in our opinion, due in large measure to the common belief that in each case the only proper procedure is removal of the appendix." And again, "In acute appendicitis we would emphasize our own adherence to the procedures outlined, and to Crile's principle of confining the primary operative procedure to incision and drainage only; if the appendix is not readily accessible, the removal of the appendix and such other exploration as may be necessary being deferred until the acute state is past."

Since this paper was read, I operated upon a patient with an acute fulminating infection which caused rupture and abscess in thirty-six hours of onset, and within twenty-three days the incision had closed and he had left the hospital. From past experiences with removal, convalescence, I am sure, would have been a stormy one had this been done.

KIDNEY AND URETERAL STONE SURGERY*

By HERMAN L. KRETSCHMER, M. D., Chicago

In presenting for your consideration the problems of kidney stone surgery, I have thought it advisable not to dwell at length on the technical side of the subject nor to burden you with the reading of statistics, but to present some of the difficulties and some of the problems encountered in our every-day work.

It is also advisable, when considering this subject, to include stones in the ureter, since some of the problems of diagnosis and many of the clinical symptoms are present both in kidney stone and stone in the ureter to such an extent that at first an absolute differentiation between them from the clinical history alone is not possible.

At one time it was the opinion that kidney stones, as well as renal infections, were rare in women; but recent intensive studies of this subject have completely disproved this. Not only do kidney and ureteral stones occur in women, but they occur much more frequently than has hitherto been supposed. This applies also to the frequency of occurrence of renal infections. In fact, if certain renal infections which occur only in women are considered—such as pyelitis during and after pregnancy, the greater number of cases of pyelitis of infancy among girl babies as compared with boy babies, the frequency of kidney infections either immediately or remotely after gynecological operations, as well as these infections associated with pathological conditions of the female pelvic organs, one may safely say that kidney infections occur much more frequently in women than in men.

Kidney stone, according to custom, is generally associated with a so-called classical history of renal colic. Not infrequently, however, kidney stones run a silent course. At times there may be no subjective symptoms suggestive of renal stone; again, the only manifestation may be the presence of pus in the urine, and this may be very slight or even absent. As examples of cases in which kidney stones were found, though not suspected, I would like to mention briefly just a few instances. One of our patients complained of frequency of urination, which, because of his age, he attributed to his prostate gland. The final diagnosis was carcinoma of the colon, which necessitated a colostomy for obstruction. Roentgen-ray examination revealed a large stone in the kidney.

Another patient, suffering from tabes for many years, had urinary incontinence. Roentgen-ray examination showed a large solitary kidney stone.

A young woman had the symptoms and signs of renal tuberculosis, the diagnosis being substantiated by means of the cystoscope and the ureteral catheter. A routine Roentgen-ray examination revealed a stone in the tuberculous kidney.

A man of 70 came to the office to have one of his periodical recurring attacks of cystitis treated by vesical irrigations, as had been his custom for many years. Routine Roentgen-ray examination showed

*Read before the Utah State Medical Association, June 22, 1923.

multiple stones in the kidney. Many more cases of this character could be cited, but I believe these few amply illustrate just what is meant by silent stones. No doubt there are many cases of this kind overlooked.

Stones having their origin in the kidney may have one of the following four terminations:

1. The stone may remain in one of the kidney calyces or in the pelvis.

2. The stone may enter the ureter, and in its course become lodged. This usually occurs with predilection at one of the physiological constrictions of the ureter.

3. The stone may pass from the ureter into the bladder, where it may remain and become the nucleus of a bladder stone. If a careful history is elicited in cases of vesical calculi, it is highly probable, in a certain percentage of cases, to obtain a history of a previous attack of renal colic. This may have occurred many years before, so that the patient may have quite forgotten it, unless his attention is specifically called to the fact.

4. The stone may be voided by the patient.

The present high plane which has been attained in the surgical treatment of renal calculi is a more or less direct outgrowth of the accurate methods of diagnosis which are at our command. Briefly, they are: The Roentgen ray, the cystoscope and ureteral catheter, the shadowgraph catheter and pyelography, and functional kidney tests.

Undoubtedly, the single factor which has contributed most to the diagnosis of kidney and ureteral calculi is the Roentgen ray. Its field of usefulness in this work is enriched by the simultaneous employment of the Roentgen ray and the cystoscope, made possible by the introduction of the shadowgraph catheter and pyelography.

While it may be possible, in a large number of cases, to make a diagnosis by means of the Roentgen ray alone, there will always remain a certain number of cases in which pyelography, or the shadowgraph catheter, or both, must be employed. For example, in cases of stone occurring in the renal pelvis, no positive diagnosis can be made without the employment of one or both of these additional aids. The value of the shadowgraph catheter in the diagnosis of stone in the renal pelvis and other conditions has been previously reported.

Not only is the Roentgen ray of value in the diagnosis of calculi, but it is of inestimable importance in watching the progress of a calculus through the ureter. Another example in which a combination of methods is of value is illustrated in cases in which a stone in the renal pelvis or ureter does not show plainly in the roentgenogram. If a solution of collargol is injected into the pelvis or ureter and a second picture is taken, the stone will appear very distinctly on the plate.

In employing the Roentgen ray, it is of prime importance to remember that the exposure should include both kidneys and both ureters. The value of this procedure is apparent when the frequency of bilateral calculi is recalled, as well as the possibility of the presence of stone in one kidney, and the occurrence of one or more stones in the ureter of the same or opposite side. The importance of this procedure is also apparent in cases in which a nephrectomy has been performed for stone, and the patient afterward returns with a stone in the remaining kidney. Under such untoward circumstances it is of more than academic interest to ascertain whether the stone was present before the first operation or whether it formed subsequently.

LIMITATIONS OF THE ROENTGEN RAY

Perhaps the greatest source of error is due to failure to interpret the shadows correctly, and not to failure to demonstrate shadows in the Roentgen plate. As is well known, there are many shadow-producing bodies located outside the urinary tract, which are often interpreted as due to lithiasis. This occurs most frequently in cases of suspected ureteral calculi. The frequency with which patients are sent to a hospital with the diagnosis of stone in the ureter and in which the patient or his physician proudly points to a small shadow as being the offending stone, is known to all. The occurrence of these shadows should always be borne in mind, and when there is any doubt as to their nature and location, the shadowgraph catheter should be employed. Although in a large number of cases this procedure is of assistance, there remain, unfortunately, a small number of cases in which even this method fails to give the desired information. It is my opinion that this small percentage can be reduced still further by resorting to a procedure, previously described, in which a double exposure upon a single plate is made with a shift in the tube.

The routine use of the Roentgen ray after operation for renal stone has not become an established procedure, although it deserves to be. While this procedure will often put the surgeon in the embarrassing position of showing that he has failed to remove all the stones, it will, on the other hand, yield data which will have a direct bearing on the percentage of recurrences, a subject which at present is deserving of closer study than it has received in the past. I can recall several instances in which there is no doubt that all the stones were not removed at the primary operation, but nevertheless were classified under recurrences, thereby belittling the operation.

Not infrequently the Roentgen ray fails to yield the desired information. This may be due to the following factors:

1. The inherent limitations of any diagnostic measure.

2. Errors in the Roentgen technique due purely to the roentgenologist.

3. The calculus may be situated in so peculiar a manner that it is overlooked when the plate is read. This occurs when a small calculus is situated behind the rib, over a transverse process, over the ilium or when the plate is so placed that the stone comes just at the edge of the plate.

4. On account of the chemical nature of the stone, its demonstration by means of the Roentgen ray is impossible.

5. The stone may have been passed.

CYSTOSCOPY AND URETERAL CATHETERIZATION

While these two diagnostic aids cannot establish a positive diagnosis in each case of renal or ureteral calculus, they can, in a definite number of cases, yield information from which a diagnosis may be made or surmised. By their employment, it is possible in nearly all cases to locate the source of the pathological elements found in the urine, such as blood or pus. In renal stone associated with profuse hemorrhage, the origin of the blood may be determined by means of cystoscopy and ureteral catheterization; and also in descending ureteral stone associated with colic, changes may often be seen about the ureteral orifice of the corresponding side. Mention should be made here of the wax-tipped catheter. If positive information is obtained by its use, one may venture the diagnosis of stone; on the other hand, if the result of this examination is negative, the presence of stone should not be excluded.

FUNCTIONAL TESTS

After the diagnosis of stone has been made and the treatment outlined, the condition of the opposite kidney should engage our attention, and especially whether the kidney is present or absent. This important point deserves due consideration in each case, no matter how simple the contemplated operative procedure may be. Not infrequently a simple operation is decided upon, but because of complications arising in its course the removal of the kidney is necessary. In such an instance, if the presence of the opposite kidney has previously been determined and its functional capacity estimated, it can readily be seen how decidedly comforting to the operator this must be.

Of the various functional tests which have been advised, the phenolsulphonepthalein test has been most frequently used, and it has answered my purpose very well. Many objections have been advanced against complete reliance upon dye tests. One should not rely altogether upon the result of the dye test, but should include careful examination of the urine, both chemically and bacteriologically.

TREATMENT

Before taking up the treatment of kidney stones, I shall briefly discuss the treatment of stones in the ureter.

In a general way, the treatment of ureteral calculi passed through three stages: The first stage may be represented by the period immediately after the introduction of the Roentgen rays. At that time many of the now well-recognized extraureteral shadow-producing bodies were erroneously diagnosed as calculi, and patients were unnecessarily operated upon. The second stage may be represented by the period immediately following the introduction of the shadowgraph catheter, by means of which more accurate diagnoses were made and the number of unnecessary operations decidedly reduced. The consensus of opinion at that time was that the treatment of ureteral calculi was surgical, and the operation employed was the extraperitoneal ureterotomy. The third period may be represented by our present-day views, and is characterized by the swing of the pendulum in the opposite direction, so that at the present time the keynote is conservatism. In other words, one resorts to operation only after a prolonged, careful and conscientious use of the non-operative measures fails to accomplish removal of the stone.

These non-operative measures consist in the use of intravesical manipulations with the cystoscope. Briefly considered they are: First, dilatation of the ureteral orifice, either with a catheter or with a ureteral dilator, in order to stretch the ureteral orifice so that the stone may be allowed to pass. Where this fails and sufficient dilatation cannot be obtained, the ureteral orifice may be enlarged by slitting it with the scissors. In cases in which the stone is smaller than the ureteral orifice and situated high above the bladder in the ureter, the stone may be dislodged by the ureteral catheter. This may be followed by intraureteral injections of local anesthesia, succeeded by the injection of oil. To aid in dilating the ureter, injections into it of a solution of papaverin have been advised.

Experience has proved that by far the largest number of stones in the ureter can be handled in this way. In the remaining small number which do not respond to repeated applications of this form of treatment, advising an open operation may be justifiable.

INDICATIONS FOR OPERATION

1. Cases in which there is a vital indication to operate. Under this head, one may consider cases of anuria, acute pyelonephritic infection, profuse hemorrhage, and conditions of retention which sooner or later lead to atrophy of the kidney.

2. Cases in which operation must be advised, but in which there is no immediate danger as regards the life of the patient or the function of the kidney. To this group belong the cases associated with chronic pyelitis, repeated attacks of colic without the passage of stone, pain or discomfort in the kidney area and the presence of stone in the ureter, which do not respond to non-operative treatment.

3. Cases in which intervention is unnecessary. In this group, cases may be considered which can be treated medically. Briefly, these are cases characterized by repeated attacks of colic associated with the passage of small stones, in which the urine is not infected and in which the Roentgen ray does not reveal large stones.

The three operative procedures in the surgical removal of kidney stone are pyelotomy, nephrotomy, and nephrectomy.

Pyelotomy, in cases in which this procedure is suitable, is simple and safe, involving little or no hemorrhage, and its great advantage over other operations is that there is no mutilation of kidney tissue, which occurs to a certain extent when nephrotomy is carried out. Pyelotomy, furthermore, prevents the occurrence of hemorrhage from the kidney into the renal pelvis, which often results in the bladder becoming distended with large blood-clots, so that the patient suffers a great deal of pain, and considerable inconvenience is experienced in freeing the bladder from these clots. The essentials for success in pyelotomy are:

1. In selection of cases to be guided by the re-

sults of the Roentgen ray and possibly by the pyelographic findings.

2. The limitations of its use to pelvic stones.

3. Its employment in cases in which there is no infection, or at best only an infection of mild degree.

4. The deliverance of the kidney.

5. The avoidance of unnecessary trauma to the pelvis.

6. The prevention of injury to the blood supply of the kidney pelvis.

Before incising the pelvis, the peripelvic fat should be carefully separated. Occasionally an accessory pelvic vessel may be present, and unless this is recognized and avoided, the patient may have a certain amount of hemorrhage. Great care should be used in performing pyelotomy so as not to tear the renal pelvis, not only because of the danger of hemorrhage, but also because large and irregular tears of the renal pelvis have been followed by persistent sinus formation. On account of the more or less limited field of operation, it is particularly desirable, before closing the incision in the pelvis, to be sure that the stone removed is intact and that no fragments have been left behind. After the stone or stones have been removed, the incision is closed with fine catgut, and then the peripelvic fat is sutured over the incision with one or two catgut sutures.

Nephrolithotomy—In cases in which the stone is too large to be removed through the pyelotomy incision or in which the stones extend into the calyces, branching in various directions, and in instances in which the pedicle is very short and in which there is a good deal of perirenal inflammation, and the kidney cannot therefore be delivered, nephrolithotomy should be done. There are instances in which a pyelotomy is the operation decided upon, having determined upon this procedure from the roentgenogram, but one or several of the aforementioned conditions being found, nephrolithotomy is the only course open. At times it may happen that a calculus must be removed with the kidney remaining in situ.

After the kidney has been delivered into the wound, it should be carefully palpated for the presence of stone; that is, the stone should be definitely located before cutting into the kidney. This may not always be possible when the calculi are very small; yet, when possible, it should always be done. Palpation of the renal pelvis may be carried out at the same time.

In cases in which the stone is seen on the roentgenogram but cannot be felt, some surgeons are in the habit of needling the kidney. This procedure is advocated by some, but condemned by many, chiefly for the reason that if a hard nodule is felt and is a calculus, it must be cut down upon anyway. If nothing is felt by needling, no one would be satisfied by the limited information obtained in this way; hence, an exploratory incision must be resorted to by all means.

If the calculus can be felt in the substance of the kidney, it should be exposed by incision, either on the convex border of the kidney, or, if the stone is near the anterior or posterior surface of the kidney, it may be cut down upon directly.

The nephrotomy incision is usually made in the convex border a little nearer the posterior portion of the convexity than the anterior, since there is less danger of injuring the vessels. After the incision has been made, the interior may be examined with the finger, or the calculus may be directly removed with the aid of the forceps. The stone must be carefully examined to ascertain whether or not it is complete, whether or not facets are present, in order that calculi may not be overlooked.

The further treatment of the nephrotomy wound will depend upon several factors, the chief of which is infection. When infection is present, it is often advisable to insert a tube for drainage, although this procedure has been criticized because of the danger of hemorrhage which may result.

Hemorrhage is one of the more important complications following nephrotomy, and has often proved so serious that a secondary nephrectomy was necessary in order to save the life of the patient. When the hemorrhage occurs at the time of nephrotomy, it can usually be controlled by grasping the pedicle when an inspection of the field is effected. Occasionally a spurting artery is seen that can be caught with the forceps. Often when the oozing appears to be general, it may be controlled by hot pads. As a rule, the sutures which close a nephrotomy incision suffice to control the bleeding.

Continued post-operative hemorrhage renders the operator absolutely helpless. As previously mentioned, the bleeding continues, the hemoglobin goes down steadily, the patient's mucous membranes become pale; hence, a nephrectomy must be done to save the life of the patient. Under these untoward circumstances, one always feels more comfortable if the status of the remaining kidney has been definitely determined before operation.

COMPLICATIONS FOLLOWING NEPHROTOMY

Urinary Sinus—The urinary sinus usually closes in a few days or a week, but occasionally the urine continues to be discharged for three weeks. If, however, a sinus persists for a longer period, closing it by passing a ureteral catheter and allowing the catheter to remain *in situ* may be attempted. However, if ureteral catheter draining fails to give relief, some exploratory operative procedure should be done to determine the reason for the persistence of the sinus.

Suppurating Sinus—The continued discharge of pus from the renal sinus should at once direct our attention to the fact that a suppurating process is still going on within the kidney. In attempting to close the sinus by local treatment, possible organic factors for keeping the sinus open should not be overlooked; therefore, local treatment should not be continued too long. As a rule, the reason for the persistence of a sinus remaining open can be found, and not infrequently this is due to a calculus which has formed after the operation, or has been overlooked at the time of the operation, as well as due to a sponge.

Nephrectomy—Primary nephrectomy for stone is

less frequently done than either of the two previously mentioned operations. As a primary operation it is resorted to in cases of stone associated with severe infection, tumor, or tuberculosis. In these cases, results are very much better following nephrectomy than nephrotomy, provided, of course, that the other kidney is present and functioning as discussed above. Secondary nephrectomy must be resorted to in cases of persistent fistula after other operative measures have failed to effect a cure; in cases of recurrence of stone, persistent infection of the kidney after the primary removal of calculi, and for the relief of uncontrolled secondary hemorrhage following nephrotomy or pyelotomy.

Nephrectomy is the most serious of the operative measures for the relief of stone, but the ultimate result, as regards recurrences, is better than with the other two operative procedures.

Hemorrhage is one of the most serious complications of nephrectomy. It usually occurs after the kidney has been cut from its pedicle and the clamp removed, but it may be due to other causes, such as failure to include the vessels in the ligature, placing the second ligature over the first, which may render the first one ineffective, and cutting the ligature when the kidney is removed. Slight oozing can usually be controlled with hot pads, but large hemorrhages are difficult to manage, since the wound rapidly fills with blood so that one cannot see. When hemorrhage occurs, the clots should be wiped out with hot pads and the site of the bleeding found. If this can be done, the bleeding vessel should be grasped with a pair of forceps and ligated. If the bleeding point cannot be seen, grasping the pedicle and exercising firm pressure with the fingers may be successful. This procedure will often allow the clots to be removed; thereby time for examination is gained and also knowledge just where the clamp should be applied. In instances where the operator attempts to stop profuse hemorrhage, injuries to the bowel by means of the clamp are prone to occur. At times the hemorrhage occurs from an accessory vessel; and, although this may be profuse, it never reaches the same proportions as does a hemorrhage from the pedicle. Bleeding may also occur from the vena cava, as a result of direct injury during operation.

Neuro-arthropathies: A Consideration of the Etiology and General Characteristics—It is the belief of Herman B. Phillips and Charles Rosenheck, New York (Journal A. M. A., January 5, 1924), that neuro-arthropathies caused by peripheral nerve disease or injury or other factors not definitely understood may occur with more frequency than is usually believed. These neuro-arthropathies are possibly misinterpreted, on account of the absence of demonstrable disease of the central nervous system. In the wake of such misinterpretation, extensive joint operations may be performed unnecessarily, as in one case cited. The possibility of neuro-arthropathy should always be considered in obscure or ill-defined joint manifestations, even in the absence of cord disease. The etiology may be found in disturbances of the peripheral neural apparatus or other hitherto unknown factors.

JUSTIFICATION FOR STERILIZATION BY EITHER SURGICAL OR RADIOLOGICAL METHODS

By REX DUNCAN, M. D., Los Angeles, California

The literature is abundant with most excellent articles dealing with the causes and treatment of sterility, but much less of scientific merit has been published pertaining to the justification for sterilization. Indication for sterilization broadly may be included under two heads. First, medical or those in which, because of some pathological condition in the woman, it is necessary to prevent pregnancy that her life may not be endangered. In advanced pulmonary tuberculosis, nephritis, diabetes, advanced cardiac lesions or other constitutional disturbances which would render pregnancy dangerous to the life of the woman, sterilization is indicated. In uterine cancer, fibroids, certain inflammatory conditions of the pelvic organ and other conditions in which sterilization would necessarily follow, appropriate treatment is undoubtedly justified. In women with deformed pelves or other conditions where delivery would require cesarian section or other dangerous operative procedure, it is a question to be determined by the patient, family, and physician. Statistical studies show quite clearly that pregnancy favors the recurrence of malignant diseases in breast cancer and malignant diseases of the genital organs, and while these conditions quite commonly occur after the child-bearing period, sterilization is undoubtedly indicated. Without entering into a detailed discussion of the numerous pathological conditions in which it might be indicated, it would seem that the woman's life should receive first consideration and it is, therefore, justifiable to produce sterilization in any of those conditions in which it might be demonstrated after proper consultation that pregnancy would endanger the life of the woman.

Secondly, the justification of sterilization for social or economic reasons or from a purely eugenic standpoint are subjects in which there is a great variance of opinion and permissible of considerable discussion. The attitude regarding sterilization for social reasons is rapidly changing. Undoubtedly, it is worthy of more thought. However, further discussion will be omitted here.

It is, of course, a well-established fact that sterilization may be produced either by surgical or radiological methods. The method to be chosen necessarily depends somewhat upon the pathological conditions rendering such a measure justifiable or permissible, the numerous indications for which need not be outlined here. Sterility may be produced by a single intra-uterine application of 2500 or more millicurie hours of radium which may be given in from four to 24 hours, depending upon the quantity of radium used or by the use of X-ray treatment over the pelvis, using such technique that the ovaries will receive approximately an erythema skin dose. This may be accomplished with high voltage X-ray equipment in one or two applications totaling approximately one hour.

While radium is commonly employed in the treatment of certain pathological conditions of the pelvis without producing sterility, sterilization pro-

duced by means of either X-ray or radium produces an amenorrhea and is associated with the usual menopausal changes. The nervous manifestations, however, are, as a rule, less prolonged and less severe than the normal or following radical surgical procedure.

Radium or X-ray is contra-indicated in the presence of acute or subacute pelvis infection. On the other hand, radiological methods are particularly appropriate in cases of severe tuberculosis or other local or constitutional diseases that would render the individual a poor surgical risk.

Because of the safety and simplicity of sterilization by radiological methods, this procedure is to be preferred to surgical means in all cases excepting those in which abdominal surgery may be indicated for the correction of some existing pathological condition, acute pelvis infection or in young women where menopausal changes are not desired.

Lay Advertising and Child Welfare — Under this heading, Frank V. Bogert (N. Y. State Journal of Medicine) says: "Never has the danger of a little knowledge been more prettily demonstrated than in the matter of public education in regard to diet. Producers of proprietary foodstuffs, in exploiting their wares, have reached a point so close to the limits of honesty that their pernicious teachings must be reckoned with in the promotion of public health. More especially does this concern the worker among children, who, dealing with the more delicate digestive apparatus of the young, an apparatus which must be protected and developed for the future, also deals with a group more vulnerable to temptation and managed dietetically by overzealous guardians. To the average mother, today, the one important consideration is to obtain the ingestion of sufficient calories, vitamines, iron, and salts by tempting, urging, coaxing, and force without regard to needs and ability to assimilate. The intemperate prohibitionist likes to believe that one can't eat too much. Weight is too often made the standard of health and the undernourishment of overfeeding is treated by more food. . . .

Every pernicious dietetic habit that we have been endeavoring for years, and with some success, to eliminate is openly encouraged. Overfeeding, underfeeding, between-meals feeding, unintelligent stimulation of the appetite, candy and sweet-eating in excess, all, are advocated by the selfish world of business in order to increase consumption. . . .

When we know that the sensible method of establishing a normal appetite is to keep food away until it is desired, our patients are advised to eat catsup to make the foods they 'like best taste better' and a brand of soups is advertised as 'your appetite's temptation.' Tonics, condiments and stimulating sauces are too commonly given to children because they are relished and because they increase food intake, and, in these days of undernourishment, justification is gladly found and the practice continued to the child's undoing."

The Business Side of the Doctor's Service—"From January 1, 1924," says a St. Louis doctor in a circular letter to his patients, "my practice will be on a business basis.

"I am compelled to pay office rent, drug bills, phone, light, gas, tires, etc., monthly and **promptly.** In consequence, I do not deem it just that I should render my services and supply drugs gratis or on an indefinite payment. Patients unable to pay, mentioning the fact, will be treated as promptly as before; those **able** to pay, and who **do not,** will oblige me by not calling me."

THE EVOLUTION OF ROENTGEN THERAPY IN HIGHER VOLTAGES *

By ALBERT SOILAND, M. D., Los Angeles

Two years have now elapsed since the present short-wave form of X-rays came into radiological favor in America, and it is now perhaps timely to venture some comments upon this theme.

For a great many years our most successful field of radiotherapy has been in lesions of the skin and subcutaneous tissues. For this work every conceivable type of electrical generator imaginable has been employed. Anything which would make a vacuum tube turn pink, blue, or green has been used with which to treat all ills that are the heritage of mankind. Little by little the pink and the blue tubes were placed in the discard, and gradually the intrepid radiologist essayed to delve deeply into the human anatomy, and finally succeeded in demonstrating beyond the possibility of a doubt that physiological and pathological response could be elicited upon structures below the body's exterior. Finally came some order out of chaos, and attempted measurements of all electrical factors entering into X-ray production brought forth a tabulation of units, destined to place Roentgen ray treatment upon a relatively scientific basis. From an uncertain and flickering voltage, giving rise to a phantom X-ray stream, there has come today a powerful generator with almost unbelievable capacity delivering through specially designed hot cathode tubes a force unseen and almost unknown, the remote effects of which we are all struggling to direct and understand. This progress, from our first feeble attempts to radiate the human skin surface to our present ability, to saturate the innermost recesses of the human body, has all been accomplished in the comparatively brief space of twenty-five years. You all know the many interesting periods of transition, of doubt, of struggles, of superstition—yes, even of death among some of our martyred pioneers—yet the science has emerged triumphant, and that which once eluded us is fast becoming our willing slave.

The present discussion will deal with the problems of deep therapy and the evolution of the higher voltages. We will, therefore, omit reference to skin and superficial radiation, and state briefly that it is now quite possible, by varying the factors of our operation, to inundate a desired depth field, with the knowledge that in this field a fairly constant effect of the energy of radiation may be obtained.

For the purpose of illustration, we may roughly state that, with a voltage of 200,000 at a 50 centimeter skin distance and with 10 millimeters of aluminum filter, effective radiation may be apparent four inches below the skin surface. With the same voltage and 15 millimeters of aluminum filter, an efficient but smaller amount of energy of radiation may be delivered six inches below the skin surface. With 20 millimeters of aluminum filter, a still smaller quantity of effective rays reach an eight-inch distance below the skin. This table is, of course, only relative, but it will serve to illustrate

* Presented to the Section on Radiology at the Fifty-second Annual Session of the California Medical Association, San Francisco, June, 1923.

the point. Rays which are not absorbed have no demonstrable action. It is only at the point of absorption that the ray gives off its energy; in other words, its corpuscular energy is dissipated with a subsequent cellular reaction, the termination of which usually results in a restored normal function.

It has been frequently stated that it did not appear logical to treat something six or eight inches below the surface of the body when the rays had to traverse so much normal tissue in order to reach the lesion, and that the intervening tissue must suffer by virtue of bearing the brunt of the attack.

While we are by no means agreed on the modus operandi of the X-ray stream, it has been demonstrated time and time again, both clinically and microscopically, that specialized cells, those of irregular formation such as the tumor type, are particularly susceptible to short-wave forms of radiation and that no appreciable lasting effect occurs in normal cells in dosage sufficiently heavy to transform completely those of pathological habit. Careful laboratory experiments and investigations have shown that only those rays which are absorbed by the tissues are capable of producing biological effects, and this knowledge has enabled the laying down of formulae which permit us to approach a therapeutic rationale.

It is to be regretted that many surgeons still look upon radiation as a rival, or something to be avoided. Surgery and radiation must work hand in hand, and one support the other in nearly all lesions which may be attacked with the prospect of cure. Surgery has reached a plane of perfection which is undeniable and which has, up to the present time, been the most acceptable method of treatment in many cases where other methods, including radiation, are failures. Yet one must admit that surgery is essentially limited to conditions where the necessity for mechanical interference or manipulation is permissible. On the other hand, radiation is a reactive process which cannot be considered mechanical in any sense of the word. It possesses properties which are reactionary, destructive, and reconstructive, acting on each individual cell in direct ratio to the inherent biochemic response and reactions of living protoplasm, and the effect of an erythema dose extends over a long period of time.

As a means of developing high voltage, the alternating current transformer, with either arms or disk, is still the instrument of general use. While this type of rectification is not ideal, it seems to have stood the test of time fairly well, the greatest drawback being the peak surge phenomenon, which is so disastrous to the life of the tubes. There is, under close investigation, the possibility of making available for Roentgen ray work a direct current generator, which, if successful, will simplify some of our present problems. Deep therapy will, in all probability, develop rather slowly and this is a point in its favor.

The problems connected with the purchase, installation, and use of a deep power plant are great enough to prohibit promiscuous broadcasting of such units. No one who is not thoroughly interested in the work will care to incur the expense and responsibility of an adequate installation. While the monetary consideration of a deep therapy plant is of some concern, this sinks into insignificance when we contemplate the dangers associated with a live line of high voltage electrical stress, sufficient to destroy human life by a careless approach to the circuit. We have become so accustomed to play around our eight or ten-inch apparatus with impunity, ordinarily with no more serious results than a bad temporary shock or a small skin blister, that, unless our attention is sharply called to the new dangers, the consequences may be disastrous.

Up to the present, there is probably no pathological condition in existence that some enthusiastic radiologist has not attempted to treat, and while many of these attempts have been futile and the reason for their institution may have bordered on the ridiculous, yet the pertinent fact remains that radiology is daily enlarging its scope of usefulness. There is perhaps nothing in the entire therapeutic armamentarium which can approach, even in a small degree, the range of physiological action and reaction of the energy of radiation, and when we stop to contemplate the enormous scale of wave lengths at our command, of which we have as yet only fragmentary knowledge, our sober duty to this wonderful science becomes apparent. What the end-result of the investigation in our present-day high voltage work will be is not easily foretold. Refinement of technique, accuracy of dosage, greater care in our clinical and laboratory diagnoses, with a standardization of our individual efforts, will surely engender confidence and respect for this strictly medical specialty.

Can we, at this time, come to a conclusion as to the limit of useful voltage for generating short-wave X-rays? The writer believes that, with our present conception of the liberation of the energy of radiation, 300,000 volts would be sufficient for all purposes; in other words, all things being equal and with tubes constituted to functionate under a voltage of 300,000, the energy would be so enormous, both in quantity and quality, that to harness the useful stream in such an output would be difficult and perhaps dangerous. This statement is based purely upon the observation of the action of the daily serviceable voltage not in excess of 220,000. The writer ventures the opinion that a stream of short-wave electrons of more than 250,000 volts would, in many instances, overshoot the mark. If this is true, higher voltages are perhaps unnecessary. On the other hand, if, with a maintained tension of say 250 kilovolts, we were able to use amperage of high degree, so that the quantity of the stream could be substantially increased, it might be possible, substantially, to increase the beneficial effects of short-wave therapy. This procedure would also permit the simultaneous operation of a number of tubes limited only to the available capacity of the space in the laboratory and the demand for this type of work. The writer feels that it would be distinctly inadvisable, however, to attempt a shorter wave force of radiation until it has been thoroughly

demonstrated what the use and limitations of the present available output may be.

1407 South Hope Street.

DISCUSSION

Alanson Weeks, M. D. (350 Post, Street, San Francisco) — I remember ten years ago or more Howard Ruggles making the statement that, if ever a nineteen-inch spark gap could be procured, deep X-ray therapy would become a fact.

It has been my privilege since Rehfisch installed the first deep power plant in this city at St. Luke's Hospital to watch the effects of such deep radiation treatment. The results are improving sufficiently to further the hope of future real usefulness. The actual destruction of the mucous membrane of the bowel when deep radiation is used for abdominal disease and the bad results of too much foreign protein being turned loose by overdosage have gradually lessened.

I trust I am speaking for all surgeons when I tell Soiland that there can be no question that surgery and radiation must work hand in hand, and that we surgeons will be grateful for the day when radiation or any other therapeutic measure shall take our place.

It is a charming thing to see a man so thoroughly wrapped up in his specialty, so modest in his claims for the same. He gives us much hope, but no false hopes.

Howard E. Ruggles, M. D. (135 Stockton Street, San Francisco) — Soiland has conservatively and completely stated the case for deep therapy as we know it at present. Further advances in this work will come with improved apparatus for which we are dependent upon the research laboratories of our universities and electric companies and with increasing experience in the application of our available equipment to a large amount of clinical material which must be carefully studied over a period of years.

The results so far are encouraging and occasionally brilliant.

Dr. Soiland (closing)—The discussion by Weeks and Ruggles is greatly appreciated, and it is a pleasure to know that they coincide with the thoughts expressed in the article.

My main object in presenting this theme before the section has been to make haste slowly in the deep voltage therapy; not to condemn because of damage alleged to have resulted from its use, neither to make extravagant claims for results, which time has not yet permitted us to definitely determine. There can be no question that short-wave X-rays are a distinct advancement in the field of radiation therapy.

A Valuable Manipulation for the Relief of Constipation—The procedure advocated by Herbert B. Whitney, Denver (Journal A. M. A., January 5, 1924), is applicable only to the evacuation of a fecal mass in the lower rectum, close to the anal sphincter, but hard to move because of its size, or density, or both. It consists in a remolding of the mass by external digital pressure. Sitting in the usual posture at stool, the patient, with the second and third fingers of the left hand, carried down from behind, presses with the necessary degree of force on the thin and distended tissues between the coccyx and anus, and through this on the fecal mass directly beneath. The pressure exerted is not for the purpose of expelling the mass, but solely of changing its shape. As soon as this is accomplished, the usual abdominal pressure is quickly effective. The digital pressure must always be considerable, sometimes excessive; but even the latter is said to be both painless and harmless, and the ease and rapidity with which the favorable change of contour is effected, and evacuation follows, is often little short of marvelous.

THE ROLE OF ALKALIES IN TREATMENT *

By ANSTRUTHER DAVIDSON, M. D., Los Angeles

Nature's one object in life is to keep the blood stream pure, and the salts therein are kept in fixed proportions to that end. In the healthy individual the blood and tissues are alkaline, the chief salts Na. K. Cal. P. are all present in fixed quantities, and nature, in disease, draws from the food or tissues whatever is available to keep the tissues alkaline. When the tissues become acid throughout, death, as you know, ensues.

All the secretions, with one exception, are alkaline; all our excretions are acid. The one notable exception is the secretion of HCL by the stomach. It is usually presumed that HCL is secreted for the sole purpose of aiding the digestion of meat products, but that is only part of its functions. This acid is the medium whereby the Na, Cal, and other salts are rendered soluble and capable of absorption by the blood stream. Hyperchlorhydria, so familiar a feature in digestive troubles, is not the result of irritation; it is a compensatory process whereby nature seeks not only to eliminate the excess of acid in the blood, but attempts to dissolve more salts to neutralize that acidity and break the vicious circle already established.

In the formative period of youth hyperacidity is a serious factor. When the food is well balanced, of course, this does not occur. The chief causes of hyperacidity are the excessive use of carbohydrates and sugars. When acidity of tissues destroys the alkaline balance of the blood, sickness is prone to supervene. The administration of alkalies in fevers and catarrhal inflammations was established empirically ages ago. The standard remedies of our predecessors were citrate of potash and liquor ammonia acetatis or some such alkali, and I know of no better now, though I think the tendency of many practitioners is to prescribe sedatives and antipyretics.

There is no more certain method of aborting an acute coryza than by administering bicarbonate of soda in large doses on the first indication of an attack. In the late influenza epidemic, I have every reason to believe, from my observation and experience, that those individuals who daily took enough soda to render the urine alkaline nearly invariably escaped the disease. At one time two of my students who invariably suffered from poison oak tried the experiment of keeping their urine alkaline when on mountain trips, and for the first time were able to return unaffected. Acidity of the tissues seems to make them more vulnerable, the alkalies restore the blood to normal and thereby increases their vital resistance. During the war many soldiers suffered from severe form sof seborrheic eczema that proved quite resistant to ordinary remedies. One medical officer succeeded in curing these cases by the administration of alkalies. Sodium bicarbonate was most commonly used, but in some cases one pound a day of this was given without altering the reaction of the urine. In such instances, one can usually alkalinize the urine with the fixed carbonates. Soda has

* Read before the Los Angeles County Medical Association November 1, 1923.

another value besides alkalinization; it is a solvent of colloids and it thus probably aids in any bacterial invasion by rendering the precipitins more soluble. In the administration of large doses of alkali, some discussion has arisen as to the possibility of such doses causing a condition of alkalosis that might prove serious. That such a condition has been established by intravenous injections in animals is evident, but that such a condition can arise in ordinary administration is doubtful. Even in experimental work it is just possible that the sodium and not the alkali is at fault as sodium in large doses is poisonous.

Copper and manganese are among the rarer of the blood salts, and may be of the nature of catalysts. When ringworm attacks the skin it spreads in increasing circles, and on the parts invaded it seldom returns. It is evident in this case that the fungus exhausts the tissues of some chemical necessary for its growth. That chemical is probably manganese, as we find it has a marked action on the growth of the closely related aspergillus.

Of the other salts of the blood, the most important in quantity at least are the Mg. P. and Cal. compounds. All are important constituents of the bony framework, but have probably many other values. The Mg. and P. have not been as carefully studied as the Cal., so reference to them will be omitted.

Calcium, on account of its influence on coagulation and reparation of tissue, has always been a subject of interest to the profession. Calcium is never found in destructive lesions such as carcinoma. The calcium in the blood of the normal individual exists in both the ionic and combined states. The salt is chiefly derived from milk and vegetables, especially in raw form. Boiling reduces the amount in vegetables to nearly half; whether it does so with milk I have not been able to ascertain; if it does this may, in a measure, explain some of the diverse results obtained in experimental work on rickets. The excess calcium is excreted by the bowels; very little passes with the urine.

In tuberculosis calcium is the chief salt concerned in the healing and circumscribing process. It was long ago noted that workers around lime-kilns were practically immune to tuberculosis. Nearly everyone is presumed to have acquired tuberculosis at the age of puberty. At that time, when the demands of puberty are straining nature to the limit to supply the necessary ingredients for the perfect development of the skeletal structures, if the individual, by excess of carbohydrates in his diet, develops acidity of his tissues, nature, in the effort to counteract this, does one of two things: it either stunts the individual growth or, failing to do so, draws from the tissues calcium enough to keep the blood stream normal. Let me illustrate this by the behavior of grain. When we have a dry season nature matures the grain rapidly; she reduces the length and strength of the stalk and limits the number of the grains, but not their quality, as the interference with the reproductive quality would ultimately destroy the species. Nature, as you know, cares nothing for the individual, but jealously preserves the type. It is the same with man. When transplanted to the slums his children under the adverse conditions will be smaller of frame and mature earlier. If on the other hand development continues or sickness or some other factor interferes, the blood, in its efforts to maintain the alkaline balance, will draw from the tissues, bones, and teeth the necessary salts available. When this is done the calcium necessary to defend the body from tuberculosis is withdrawn and active tuberculosis may result. If in the growing period the individual is liberally supplied with meat, hyperacidity is less likely to develop. The carbohydrates have not the combining power for acids that proteins have. When fixed alkalies are not available to correct the acidity, ammonia is drawn from the amino-acids to supply the want; the mucous membrane of the stomach and bowels contain large amounts of ammonia. In a rather long experience in medical practice I have never seen a case of tuberculosis in a butcher's boy.

In a leading article in the Journal of the A. M. A. last year, the writer says: "Bread and meat, the most popular ingredients of the American dietary, are decidedly poor in calcium. Indeed it would be virtually impossible to consume enough of those articles of food to supply the estimated quota of lime without making intolerable demands on the metabolic capacity of the body." I wonder if the writer ever considered where the Esquimaux gets his calcium. Some of them, at least, never see a vegetable; cereals are unknown; they live entirely on meat, which is very poor in calcium. The mature individuals among them may acquire some calcium from the small bones and the fresh blood, but that would scarcely apply to the toddling child, and yet rickets and imperfect teeth are practically unknown. As the Esquimaux apparently acquires all the necessary calcium from a purely meat diet, it is obvious that he must utilize all the calcium available and, having acquired it, he does not develop hyperacidity and lose it again by reabsorption to maintain the alkaline balance in the blood. He eats his food raw, or nearly so; eats everything, acquires considerable calcium from the blood and ammonia from the entrails. He consumes enormous amounts of fats, which have a marked influence on the absorption of calcium, yet the amount he acquires seems so far below what we consider adequate that it is fair to assume that he is not subject to the hyperacidity our diet so often entails or he would show more evidence of it in his bony structures. It may be, on the other hand, that our theories as regards the amount of calcium are all wrong or that, in special circumstances, other salts contribute to its functions.

The teeth of all savages, who, fortunately, are unable to acquire cooking ranges, are usually perfect. With us only the generously meat-fed youth have perfect dentition. A vast amount of ink has been spilled over the causes of tooth decay. Specific bacteria have been identified with the destruction of the enamel as the primary cause. When those pathologists explain to me how it is that the African and Brazilian savage can file or chip his teeth to triangular points, sacrificing all the enamel on the sides and yet retain these teeth to old age (they themselves assert it preserves them), then we may consider the bacterial problem. The condition of the

teeth is wholly dependent on the alkali balance of the blood stream. Among civilized nations the pregnant woman is not always able to supply the necessary calcium for the foetus from the ordinary food supplied, so the saying "every child costs a tooth" has become proverbial. The fault in this instance may be in the endocrine insufficiency. Hyperthyroidism is always associated with increased calcium excretion, and it is possible that in cases of pregnancy, associated as they frequently are, with enlarged thyroid that the function of the parathyroids which conserves the calcium is suppressed.

The increase of respiration in febrile diseases is nature's attempt to diminish the acidity in the cells by increasing the carbonic acid output, encouraging the proteolysis in the cells and setting free ammonia. The capacity of calcium to increase the coagulability of the blood has led to its use in urticaria and other diseases of the skin associated with edema. Bile salts are necessary for the absorption of calcium, and the absence of these is the cause of the tendency to hemorrhage in jaundice. Fats have some special value in the absorption of calcium apart from their relation to the fat soluble vitamins, and I believe our predecessors, in combining the hypophosphates of Cal. and Na. with cod liver oil in the treatment of tuberculosis, were utilizing a remedy that is too much neglected now.

Calcium is usually abundant in our dietary, but in some circumstances the cells are unable to utilize it. It remained for Grove and Vines to find the reason thereof. The calcium of the blood is present in a combined or ionized form, the latter normally 10.5 per cent. They found that in many ulcerative conditions of the limbs the calcium was in excess in the combined form. The administration of calcium by hypo slightly improved conditions, the oral use of it not at all, but by the use of parathyroid the calcium balance was restored to normal, and healing rapidly ensued. Their reasons for this may be thus summarized. The parathyroids have, with their other functions, a specific action on calcium metabolism, and calcium is necessary to sustain the resistance of the cells against bacterial and other toxic agencies. As in all chronic diseases, there are toxic substances being absorbed that ultimately break down the cell resistance, and of the defensive, salts calcium is the most important. In varicose ulcers, in examination of the blood, there was invariably found a deficiency of ionic calcium. In these cases when parathyroid was administered and the normal balance was established, the ulcers rapidly healed. In one leg ulcer under my own care, I had for two years vainly attempted to heal it by the current remedies, but it healed in four weeks under parathyroid, with vaseline alone as a local application. Those authors have extended this method of treatment to all ulcers—stomach, duodenal, etc., to suppurative and non-suppurative, and to all diseases in which a deficiency of ionic calcium was found. Among the cases detailed by them were twelve of stomach and duodenal ulcers in all of which clinical cures resulted. It would seem that they have at least established a method of procedure that promises fruitful results.

I do not wish to imply by these remarks that the salts I have spoken of are all the important ones, nor do we know if they are the most important in the conservation of the vital forces. I have said nothing about acetonuria in diabetes or acute acidosis in children, as that is outside the range of this paper. It must not be assumed from these remarks that all diseases are the result of acidity of the tissues, but that the presence of acidity lowers the defensive qualities of the body and renders it more liable to bacterial and other invasions.

Many of our remedies fail to relieve because the condition of the blood stream is abnormal, and the aim of this paper is to induce you, when your remedies fail, to examine the blood for any deficiency in the salts and restore the chemical balance in the cells on the physico-chemical action of which all health depends.

419 South Alvarado Street.

Diet in Pellagra — In summarizing this subject, Joseph Goldberger and W. F. Tanner (Public Health Reports) say:

1. Eight well-marked though not very severe (mainly dermal) cases of pellagra were treated with fresh beef, as the only known therapeutic element in the diet.
2. In all eight cases clinical improvement followed the inauguration of the beef treatment.
3. In four of these cases the treatment with beef followed an unsuccessful period of treatment with gelatin, the contrast in results tending to emphasize, on the one hand, the inadequacy of gelatin, and, on the other, the therapeutic potency of fresh beef.
4. The preventive value of milk was tested by daily supplementing the basic diet of a group of twenty-nine inmates of the Georgia State Sanitarium with approximately 40 fluid ounces (1200 grams) of buttermilk.
5. None of these patients developed any evidence of pellagra at any time during the period of observation, which for twenty-five of the group, lasted one year, although it is believed that without the buttermilk or equivalent supplement upward of 40 or 50 per cent of the group would have developed pellagra within a period of three to eight months.
6. Fresh meat and milk contain the essential pellagra-preventive factor or factors.
7. It is estimated that about 4 to 4½ ounces (125 grams) of fresh beef (lean round steak) and not over about 40 fluid ounces (1200 grams) of buttermilk will suffice to prevent pellagra in all but very exceptional instances.
8. Fresh butter (from cows largely pasture-fed) ingested daily in quantities averaging approximately 125 to 135 grams (butter fat 100 to 110 grams) failed to prevent pellagra in several instances in which it was tried.
9. Cod-liver oil ingested daily in quantities averaging upward of 2 grams per kilo of body weight failed to prevent pellagra in several instances in which it was tried.
10. The primary etiological dietary factor in pellagra is a faulty protein (amino acid) mixture, a deficiency in some as yet unrecognized dietary complex (possibly a vitamine), or some combination of these.

Protection of the Public From Incompetent Doctors — One of the most encouraging signs of the present time is that the public conscience is becoming aroused to the fact that, no matter under what label the doctor may be listed, the essential prerequisite is that he is competent and has the proper scientific training in the knowledge of disease and the care of the sick. In fact, that is the only way in which the public is particularly concerned in the matter.—Federation Bulletin.

MENTAL DISORDERS CONSIDERED AS MALADJUSTMENT OR BROKEN ADAPTATION TO THE ENVIRONMENT *

By GLENN E. MYERS, M. D., Los Angeles

In 1913, Hoch and Amsden published a "Guide to the Descriptive Study of the Personality," which has been very useful and instructive but too lengthy and diffuse to employ as a routine procedure. At the Quebec meeting of the American Psychiatric Association, Amsden offered a revision of this first plan of attack, with the idea of focusing the information into more narrow channels. In the paper Amsden defined personality as *the aggregate of those tendencies predisposing to reactions which the individual has come habitually to display in the adjustments his life has required of him.* Amsden has said further: "These preferred reactions, or personal traits, may be those whose nucleus is of an instinctive nature; they may relate to behavior in which complex emotions are especially in the foreground; they may relate to the ease or difficulty of conscious response to new situations. A statement or summary of a personality would, therefore, attempt to indicate the reactional assets and liabilities of the individual in such wise that an insight is gained into the probable general course of action he would, under given circumstances, follow."

I quote Amsden to call attention to his instructive paper, and because my following remarks are allied to the general trend that he has expressed. I shall not try to present anything startlingly new and my remarks are, perhaps, directed more to other medical men than to the psychiatrist. Yet I have the feeling that, although so much has been written about mental mechanisms, there is still a too considerable tendency to be satisfied with the making of a diagnosis, and a still too considerable attempt to force objective symptoms into the form which one usually conceives under the name of one or another diagnosis, oftentimes like putting a square peg into a round hole, without much attempt to really understand the mechanism of the disorder. The fundamental principles of mental mechanisms, as we conceive them with our present knowledge, are simple and readily understood. I believe, then, that a repeated presentation of a review of these mechanisms is indicated.

In order to understand a mental upset, one must understand the patient's previous mental make-up, the difficulties that have confronted him and the manner in which he has failed to adapt himself to them. First, let us consider the development of the mental make-up or personality, taking up in order the influence of heredity and then of environment.

We come into the world as a product of our ancestry. We resemble our parents in physical appearance, show physical characteristics of our stock further back, and show certain unmistakable physical characteristics of our race. That fact is well known and need not be elaborated. It is also fairly conclusively demonstrated that we inherit mental attributes from parents, forebears and race, very much as we inherit physical traits. We tend to show most markedly those mental traits which have been handed down through generations and have been characteristic of our stock. That we actually *inherit* these traits and do not acquire them solely from our environment, is shown in the instances in which a child or adult manifests certain unmistakable mental characteristics of a parent or grandparent, after having been completely dissociated from his family since birth. The persistence of racial traits is well shown in the Jew, who has been relatively uninfluenced by various changing environments through centuries. It is generally granted that we inherit certain instincts, such as those having to do with self-preservation, gregariousness, sex, fear, play, imitation, curiosity, motion, flight, repulsion, pugnacity, acquisition, constructiveness, etc. As primitive peoples are governed more by instinct than are civilized peoples, a notable instance of the exhibition of primitive traits is that of the negro, who was transported to a civilization perhaps a thousand years more advanced than his own, and to which, in a comparatively short time, he has made a superficial adaptation, but who, in his psychoses, shows primitive, animal-like behavior which one never sees in the mental disorders of the white man.

Our stock is, then, of great importance and some of us have cause to regret that we cannot choose our parents. For upon the mental and physical attributes of our parents and forebears depends our coming into the world with healthy or diseased body and mind. I cannot conceive, however, the inheritance of an actual psychosis, although it cannot be gainsaid that inherited organic defects or bad mental traits predispose to the development of insanity. This distinction is not always drawn. Fortunately, just as proper hygiene and medical treatment may do much for the benefit of an inherited physical defect, so an inherited tendency to insanity need not result disastrously, providing it is not too marked and providing the proper environmental influences are brought to bear. The unfortunate exception to this is the fact that the capacity for intelligence with which we come into the world is fixed in its limits and cannot be enlarged upon through environment. The child who is born mentally defective, no matter what his opportunities, can never reach the intellectual expansion of the normal adult. He can acquire only the knowledge possible to a child. The extent of the knowledge that he acquires is influenced by his environment, it is true, but his ability to assimilate that knowledge has definite limitations from birth. The limits of such capacity for intelligence depend directly upon the limits of such capacity in the parents, influenced, of course, by alcohol or syphilis or other disease or trauma of parent or child. The importance of the traits that we inherit as regards our future personality is the fact that they are in large extent primitive and instinctive, and tend to be unorganized and turbulent, and many of them must be repressed for the good of the individual, and after having been repressed they tend to reassert themselves to the disorganization of the personality. If the environment is good, they are moulded to

* Presented to the Section on Neuropsychiatry at the Fifty-second Annual Session of the California Medical Association, San Francisco, June, 1923.

subservience of good trends; if bad they are liable to be added to or enlarged upon, interfering with the full development of the personality.

It seems to me that an entirely too pessimistic attitude is entertained by some psychiatrists and rather generally by other medical men, in regard to the influence of heredity upon the production of abnormal mental conditions, and that too little consideration is given the influence of environment upon the individual. Because a patient manifests abnormal mental traits, which were also present in a parent or other relative, it is not conclusively indicated without further study, that they were inherited. The patient may show such traits, not present in a member of his family, but exhibited by someone not a blood relation. They who so conclude fail to realize that certain traits of the personality which they had attributed to heredity were really not acquired before birth, but were assimilated from the environment during infancy and childhood. Certainly, a mental instability may be inherited from mentally unstable parents, and a tendency to insanity from insane parents. Yet such an inherited tendency need not lead to insanity any more than the child of tubercular parents need develop tuberculosis, providing the tendency is not too marked and the child grows up in the proper environment.

As the mental make-up, or personality, is the sum of expression of our mind, let us next consider what the mind is and how it develops. In order to form a memory something must be observed, attention must be given it and it must be associated with other memories. The enormous accumulation of associated memories constitutes the mind. If these memories can be recalled, they are a part of the conscious mind; if they cannot be recalled, they are a part of the unconscious mind. The majority of our experiences are forgotten; in other words, memories of them become unconscious, and so our unconscious mind determines largely our attitude toward our environment. I have already stated that the child inherits certain mental characteristics. He may also have received certain mental impressions of his life within the uterus. Certainly, he begins to get impressions of his environment from the time of birth. While his reactions are at first preponderatingly reflex in character, in other words, they are not consciously directed, the impressions from his environment accumulate fast, and he soon begins to manifest a type of personality that becomes more and more characteristic of him as an individual. The sensations of light, warmth, hunger, the satisfaction of hunger, are experiences, and the child soon learns to react to them with crying, or smiling, or sleeping. Displeasure and anger may be early shown. As impressions and memories of impressions accumulate, the reactions become correspondingly more complex. Indeed the new impressions of a child are many times more numerous during the period when all the world is new than is true in any period of time of corresponding length in the adult, whose new experiences are relatively limited. Consider how observant a child is, how soon after birth it is attracted to objects or occurrences, how impressionable it is. That is the proper time for laying a stable foundation for a good mental make-up. This is especially important if there has been mental instability in the parents. The child of tubercular parents should be removed to an environment where he will not be exposed to infection, but where that disease may be avoided through healthful out-of-doors living. It is equally important that the child of mentally unstable parents shall not be permitted to assimilate the bad mental traits of his parents or of others in his environment through association. He should, on the contrary, be intimately associated with persons whose mental traits are normal and, accordingly, exemplary.

Much has been written about the proper environment for a child. Briefly, in addition to remarks already made, I believe that the child should be let alone for the most part during that period when its activities are mostly reflex in character. It should not be mauled about, and taken up and put down again, but should be permitted to learn the rudiments of regularity and routine through regular feeding, regular hours of sleep, and gradually regular attention to its other habits. Later, care should be taken in its sexual education. It will learn from others, if not instructed about sex by its parents, and it is important that this instruction shall come from the parents, who should take care never to practice deception, but should tell enough to satisfy and to insure a return to the same source for further information. Possibly, next to the inheritance of a normal capacity for intelligence, the development of a normal attitude toward sex is of greatest importance for the mental welfare of the individual. There is especial danger in the development of a too strong attachment to a parent. Through such an attachment many a man does not marry because he cannot find a woman sufficiently like his mother, and many a woman cannot break away from her father to go and live with another man as his wife. Much matrimonial inharmony, overindulgence in alcohol, paranoid trends, etc., may be traced to a poorly balanced attitude toward sex. The child should not associate exclusively with adults or with children who are much younger than he, but should have opportunity to play, especially with children of his own age, but also with older and younger children. In that way he can best learn to give and take, to lead and to follow, to have the proper admixture of success and failure which will render him best fitted to meet the world. Repeated failure engenders a feeling of inferiority to situations, and handicaps the individual for getting on in the world. Unbridled success engenders an hypertrophied ego. The only child or the sickly child is often subject to too much sympathy and attention, with the result that he grows up without initiative and forcefulness and is a failure, even though he recover his physical health. If the parent is too severe, the child is liable to become sullen and resentful and to hate the parent, and later to hate the parent substitute in the person of the school master or employer. The development of the personality should be closely followed in order to learn what trend the child's best abilities take and to educate him along that line. The scope of this paper does not permit further details.

It is thus seen that the first few years of life are of the utmost importance in the development of a type of mental make-up through which the individual will later be able to adapt himself well to the world. Mental disorders may be potentially instituted in childhood through faulty modeling of the mental make-up by bad environment, and the bad environment may consist in the association with someone who is mentally unstable or insane, or through an improper attitude toward the child by quite normal persons. And, vice versa, defects in the mental make-up, originating in childhood, are to be looked for in the investigation of mental disorders rather than to expect to find that they have been transmitted directly from parent to child. The individual grows up with a mental make-up which fits him or unfits him for overcoming difficulties or adjusting himself to difficulties that arise during the course of his life. Few, if any of us, may be said to be perfectly well balanced and perfectly normal mentally. The majority of us have difficulty to adjust ourselves to various situations that arise, and in reaction to such situations we show anger, or irritability, or depression, or worry, or any one of various trends of thought or conduct which may be present in others as important symptoms of psychoneuroses or psychoses. Some of us are able to meet ordinary conditions of life, but, owing to an inherent instability of make-up, break down when confronted with especially trying conditions. Others are so unstable that they break down when they encounter the least difficulty. No one of us knows exactly his limitations. The sufficiently normal person will be able to meet all conditions of life without developing a mental disorder; he will find some adaptation to every situation that arises.

Further, in order to understand mental disorders, one must have a conception of the mechanism of regression. All of us must exert a certain amount of energy in pushing our way in the world; we seldom run long on our own momentum without some propelling force. Otherwise we tend to slide back. If we meet obstacles and our mental make-up is good enough, we make every effort to overcome them and persist to success. If our mental make-up is less good and we slide back, after a time we recover our energy and make another effort and succeed. If our mental make-up is still less good, after sliding back we tend to make less and less effectual efforts, and after a time cease to make efforts at all, and slide to lower and still lower levels from which, notwithstanding help from others, we are unable to progress. That sliding back is regression. Regressive forces are constantly operative within us, tending to draw us back from active combat with the world toward a state similar to that of our infancy, when everything was provided for us without effort on our part. The man who, during an illness, shows a childish dependency upon his wife or mother shows a regression. The mental chronic invalid, who makes such demands upon the patience and attention of her relatives, shows a regression into that state of dependency. The patient who has slumped into the deterioration of dementia praecox, through repeated failure of adaptation to sexuality in its broadest sense, shows a regression. Usually, one finds some attempt at compensation; one sees that the patient seeks a ballast. A sudden, unusual interest in religion is, in most cases, indicative of threatening difficulty of adaptation and the effort to find a ballast. The crippled or sickly child may ballast his feeling of inferiority with fancies and tales of his ability and prowess. A regression is then another manner of adaptation to difficult situations, but it is an adaptation through running away and not through fighting. We all, from time to time, wish that life were easier, but if we spend all our time day-dreaming about happier conditions instead of making the effort to bring them into reality, we slide back into a pathological state. We go to the theater and enjoy the play, identifying ourselves with one of the characters. We identify ourselves with a character in a book that we read. In either case, we lose ourselves in greater or lesser extent in dreams and wish-fulfillment, but, if normal, we come back to reality, refreshed by our recreation in fancy, ready to again assume active adaptation to the world.

From the foregoing remarks, it should be clear that a mental upset depends upon one's ability, through his personality, to adapt himself to difficulties that arise and upon the nature and extent of the difficulties that he encounters. If the primitive instincts that he has inherited have not been well submerged within his personality, if he has grown up with a distorted attitude toward the world, if he has inner conflicts interfering with the main trends of his personality, if, in other words, his unconscious mind is not well ordered but, on the contrary, is seething and turbulent, with difficulty suppressed and constantly tending to express its potentiality in abnormal conduct, then he is prone to develop a mental disorder. The external situation would need be but mild, to break down the low powers of adaptation of such an individual. This is especially true in the case of some external situation which connects directly with a conflict in the unconscious mind, by following associated memories into the unconscious, like an electric current from one station to another through a maze of unconnected wires. In other words, the more directly the external difficulty is associated with unconscious conflicts within the individual's mind, the less marked the difficulty need be to create disorder, overcome an adjustment to the environment and produce a psychoneurosis or psychosis. The better ordered and more stable the individual's unconscious mind is, the greater the external difficulties that are required to break down his powers of adaptation. Thus, it is clear why some people get along so well in the world, why they do not break down under all sorts of marked difficulties, and why others break down markedly when they encounter relatively simple external situations. It is seen that, in some instances, the external situation is merely the relatively unimportant, exciting factor in the production of the psychosis, the flash of the percussion cap that sets off the explosion. In other instances, the external situation is the important factor in the etiology of the psychosis, being sufficient, through its enormity, to break down the relatively good power of adaptation of the individual.

It is true that human beings are much alike, that certain mental trends run through all beings like a red thread, and that, consequently, abnormal mental reactions tend, through their similarity, to fall into certain groups, but it is to be recognized that, within these groups, there are marked variations from uniformity, and these variations are the expression of individual characteristics of the personality. I believe that the chief difficulty in an understanding of mental disorders has been through the tendency to think of them as disease entities, which they are not. We may observe symptoms, all in one patient, which we generally think of as characteristic of various mental disorders as, for example, constitutional psychopathic inferiority, dementia praecox, manic-depressive psychosis, psychoneuroses. It is a common experience to have difficulty in the differential diagnosis of dementia praecox and manic-depressive psychosis, because symptoms which we consider to be characteristic of each disorder may be present in the one patient. We go about it in a sorry way if we merely try to fit the objective symptoms into one or the other diagnosis, and try in that way to tell if the patient will get well or not, see-sawing from one diagnosis to the other. The surer way is to make a study of the personality, of the manner in which the individual has made or has failed to make his adaptations to the world, and draw our conclusion about the prognosis from our knowledge of his reactions throughout his life, as well as from our observations of his psychosis. In the case of a profound stupor, in which there is no known symptom which aids us in differential diagnosis, our sizing up of the outlook must depend entirely upon our information about the patient's previous personality.

While an understanding of the mental make-up is of most importance in the functional mental disorders, it is also of importance in the organic conditions. Through that means, one can understand the various mental trends and different types of reaction in, for example, general paralysis. In that condition, mental trends, which had previously been held more or less well in restraint in the individual's adaptation to his environment, are liberated through the disorganization of his personality, and the consequent abandonment of efforts at adaptation, brought about by the invasion of his brain by the organic disease. From the standpoint of treatment, an understanding of the previous mental make-up is also of most importance in functional disorders; yet, in organic disease, it is frequently of advantage for the patient's comfort and his care, even if his actual organic condition cannot be relieved, to do what one can for the symptoms that are brought out of his personality by the organic condition.

In conclusion, it is well to remember that the time to treat mental disorders is before they develop as such, when they exist as relatively minor deviations from the normal personality, and when they express themselves through relatively minor defects in adaptation to the environment. Thus the shut-in type of mental make-up should be treated as incipient dementia praecox. With our limited experience, it would appear that, as should be expected, efforts at correction of bad types of mental make-up are singularly successful in warding off a psychosis, even one as severe as dementia praecox.

Marsh-Strong Building.

DISCUSSION

Edward W. Twitchell, M. D. (909 Hyde Street, San Francisco)—While the influence of environment in mental disease must be admitted to be profound, there is great danger of attributing too much to it and undervaluing heredity. If a psychosis is not actually inherited, the "makings" are, and then much depends on the type of disease as to the part environment must play.

Broadly speaking, of course a mental disease is the result of failure of adjustment to environment, particularly when one goes beyond the more obvious reactions between the individual and his physical surroundings, but the actual inability to adjust is usually bound up with heredity.

The schizophrenic has always seemed to me to be relatively independent of environment to this extent, that he develops in a vast number of cases in spite of being surrounded by the best of conditions. In fact it is every-day experience to see these schizophrenics coming out of the least expected places, regarded even from a Freudian standpoint. The manic-depressive, on the other hand, whose psychopathic heredity is so generally demonstrable, in contradistinction to the apparently untainted heredity in so many schizophrenics, can be surrounded with safeguards that will protect him from outbreaks, or not subject him to strains which will precipitate them.

The revolutionary changes in living in the past three generations have made themselves felt in a variety of ways. We are suffering particularly now because the speed of adjustment of the mind to the change has not kept pace with that of the change. Many of the recent changes have not yet shown what their effects are to be. The future psychiatrists will tell us what are the effects of radio on the mind, which may be as definite as those of the X-ray and radium on the body and a new category of diseases may result from the loosening of hitherto imprisoned powers. It is fascinating to speculate on what new ailments will follow the eventual releasing of atomic energy.

H. Douglas Eaton, M. D., (1136 West Sixth Street, Los Angeles)—Careful evaluation of hereditary and environmental factors in any case of nervous or mental disease is essential to a proper diagnosis and to competent therapy of such a case. Some cases of nervous or mental disease are due to poor inheritance alone—others in the writer's experience, a much smaller number, are due to environmental conditions alone, but by far the largest number result from the interaction of both factors. As a rule, the individual who develops a psychoneurosis or psychosis starts with a diminished resistance which is still further lowered by adverse environmental conditions.

The relative value of each factor in the genesis of the final disorder is still a matter of theory rather than fact. The birthright of lowered resistance to mental or nervous trauma is not necessarily an unchangeable condition any more than is a similar lowered resistance to tuberculosis. Proper individual care of a large series of cases of good and bad inheritance starting at birth and continuing during the formative period would be the only adequate way to determine the relative value of poor inheritance and environmental trauma. This has never been done to the writer's knowledge. It is his belief that such early and long continued skilled individual care would cure many cases now classed as defective from birth. On the other hand, it would leave many cases of true organic weakness or instability.

Too much emphasis cannot be laid upon a comprehensive study of the individual case of nervous and mental disease. Therapy founded upon such

work will be valuable always and successful in an astonishing number of cases.

Dr. Myers (closing)—In closing, I should like to say that I have not desired to belittle the importance of heredity, but to combat the rather general tendency to believe that bad mental traits, psychoneuroses and psychoses are solely hereditary in origin. I believe that both heredity and environment play their part in the formation of personality or mental make-up, good or bad, and consequently that both have to do with the development of mental disorders. It seems to me that our knowledge of mental mechanisms must be markedly retarded, if we do not make an exhaustive study of the environment of our patients and, by environment, I refer not only to physical surroundings, but more particularly to the mental influence upon the individual of those persons with whom he has been brought intimately in contact. With the exception of intelligence defect with psychosis, I believe that environmental etiological factors in the development of an abnormal mental state can always be found, no matter how harmless the environment may superficially appear to have been. Furthermore, is it not true that the mental traits that we inherit were formed through the influence of environment upon our ancestors? It is well known that we acquire new physical characteristics through change of environment and that we transmit these charcteristics to our progeny; further, that these new physical characteristics are strengthened as long as our descendants continue to remain in the new environment. Does not this truth hold in the same way in the development of the mind?

It is through our mental make-up that we adapt ourselves to the world and mental disorders, therefore, may be looked upon as maladjustment or broken adaptation to the environment. Inversely, in the study of mental disorders, we should investigate the influence of both heredity and environment upon each individual patient, with the expectation that, through such study, our knowledge of etiological factors, of mental mechanisms both normal and abnormal, and our efficiency in treatment will all be increased. The study is fascinating.

The Workings of the Sheppard-Towner Law—Release publicity from the United States Civil Service Commission reads: "Specialist in maternal and infant hygiene, $3500 a year; assistant in maternal and infant hygiene, $2000 to $3000 a year; expert in maternal and infant care, $3000 a year. Receipt of applications will close February 26. The examinations are to fill vacancies in the Children's Bureau, Department of Labor, at the entrance salaries named above, and vacancies in positions requiring similar qualifications. Appointees at an annual salary of $2500 a year or less, may be allowed the increase of $20 a month granted by Congress. Appointees will also be allowed actual traveling expenses and $4 a day for subsistence when away from headquarters on official business. The duties of specialist in maternal and infant hygiene are to plan, conduct, or assist in investigations into the causes of infant and maternal mortality and morbidity in selected communities, rural and urban, with special reference to maternal and infant care at the time of confinement, and to make reports of such investigations; to inquire into the methods of prevention of infant and maternal mortality, and to conduct conferences with directors of bureaus of child hygiene, supervisors, and teachers of midwives. The duties of the assistant in maternal and infant hygiene are similar to those of the specialist, but in a subordinate capacity. The duties of the expert in maternal and infant care are to teach public health nurses the newer methods of maternal and infant care and related duties." Surely, comment upon this would be superfluous. President Coolidge has assured us that activities of the Federal Government will not expand this line of development while he is President.

RATES FOR STATE MEETING

SOUTHERN PACIFIC

Leaving Friday, Saturday, Sunday — Sixteen-day ticket (round trip), $19.

Leaving Monday—Thirty-day ticket (round trip), $22.50.

Lower berth, $4.50; upper berth, $3.60; drawing-room, $16.50—two tickets; compartment, $12.75—two tickets.

THIRD AND TOWNSEND STREETS

HOTEL RATES

Los Angeles Biltmore
Fifth and Olive Streets, Los Angeles

Single Rooms
$5 to $10 per day.

Double Room With Double Bed
$7, $8, $9, and $10 per day.

Double Room With Twin Beds
$10 and $12 per day.

Two Connecting Rooms
Three persons—one equipped with twin beds and one single, $14 to $22 per day.
Four persons—two double connecting rooms, $18 to $24 per day.
Each and every room has its own bath.

The Economic and Military Importance of Health—Public health activities show a strange line of demarkation in their relative solicitude for the sick and for the well. Unless a patient's malady endangers the health of others, his relief is viewed solely as a matter of charity, and the fact that his health, quite as much as the health of anyone else, is of economic and military importance is ignored. The distinction has, however, no sound basis in theory or practice. The health of the sick is possibly of even the greater importance; for one who is no longer an effective member of the community is a liability; he does not produce even the cost of his maintenance, is unable to defend himself, and requires the support and protection of others, who are thus kept from the fields of productive activity. It cannot be too strongly insisted that the more promptly and effectively the sick and injured are made well, the richer, the more powerful and the more contented and happy is the community.—Regulation of the Healing Arts, in Principle and Practice, by William C. Woodward.

EDITORIALS

FIFTY-THIRD SESSION OF THE CALIFORNIA MEDICAL ASSOCIATION

Don't forget to make plans to attend the Fifty-third Session of the California Medical Association, to be held at the Biltmore Hotel, Los Angeles, Monday, May 12, to Thursday, May 15.

The Los Angeles committee of arrangements consists of William H. Kiger as chairman, and the following colleagues, each of whom is chairman of the sub-committee indicated after the name:

George H. Kress (entertainment); Donald J. Frick (golf); W. T. McArthur, Harlan Shoemaker.

It is planned to have a dinner-dance and grand ball and president's reception on the evening of Tuesday, May 13. This will be in the large and beautiful ballroom of the Hotel Biltmore. Members of the Association will be able in this manner to have their own table and dancing groups, and at the proper time the Grand March will be formed and the reception to the president of the C. M. A. will take place.

On Wednesday afternoon it is proposed to have an auto trip to the beaches, with a stopover at one of the beach country clubs. The program for this will be in charge of Kress.

A golf tournament will be staged for each morning of the session, and this will be under the supervision of Donald Frick. There are thirty-two golf courses within a short distance of Los Angeles, so there will be plenty of room for everybody. It is planned to have a cup for the winner of each day's tournament, which the winner will be able to keep as a souvenir; and in addition there will be a large and handsome president's cup, which will only go to that member of the Society who will be able to hold the same as winner of the golf tournaments for three different years.

Other plans in the matter of informal smokers, medical fraternity meetings, and so on, are also under way. The meeting gives every promise of being replete not only with a most satisfactory scientific program, which is now complete and published on pages 168-180 of this issue of CALIFORNIA AND WESTERN MEDICINE, but with a large number of entertainment features that should appeal to out-of-town as well as to local members of the Association.

Remember what Roosevelt said about what a man owes to his craft, and attend this annual session. You will receive much of interest and importance. What is much more worthwhile, you will have opportunities to give of your own ideas, experiences, and knowledge.

Information regarding hotel rates, transportation rates, and time-tables is published on page 157 of this issue.

THE PROBLEM OF GIVING

Andrew Carnegie is credited with once having made the statement that intelligent giving was a far greater problem than the accumulation of wealth. Experiences both before and since Carnegie's time have demonstrated the wisdom of his remark. The subject has its greatest importance in the health field, because of the human appeal in promoting better health service.

It is our present purpose to call attention to a phase of the giving problem now acute in a California community, which apparently has no parallel in the history of private munificence. Essentially, the situation is this:

Colonel Simeon J. Murphy, a prominent and wealthy California citizen desired to present a memorial to his father's memory to the citizens of Whittier, a small city in Southern California. After consulting his physician and other advisors, he decided to build and equip a fine hospital, costing about $325,000. A splendid idea which one would think would have the endorsement, support, and cooperation of all citizens in its execution. Not so, however; difficulty after difficulty has been thrown in the way of the execution of the plan, until it is reported that the benefactor is quite disgusted and is awaiting an opportunity to revert to his estate the several hundred thousand dollars already spent.

In the first place, California not only is without laws that lend themselves to encouraging private philanthropy, but the laws are in some instances inimical to the development of the practice of private giving. Finally, after prolonged discussion, the legal technicalities were made as harmless as possible, and the project was undertaken. The deed of gift was made to the citizens of the city through the city council as their representative contingent upon certain conditions being continued in perpetuity. The most important of these conditions was that the city council should appoint a board of trustees who were to have the usual complete control of the trust. One condition required that the hospital site, located in the city park, should be furnished by the city. Another condition was *"that said hospital should be so conducted and managed that it will at all times rank as a Class A institution."* There were several other conditions in the trust which need not be discussed here, except the very important one, that, in case the conditions of the trust were violated, the property and other assets were to revert to the private estate of the donor.

The city councilors appointed the board of trustees, and a number of conferences between the donor, the trustees, and the city councilors were held. It is to the credit of all these interested persons that they settled the numerous questions and problems with the right spirit, and at no time has there been any serious trouble among those charged with the execution of the provisions of the trust. A splendid fifty-bed hospital was built, equipped and personneled, and was so successful that it soon be-

came too small and a new forty-bed annex has just been added by the munificence of the original benefactor.

After the hospital was in successful operation, the osteopaths and chiropractors claimed the unwarranted privilege of treating their patients in the hospital. Their request was refused by the trustees, and the refusal was sustained by the city councilors and by the donor himself in writing. This experience suggested the advisability of accurately defining the phrase "Class A hospital." This was done in a hospital by-law, which, with all other by-laws, had the endorsement of the staff, consisting of the educated doctors of medicine of the community; approved by the trustees, the city council, and by the benefactor himself. When the new annex was built, the whole question of the purposes of the giver and the conditions necessary to maintain the complete hospital as a worthy agency of scientific medicine with its staff and medical privileges limited to educated physicians was restated and re-endorsed by the philanthropist, the officials of the municipality, and the trustees.

ENTER POLITICS

While this philanthropic citizen is still living, and in spite of his own signed wishes on the point which have been agreed to by the city officials and the trustees, and in defiance of his public protests, certain groups of people, whose motives surely need no comment, have secured the necessary signatures and have placed on the ballot, to be voted upon April the 12th, a local initiative directing that the hospital be opened to all "doctors," regardless of educational qualifications, who hold any sort of a license from any of the several so-called boards who license persons to treat the sick in California. This local initiative also carries a severe penalty clause.

If the hospital is to live up to the meaning of "Class A," as used in the trust and as defined in a by-law having the endorsement of the trustees and Colonel Murphy, it should be on the list of hospitals "accredited" by the American Medical Association. This official accrediting agency has several important rules of good hospital conduct. The most important one, so far as The Murphy Memorial Hospital is concerned, is that only those holding the degree of doctor of medicine from acceptable bona fide institutions of learning may practice in the hospital. This educational requirement is above the fluctuation of political standards, and it is quite broad enough to include all those really adequately educated to treat the sick. The methods they apply may be any that have reasonable basis in scientific fact and experience. The term "legally licensed" to treat the sick in a state with adequate laws effectively enforced ought to be sufficient; but the laws of California and several other states are so inadequate and so poorly enforced that the legal standing of a "doctor" is not and cannot be used as a basis of rating his educational qualification and, therefore, of his privilege of practicing in a hospital "accredited" as a legitimate agency of scientific medicine. The people of Whittier should be assured that, if they were to succeed in passing their local initiative and it should be sustained in law, the hospital will thereby forfeit its present opportunity to be officially "accredited," and thus would pass below a "Class A" institution as defined in its approved by-laws. How much this will mean to the community, we will discuss at another time. It may be said in passing that no community is sufficient unto itself.

A SAD SITUATION

The proceedings in this situation no doubt will have far-reaching consequences upon private philanthropy in health fields. If this, or some other similar initiative should pass, an amazing amount of bitter controversy and litigation immediately becomes possible, by which the community will be divided and the sick will suffer.

That the initiative violates the conditions of the trust there can, of course, be no question. If so, the property reverts to the estate by a definite provision of the same trust.

If the city councilors who acted in good faith had the power to accept this splendid trust, can this initiative make null and void or modify the terms and conditions of a large financial transaction already long since closed? It appears that the action of the city council was either valid or invalid. If valid, no arbitrary political upheaval can abrogate the action; if invalid, then the trust has no legal existence, and if repudiated, as now proposed, the trust reverts to the original donor. The election will, therefore, merely determine how many people there are in this particular community who believe in regarding a trust as a "scrap of paper."

Is this initiative itself legal? Will it be sustained by the courts? It is so loosely drawn that it is susceptible of many interpretations.

There is no objection to any group of so-called "doctors" building hospitals or inducing philanthropists to build for them. They may follow out their peculiar theories in their own hospitals, so long as they comply with the law. That is precisely the demands of educated doctors of medicine for themselves, and the hospitals and other agencies of medicine they utilize. It is the stand of the official accrediting body of their own national organization and, in the case in point, is the wish of the benefactor. The two groups, the educated physicians on the one hand, and the inadequately educated group on the other, cannot be scrambled. Neither can the agencies through which they operate be mixed any more than can oil and water. The greatest weakness of all the non-medical groups is that they are constantly fighting to be attached to and become part of the work of educated physicians. One would think that if they really believe in their methods they would want to stand out for themselves and not be "barnacles on medicine," as they have been termed.

There are less than 100 beds in less than five hospitals in the state operated by or for the inadequately educated medical cultist groups, while there are over 40,000 beds in over 500 hospitals in the state operating as agencies of scientific medicine. This shows conclusively that the patients of cultists do not need hospital accommodations, or that they have been derelict in meeting the hospital need for the care of the sick.

DUTIES OF COUNCILORS OF THE C. M. A.

In publishing the proceedings of the last meeting of the Council of the California Medical Association in Los Angeles, one resolution was deliberately held out for editorial mention. That resolution reads as follows:

> "Resolved, That it be understood to be a duty of the Councilor for each councilor district to visit at least one meeting a year of each constituent society within his district; and that he, in the discharge of this duty, should arrange with the secretary of the society to be visited for the program for that particular meeting; and that each councilor report on the execution of this part of the program at the State meeting."

If we are to progress in medical organization work, the letter and the spirit of this resolution must be faithfully carried out. It is difficult to do: The councilors of our association are, like the other members, very busy practicing physicians; they already give much of their time to the serious consideration of the complicated and difficult problems of medicine that come before them in ever-increasing numbers at each meeting. These meetings are held in different parts of the state and involve not only loss of time to these executive officers, but a not inconsiderable outlay of their own funds. To ask them to comply with the resolution is to add to the responsibilities, duties and expenses of their office. Yet this work must be done, if we are to go ahead, and only men like councilors, who are familiar with the problems of the organization, are really prepared to meet the local situations in their various communities.

It is to the credit of our councilors that they, almost without exception, attend their meetings with regularity, and devote whole days and oftentimes a good portion of the nights to consideration of problems in which we all should be interested.

TAKING THE "CLINIC" TO THE PATIENT

An interesting movement in providing skilled care for patients is gaining headway in sporadic centers in California. Essentially, it consists in taking the specialist to the patient rather than the other way round, which is the customary procedure.

By way of illustration, which we could repeat many times, a small community has, let us, say, several crippled children, some of them poor and others of well-to-do families. The nearest specialist in orthopedic surgery may be twenty-five or three hundred miles away. Instead of going to the tremendous expense of transportation for patients and attendants, hotel expenses for attendants, and hospital expenses for the patients, with all sorts of additional expenses of transients in the city, the local physicians and authorities get their patients together in their home town and arrange for the specialist to come to them. With the preliminaries cared for by local initiative, the specialist may readily render a phenomenal amount of service in a very limited time. The after care of the patients is carried on by the family physician, either in the local hospital, or in the home. If wisely developed, this movement gives promise of going far in rendering better service at less cost to many people.

Members of the Hospital Betterment Service have watched the growth of this movement, particularly in Southern California, with growing interest and appreciation of its possibilities in many ways. There are also dangers that threaten. So far, it is not a concerted movement promoted by anyone. It should be taken hold of by physicians' organizations, guided and developed along constructive lines. It offers possibilities in every medical specialty. Possibilities of better medicine for everyone at greatly diminished costs to the public, with adequate compensation for the specialist and the family physician.

THE COOLING EFFECT OF MENTHOL

The cause of the local cooling effect on mucosae exerted by menthol appears to be more than a case of volatilization produced by any volatile agent whatsoever. That is, there appears to be a direct stimulation of cold nerves, indicating a peculiar specificity or predilection of this agent for these structures. This is indicated by the recent work of Heubner of the Pharmacological Institute at Göttingen, who studied the question in human subjects.

By passing air at different temperatures through a tube containing menthol, Heubner found that there was produced invariably a cooling sensation in the mouth and nose and on the tongue, gums, lips, and conjunctiva. The skin gave variable responses. This was due to stimulation of the cold sensory endings by, and not to physical volatilization of, the drug, because when air at a temperature of 37.5 degrees C. was passed on mucosae the sensation was indifferent, but the moment that mentholized air at the same temperature was admitted a cooling sensation occurred. Hence, it followed from this that the nerve endings, which appreciate cold, were irritated or stimulated directly. These nerve endings not only were stimulated at the time of the application of the vapor containing menthol, but also remained irritable after the menthol was removed because now a cooling from any source could be more readily appreciated.

Presumably, other effects as a result of stimulation of sensory cold endings were reflex stimulation of the higher centers, including the vasomotor center. Stimulation of the vasomotor center would result in peripheral vasoconstriction, and this, in part, might explain the subjective sensation of relief in, or clearing of, the respiratory passages experienced by patients treated with various mentholized applications. This effect would tend to lessen hyperemia. In this connection, it will be recalled that McGuigan of the Pharmacological Laboratory at the University of Illinois pointed out that the menthol or volatile oil (peppermint oil) type of medicament lowers the surface viscosity and tension of edematous and mucous fluids through a strictly physical effect on these secretions. The result of this is lessened tenacity and increased fluidity of such secretions facilitating their removal by expectoration.

It appears from all this that menthol acts as more or less of a specific stimulant to cold nerve

endings, reduces local hyperemia reflexly, and facilitates the removal of secretions by direct physical action, and, therefore, is not merely an inert deodorant and placebo.

McGuigan, H: J. Am. Med. Assoc., 1921, 76:303, "Menthol and Peppermint in Acute Catarrhal Conditions of the Respiratory Tract."

MEDICAL FICTION

The cause of scientific medicine is being injured by what may be appropriately termed medical fiction. It is not called that to be sure, but it finds its origin in the same sort of fanciful dreams. It is promulgated in the same breezy style, and it is motivated by the same underlying principles. Like some other fiction, it plays with perverted truths, twisted half-truths, or more often, it is the creature of the imagination. Like some other fiction, too, it utilizes old and substantiated scientific knowledge; old and obsolete and long since disproved theories, or even the meanderings of the medical theorists of other days, and by dressing them with new verbiage, promulgates them as new contributions to science.

If most of these modern medical—including public health—fiction writers had the true novelist's instincts and the facility to write well, they would do incalculable harm. Even their choices of subjects is held in fairly narrow fields. One of their favorite sports is to launch an attack upon the family physician. They attack his inadequate education, his craftsmanship, and even his integrity. They seem to think that he is only fit to sign the death certificates of patients of these reformers, and "near doctors" and alleged public health experts of one kind or another. Two of their other luscious subjects are "child health" and "psychology." Here, again, they can rarely complete a paragraph without sticking a barb in the "family doctor."

Most of them in these and other fields of medical fiction rehash things more centuries old than they themselves are years old, and promulgate them as "new." They love to revel in the idea that prevention of disease is a new subject; that nothing was known about nutrition and other branches of physiology or psychology longer than a few days or weeks ago. They appear to be totally ignorant of real medical history, or if they are not, they are as unspeakably vicious as their writings indicate. These man-handlers of medical truths are finding hard sledding to get their "stuff" over with medical editors, but they are still in clover with book publishers and "news" distributing agencies. Their strong and enlarging forte is in the "free" bulletins given out from clinics, health centers, and various political agencies of government.

There is plenty that *is* "new" about medicine that ought to be promulgated. Judged from their writings, it is also new to these expert promulgators. There are old truths that ought to be restated, and restated where possible in language understandable by everyone. But why is it necessary to attack the great mass of educated physicians and insult the intelligence of even other intelligent readers of history, in efforts to advance themselves and the more general understandings of the simple truths of health?

Above all, what sorts of souls, visions or hearts have the few of these medical fiction writers who are doctors of medicine and who ally themselves with and support emotional uplifters and go them one better by attacking their fellows who graduated from the same schools, often in the same classes as themselves, and who are carrying our real health burdens now as they always have carried them?

SHALL WE PROTECT OR DISCARD "DOCTOR"?

What a confession for a Government to admit its inability to protect against impositions and fraud a title as important to progress as that of "doctor"!

What a miserable compromise with knavishness to attempt to abolish the word "doctor" that is woven by college looms so deeply into the fabric of civilization!

Why in the first place pick upon our college degree of "doctor"? Some people forget that doctor is not a political or other title conferred by the State, but that it is wholly an expression of educational attainment made by universities and colleges, and constitutes the highest degree they award. In this respect, as well as that of usage and understanding, it is only one of several other terms, like "professor," that have been prostituted to a nauseating and disgusting extent.

If our State Government will not protect the use of these terms and not only admit their inability to do so, but frankly attempt by law their destruction, will they be able to succeed? When weeds grow up in the farmer's corn-field, he does not dig up his corn or move to a new field, but destroys the weeds and protects his corn.

We believe that the vast majority of our people, whether themselves physicians, professors, or not, will disapprove any attempt to destroy these appropriate terms which have come to mean so much to so many people. We believe, furthermore, that the majority of our people will support legislation and the enforcement of laws to protect hard-earned titles. At least they will be given the opportunity to do so when the next legislature meets.

Two years ago, after an exhaustive study of the needs of the situation, what was known as the "Medical College Bill" was prepared by physicians and introduced into the legislature by the League for the Conservation of Public Health. It passed the senate and died in a committee of the assembly. That bill will be before the legislature again. It provides that any school or college purporting to teach the healing art and confer any sort of "doctor" degree must comply with certain reasonable requirements. This would stop the output of diploma-mills, whose principal occupation is to issue a diploma with doctor on it, and it would thus correct a situation at its source.

The last legislature passed a law all but unanimously that placed adequate safeguards about "doctor." At least it required each "doctor" to make public his authority for use of the title. This bill

was vetoed by the Governor of the state. His reasons for so doing were not popular at the time, and they are growing more unpopular as times goes by.

For the Governor's administration to now make an attempt to destroy by law what they refused to protect, because the situation is so hopelessly bad, will be another blunder, and place the Governor's administration in a more damaging light than it now is.

The "Doctor bill," as it was called, for the protection of those who are entitled to its use, as well as the protection of the public, will be again before the legislature. When this measure and a destructive one introduced by the administration on the same subject meet in the legislature, there ought to be further opportunity for assaying values.

We are convinced that such destructive legislation will never secure the endorsement of the majority of doctors who hold this enviable degree from good schools, and which they spent so many hard years of study and sacrifice to secure.

COUNTY HOSPITAL FEES

There is a gradual spread of the practice of county hospitals in California not only to charge patients fees, but to develop an ascending scale of fees. Leading the promotion and development of the idea are some of the largest and most prominent of the county hospitals, located in centers where there is not the excuse of insufficient number of beds in other hospitals.

Some of the plans and schemes that are employed in deciding how much these various grades of citizens shall pay would make a Russian Communist dizzy. They grade people like pigs, as a, b, c, d, etc.—classes with a lot of algebraic formulas with these letters to make them fit any pocketbook. In fact, some of these hospitals have already reached a plane whereby almost the only "free" service about them is the doctors' services. Some of them are reporting, apparently as something to be proud of, that they have only small percentages of patients who do not pay, and that this percentage is decreasing year by year.

Recent reports from several Eastern centers show that these "free" hospitals and other "charities" are collecting from 40 to 75 per cent of the costs of all their services from the people they are serving. They are beginning to point with pride to the millions they are collecting from those who the general public believe are getting free treatment.

What is called "business methods in charity" is swinging rapidly into a dangerous situation which, unless corrected, will produce unlooked for reactions. Some such reactions are already making themselves quite apparent in some centers where the operation of charity as a business is oldest.

Whatever one's opinion may be about religion, the first instance of permanent progress along lines contrary to the teachings of the Master has yet to be noted by historians. He spoke unmistakably and emphatically about "charity" and "the poor."

A SIGN OF THE TIMES

New Jersey doctors are much excited, and with good reason, over a bill pending in the Legislature to create a special health board called the Bureau of School Health, under the control of the Board of Education. As a sop to the medical profession, a "regular licensed practitioner of medicine" is to head this new bureau.

In discussing the proposal editorially, the Journal of the New Jersey Medical Society says:

"It is expected that the measure will have the backing of insurance, manufacturing, and lay health organizations. It will probably be opposed by the associations of physical education, teachers, who, in 1917, while the profession was unaware, had a program of physical education set up instead of a program of health, one of their number now being a pseudo-director.

"*Every doctor* should join the battle. Do we wish to be beaten by a crowd of 'gym' people? Shall the people be allowed to suffer to enable one 'gym' man to thwart public welfare? *Every doctor* should call upon or call up his legislators and urge the passage of the School Health Program bill."

Of course, to retain a health program of education and practice in the hands of a physician is important. But why have two boards?—one for school children from ? age to ? age, this board responsible to the educational authorities; the other the regular health board for the rest of our citizens, this board responsible to the usual Government authorities and to the public for the carrying forward of all phases of a better health program.

The real reasons why the New Jersey school authorities, and those of many other states moving in the same direction, want their own health board under their own orders are perfectly clear to any thinking person.

THE TWELVE-HOUR DAY FOR NURSES

To Californians it is almost like reading history to watch the controversy between doctors, nurses and hospitals and the public over the nurses, demands for a twelve-hour day. In Buffalo, New York, for example, the fight is bitter and aggressive.

The twelve-hour day, as it is called, is in quite general use in California and has been for some years. The exceptions are, that nurses will look after chronics and convalescents on a twenty-four-hour day basis, provided reasonable hours for recreation and sleep are provided. This, in our opinion, is as it should be. If nurses are really needed, and if they really work while on duty, twelve hours is rather more than less to ask of them. When there are only a few things to do for the patient at a certain few times during the twenty-four hours, one nurse can easily handle the task and, with a little reasonable understanding with the doctor, have plenty of time to sleep and look after her own health.

Most worthwhile nurses like to be kept "busy" while they are on duty, and to be free when not serving the sick.

The argument that, reducing a nurse's day to twelve hours will increase the cost of sickness, while probably a fact, is nevertheless no argument. Sick-

ness costs less also in a "firetrap" hospital, but no one would condemn fireproof buildings for hospitals on that basis.

No, nurses are not unreasonable in asking for a twelve-hour day. They were, and are, foolishly advised in using the methods they sometimes employ in bringing the shorter day about.

The costs of sickness ought to be, can be, and will be decreased somewhat by better organization, elimination of waste, substitution of necessities for luxuries in buildings, equipment and otherwise, but we should not try to fasten "sweatshop" methods upon any group of employes in order to make a showing.

It is not the twelve-hour day but other dangers, and some of them serious, that threaten the standing of this splendid and important technical group of the medical and health agencies. Of the many dangers that threaten, the most important and far-reaching is the overspecialization in nursing organizations and among individual nurses. The second greatest danger is, that too many nurses are so conducting themselves as to merit the designation of super-nurse, etc., that is being bestowed upon them in ever-widening circles.

With wise leadership among themselves, these and other pitfalls may be avoided. We hope they may and that the world may continue to hold nursing as the sacred service-loving calling that Florence Nightingale made it.

WHO IS RESPONSIBLE FOR THE CHILD?

Numerous educational and political documents now being issued from time to time make it perfectly apparent that many of our organizations consider control of the child a public duty rather than the responsibility of parents, which was the vogue when we were all youngsters. These organizations are making headway and it looks very much as if in the course of time they might win the point they are striving for.

We wonder how many people think what will happen after this point is gained.

One thing that already is happening is indicated by Mr. J. C. Astredo, probation officer of San Francisco, when he says, "THERE SEEMS TO BE A WILLINGNESS UPON THE PART OF PARENTS TO LET THE COMMONWEALTH ASSUME EVER-INCREASING RESPONSIBILITIES FOR THE CARE AND DIRECTION OF CHILDREN." Mr. Astredo is in a position to secure accurate data upon subjects of this character, and his fair-mindedness in presenting this data cannot be questioned. Statements of this kind cause those who are trying to push the nation headlong into a difficult situation to pause and consider what they are doing.

Many mothers need help and many children need help, but could we not plan so as to render assistance of whatever character to or through the mother and thus prop up and support the independence and integrity of the home? Surely our people, when they know the facts, are not ready to make of motherhood a "brooding plant" and the weaned child an exclusive responsibility of the commonwealth.

THE FORDS OF MEDICINE

Every so often some new genius discovers again the old, old formula that everybody can have expensive hospital and medical care except the "poor middle class." They say the rich can buy it and the poor can have it for nothing, but those "middle class" people can't pay present costs of doctors' service or hospitals.

Nearly every one of these financiers expects either that wealthy people will provide subsidies, that the costs of hospitals and doctors' fees be reduced, or that the state take over all hospital, and, consequently of course, all medical work. The answer, of course, is to first catch your bird.

Henry Ford decided that there were millions of poor "middle class" people—God bless them—who wanted, and therefore should be allowed, to ride in automobiles. By a combination of business genius, energy, and common sense he has been able to provide them a car. It travels and delivers its passengers at their destination, but it does not satisfy, and every owner wishes for a *better* car more intensely than he originally wished for *any* car.

The only possible way, except by gifts from persons or the state, by which hospital service and medical fees can be brought much below their present scale is, by doing what Ford did to automobiles—put cheap material together in a "standardized" plant and use unskilled drivers. Such tactics will neither satisfy the demands of the sick nor give the service they should have.

Handing the problem to the state does not decrease the cost. Good government hospitals cost every bit as much, and even more than others, to operate. There is plenty of voluntary sickness and health insurance offered by many reliable companies at premium rates that even the "poor middle class," which, by the way, include most physicians, can pay. Instead of wasting our time on economic absurdities, why not spend more effort in pointing out to people the available practical remedies that exist?

Henry Ford, be it remembered, tried the hospital game. He has a fine plant, which charges only quite moderate rates for service, *but* it takes a Ford to absorb the deficit.

A very large percentage of the people who can well afford to pay costs of sickness, and for luxuries if they want them, carry every form of sickness, accident, and health insurance. They do it as a good business policy. Why in the name of justice should not others who need such protection pay the small premiums it takes to carry it?

NEVADA MEDICAL ASSOCIATION

The annual meeting of the Nevada Medical Association will be held this year September 12 and 13, at Bowers Mansion near Reno. The committee having the arrangements in charge is already active, and is preparing a very attractive program, including some unusually promising social features.

Physicians interested in the development of the program should communicate promptly with the secretary, Claude E. Piersall, Masonic Temple, Reno.

The complete program of the session will be published in CALIFORNIA AND WESTERN MEDICINE in due course of time.

SHALL PHYSICIANS OR LAYMEN DIRECT AND CONDUCT HEALTH WORK AMONG SCHOOL CHILDREN?

Of all health movements there is none more definite, better organized or more certain of its program than are school administrators in their campaign to have teachers and not physicians and health boards control the practice of diagnosis, prevention and curative medicine among school children.

Government publications paid for out of Federal taxes are extensively utilized for extensive propaganda. We have called attention before to what is said in some of these publications, and there is now before us a recent number of "School Life," which contains interesting reading. One writer, and he is a physician, outlines the history of physical education and health work. Among other illuminating statements we find these:

"School health agencies now control the machineries of communicable-disease prevention and control. In other words, the school health service, including its staff of physicians, dentists, and nurses, is best prepared to handle most of the positive health and physical efficiency program of the school."

"In its attempt to assert itself and to convince itself and the public of its value, finding its traditional field fairly well covered by the school health movement and wishing more or less independence of the school health agency, physical education began to cast about for other objectives outside of those concerned with the body. It found them in a large measure in certain mental, moral, and social values, that physical education claims are the invariable products, particularly of games, sports, and athletics. As a result, in at least one state there is a state director of physical education and a state director of school health."

"Let us assume that both the school health service and physical education are fundamentally interested in the positive health and physical efficiency of school children. If this is true, there is no reason why separate administration should be maintained. Independent supervision leads to duplication, friction, misunderstanding, economic waste, and, worst of all, to poor results. Some phases of the work may be overemphasized, others slighted."

Other government publications emphasize the rapid gain that is being made in wresting the control of medical work in schools from boards of health and placing it where they claim it belongs—under control of boards of educators.

COUÉ

"The more stupid they are the easier they get my theory," said Emile Coué, in an interview with Mollie Merrick of the San Francisco Examiner, upon his first arrival in San Francisco. Continuing, he pictured the "dumb," the "unconscious," the "mentally nil" as enjoying the benefits of the Coué philosophy with greater facility than do other persons.

Quite a compliment (?) to his followers, but that is his business; and that's all for Coué so far as we are concerned.

WHY NOT TRAVEL BY WATER

to the annual meeting of the California Medical Association?

In this number we carry a full-page advertisement of the Los Angeles Steamship Company, offering rather remarkable inducements in rates and comforts to those members, particularly those from Central and Northern California, who will enjoy going to the Southland by steamer. The service and schedule of the steamers Yale and Harvard offer a very convenient and pleasant way to the meeting. There will be a sailing from San Francisco at 4 p. m. Saturday, May 10, putting passengers into Los Angeles at 11 a. m. Sunday the 11th. Return sailings will be Friday, May 16, and Sunday the 18th, at 3 p. m. from Los Angeles, arriving in San Francisco at 10 o'clock the following morning. There will be additional sailings southbound on Tuesday, Wednesday and Friday, and northbound on Tuesday and Wednesday. So you may enjoy a week-end vacation and rest both going and coming from the meeting.

Very low round-trip fares include berth and meals. Special entertainment features will be provided by the ships' orchestra in the ballroom.

"CONGENITAL DISEASES"

During the first eight months of 1923, according to the State Board of Health, 46.3 per cent of the deaths among infants was due to "congenital" diseases.

It would be interesting, but unprofitable in the present state of knowledge and statistics, to speculate upon the proportion of these deaths that parents are responsible for. It would likewise be worthwhile, if possible, to trace the causes back through more distant ancestry and distinguish these from the influences of antenatal diseases and injuries to the child.

Another point more important perhaps than any of these would be a determination of the morbidity among the 53.7 per cent of infants who did not succumb to "congenital diseases." Undoubtedly, morbidity and injuries among infants before birth constitute not only the basis of many health failures in after life, but are unavoidably included under other headings in mortality statistics.

"THE KINDERGARTEN AND HEALTH"

Under this title, the Bureau of Education, Department of the Interior, Washington, has issued another pamphlet containing information of interest to physicians.

The position is taken that the most important function of a kindergarten is to serve as a public health station connecting the infant welfare station on the one hand with the health service under control of the public schools on the other.

Copies of this pamphlet may be secured from the government printing office in Washington.

Medicine in the Public Press

Board of Medical Examiners Endorse Doctors' College Bill—In a report to the Governor, a committee of the Board of Medical Examiners endorse the principles contained in Senate Bill 364, known as he medical college bill, introduced by the League for the Conservation of Public Health in the 1921 Legislature. That bill passed the Senate by an overwhelming majority, and was delayed and obstructed by a hostile committee in the Assembly, to which it was referred. It will be reintroduced at the next Legislature, and the strong and united support of the Board of Medical Examiners will be of help in securing its passage.

We hope, in the interest of public health, that Governor Richardson, who was not in office when the bill was before the Legislature, will endorse the recommendation contained in the official board's report, and lend his support to a movement that strikes at the source of legalized quackery in California.

Those "Controlled Surgeons" Again—We revert again to Mr. William G. Shepherd's article in Harper's Magazine about "controlled surgeons" who are out to save the public from incompetent and dishonest surgeons and whose names he could not give to the public because of their alleged ethics, supported by an oath "on the honor of a gentleman," that they would not utilize personal puffery to gain their ends. Three prominent members of the organization excepted by Mr. Shepherd in his drastic arraignment of the medical profession were in Vancouver recently on their way to the Orient. The Vancouver Sun, among other encomiums about these "controlled surgeons," says:

> Dr. William James Mayo is one of the renowned Mayo brothers whose outstanding work in the surgical world has made their clinic at Rochester, Minnesota, known the world over. In 1915, in conjunction with his brother, Dr. Charles Horace Mayo, he donated the sum of $2,000,000 to establish the Mayo Foundation for Medical Education and Research at Rochester, in affiliation with the University of Minnesota. Dr. W. J. Mayo was born at Le Sueur, Minn., June 29, 1861, and gained his M. D. at the University of Michigan in 1883, later being awarded the A. M. degree. In 1905, at Edinburgh, he was made a Fellow of the Royal College of Surgeons. Other degrees held by Dr. W. J. Mayo and the year in which they were granted are LL. D., University of Toronto, 1906; University of Maryland, 1907; University of Pennsylvania, 1912; D. Sc., University of Michigan, 1908; Columbia, 1910; F. R. C. S., England, 1913; Ireland, 1921.
>
> Dr. Franklin H. Martin, director-general of the American College of Surgeons, is also a distinguished man in his profession. His research work has been of great value to the medical world. Dr. Richard H. Harte is also widely known and has contributed many valuable works to the world of medical science. He is the author of the "Handbook of Local Therapeutics." During the Great War Dr. Harte distinguished himself serving overseas, and his work received much recognition from allied nations. He was mentioned in the dispatches of General Haig and received the British Order of St. George and St. Michael. Dr. Harte was made a "Companion of the Order of Leopold" by the King of Belgium, and "for conspicuous service rendered to the British Expeditionary Force" was made a Fellow of the Royal College of Surgeons, Ireland.

This intimate and probably accurate biographical data has earmarks familiar at least to all men engaged in any way in publicity, and its source probably will not be misunderstood by many intelligent readers. This memorandum is not intended as an arraignment of these prominent men for their newspaper publicity. They are all excellent and prominent physicians. What we would like to know is, have these men lived up to the standards Mr. Shepherd says these "controlled surgeons" are sworn to sustain?

Reptiles and Angels—Doctor, some evening when you are too tired to talk, gently remove your telephone receiver, get into a semi-reclining position, light a good cigar, pick up your March Atlantic and read Mr. Charles D. Stewart's delightful article with the above title. A copy of this article would save you many wearing explanations, and be good medicine for some of your more intelligent "heart cases."

Does This Apply in California?—Under a medical slang title of "The Challenge of the Chronic Patient" (Survey) a writer, in discussing the present service being rendered to patients suffering with chronic diseases, says: "A recent survey of the leading institutions for chronic patients, most of which call themselves homes for incurables, shows that almost without exception the scientific study of disease is ignored, and even the importance of medical treatment is minimized. Apparently, these institutions work on the principle that their patients are incurable, beyond all hope of even partial rehabilitation, and that their sole function is the maintenance of a home where such unfortunates may linger until they die.

". . . It is not only the individual who suffers from this neglect. Many inmates of almshouses remain public pensioners for years. They are accepted as human derelicts who, to appease the rudimentary public conscience, must be supported and maintained, preferably where they will not be seen, until death relieves them and the taxpayer from further worry and responsibility. Yet many of them, if they were to get a fighting chance, could be rehabilitated and returned as useful members of the community."

Selma School Nurse's Report Contains Interesting Features—The nurse says in her medical report that all children have been weighed and "it was gratifying to find that many of the children have gained since last weighing. . . . Four children have been taken to doctors, ten to the optometrist, and one sent to the dentist."

Is the Quality of Medical Practice Improving?—"In spite of the attainments of preventive medicine," says Hospital Social Service editorially, "the vast majority of people of New York State and an enormous percentage of the people of the United States, over 90 per cent probably, have, to a large extent, the same kind of medical service, or in many instances a poorer quality of medical service than they had twenty-five or thirty years ago. Even where public health agencies are thickest, an all-round preventive service is not universal in any given unit of population. Certain sanitary and isolation laws are the only health measures which affect every member of a given community. Other health measures such as work with malnourished children, maternity care, and even tuberculosis clinics are sporadic, affect only a limited clientele and, however sensitive, do not reach all the people who might benefit by them."

And I Learned My Medicine from Her—A new idea in diet has recently been promulgated by a dietetic "savant." It is to the effect that a person's temperament is made and changed at will by the effects of vegetables. Potatoes, it is said, "balance the mind and calm it." Carrots are excellent antidotes against jealousy; spinach speeds up ambition; beans develop the artistic sense; parsley produces sadness; but the good old-fashioned baked beans stimulate the desire for work. A wag has said that this savant's findings for the first time explain why the Irish race have such calm temperaments. To secure all of these results, the patient must plant, cultivate and harvest the vegetables with his own hands, and for that statement, we will forgive his dreamings.

Reaction Against School Authorities Practicing Dentistry—From New York and several other centers, the practice of dentistry by boards of education is being severely criticized and in some places stopped altogether. The charge is being made that schools have no more business practicing dentistry or medicine—they are doing both—than they have to practice law or engineering. It is not understood

that there is opposition to the movement for good dentistry for school children as well as for all other persons, nor is their criticism of legitimate movements to insure free dental work for those who can't pay for it. The main point in the opposition that is cropping out in many places is against this work being done under boards of education, and in some places, it is said, by inadequately educated technicians.

Back to States' Rights!—A call for release from Federal interference in local affairs and for relief from Federal taxes that amount to five times those that the States collect. Physicians who care to interest themselves in the ever-broadening field of governmental interference in private business, and who are opposed to State medicine as they are opposed to governmental operation of other businesses are invited to read an article under the above title by Governor Ritchie of Maryland, in the March number of World's Work. Governor Ritchie shows that the enormous Federal taxes we now pay are only in their infancy if Federal subsidies to States for this or that purpose are continued. Legislation of this character is before Congress now.

San Diego Has Eleven New Sheppard-Towner Health Centers—A Sheppard-Towner nurse of San Diego reports the establishment of eleven new health centers. According to local reports, "San Diego county is one of the five very fortunate counties in California to have a Sheppard-Towner nurse, whose work is that of general health supervision of children during the impressionable pre-school age covering the period from birth to six years, inclusive."

Wheat Valorization of Medical Fees—"In view of the fluctuation of the Hungarian currency, the medical profession has been obliged to raise fees almost from week to week," according to the Budapest correspondent of the Journal of the American Medical Association. "Although the increase has never corresponded to the depreciation of the currency, and, in fact, medical fees are the only ones in Hungary which do not reach the so-called gold parity, yet the general press has commented on the raise of medical fees as inhuman and not worthy of the medical profession. Some medical journals even have had disputes with the lay press on this subject; but, judging from the correspondence addressed to the journals, it seems that the general public believes that the physician should be satisfied with only half pay for his work, the other half being taken out in love for his work. These discussions have led some branches of the National Medical Association to introduce the wheat valorization: a medical consultation is priced at the value of 5 kg. of wheat. The fees paid at present not being equivalent to 2 kg. of wheat, the increase is considerable; but, even so, it is only half of the pre-war fees, the price of a medical consultation being then at least 2 kronen (40 cents), the value of at least 10 kg. of wheat. The board of the association has stated that, in accordance with its well-known altruism, officials and private clerks are made exceptions to the rule, and will pay according to their financial means."

The Blood "Donor" Problem—The frequent legal complications connected with the transfusion of blood and the "news value" so frequently attached to one phase or another of the problem warrants consideration of the whole question as of the first importance professionally, and from an economic standpoint.

Most of the economic problem centers in the rights of "donors." These people often claim about all the injuries to their health by the removal of small amounts of blood that one could bring about with an ax. Often courts sustain them in their claims. Sometimes there are unavoidable accidents, even in the hands of experienced physicians, and it does appear that occasionally an operator is incompetent. In all such instances, it is perfectly proper that responsibility be fixed and reparation made by reasonable compensation. This is a matter easily cared for by insurance and all physicians, and hospitals should see that their policies protect them in this field. The "donor" also should be protected by special insurance provisions, in addition to any protection they may have under the industrial accident law.

It is a well-known fact that safe "blood grouping" between "donor" and patient should be made and recorded before any transfusion is given. Physicians have been convicted upon evidence of their colleagues for unfavorable results where this procedure was not adequately followed. There is no excuse in law or ethics for such carelessness, and it is doubtful if insurance protection could be secured which would protect against it. Criminal liability has been established in some cases of this kind.

Treating the Ambulatory Sick in New York City—The annual report of the United Hospital Fund of New York shows that the 225 "free" and "part pay" clinics of the city treated 1,250,000 citizens during the year, or about one-fifth of the entire population. The amount collected from the patients is not given, but some 3000 physicians were the only ones who rendered their services free. Basing the costs of these services upon the average costs worked out by other clinics, they cost someone at least $2,000,000. Based also upon average statistics, at least half and probably more was paid for by the patients in small fees. Some very interesting figures are being collected here and there as to the funds being collected from patients by health centers and clinics. We will have more to say about these from time to time.

Modesto Handles Diphtheria Immunization in a Commendable Manner—Modesto, like other communities, has the problem of protecting its young inhabitants against the epidemic of diphtheria. J. W. Morgan, the city health officer, took charge of the educational publicity, and secured an appropriation from the city authorities to purchase the materials. He then made arrangements with the physicians of the community to give the complete immunization to all comers at the nominal charge of $3 per patient. Citizens able to do so pay their own doctors, and those unable to pay were allowed to go to the doctor of their choice, and the city paid the $3 to the doctor.

Many cities and other communities in Eastern States follow this method for diphtheria and other medical services, but it's rare enough to comment upon in California. Here we establish special "clinics" with all the fuss and "labeling" of the poor to render this and other simple services which all physicians are prepared to render in the offices.

Medical Examinations by Family Physicians—Since our articles upon the subject of who is competent to make medical diagnosis began to appear, our correspondents report from several places in California a tendency to give an educated physician's opinion precedence over scales, measuring rods, and the new ouija diagnostic board, patented by a Government bureau. In other places, the comparisons are still made between the reliability of the doctor and the ouija board or scales in distinguishing between health and disease.

In Fresno, Miss Lillian Dahlgren, nutrition specialist, emphasizes the willingness of the doctors to examine children who come to them in their offices, and they have examined many. The mechanical diagnostic devices are still maintained also, and their readings apparently interpreted and accepted without physician's examinations in many instances. We presume that physicians furnished the data for that part of the report which says: "Examination of the children has revealed that three-fourths have carious teeth, diseased tonsils and adenoids, enlarged glands of the neck, round shoulders, flat chests, anaemia or

lowered body temperature. Many have serious defects of vision and ear diseases."

The Department of Agriculture Clinics—The department of agriculture does not propose to be behind the Department of Labor or any of the other numerous departments at Washington, who are practicing medicine by mail. Like the others, they have the great Government printing plant at their call. They have mail-franking privileges, and their clerks are as competent to give medical advice as are those of the other political bureaus. One of their recent expensive health sermons by mail told the world that a soup of chopped creamed lettuce, spinach, and cabbage was desirable for children because it contained vitamins, and that the addition of a little onion would add flavor plus more vitamins.

Now, isn't that interesting and illuminating? It sounds like the action of another department that started out to equip all mail-delivery wagons with scales to weigh all the babies with. This policy of more medicine in government and more government in medicine is still popular—at Washington.

San Luis Obispo Vaccination Clinic — The clinic operated by the San Luis Obispo health board has succeeded in vaccinating 229 persons during the period of its existence. The work was performed for persons in all walks of life free. It is said that most of the citizens went to their family doctors for vaccination, and that those who were able to do so paid for the service, and that others had it for nothing.

Schools' Responsibility for Child Welfare Repudiated—In a recent address, Edward I. Cook, professor of social science of the Junior College of Sacramento, is quoted as having said that "there has been a tendency of late to shift more and more responsibility for school children upon the shoulders of school officials. This is unjust. Taxpayers and others who should be interested in the welfare of children pay little or no attention to them. When an occasion arises in which the children's actions are criticized, the school officials are blamed for it."

"It is up both to the college and to the citizens of the city," said the speaker, "to teach students the duties of citizenship. We must teach them, by example, the road to good citizenship, and not merely hand out a prescription by which it may be attained."

Some of these days when educational leaders, less far-seeing than Cook, realize the trouble they have invited and the dangers it is bringing to the worthy cause of education, they will be glad to shift more responsibility back to parents from whom their propaganda has wrested it. They will be glad to ask the family physician to again assume the duties and responsibilities of health advice; and possibly the movement in some States to wrest spiritual development from its traditional position may be arrested.

The High Cost of Wasting — Ida Clyde Clarke (editorial, Pictorial Review) calls us a nation of wasters. We waste our time and our energy and our talents and our money, and, above all, we waste our power. We have enough organizations and enough professional reformers and enough people with the instinct for reform to clean up the country generally, if we really wanted to do it. But the trouble is we are not interested in concrete reforms. We don't want to see the end. We seem to be afraid of finishing things. We like the all-day-sucker variety of reform. We will work in a frenzy of zeal for anything that is intangible and afar off. Such loose terms as "Americanism" and "welfare" are music to our ears, and we simply adore the very thought of "standardization." Many of our great "movements" sweep majestically on toward nothing. Yet in spite of this we fall into line quite readily with every new idea that is suggested.

Medical School News

Stanford University School of Medicine (reported by W. Ophuls, dean)—The Medical Faculty has reorganized its schedule in such a way as to reduce the required hours to the minimum required by the laws of the State of California, which is 4000 for the instruction in the first four years in medicine. Three thousand eight hundred hours of this will be prescribed, leaving 200 hours for elective work. It is hoped that in the course of time the amount of elective work can still be further increased.

It has been pointed out frequently that, although physicians naturally should be leaders in public health movements, very little if any attempt is made to teach the students in medical schools personal hygiene and supervise their activities in such a way as to keep them in good health and physically fit. In order to overcome this just criticism, the Medical Faculty has decided to appoint a physical adviser to the medical students at the Medical School in San Francisco, who will take a personal interest in them and will encourage them to take the necessary amount of physical exercise in one form or another.

There has been a good deal of complaint in and outside of medical schools that there is a large amount of duplication in the different courses that make up the medical curriculum. There is no question that this is one of the causes of the overburdening of the medical students with required work. In order to obtain accurate data as to the actual state of affairs, the Medical Faculty has appointed a committee on correlation of courses, who have been asked to study the situation and make a thorough report with suggestions for improvement.

Changes in Faculties—E. B. Towne was promoted from the rank of Assistant Professor of Surgery to the rank of Associate Professor of Surgery, and Jean Oliver was promoted from the rank of Associate Professor of Pathology to that of full Professor of Pathology, these promotions to take effect with the beginning of the new college year, on September 1.

George de F. Barnett, who has been in private practice at Palo Alto for several years, has been recalled to the Medical School as Associate Professor of Medicine. Professor Barnett will devote most of his time to our medical service at the San Francisco Hospital.

Mr. Maurice L. Tainter has been promoted from assistant in Pharmacology to instructor in Pharmacology.

Health Insurance in Colleges—"The idea of health insurance, bordering on the old 'lodge practice idea,' has invaded the campus at the University of California, American Medicine recently pointed out," says the Ohio State Medical Journal editorially.

"This great American university with 'no tuition fees, but certain small incidental fees,' exacts from the student a 'fee' for both the sick and the well.

"Each student is required to pay $6 annually. This sum is the premium charged for health insurance, not 'only entitling one to examination, but to full care of his health for that period.'

"It is further shown that there are between seven thousand and eight thousand students at the university who pay the fee. It is estimated that the revenue is about $42,000, which goes to maintain a small hospital and staff of physicians.

"It comes as a surprise that such an institution as the University of California would foster such paternalistic measures as health insurance, not alone from the immediate effect upon its students, but from the 'viewpoint' which is being developed toward relationship of the individual toward society."

PROGRAM

THE FIFTY-THIRD ANNUAL SESSION
OF THE CALIFORNIA MEDICAL ASSOCIATION TO BE HELD
AT LOS ANGELES, CALIFORNIA, MAY 12, 13, 14, 15, 1924

LOS ANGELES BILTMORE
Headquarters for Meeting of California Medical Association

OFFICERS AND COMMITTEES, 1924

T. C. Edwards, Salinas, President.
Granville MacGowan, Los Angeles, President-Elect.
W. H. Strietmann, Oakland, First Vice-President.
R. A. Cushman, Santa Ana, Second Vice-President.
Emma W. Pope, San Francisco, Secretary.
W. E. Musgrave, San Francisco, Editor.
Hartley F. Peart, San Francisco, General Counsel.
Hubert T. Morrow, Los Angeles, Assistant General Counsel.
Mr. William H. Barry, Superintendent of Publications.

COUNCILORS

First District—Paul M. Carrington, San Diego (1924)—San Diego, Riverside, Orange, San Bernardino, and Imperial Counties.

Second District—William H. Kiger, Los Angeles (1925)—Los Angeles, Santa Barbara, Ventura, and Kern Counties.

Third District—W. M. Stover, San Luis Obispo (1926)—San Luis Obispo and Monterey Counties.

Fourth District—Fred R. DeLappe, Modesto (1925)—Fresno, Kings, Tuolumne, Merced, Mariposa, Madera, Tulare, and Stanislaus Counties.

Fifth District—David A. Beattie, San Jose (1926)—Santa Clara, San Mateo, San Benito, and Santa Cruz Counties.

Sixth District—Walter B. Coffey, San Francisco (1926)—San Francisco County.

Seventh District—Edward N. Ewer, Oakland (1926)—Alameda, Contra Costa, San Joaquin, and Calaveras Counties.

Eighth District—James H. Parkinson, chairman, Sacramento (1925)—Sacramento, Amador, El Dorado, Alpine, Placer, Nevada, Yuba, Sutter, Sierra, Yolo, Butte, Plumas, Lassen, Mono, Inyo, Glenn, Colusa, Tchama, Shasta, Modoc, and Siskiyou Counties.

Ninth District—James H. McLeod, Santa Rosa (1926)—Marin, Sonoma, Lake, Mendocino, Solano, Napa, Del Norte, Humboldt, and Trinity Counties.

Councilors-at-Large—O. D. Hamlin, Oakland (1925); Rene Bine, San Francisco (1926); George H. Kress, Los Angeles (1926); William T. McArthur, Los Angeles (1926); Saxton T. Pope, San Francisco (1924); C. L. Curtiss, Redlands (1926).

DELEGATES AND ALTERNATES TO A. M. A.

Delegates—Charles D. Lockwood, Pasadena (1924); Victor G. Vecki, San Francisco (1924); C. Van Zwalenburg, Riverside (1925); E. C. Fleischner, San Francisco (1925).

Alternates—Walter V. Brem, Los Angeles (1924); Harry J. Spiro, San Francisco (1924); Albert Soiland, Los Angeles (1925); Walter C. Alvarez, San Francisco (1925).

COMMITTEES

Committee on Scientific Program—Emma W. Pope, chairman; Lemuel P. Adams, Oakland (1926); F. M. Pottenger, Monrovia (1927); F. F. Gundrum, Sacramento (1924); Walter V. Brem, Los Angeles (1925).

Committee on Arrangements—William H. Kiger, chairman; Harlan Shoemaker, W. T. McArthur.

Entertainment Committee—George H. Kress, chairman; Donald J. Frick (golf), W. T. McArthur, Harlan Shoemaker.

Executive Committee—Rene Bine, chairman; T. C. Edwards, Granville MacGowan, William H. Strietmann, James H. Parkinson, Emma W. Pope, W. E. Musgrave, Hartley F. Peart.

Auditing Committee—Rene Bine, chairman; Saxton T. Pope.

Committee on Bunnell Memorial—Emmet Rixford, chairman; Saxton T. Pope, Egerton Crispin.

Commercial Exhibits—William Duffield.

Publicity for 1924 State Meeting—Mr. Celestine J. Sullivan.

Assistant Secretaries for Convention—Elizabeth McVeen Saphro, Belle Wood Comstock, Brett Davis, John H. Woolsey.

GENERAL HEADQUARTERS AND MEETING HALLS

All meetings will be held in the Los Angeles Biltmore. Information and registration desks will be maintained in the Galleria.

GENERAL OUTLINE OF THE MEETINGS

There will be three sessions on Monday, Tuesday and Wednesday, and two sessions on Thursday.

Uniform hours for all meetings are provided for: 10 a. m. to 12:30 p. m.; 2 to 4:30 p. m., and 8 to 10 p. m. The time of each meeting is shown in the diagram.

General Sessions—Two general sessions open to mem-

DIAGRAM OF MEETINGS

Sunday May 11	8-10									Council
Monday May 12	10-12:30	General Sessions								
	2-4:30	General Surgery	Radiology	Obstetrics	Dermatology Syphilology	Eye, Ear, Nose and Throat	Pathology	Neuropsychiatry	Anesthesiology	Council
	8-10	House of Delegates		Pediatrics	Urology	Orthopedics	Industrial Medicine			
Tuesday May 13	10-12:30	General Medicine				Eye, Ear, Nose and Throat	Open Meeting Industrial Medicine		Tech. Spec. Med. Soc. Workers	
	2-4:30	General Surgery	Radiology	Pediatrics	Urology	Orthopedics	Pathology	Neuropsychiatry	Anesthesiology	Council
	8-10		DINNER	DANCE	IN	BALLROOM				
Wednesday May 14	10-12:30	League							Tech. Spec. Physiotherapist	
	2-4:30	General Surgery	General Medicine	Obstetrics	Dermatology Syphilology	Eye, Ear, Nose and Throat	Pathology	Neuropsychiatry	Anesthesiology	Council
	8-10	House of Delegates								
Thursday May 15	10-12:30	General Sessions								
	2-4:30	General Medicine	Radiology	Pediatrics	Urology	Orthopedics	Industrial Medicine	Neuropsychiatry	Anesthesiology	Council

bers and guests will be held on Monday and Thursday mornings.

Section on Medical Economics, Education, Public Health and Hospitals—This meeting is held under the auspices of the League for the Conservation of Public Health on Wednesday morning.

The following sections will hold meetings:

Anestheslology.
Dermatology and Syphilology.
Eye, Ear, Nose and Throat.
General Medicine.
General Surgery.
Industrial Medicine and Surgery.
Neuropsychiatry.
Obstetrics and Gynecology.
Orthopedic Surgery.
Pathology and Bacteriology.
Pediatrics.
Radiology, Roentgenology and Radium Therapy.
Technical Specialties.
Urology.

Council Meetings

First Meeting—Sunday, May 11, at 8 p. m.
Second Meeting—Monday, May 12, at 2 p. m.
Third Meeting—Tuesday, May 13, at 2 p. m.
Fourth Meeting—Wednesday, May 14, at 2 p. m.
Fifth Meeting—Thursday, May 15, at 2 p. m.

Meetings of the Council With the Presidents and Secretaries of Constituent Societies

All members of the Council and all presidents and secretaries and assistant secretaries of constituent societies are requested to be present at a luncheon on Tuesday, May 13, at noon. Matters of great importance will be discussed.

HOUSE OF DELEGATES

Membership

Councilors—First District, Paul M. Carrington (1924); Second District, William H. Kiger (1925); Third District, W. M. Stover (1926); Fourth District, Fred R. DeLappe (1925); Fifth District, David A. Beattie (1926); Sixth District, W. B. Coffey (1926); Seventh District, Edward N. Ewer (1926); Eighth District, James H. Parkinson (1925); Ninth District, James H. McLeod (1926).

Councilors-at-Large—O. D. Hamlin (1925), Rene Bine (1926), George H. Kress (1926), William T. McArthur (1926), Saxton T. Pope (1924), C. L. Curtiss (1926).

DELEGATES	ALTERNATES

FIRST MEETING OF HOUSE OF DELEGATES

Music Room, Monday, May 12, at 8 p. m.

Order of Business

1. Calling to Order.
2. Roll Call.
3. Report of President.
4. Appointment of the Reference Committee by the President.
5. Report of the Council, James H. Parkinson, chairman (presented before the General Sessions).
6. Report of the Committee on Scientific Program, Emma W. Pope, chairman.
7. Report of the Auditing Committee, Rene Bine, chairman.
8. Report of Committee on Bunnell Memorial, Emmet Rixford, chairman.
9. Report of Secretary, Emma W. Pope.
10. Report of Editor, W. E. Musgrave (presented before General Sessions).
11. Unfinished Business.
12. New Business.
13. Reading and Adoption of Minutes. Adjournment.

SECOND MEETING OF HOUSE OF DELEGATES

Music Room, Wednesday, May 14, at 8 p. m.

Order of Business

1. Calling to Order.
2. Roll Call.
3. Announcement of the Place of Meeting, 1925.
4. Election of Officers:
   (a) Election of President-Elect.
   (b) Election of Vice-President.
   (c) Election of Councilors.
   First District—Incumbent, Paul M. Carrington (1924)—San Diego, Riverside, Orange, San Bernardino, and Imperial Counties.
   Councilor-at-Large—Saxton T. Pope (1924).
   (d) Election of Member on Program Committee (four years)—Incumbent, F. F. Gundrum (1924).
   (e) Election of two Delegates to A. M. A. (four authorized)—Incumbents, Charles D. Lockwood (1924); Victor G. Vecki (1924).
   (f) Election of two Alternates to A. M. A. (four authorized) — Incumbents, Walter V. Brem (1924); Harry J. Spiro (1924).
5. Report of Reference Committee.
6. Presentation of President.
7. Presentation of President-Elect.
8. Reading and Adoption of Minutes. Adjournment.

GENERAL INFORMATION

Assistant Secretaries—Elizabeth McVeen Saphro, Belle Wood Comstock, Brett Davis and John H. Woolsey—can be reached through the Registration Desk whenever needed by officers of scientific sections for information or assistance with their programs or with other problems which may arise.

Registration and Information—The registration and information desk is located in the Galleria. All persons attending the Convention, whether members or not, are requested to register immediately on arrival. Beginning Sunday, May 11, registration secretaries will be on duty daily from 9 a. m. until 4 p. m.

Guests and Visitors—All guests and visitors are requested to register. All General Sessions and scientific meetings are open to visitors and guests.

Badges—Two kinds of badges will be issued by the registration bureau. All members of the California Medical Association will be issued the usual membership badge. A special badge will be issued to all guests and fraternal delegates who are attending the meetings upon official invitation of the Association.

Ribbons for Delegates and Alternates—The usual official ribbon is provided for this purpose and will be issued to all persons authorized to wear it.

Membership Cards—Every member in good standing in the California Medical Association has been issued an official membership card for 1924. This card may be useful in connection with railroad tickets, and all members are requested to have their cards with them.

Suggestions and Constructive Criticism—The officers and committees have tried to do everything possible to make the meeting a success. Suggestions and constructive criticism calculated to make future meetings more useful will be welcomed by any of the officers or by the assistant secretaries. Complaints of whatever character should be made to the Registration Desk where they will receive the attention of the assistant secretaries.

Social Program—The social program is in the hands of the Entertainment Committee, and is published on page 158 of this issue.

Press Representatives—Accredited press representatives are welcome and they will be accorded every possible courtesy.

Publicity—All publicity is in the hands of the Publicity Committee. It is requested that all persons having matter of "news" value report it to this committee. It is particularly requested that all "news" about any phase of the Convention be given out through the official committee and in no other way.

Rules Regarding Papers and Discussions at the State Meeting—Upon recommendation of the Executive Committee the following rules regarding papers have been adopted by the Council:

1. The maximum time that may be consumed by any paper is fifteen minutes, provided that not to exceed ten minutes' latitude may be allowed invited guests at the discretion of the presiding chairman.

2. Motions from the floor to extend the time of an author may not be entertained by the presiding officer.

3. The maximum time permitted any individual discussant on any paper is four minutes. This also applies to the author in closing his discussion. No discussant may speak more than once upon the same subject.

4. A copy of each and every paper presented at the State meeting must be in the hands of the chairman or

secretary of the section or in the hands of the general secretary before the paper is presented.

5. Manuscripts not accepted by the Executive Committee for publication in the Journal will be returned to the author as soon as practicable. Authors desiring to publish their paper elsewhere than in the Journal may have their manuscript returned to them upon written request to the State Secretary.

6. No paper will be accepted by the General Program Committee nor by Section Program Committees unless accompanied by a synopsis of not to exceed fifty words.

7. Papers shall not be "read by title."

8. No member may present more than one paper at any one State meeting, provided that members may present additional papers before Sections on Technical Specialties; and provided further, that a member may be a collaborator on more than one paper, if these papers are presented by different authors.

9. Failure on the part of an author to present a paper precludes acceptance of future papers from such author for a period of two years, unless the author explains to the satisfaction of the Executive Committee his inability to fulfill his obligation.

GENERAL SESSIONS

T. C. Edwards, M. D., President,
224½ Main Street, Salinas.

Emma W. Pope, M. D., Secretary,
1016 Balboa Building, San Francisco.

FIRST GENERAL MEETING

Music Room, Monday, May 12, 10 a. m.

1. *President's Annual Address* — T. C. Edwards, M. D., 224½ Main Street, Salinas.
2. *Address of President-Elect* — Granville MacGowan, M. D., Brack Shops Building, Los Angeles.
3. *Annual Report of the Council* — James H. Parkinson, M.D., Chairman, 1601 I Street, Sacramento.
4. *Report of the Editor* — W. E. Musgrave, M. D., 806 Balboa Building, San Francisco.
5. *Report of the Legal Department* — Hartley F. Peart, General Counsel, 514 Humboldt Bank Building, San Francisco.

SECOND GENERAL MEETING

Medical Economics, Education, and Hospitals

This Section is under the auspices of *The League for the Conservation of Public Health*

Dudley Smith, M. D., President,
Oakland.

W. T. McArthur, M. D., Secretary,
Los Angeles.

Open to the public as well as to all members of the State Association

Music Room, Wednesday, May 14, 10 a. m.

1. *The Increasing Importance of Medical Leadership and Public Health Education* — Dudley Smith, M. D., President League for the Conservation of Public Health.
2. *What Hospital Betterment Means to California*—W. E. Musgrave, M. D., Chairman Hospital Betterment Service Bureau.
3. *The Child Welfare Work of California Federation of Women's Clubs* — Mariana Bertola, M. D., State Chairman Division of Child Welfare.
4. *What Does the Public Want?* — William Duffield, M. D., Los Angeles.
5. *Is the State Spending Your Money for the Best Interests of the Whole People?*—Hon. C. C. Young, Lieutenant-Governor of California.

THIRD GENERAL MEETING

Music Room, Thursday, May 15, 10 a. m.

1. *Address by President of American Medical Association*—Ray Lyman Wilbur, M. D., Stanford University, Palo Alto.
2. *Relation of the Doctor to Expert Medical Testimony*—Judge Paul D. Burke, Los Angeles.
3. *The Relation of Laboratory to Clinical Medicine*—Paul G. Woolley, M. D., Assistant Professor of Pathology, Detroit College of Medicine and Surgery, Detroit, Michigan.
4. *Indications for Splenectomy*—Alfred Decastello, M. D., Professor and Primarazt of Medicine, University of Vienna, 30 Burggasse, Vienna.

ANESTHESIOLOGY SECTION

R. F. Hastreiter, M. D., Chairman,
Brockman Building, Los Angeles.

Edwin Forrest Boyd, M. D., Secretary,
Auditorium Building, Los Angeles.

MEETING

Monday, May 12, 2 p. m.

1. Chairman's Address: *The History and Progress of Anesthesia in California* — R. F. Hastreiter, M. D., Brockman Building, Los Angeles.

   Secretary's Report.
2. *Further Studies in Nitrous Oxide Percentages* — Mary E. Botsford, M. D., 807 Francisco Street, San Francisco; Dorothy A. Wood, M. D., 1390 Seventh Avenue, San Francisco.
3. *Paravertebral or Regional Anesthesia*—Roy H. Johnson, M. D., Auditorium Building, Los Angeles; Charles E. Phillips, M. D., Pacific Mutual Building, Los Angeles.
4. *Sacral Anesthesia and Proctological Surgery* — A. J. Murrietta, M. D., Pacific Mutual Building, Los Angeles.
5. *The Antagonistic Functions of the Uterus in Relation to Regional Nerve Blocking* — H. T. Cooke, M. D., 307 South Hill Street, Los Angeles.
6. *The Manufacturer and Standardization of Nitrous Oxide Gas*—Donald E. Baxter, M. D., 910 N. Brand Street, Glendale.

Social—There will be a barbecue at one of the nearby Country Clubs one afternoon and evening, a banquet at the Biltmore, and a visit to the plant of Donald E. Baxter, M. D., Glendale, to witness the manufacture of nitrous oxide, ethylene oxygen and other interesting factors incident to anesthesia.

Pacific Coast Association of Anesthetists

Joint meeting with the Section on Anesthesiology of the California Medical Association

Mary E. Botsford, M. D., President,
807 Francisco Street, San Francisco.

Neil C. Trew, M. D., Secretary,
2919 Waverly Avenue, Los Angeles.

FIRST MEETING

Tuesday, May 13, 2 p. m.

1. *Presidential Address* — Mary E. Botsford, M. D., 807 Francisco Street, San Francisco.
2. *Studies of Arrythmias by the Electrocardiograph*—J. M. Wilson, M. D., Citizens' Savings Bank Building, Pasadena.
3. *Anesthesia for Prostatectomies* — John R. Burrows, M. D., 2238 California Street, San Francisco.
4. *Ethylene Oxygen Anesthesia—A New Apparatus for Giving Gases in Mixture* — John S. Lundy, M. D., Cobb Building, Seattle, Wash.
5. *Gas Oxygen Anesthesia in Thyroidectomies*—Mary F. Kavanagh, M. D., 701 Post Street, San Francisco.

SECOND MEETING

Wednesday, May 14, 2 p. m.

1. *Myocardial Insufficiency in Relation to Surgery and Anesthesia*—R. K. Barry, M. D., First National Bank Building, San Diego.
2. *Report on De-Etherization Carbon Dioxide from St. Luke's Hospital, San Francisco* — Edgar I. Leavitt, M. D., St. Luke's Hospital, San Francisco; Elizabeth B. Christiansen, M. D., 2215 Buchanan Street, San Francisco.
3. *Blood Chemistry in Nephritis and Toxemias of Pregnancy* — Edward H. McLean, M. D., Oregon City, Oregon.
4. *Psychology in Anesthesia* — Harry R. Carson, M. D., Goodrich Building, Phoenix, Ariz.
5. *Basal Metabolism Studies in Fatigue States*—Ronald Cummings, M. D., Pacific Mutual Building, Los Angeles.

DERMATOLOGY AND SYPHILOLOGY SECTION

ANSTRUTHER DAVIDSON, M. D., Chairman,
419 South Alvarado Street, Los Angeles.

MOSES SCHOLTZ, M. D., Secretary,
Brockman Building, Los Angeles.

FIRST MEETING

Monday, May 12, 2 p. m.

1. Chairman's Address and Secretary's Report.
2. *Rice Workers' Dermatitis*—Harry E. Alderson, M. D., 240 Stockton Street, San Francisco; Aubrey Rawlins, Stanford Hospital, San Francisco.

   Description and prevalence. Industrial Accident Commission reports and experiences. Personal observations. Experimental work at Stanford. Conclusions.
3. *Carbohydrate Intolerance Associated with Eczemas*—Samuel Ayres, Jr., M. D., 2007 Orange Street, Los Angeles.

   (1) A preliminary report is presented dealing with the glucose tolerance reaction in a series of thirty-six consecutive cases of typical eczema. (2) The tests were made in two laboratories, each using the Folin-Wu colorimetric technic. (3) The fasting blood sugar values in these cases of eczema were not found to be abnormally high except in a few cases. (4) Very striking deviations from normal were found, however, at the one and two-hour periods following the administration of the test glucose solution. Of the thirty-six eczema cases, 33.3 per cent showed 200 mgs. or more of glucose per 100 cc. 2 of blood at the end of one hour in contrast with only 3.6 per cent of 300 normal controls; and 16.6 per cent of the eczema cases showed 200 mgs. or more at the end of two hours in contrast with only .3 per cent of 253 normal controls. (5) Of the thirty cases which were tested at the end of three hours, 40 per cent had not returned to a conservative estimate of normal (110 mgs.).
4. *Red Light in the Treatment of Dermatoses*—Harry P. Jacobson, M. D., Broadway Central Building, Los Angeles.
5. *The Relationship of Metabolic Toxins to Dermatoses*—Oscar Schroeter, M. D., Union Oil Building, Los Angeles.

Tuesday, May 13, 10 a. m.

Clinical Session at the Los Angeles General Hospital.

SECOND MEETING

Wednesday, May 14, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Cancer of the Lip Treated by Radium*—Douglas W. Montgomery, M. D., 323 Geary Street, San Francisco; George D. Culver, M. D., 323 Geary Street, San Francisco.
3. *Ringworm of the Scalp*—Hiram E. Miller, M. D., 380 Post Street, San Francisco.
4. *Morphologic Instability of Cutaneous Lesions*—Moses Scholtz, M. D., Brockman Building, Los Angeles.

   Dynamics versus statics in dermatology. Static point of view prevailing in pathology and morphology. Static conception of clinical entity-unit of current dermatologic classification. Morphologic phenomena unexplainable under static point of view: 1. Borderline forms. 2. Polymorphism. 3. Combined lesions. 4. Freakish forms. 5. Morphologic metamorphosis. Dynamic conception of cutaneous reaction introduced by Brocq. Strong and weak features of Brocq's classification. Suggested modification of Brocq's ideas. Theoretical and practical advantages of the dynamic point of view.

EYE, EAR, NOSE, AND THROAT SECTION

HARVARD MCNAUGHT, M. D., Chairman,
Butler Building, San Francisco.

PERCIVAL DOLMAN, M. D., Secretary,
Flood Building, San Francisco.

FIRST MEETING

Monday, May 12, 2 p. m.

1. Chairman's Address: *Diagnosis and Treatment of Chronic Ethmoidal Conditions*—Harvard McNaught, M. D., Butler Building, San Francisco.
   Secretary's Report.
2. *Treatment of Lime Burn of the Eye*—Otto Barkan, M. D., 516 Sutter Street, San Francisco.
3. *Blood Staining of the Cornea*—Charles Maghy, M. D., 1136 W. Sixth Street, Los Angeles.
4. *Plastic Surgery of the Nose.* (Lantern slides)—George Warren Pierce, M. D., 870 Market Street, San Francisco.

SECOND MEETING

Tuesday, May 13, 10 a. m.

1. *Surgical Treatment of Acute and Chronic Conditions of the Antrum of Highmore*—Cullen F. Welty, M.D., 210 Post Street, San Francisco.
2. *The Present-Day Advance in Plastic Surgery With Special Reference to the Correction of Deformities of the Nose and About the Orbit*—J. Paul de River, M. D., United States Veterans' Bureau, San Francisco.
3. *The Importance of Accuracy in Refraction Work*—M. Morgan Cloud, M. D., Baker-Detwiler Building, Los Angeles.
4. *Allergies in Relation to Rhino-Laryngology*—George Piness, M. D., Medical Office Building, Los Angeles.

THIRD MEETING

Wednesday May 14, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Testing the Cochlea Directly—With Presentation of the New Instrument for Testing Hearing*—Isaac H. Jones, M. D., 448 Arden Boulevard, Los Angeles.
3. *A New Method of Treatment for Chronic Laryngeal Stenosis*—Edward Cecil Sewall, M. D., 3515 Pacific Avenue, San Francisco.
4. *Foreign Bodies in Respiratory and Upper Digestive Tracts* (Lantern Slides)—Simon H. Jesberg, M. D., 1151 W. Sixth Street, Los Angeles.
5. *Removal of Tonsils by Electro-Coagulation*—Albert C. Carlton, M. D., 117 Post Street, San Francisco.

GENERAL MEDICINE SECTION

A. S. GRANGER, M. D., Chairman,
2007 Orange Street, Los Angeles.

ERNEST S. DU BRAY, M. D., Secretary,
Flood Building, San Francisco.

FIRST MEETING

Tuesday, May 13, 10 a. m.

1. Chairman's Address and Secretary's Report.
2. *Disturbed Metabolism as a Background for Disease*—Lovell Langstroth, M. D., 240 Stockton Street, San Francisco.

   The relation of heredity, feeding, exercise, rest, and sun exposure to metabolic processes and the health of the individual. A broader conception of metabolism. Degenerative disease or infection as expressions of its disturbance.
3. *The Present Status of the Treatment of Diabetes with Insulin*—W. D. Sansum, M. D., Third Avenue and Bath Street, Santa Barbara; N. R. Blatherwick, Ph. D., Third Avenue and Bath Street, Santa Barbara.

   A. A brief summary of the methods used and the results obtained in a group of extremely severe patients who have had insulin for one year or longer. B. The glucose equivalent of the insulin rabbit unit. C. A review of our attempts at mouth medication, together with the results obtained.

4. *Symptoms Associated with the Use of Insulin in Diabetes*—Bertnard Smith, M. D., 1032 West Eighteenth Street, Los Angeles.

   1. Symptoms of insulin overdosage. 2. Symptoms appearing after periods of insulin therapy. Analysis of these complex symptoms. Comparison of these complex symptoms with those of insulin overdosage. 3. Laboratory studies of selected cases that show these complex symptoms.

5. *The Frequency of Endogenous Endocrine Obesity and Its Treatment by Organotherapy* (Illustrated by lantern slides)—H. Lisser, M. D., 240 Stockton Street, San Francisco.

   It is generally thought that the vast majority of obese persons eat voraciously and exercise insufficiently, and that this obesity is exogenous. This view is probably exaggerated. Many fat people eat moderately, or even meagerly, and are normally active. Many thin individuals consume large quantities of food, and are not athletic. Slides will be shown of various types of endocrine obesity in children and adults; hypophyseal and gonadal; the hypophyseal predominate. The value of basal metabolism estimations is discussed. These patients are difficult to reduce by diet and exercise alone; reasons given; organotherapy is indicated and usually efficacious. It is not harmful, if properly controlled. Examples given.

SECOND MEETING

Wednesday, May 14, 2 p. m.

1. *Treatment of Intestinal Protozoan Infections with Mercurochrome 220* — George A. Gray, M. D., Twohy Building, San Jose.

   Being a report on the treatment of twenty cases of infestation with Giardia enterica, Chilomastix, Councilmania and Endamoeba dysenteriae by means of Mercurochrome 220, administered by mouth. Stools have remained negative for as long as two to six months after treatment. All stool analyses were made by the State Hygienic Laboratory at Berkeley.

2. *The Clinical Data Obtained from the Study of a Series of Cases of Pernicious Anemia* — Edwin L. Bruck, M. D., 240 Stockton Street, San Francisco.

   Introduction with historical data. The presence of certain constant findings in the histories and in the examination of these patients. Attempts to explain these findings by clinico-pathological and autopsy data. The futile search for definite etiology. The course of the disease. The aim of therapy. The influence of therapy. Conclusions.

3. *The Treatment of Post-Influenzal Asthma*—Samuel H. Hurwitz, M. D., 516 Sutter Street, San Francisco.

   As an aftermath of the waves of influenza, which began with the great pandemic of 1918, there are now a large number of patients who are suffering from some of its sequelae. Of these we have found asthmatic bronchitis to be an extremely important sequel and one not sufficiently emphasized. During the routine treatment of over several hundred asthmatics during the past five years we became impressed with the observation that, of those instances of bacterial asthma which we were called upon to treat, two groups of cases responded better than the others. Those were the children whose asthmatic bronchitis followed upon some acute respiratory infection such as whooping cough, broncho-pneumonia, grippe, a neglected bronchitis or a tonsillitis, and secondly, those adults and children whose asthmatic paroxysms were definitely the outcome of an attack of influenza of varying severity. The role of infection and the treatment of bacterial asthma in childhood has been presented in a former communication. In this paper we wish to emphasize the value of properly prepared and careful administered autogenous vaccines in the post-influential group, and to call attention to the end-results obtained by this mode of therapy.

4. *Baumgarten's Disease*—V. R. Mason, M. D., 919 Pacific Mutual Building, Los Angeles.

   (1) Report of cases which have been classified under the term "Von Baumgarten's disease." (2) Discussion of their relationship to the umbilical vein, as well as their relationship to ordinary cirrhosis of the liver. (3) Venous hums in the episgastrium which may accompany diseased conditions.

5. *Report of 300 Cases of Pulmonary Tuberculosis Treated with Partial Antigens (Much-Deycke) During the Last Three Years.* (Lantern Slides)—Max Rothschild, M. D., 350 Post Street, San Francisco.

   Differentiation of partial antigens and tuberculins. Indication for treatment with partial antigens based on prevailing pathological condition and how determined.

THIRD MEETING

Thursday, May 15, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.

2. *Vincent's Disease and Parasyphilis* — F. F. Gundrum, M. D., Capital National Bank Building, Sacramento.

   An acute contagious disease due to a specific cause. Generally local, but also producing septicemia. Widely disseminated throughout the world. Common sites of infection. Evidences of invasion. A fatal case. Skin rashes. Parasyphilis of Stern.

3. *The Treatment of Chronic Arthritis* — Leonard W. Ely, M. D., Lane Hospital, San Francisco.

   In order to treat successfully the diseases of any organ, an idea at least of their pathology is necessary. Inflammation in the joints forms no exception to this rule. Its treatment is comparatively simple in most instances. Sketch of the various forms of arthritis, and the treatment of each.

4. *Changes in Heart Area as the Result of Decompensation and Compensation — With Report of Twenty Cases* — Donald Jackson Frick, M. D., 1136 West Sixth Street, Los Angeles.

   This report was prompted by lack of accurate data on changes of heart outline. Brief review of method of obtaining cardiac areas by use of orthodiagrams. Discussion of findings in twenty cases of decompensation. Tables showing lesions, etiologic factors, electrocardiographic findings and heart areas. Brief review of four of the more interesting cases, with lantern slides demonstrating change in cardiac outline. Conclusions.

5. *Coronary Obstruction* — James F. Churchill, M. D., Timken Building, San Diego.

   Acute coronary obstruction one of the grave cardiac accidents, though not necessarily fatal. Anatomy of the coronary vessels. Discussions of variations in the clinical picture. Report of cases. Remarks on a differential diagnosis, prognosis and treatment.

6. *Heart Pain*—Thomas H. Kelly, M. D., 240 Stockton Street, San Francisco.

   The origin of heart pain is an exhausted heart muscle. Its location, character and occurrence are variable. Its occurrence is brought about usually through heart strain, and the factors influencing its origin and occurrence are discussed. The prognosis must be guarded, and treatment is directed toward providing all possible cardiac rest compatible with an endurable existence. Examples are cited showing varieties of causes at work, and the results of treatment.

GENERAL SURGERY SECTION

Rea Smith, M. D., Chairman,
Medical Office Building, Los Angeles.

Leo Eloesser, M. D., Secretary,
Butler Building, San Francisco.

FIRST MEETING

Monday, May 12, 2 p. m.

1. Chairman's Address and Secretary's Report.
2. *Cautery Knife Excision of the Malignant Uterus. (Technique and Results)* — James F. Percy, M. D., 1030 South Alvarado Street, Los Angeles.
   This paper urges the substitution of the cautery knife for the usual sharp dissection in the removal of the uterus and adnexa. The former neither encourages the dissemination of the disease into uninvaded areas nor stimulates it into new virulence.
3. *Doubtful Tumors: Shall We Cut Out a Piece for Diagnosis?*—A. R. Kilgore, M. D., 391 Sutter Street, San Francisco.
   (1) In experimental animals—influence of trauma and of surgical section on metastasis of tumors. (2) Clinical evidence. (a) Necessity of particularizing with reference to organ or tissue from which tumor arises. (b) Effect on statistics of cures of failure to recognize different degrees of malignancy in tumors arising from the same tissue. (3) Safe procedures in cancers of: (a) Lip; (b) Mouth; (c) Skin; (d) Breast; (e) Cervix; (f) Fundus of uterus.
4. *Some Unusual Bone Cases* (With Lantern Slides)— W. W. Richardson, M. D., Brockman Building, Los Angeles.
   Acute non-suppurative osteomyelitis with sequestration. Report of two cases, onset, course, X-ray appearance as in the ordinary suppurative type.
5. *Factors Influencing Morbidity and Mortality of Exophthalmic Goiter* — John Hunt Shephard, M. D., Growers' Bank Building, San Jose.
   (1) Present statistics: Types and severity of thyroid intoxication not segregated in present statistics. (2) Early diagnosis: Diagnosis possible before classical text-book picture develops. (3) Pre-operative care: Evaluation of patient's cardiac and nervous reserve. Establishment of water balance; use of iodine. (4) Operative Procedure: Selection of cases for multiple-stage operation. (5) Post-operative care: Cure not immediate. Supervision of post-operative life.
6. *Importance of Differential Leucocyte Count in Inflammatory Conditions* — Newton Evans, M. D., Loma Linda; Phillips J. Tunnell, M. D., Loma Linda.
   Meaning of increase of leucocytes—indicator of degree of reaction against infection. Increase of polymorphonuclears—indicator of severity of infection. Differential count of greater importance than total count. Danger of misinterpreting absence of leucocytosis in severe infections. Relation of polynucleosis to suppuration. Report of cases. Walker's Index of Resistance. Exceptions.

SECOND MEETING

Tuesday, May 13, 2 p. m.

Symposium on Chronic Gall-bladder Disease

1. *Treatment of Chronic Cholecystitis* — W. W. Boardman, M. D., 350 Post Street, San Francisco; G. D. Schoonmaker, M. D., 350 Post Street, San Francisco.
   Frequency of the occurrence; often unrecognized as the cause of chronic gastro-intestinal; nervous and other symptoms. General confusion regarding the methods of treatment; prophylactic measures; diet; drugs; Lyon Meltzer method, with results in a series of cases. What cases are surgical?
2. *Conservative Treatment of Gall-bladder Conditions*— H. P. Hill, M. D., 177 Post Street, San Francisco; R. V. Lee, M. D., 177 Post Street, San Francisco.
3. *Obstruction of the Cystic Duct and Its Surgical Consequences* (Lantern Slides) — A. S. Lobingier, M. D., Merritt Building, Los Angeles.
4. *Surgical Aspects of Gall-bladder Diseases*—Guy Cochran, M. D., Pacific Electric Building, Los Angeles.
5. *Gall-bladder Diseases from a Surgical Standpoint*— J. J. Van Kaathoven, M. D., 1136 West Sixth Street, Los Angeles.
   Discussion opened by Rea Smith, M. D., Medical Office Building, Los Angeles; A. W. Lobingier, M. D., Merritt Building, Los Angeles.
6. *Acute Pancreatisis* (With Report of Four Cases) — C. G. Toland, M. D., Pacific Mutual Building, Los Angeles.
   A brief description of acute pancreatitis and its characteristic differentiating symptoms, followed by a report of four cases.

THIRD MEETING

Wednesday, May 14, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Unusual Conditions in the Duodenum and Their Significance*—Gunther W. Nagel, M. D., Mayo Clinic, Rochester, Minn.
   Congenital stenosis in adult, with case history. Duodenal diverticula (acquired). Carcinoma of duodenum: diffculty of diagnosis, and poor prognosis.
3. *Esophageal Diverticula.* (Lantern Slides) — E. C. Moore, M. D., Merchants National Bank Building, Los Angeles.
   Anatomy of the esophagus. Etiology: Inflammatory lesion. Congenital nature. Symptoms: Signs of throat irritation. Difficult swallowing. Changes in physical condition. Diagnosis: Characteristic history. X-ray findings. Esophagoscopy. Classifications: Pulsion. Traction. Severity, depending on size and location. Treatment. Traction: Medical treatment. Pulsion: Surgery, types of operation, after care. Case histories. Illustrated by slides.
4. *Diverticulitis of the Large Intestine*—Maurice Kahn, M. D., Brockman Building, Los Angeles.
5. *Surgical Treatment of the Diseases of the Colon*— Charles E. Phillips, M. D., Pacific Mutual Building, Los Angeles.
   Rest and cleanliness are the first essentials to insure success in the treatment of diseases of the colon. A simple cecostomy at the margin of the ileo-cecal valve completely sidetracks the large bowel as the valve presents through the wound. The operation, care, and closure of the same is a simple matter.
6. *Cancer of the Rectum*—M. S. Woolf, M. D., 240 Stockton Street, San Francisco.
   Stagnation of bowel contents as a factor in intestinal cancer. Analysis of cases of cancer of the rectum in the University of California Hospital according to age, signs, and symptoms. Significance of pain, constipation, and bleeding in diagnosis. Duration and position of the growth. Mode of spread. Earliest appreciable warning of the disease. Treatment.

INDUSTRIAL MEDICINE AND SURGERY SECTION

Ross W. Harbaugh, M. D., Chairman,
350 Post Street, San Francisco.

W. C. Adams, M. D., Secretary,
Medical Arts Building, Oakland.

FIRST MEETING

Monday, May 12, 8 p. m.

1. Chairman's Address and Secretary's Report.
2. *Lengthening the Quadriceps Tendon for Stiff Knee*— George J. McChesney, M. D., 870 Market Street, San Francisco.
3. *Fracture of the Surgical Neck of the Humerus* (Lantern Slide Demonstrations)—Emmet Rixford, M. D., 1795 California Street, San Francisco.
4. *Previous Pathology Modifying Results in Industrial Skeletal Injuries* — S. J. Hunkin, M. D., 1155 Bush Street, San Francisco.

SECOND MEETING

Tuesday, May 13, 10 a. m.

Open Meeting for the consideration and discussion of industrial medicine questions.

THIRD MEETING

Thursday, May 15, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Relation of Head and Back Trauma to Traumatic Neurosis* — Gilbert M. Barrett, M. D., 2740 Lake Street, San Francisco.
3. *The Industrial Aspects of Abdominal Conditions*—Edwin I. Bartlett, M. D., 240 Stockton Street, San Francisco.
4. *When Is a Hernia?*—Phillip H. Stephens, M. D., Pacific Electric Building, Los Angeles.

NEUROPSYCHIATRY SECTION

C. L. Tranter, M. D., Chairman,
209 Post Street, San Francisco.

Glenn E. Myers, M. D., Secretary,
Marsh-Strong Building, Los Angeles.

FIRST MEETING

Monday, May 12, 2 p. m.

Symposium on Child Guidance

1. *Reasons for Child Guidance Clinics* — Robert Lewis Richards, M. D., 240 Stockton Street, San Francisco.
   (1) Lessons learned from many surveys in many places. (2) Modifiable elements in the personality problems. (3) Stages and stresses in mental growth and lessons therefrom. (4) Is a Child Guidance Clinic a duplication of existing work? What are its relation to other medical sociological or educational work in general.
2. *Mental Health of Children—A National Asset*—V. V. Anderson, M. D., Director Division of Prevention of Delinquency of the National Committee for Mental Hygiene, New York City.
3. *The Habit Clinic for Pre-School Children* — Sydney Kinnear Smith, M. D., Medical Building, Oakland.
   (1) A brief review of the development of mental hygiene as applied to the problems of childhood. The appearance of the habit clinic idea in this country, with special reference to the recent work in the State of Massachusetts. (2) A general survey of the scope of a habit clinic with resumé of typical cases, leading to a discussion of the role of faulty habits in childhood as in influencing adult adaption and mental health. (3) The organization and technique of a habit clinic, and a description of methods of re-education employed.
4. *Adult Delinquency: Its Prevention by Mental Hygiene in Childhood*—Joseph Catton, M. D., 209 Post Street, San Francisco.
   Consideration of cases. The role of childhood mental hygiene in (a) dealing with hereditary factors, (b) prevention of disease and accident or caring for them when they occur, and (c) guidance of intellectual, emotional, moral, religious and social development—all these toward the prevention of later criminality or other evidence of maladjustment.
5. *The Problem Case*—Richard W. Harvey, M. D., 380 Post Street, San Francisco.
   Definition of the term. Causative factors in the development of problem cases. Relation of problem cases to vocational training. Social aspects of problem cases. Results attained in rehabilitating veterans. Results attained in handling private cases. Relation of clinics and training centers to problem cases.
6. *Experience in Los Angeles in Child Guidance Work*—Aaron J. Rosanoff, M. D., 2007 Orange Street, Los Angeles.
   Negotiations with the National Committee for Mental Hygiene to secure for one year a demonstration Child Guidance Clinic for Los Angeles. Requirements of the National Committee. Creation of the Menal Hygiene Organization of Los Angeles County. Plans for meeting the requirements of the National Committee. Clinic staff. Volunteer staff. Co-operation of social agencies. Type of cases selected. Clinic procedure. Co-operation of social agencies. First three months' work of the Child Guidance Clinic.
   Discussion on all of the above papers opened by Ray Lyman Wilbur, M. D., Stanford University, Palo Alto; William Palmer Lucas, M. D., University California Hospital, San Francisco; Robert Langley Porter, M. D., 380 Post Street, San Francisco.

SECOND MEETING

Tuesday, May 13, 2 p. m.

1. Chairman's Address: *The Surgery of the Sympathetic System*—Charles L. Tranter, M. D., 209 Post Street, San Francisco.

   Secretary's Report.

2. *Osteomyelitis of the Skull* — Howard W. Fleming, M. D., 291 Geary Street, San Francisco.
   Brief review of the literature and reported cases. Summary and outline of cases under personal observation. Etiological factors. Symptomatology and clinical course. Complications. Treatment. Prognosis. Conclusions.
   Discussion opened by Edward B. Towne, M. D., Stanford University Hospital, San Francisco; Carl W. Rand, M. D., 870 Market Street, San Francisco.
3. *The Value of Cerebral Pneumograms in the Localization of Tumors of the Brain* — Edward B. Towne, M. D., Stanford University Hospital, San Francisco.
   A certain proportion of tumors of the brain cannot be definitely localized, especially those lying in the frontal and temporal lobes. Palliative decompression may stop headaches and save vision, but frequently allows a benign tumor to grow beyond the operative stage. Roentgenograms of air-filled ventricles show a deformity caused by encroachment of the tumor; thus allowing exposure of operable tumors, and preventing useless extensive expirations for inoperable tumors. Case reports and lantern-slide demonstration.
   Discussion opened by Thomas G. Inman, M. D., 870 Market Street, San Francisco; Carl W. Rand, M. D., 870 Market Street, San Francisco; Howard C. Naffziger, M. D., 291 Geary Street, San Francisco.
4. *The Cerebral Subarachnoid Space and Its Importance in Surgery and Medicine*—Charles E. Locke Jr., M. D., University California Hospital, San Francisco; Howard C. Naffziger, M. D., 291 Geary Street, San Francisco.
   The arachnoid membrane in neurosurgical problems is as important as is the peritoneum in abdominal surgical conditions. It is not only concerned with both acute and chronic infections, but from it also certain tumors take their origin. We are fortunate in that the fluid contained in the subarachnoid space, that is, the cerebrospinal fluid, is easily available for study, thus shedding light indirectly upon the condition of the arachnoid membrane. Because little has been written concerning the arachnoid membrane and the subarachnoid space, very few of us have an accurate conception as to its extent. In hopes of clarifying this obscure conception, we have made celloidin casts of the cerebral subarachnoid spaces and ventricles, photographs and drawings of which will be thrown upon the screen. A thorough knowledge of the subarachnoid space is of utmost importance in the localization of an extraventricular obstruction in hydrocephalus. It is also of importance in the understanding of clinical signs associated with acute and chronic forms of meningitis. Never, however, has our ignorance of the subarachnoid space been more in evidence than when we commenced two or three years ago to at-

tempt interpretations of cerebrograms and ventriculograms.

Discussion opened by Milton B. Lennon, M. D., 380 Post Street, San Francisco; Carl W. Rand, M. D., 870 Market Street, San Francisco; Edward B. Towne, M. D., Stanford University Hospital, San Francisco.

5. *Complications Following Brain Injuries* — Carl W. Rand, M. D., 870 Market Street, San Francisco.

Cases of skull fracture associated with intracranial hemorrhage, hemiplegia, hemianopsia, aphasia, brain abscess, meningitis, or epilepsy. Lantern slides.

Discussion opened by Edward B. Towne, M. D., Stanford University Hospital, San Francisco; Howard C. Naffziger, M. D., 291 Geary Street, San Francisco; Samuel D. Ingham, M. D., 1920 Orange Street, Los Angeles.

6. *Further Points in the Physiology of Brain Surgery*— Cecil E. Reynolds, M. D., 1965 Cheremoya Avenue, Hollywood.

(1) Various methods of approach to the cranial contents. (2) Physiologically necessary exceptions to mechanical ideals. (3) Effects of negative pressure. (4) Examples in cases of extradural hemorrhage, subarachnoid hemorrhage and arachnoid cysts. (5) Essential difference in the symptoms and results of extradural and intradural hemorrhage. Differential diagnosis and complications in each case. (6) Effect of combined dural adhesions and brain shrinkage in old age. (7) Comparison of the wet and dry operations upon the brain and cord. Explanation of the Victor Horsley technique.

THIRD MEETING

Wednesday, May 14, 2 p. m.

1. *Serous Meningitis and Arachnitis* — Edward W. Twitchell, M. D., 909 Hyde Street, San Francisco.

Early work of Quincke. Case reports of Placzek, Oppenheim, Unger, Spiller, and others. Recent work of Claude. Conception of pathology and pathegenesis. Personal observations of cases of meningismus relieved by spinal drainage. Report of case of arachnitis circumscripta relieved by operation.

Discussion opened by Thomas G. Inman, M. D., 870 Market Street, San Francisco; Howard W. Fleming, M. D., 291 Geary Street, San Francisco.

2. *Radiographs of the Head in Childhood from the Clinical Standpoint*—Henry Douglas Eaton, M. D., 1136 West Sixth Street, Los Angeles.

A study of 250 radiographs of the head in children, with an attempt to correlate the X-ray findings with the clinical picture.

Discussion opened by Rolla G. Karshner, M. D., 1136 West Sixth Street, Los Angeles.

3. *The Progression Reflex: Its Manifestation and Value in Diseases of the Central Nervous System*—Isadore Leon Meyers, M. D., Brockman Bldg., Los Angeles.

The Flexion Reflex of the Spinal Animal. The Reflex of Defense. Reflex "Stepping." The Flexion Reflex in Man. The Progression Reflex as observed by the author. Its Relationship to the Babinski Toe Response. Its Diagnostic Value.

The Reflex Nervous Disorders as Described by Babinski—A. R. Timme, M. D., Brockman Building, Los Angeles.

(1) History: First described by Hunter, Charcot, and Vulpian. Confused with muscular atrophy, secondary to arthritic conditions. (2) Speculations as to Pathogenesis. (3) Symptomatology: Contractures and paralyses. Vasomotor changes. Changes in muscular excitability. Changes in electrical excitability. Changes in tonus. Changes in reflexes. Changes in sensation. (4) Differential diagnosis. (5) Prognosis and treatment. (6) Presentation of case.

Discussion opened by S. D. Ingham, M. D., 1920 Orange Street, Los Angeles.

5. *Consideration of Progressive Muscular Dystrophy with Pseudo-hypertrophy from an Endocrine Standpoint.* (Illustrated by short motion picture and lantern slides) — Clifford A. Wright, M. D., Auditorium Building, Los Angeles.

Introductory discussion; classification of cases; hereditary and familial tendencies; usual progress of disease; general symtomatology; endocrine symptoms; X-ray findings; case histories; endocrine treatment; orthopedic treatment; results in cases treated.

6. *Observations on the Treatment of Lethargic Encephalitis*—Julian M. Wolfsohn, M. D., 177 Post Street, San Francisco.

Report based on seventy cases treated by various methods. 1. Definition. 2. Anatomical classification, while inadequate, gives a working basis for diagnosis and treatment. 3. Clinical types of cases treated, with examples. 4. Treatment: (1) Internal medicaments; (2) Hypodermic medicaments; (3) Serum treatment; (4) Intraspinal autoserotherapy; (5) Combined serum and intraspinal autoserotherapy. 5. Conclusions.

Discussion opened by Ross Moore, M. D., 520 West Seventh Street, Los Angeles; Albert H. Rowe, M. D., 119 Thirteenth Street, Oakland.

FOURTH MEETING

Thursday, May 15, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.

2. *The Inferiority Complex and Its Psychiatric Significance*—Harold W. Wright M. D., 870 Market Street, San Francisco.

This complex considered as always acquired, even when associated with a constitutional inferiority. The far-reaching and lasting effects of childhood impressions obtained from the psychological environment are the real causes of this complex. Therefore, it is a preventable disorder. Its effects are of great importance in respect to the developments of psychoneuroses and psychoses, inefficiency, and friction, maladjustment and failure in the social, industrial, and spiritual life. Some of the psychoses are considered as symptomatic expressions of this complex which has been for years causing a psychoneurosis. Even in psychoses of toxic and organic causation, the symptomatology is dependent in part upon the previous psychological make-up and colored thereby. The importance of psychiatric knowledge and methods of approach in relation to preventive pediatrics.

Discussion opened by A. J. Rosanoff, M. D., 2007 Orange Street, Los Angeles; V. H. Podstata, M. D., Livermore; Ross Moore, M. D., 520 West Seventh Street, Los Angeles.

3. *The Psycho-neuroses: Psychastenia, Neurasthenia, Hysteria, Ambulatory Automatism, with Special Reference to a Certain Method of Treatment*—Thomas J. Orbison, M. D., 2007 Orange Street, Los Angeles.

My paper will be based upon 300 cases that have been under my personal observation and of which I have case histories. The method of treatment, which I shall discuss, I have called the "Training Camp Method."

Discussion opened by Henry D. Eaton, M. D., 1136 West Sixth Street, Los Angeles; V. H. Podstata, M. D., Livermore.

4. *Affectivity: Its Importance in Practical Medicine* — Charles Louis Allen, M. D., Los Angeles Railway Building, Los Angeles.

Definition of affectivity. Psycho-physiology. Its influence in disease processes and on symptoms both mental and physical. Evaluation of this factor and the diagnostic, prognostic and therapeutic indications which may be drawn from so doing.

Discussion opened by Edward A. Franklin, M. D., Bank of Italy Building, Los Angeles.

5. *Treatment of Morbid Fear*—Samuel D. Ingham, M.D., 1920 Orange Street, Los Angeles.

Introduction: Covering a general discussion of the problems relating to the disturbances of fear instinct and the consideration of the position occupied by fear in neuro-biology. (1) Morbid fears and the

mechanism of their production. (2) The differentiation of morbid fears as compared to normal fears. (3) The biologic value of the fear instinct, and the destructive effect of excessive fear reactions. (4) The character of morbid fears compared to tissue allergies; sensitization and desensitization. (5) The treatment of morbid fears: Analysis of individual case. Educating the patient. Desensitization.

Discussion opened by Nathaniel H. Brush, M. D., San Marcos Building, Santa Barbara; Robert Lewis Richards, M. D., 240 Stockton Street, San Francisco.

6. *Some Fears of Endocrine Origin* — Edward Huntington Williams, M. D., Pacific Mutual Building, Los Angeles.

General discussion of the subject, with some practical illustrations. Suggestions for treatment.

Discussion opened by Ernest B. Hoag, M. D., 325 Oak Lawn, Pasadena; George G. Hunter, M. D., Pacific Mutual Building, Los Angeles.

7. *The Practitioner and the Diagnosis of General Paresis* —Nathaniel H. Brush, M. D., San Marcos Building, Santa Barbara.

General paresis can simulate any known mental disorder. The earliest symptoms of paresis may be entirely somatic, and the patient's first complaint may have no reference to the central nervous system. The text-books give excellent descriptions of the standard paretic, but it is the paretic who is not standardized that causes the difficulty. Not all paretics show Argyll-Robertson pupils, the reflexes are often exaggerated in the various neuroses, and often all that the patient shows is the so-called neurasthenic reaction. The practitioner should be on his guard in the presence of any slight physical abnormalities coupled with the history of a slight memory failure, and a mental and moral delapidation. He should search further for other difficulties, and above all a thorough serological examination is indicated.

Discussion opened by S. D. Ingham, M. D., 1920 Orange Street, Los Angeles; V. H. Podstata, M. D., Livermore.

OBSTETRICS AND GYNECOLOGY SECTION

A. B. Spalding, M. D., Chairman,
Stanford University Hospital, San Francisco.

Peter O. Sundin, M. D., Secretary,
H. W. Hellman Building, Los Angeles.

FIRST MEETING

Monday, May 12, 2 p. m.

Symposium on Carcinoma of the Uterus

1. Chairman's Address: *Mortality Rates of Carcinoma of the Uterus in California* — A. B. Spalding, M. D., Stanford University Hospital, San Francisco.

Secretary's Report.

2. *Recent Advances in Cancer Research* — Ludwig A. Emge, M. D., Stanford University Hospital, San Francisco.

In this review it is attempted to correlate in a concise and comprehensive form, the various lines of cancer research, including the questions on inheritability, irritability, serum diagnosis, and treatments not radiological in nature.

3. *The Prevention of Carcinoma of the Uterus*—Roland E. Skeel, M. D., Westlake Professional Building, Los Angeles.

Discussion opened by Frank R. Girard, M. D., 870 Market Street, San Francisco.

4. *Treatment of Early Carcinoma of the Uterus*—John W. Sherrick, M. D., 350 Twenty-ninth Street, Oakland.

Discussion opened by William H. Gilbert, M. D., Brockman Building, Los Angeles.

5. *Treatment of Inoperable Carcinoma of the Uterus*—Albert Soiland, M. D., 1407 South Hope Street, Los Angeles.

Reviews briefly history of radiation treatment alone, and in conjunction with surgery in uterine cancer. Discusses problems connected with the work. Ventures the opinion that, with modern refinement of treatment technique compatible with observed immediate effects, radiation offers perhaps better curative figures than those named by conservative surgeons.

Discussion opened by A. J. Lartigau, M. D., 391 Sutter Street, San Francisco.

SECOND MEETING

Wednesday, May 14, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.

Symposium on Caesarean Section

2. *Are the Present Indications for Caesarean Section Justifiable?*—Lyle McNeile, M. D., Pacific Mutual Building, Los Angeles.

Discussion opened by H. A. Stephenson, M. D., 516 Sutter Street, San Francisco.

3. *Caesarean Section for Haemorrhages*—Reginald Knight Smith, M. D., 391 Sutter Street, San Francisco.

Discussion opened by Karl Schaupp, M. D., 516 Sutter Street, San Francisco.

4. *Caesarean Section for Toxemia of Pregnancy*—E. M. Lazard, M. D., 2007 Orange Street, Los Angeles.

Toxemias of pregnancy essentially medical complication. Two general clinical classes of toxemias: first, those not improving or getting progressively worse under treatment; second, those which come under observation, profoundly toxic or eclamptic. Interruption of pregnancy indicated in those cases not improved or getting progressively worse under treatment. Method of termination of pregnancy dependent on obstetric conditions present. Caesarean section indicated when advisable to terminate pregnancy in primiparae with rigid cervices undilated os, where pelvic measurements are small. Rational treatment of toxemias, medical; with surgical termination of pregnancy or labor, a necessary help in a limited class of cases.

Discussion opened by Adelaide Brown, M. D., 909 Hyde Street, San Francisco.

5. *Caesarean Section for Pelvic Obstruction* — Alice F. Maxwell, M. D., 1701 Bush Street, San Francisco; Frank Lynch, M. D., University of California Hospital, San Francisco.

Discussion opened by Titian Coffey, M. D., 1136 West Sixth Street, Los Angeles.

ORTHOPEDIC SURGERY SECTION

H. H. Markel, M. D., Chairman,
380 Post Street, San Francisco.

John C. Wilson, M. D., Secretary,
Medical Office Building, Los Angeles.

FIRST MEETING

Monday, May 12, 8 p. m.

1. Chairman's Address and Secretary's Report.

Symposium on Chronic Back Pain

2. *The Neurological Aspect of Low-back and Sciatic Pain* —Milton Lennon, M. D., 380 Post Street, San Francisco.
3. *Gynecological Conditions as a Cause of Backache and Sciatica*—Frank W. Lynch, M. D., University California Hospital, San Francisco.
4. *The Prostate and Its Influence on Low-back Pain*— L. P. Player, M. D., 516 Sutter Street, San Francisco.
5. *Focal Infection as Related to Chronic Back Pain*— Herold P. Hare, M. D., Westlake Professional Building, Los Angeles.
6. *Anomalies and Abnormalities of the Lumbo-Sacral Spine as Etiological Factors in Chronic Back Pain.* (Lantern slides) — William B. Bowman, M. D., Brockman Building, Los Angeles.
7. *Chronic Back Pain from a Mechanical Viewpoint*— John Dunlop, M. D., Pacific Mutual Building, Los Angeles.

Discussion opened by Walter I. Baldwin, M. D., 380 Post Street, San Francisco; C. L. Lowman, M. D., Brockman Building, Los Angeles.

SECOND MEETING

Tuesday, May 13, 2 p. m.

1. *Treatment of the Helpless Arthritic Patient* — Harry Leslie Langnecker, M. D., Stanford University Hospital, San Francisco.
   Discussion opened by C. L. Lowman, M. D., Brockman Building, Los Angeles.
2. *Early Rachitic Changes in the Femur and Tibia*—H. W. Chappel, M. D., 134 South Morton Avenue, Los Angeles.
   Discussion opened by George J. McChesney, M.D., 380 Post Street, San Francisco.
3. *The Treatment of Hip Flexion Contracture of the Hip* —Steele F. Stewart, M. D., Union Bank Building, Los Angeles.
   Discussion opened by Lionel D. Prince, M. D., 870 Market Street, San Francisco.
4. *Arthroplasty of the Elbow* (lantern slides)—William R. MacAusland, M. D., 240 Newbury Street, Boston Mass.
   Discussion opened by Walter I. Baldwin, M. D., 380 Post Street, San Francisco; C. L. Lowman, M. D., Brockman Building, Los Angeles.
5. *Metatarso-Phalangeal Osteochondritis* (Koehler's disease) — A. Gottlieb, M. D., Consolidated Realty Building, Los Angeles.
   Discussion opened by Edward C. Bull, M. D., 291 Geary Street, San Francisco.
6. *Delayed Ossification of the Tarsus in Congenital Clubfeet* (lantern slides)—Edward N. Reed, M. D., 824 Eighth Street, Los Angeles.
   Discussion opened by Trusten M. Hart, M. D., Brockman Building, Los Angeles.

THIRD MEETING

Thursday, May 15, 2. p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *The Operative Treatment of Abnormalities of the Fifth Lumbar Vertebra* (lantern slides) — Alfred E. Gallant, M. D., Van Nuys Building, Los Angeles; Walter C. Koebig, M. D., Story Building, Los Angeles.
3. *Traumatic Fractures of the Articular Processes of the Fifth Lumbar Vertebra*—Thomas A. Stoddard, M.D., 291 Geary Street, San Francisco.
4. *Ambulatory Cases of Fractures of the Spine* — H. W. Spiers, M. D., 2007 Orange Street, Los Angeles.
   Discussion opened by W. W. Richardson, M. D., Brockman Building, Los Angeles; E. W. Cleary, M. D., 177 Post Street, San Francisco.
5. *The Correction of Flexion and Abduction Deformity of the Lower Extremities Resulting from Infantile Cerebral Palsy* (moving pictures) — Richard H. Pyles, M. D., 2417 South Hope Street, Los Angeles.
   Discussion opened by Harry Schott, M. D., Brockman Building, Los Angeles.

PATHOLOGY AND BACTERIOLOGY SECTION

GLANVILLE Y. RUSK, M. D., Chairman,
University of California Hospital, San Francisco.

ROY W. HAMMACK, M. D., Secretary,
Pacific Mutual Building, Los Angeles.

FIRST MEETING

Monday, May 12, 2 p. m.

1. Chairman's Address and Secretary's Report.
2. *Clinical and Pathological Studies of Coronary Sclerosis and Myocardial Degenerations* — William J. Kerr, M. D., University California Hospital, San Francisco.
3. *Werdig-Hoffman Progressive Muscular Atrophy*—C. E. Nixon, M. D., 870 Market Street, San Francisco.
4. *The Status of the Clinical Pathologist*—Robert A. Kilduffe, M. D., Hollingsworth Building, Los Angeles.
5. *A Plea for a Standardized Technique for the Wassermann Test*—E. H. Ruediger, M. D., Angeles Hospital, Los Angeles.
6. *Results of Treatment of Cerebro-spinal Lues by the Mehrtens Method*—H. R. Oliver, M. D., 870 Market Street, San Francisco.

SECOND MEETING

Tuesday, May 13, 2 p. m.

1. *Lymphosarcoma.* Presentation of a Case—H. S. Wisman, M. D., University California Hospital, San Francisco; W. D. Faulkner, M. D., University California Hospital, San Francisco.
2. *A Study of Primary Carcinoma of the Lungs*—Victor S. Randolph, M. D., San Francisco Hospital, San Francisco.
3. *Chronic Granuloma of Unknown Etiology Developing Endothelioma*—Harold Brunn, M. D., 350 Post Street, San Francisco.
4. *Adenomyomata of the Uterosacral Region* — J. Craig Neel, M. D., 516 Sutter Street, San Francisco.
5. *A Study of a Series of Brain Tumors*—G. D. Maner, M. D., 1100 Mission Road, Los Angeles.

THIRD MEETING

Wednesday, May 14, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Further Studies With Germanium Dioxide* — W. T. Cummins, M. D., Southern Pacific Hospital, San Francisco.
3. *Uremic Casts*—T. A. Addis, M. D., Lane Hospital, San Francisco.
4. *The Quantitative Amount of Lipoid Material in the Kidneys and Its Relation to the Functional Response in the Experimental Nephritis*—F. R. Nuzum, M. D., Cottage Hospital, Santa Barbara.
5. *Tuberculosis of the Tongue*—Howard Morrow, M. D., 380 Post Street, San Francisco.
6. *Pulmonary Spirochetosis*—C. E. Smith, M. D., University of California Hospital, San Francisco.
7. *Spirochetal Dysentery*—Leroy H. Briggs, M. D., 380 Post Street, San Francisco.

PEDIATRICS SECTION

EDITH BRONSON, M. D., Chairman,
1289 Second Avenue, San Francisco.

ROBERT E. RAMSAY, M. D., Secretary,
Marsh-Strong Building, Los Angeles.

FIRST MEETING

Monday, May 12, 8 p. m.

1. Chairman's Address: *Cardiac Disease in Childhood: A Problem in Preventive Medicine*—Edith Bronson, M. D., 1289 Second Avenue, San Francisco.
   Secretary's Report.
2. Lactic Acid Milk in Private Practice—James W. Chapman, M. D., Citizen's Savings Bank Building, Pasadena.
3. *Artificial Feeding of Breast-fed Infants*—William M. Happ, M. D., Pacific Mutual Building, Los Angeles.
4. *The Development and Re-establishment of Breast Milk by the Use of Electric Breast Pump*—Earl M. Tarr, M. D., Westlake Professional Building, Los Angeles.
5. *Summary of Unsupervised Diets of Infants Up to One Year of Age* — Adelaide Brown, M. D., 909 Hyde Street, San Francisco; Ernest L. Botts, Stanford University Hospital, San Francisco.

SECOND MEETING

Tuesday, May 13, 2 p. m.

1. *Synostosis of the Cranial Sutures in Infancy and Childhood*—Harold K. Faber, M. D., Stanford University Hospital, San Francisco.
2. *Empyema in Children at the Los Angeles General Hospital During the Last Ten Years* — Alfred J. Scott, M. D., 1501 South Grand Avenue, Los Angeles.
3. *Intensive Treatment of Congenital Syphilis*—Hermann Schussler, M. D., 391 Sutter Street, San Francisco.
4. *Diphtheria Immunization in Los Angeles* — Abraham Metzner, M. D., Union Bank Building, Los Angeles.

THIRD MEETING

Thursday, May 15, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *The Work of the Los Angeles Child Guidance Clinic*—

R. P. Truitt, M. D., 1401 South Grand Avenue, Los Angeles.

3. *Some Notes on the Psychology of Juvenile Delinquency* —Olga Bridgman, M. D., 680 Sutter Street, San Francisco.

RADIOLOGY SECTION

(Including Roentgenology and Radium Therapy)

M. P. Burnham, M. D., Chairman,
900 Hyde Street, San Francisco.

Ray G. Taylor, M. D., Secretary,
302 South St. Andrews Place, Los Angeles.

FIRST MEETING

Monday, May 12, 2 p. m.

1. Chairman's Address and Secretary's Report.
2. *X-ray of the Urinary Tract, With Report of a Case of Congenital Unilateral Kidney* (Lantern Slides)—Francis B. Sheldon, M. D., Mattei Building, Fresno.
   The paper will deal with the various conditions that are found in the course of X-ray examination of the urinary tract, and the presentation of this case of congenital unilateral kidney.
3. *Secondary Pulmonary Hypertrophic Osteoarthropathy Associated With Metastatic Sarcoma of the Lungs*—Lloyd Bryan, M. D., 135 Stockton Street, San Francisco.
   Report of two cases. Brief review of the literature. This condition is rare in acute cases, but occasionally it occurs. Usually associated with chronic pulmonary or circulatory pathology. These are skeletal stages associated with clubfingers, as described by Marie.
4. *Metastatic Bone Carcinoma*—Lyell Cary Kinney, M.D., 415 Elm Street, San Diego.
5. *Metastatic Carcinoma Involving the Abdominal, Mediastinal and Supraclavicular Glands Treated by X-rays. Well After One and One-half Years*—Henry J. Ullman, M. D., Cottage Hospital, Santa Barbara.
   Testicle removed. Microscopic diagnosis: Teratoma. Masses in abdomen, mediastinum and left clavicular region appeared five months later. Details of treatment. No evidence of tumor after one and one-half years.

SECOND MEETING

Tuesday, May 13, 2 p. m.

1. *Simultaneous Stereoscopic Examination of the Two Mastoids* — James B. Bullitt, M. D., Garden City Bank Building, San Jose.
   The roentgenogram is important, if not imperative, in the determination of mastoid disease and in reaching a decision as to treatment. The otologists, however, have apparently not reached unanimity as to the value of the roentgenogram. In the end the excellence of the radiographic examination must win recognition of its usefulness. The method described is offered as an advance toward the perfection of this form of examination.
2. *X-ray Diagnosis of Disease of the Nasal Accessory Sinuses With Reference to Sphenoid and Ethmoid Diseases*—Robert A. Powers, M. D., Palo Alto.
   Discussion of present methods. Dangers of erroneous interpretations of ethmoid conditions. Cross section X-ray studies of the ethmoid cells. Unit for super-imposed studies of the bones of the skull. A practical method for examination.
3. *Calibration of Roentgen Therapy Machines in California*—W. Edward Chamberlain, M. D., Stanford University Hospital, San Francisco; Robert R. Newell, M. D., Stanford University Hospital, San Francisco.
   An ionization chamber and galvanometer have been carried to the laboratories of California doing deep roentgen therapy. Measurements have been made of actual X-ray output. Standardization factors have been calculated for each laboratory.
4. *Radiotherapy in Benign Lesions of the Uterus*—Frederick H. Rodenbaugh, M. D., 516 Sutter Street, San Francisco; Irving S. Ingber, M. D., 516 Sutter Street, San Francisco.
   Comparative results of radium and high voltage therapy singly and in combination, with comparative dosage. Indications and contra-indications. Complications, with comparison of other methods of treatment. End-results, with possible danger from malignant degeneration.
5. *Roentgen Therapy of Uterine Myoma During Pregnancy*—John D. Lawson, M. D., Woodland.
   Review of the literature. Moderately hard radiation with aluminum filtration. Hard Roentgen rays with copper infiltration. Reaction of the tumor. Effect upon the fetus. General effect on the patient. Report of a case.

THIRD MEETING

Thursday, May 15, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Survey of Non-Tubercular Chest Lesions* — Henry Snure, M. D., 1501 South Figueroa Street, Los Angeles.
   Survey of non-tubercular chest lesions with regard to differential diagnosis, especially lung tumors and infections. Changes in lung tissue due to deep X-ray therapy.
3. *An Interesting Case Report of Pulmonary Infarct Demonstrated by the Roentgen Ray*—Lloyd B. Crow, M. D., 391 Sutter Street, San Francisco.
   Pathology: Clinical, morbid, experimental. Anamnesis, brief. Physical findings. Laboratory, brief. Roentgen ray. Conclusions.
4. *Biological Effects Connected With Modern Deep Therapy*—Kurt F. Behne, M. D., 1407 S. Hope Street, Los Angeles.
   A resumé of the general effect of the energy of radiation upon blood and the circulatory system, and on the body metabolism. A general resumé of the importance of these body changes as produced by radiation when considered in the light of the pathology to be combated.
5. Lantern Slide Demonstration.

TECHNICAL SPECIALTIES SECTION

Ray Lyman Wilbur, M. D., Chairman,
Stanford University, Palo Alto.

John C. Wilson, M. D., Secretary,
Medical Office Building, Los Angeles.

MEETING

Wednesday, May 14, 10 a. m.

1. Election of Section Officers and Transaction of Other Section Business.

California Association of Physiotherapists

Hazel Furscott, President,
380 Post Street, San Francisco.

Hilda C. Rodway, Secretary,
177 Post Street, San Francisco.

Joint meeting of Technical Specialties Section with California Association of Physiotherapists.

1. President's Address and Secretary's Report.
2. *Localization of Effort in Muscle Training*—Harold D. Barnard, M. D., 2417 South Hope Street, Los Angeles; C. L. Lowman M. D., Brockman Building, Los Angeles.
3. *Torticollis*—William A. Clark, M. D., Central Building, Pasadena.
4. *Nutrition in Children* — Herbert M. Coulter, M. D., 1949 Huntington Drive, Pasadena.
5. *Muscle Re-education Following Reduction of Congenital Dislocation of the Hip* — Howard W. Chappel, M. D., 134 South Morton Avenue, Los Angeles.
6. *Endocrines Consideration of Body Types*—Clifford A. Wright, M. D., Auditorium Building, Los Angeles.
7. Business Meeting.

Wednesday, May 14, 2 p. m.

Clinic at Children's Hospital, Los Angeles.

Wednesday, May 14, 7 p. m.

Banquet—Mary Louise Tea Rooms.

Thursday, May 15, 2 p. m.

Clinic—Orthopedic Hospital School, Los Angeles.

California Association of Medical Social Workers

JOSEPHINE ABRAHAM, President,
Mt. Zion Dispensary, San Francisco.
MRS. SOPHIE MERSING, Secretary,
Mt. Zion Dispensary, San Francisco.

MEETING

Tuesday, May 13, 10 a. m.

1. President's Address and Secretary's Report.
2. *Influence of Medical Social Work on Obstetrics*—Armstrong Taylor, M. D., 135 Stockton Street, San Francisco.
3. *Introduction to Medical Social Service*—Miss N. Florence Cummings, Stanford Hospital, San Francisco.
4. *Motion Picture*—"The Watchful Eye": New York Hospital Social Service and Convalescent Work.
5. *Medical Social Service*—Percy T. Magan, M. D., White Memorial Hospital, Los Angeles.
6. *State Assistance to Its Dependent Children*—Miss Geneva S. Orcutt, Children's Agent, State Board of Control, State Building, San Francisco.
7. Business Meeting.

UROLOGY SECTION

LOUIS CLIVE JACOBS, M. D., Chairman,
Flood Building, San Francisco.
FRANK S. DILLINGHAM, M. D., Secretary,
Merchants National Bank Building, Los Angeles.

FIRST MEETING

Monday, May 12, 8 p. m.

1. Chairman's Address: *Unusual Problems in Surgical Prostate*—Louis Clive Jacobs, M. D., Flood Building, San Francisco.

   Leukemia in prostatectomy. Report of cases. Prostatic adenoma associated with vesical diverticuli. Report of cases. Retention of urine following prostatectomy. Lantern slides.

   Secretary's report.
2. *Case Report of an Unusual Type of Urinary Retention*—Wilbur B. Parker, M. D., 527 West Seventh Street, Los Angeles.

   Unusual urinary retention associated with simple generalized prostatic hypertrophy both unknown and unsuspected. Retention followed attack of food poisoning, and developed features commonly noted in urinary suppression such as lethal point in blood retention products, general water-logging relieved by gradual, prolonged withdrawal of vesical contents, preparatory to successful prostatectomy.
3. *Some Important Points in the Rapid Healing, Complete Restitution of Function, and Low Mortality in Suprapubic Prostatectomy Cases*—Herbert A. Rosenkranz, M. D., W. P. Story Building, Los Angeles.

   Preparatory: (1) Important prognostic points. (2) Selection of trustworthy nurses. (3) Common diagnostic mistakes. (4) Digitalization. (5) Gastrointestinal hygiene. One-stage versus two-stage operation. Anesthetics: Gas and spinal. Operative: Simplicity, dispatch, avoidance of shock. Post-operative: Patients almost as dry as ordinary laparotomy cases. Asepsis of tubing and bottle. Post-operative complications: Avoidance of hemorrhage, uremia, hiccough, epididymitis, bed-sores. Remote results. Impotence, residual urine, cystitis, longevity.
4. *Kidney Anomalies. Report of a case of Bilateral Fusion of a Supernumerary Kidney*—William E. Stevens, M. D., Flood Building, San Francisco.

   Fused kidney, supernumerary kidneys. Report of a case of supernumerary kidney with fusion of the three kidneys. Lantern slides.
5. *Injuries to the Urinary Organs in Relation to Industrial Accidents*—Robert V. Day, M. D., Detwiler Building, Los Angeles; Harry W. Martin, M. D., Black Building, Los Angeles.

   (1) Urethral injuries without fracture of any pelvic bone. (2) Incidence of injuries to urethra and bladder in cases of fractured pelvis. (3) Injuries to the kidney. (4) Injuries to the testicles or epididymis.

SECOND MEETING

Tuesday, May 13, 2 p. m.

1. *Malignant Tumors of the Kidney*—Frank Hinman, M. D., 516 Sutter Street, San Francisco; A. A. Kutzmann, M. D., University California Hospital, San Francisco.
2. *Carbuncle of the Kidney*—Charles P. Mathe, M. D., 760 Market Street, San Francisco.

   (1) Portal of entry with its relation to infections of the skin, i. e., furunculosis, boils, and carbuncles. (2) Case report. (3) Pathogenesis. (4) Treatment.

   Discussion opened by L. Player, M. D., 516 Sutter Street, San Francisco.
3. *The Relation of the Appendix to the Right Ureter and Kidney*—Henry A. R. Kreutzmann, M. D., 1195 Bush Street, San Francisco.

   Report of three cases of appendicitis simulating urinary disease. Discussion of the anatomical relation of the appendix to the right ureter and kidney.
4. *Stricture of the Ureter With Report of Cases*—R. L. Schulz, M. D., Story Building, Los Angeles.

   Etiology, histogenesis, mechanism involved. General symptoms. Findings, positive and negative. Procedures, ordinary and special. Precautions as to methods for diagnosis. Unfavorable reactions which sometimes occur with ordinary methods and how to avoid them. Treatment: The importance of overdilatation and the mischief of insufficient dilatation. Removing foci of infection.
5. *Polyps of the Vesical Orifice; Symptoms and Treatment* (with slides)—Miley B. Wesson, M. D., 870 Market Street, San Francisco.

THIRD MEETING

Thursday, May 15, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Some Problems in the Management of Tumors of the Urinary Bladder*—Paul A. Ferrier, M. D., 2211 Mar Vista Avenue, Pasadena.

   Pathology: Practical importance, clinical types, difficulties in diagnosis, prognosis. Treatment: Limitations of fulguration, diathermy, radium, deep X-ray therapy. Operable-condition of patient, operative technique, palliation. Cases, results, conclusions.
3. *Tuberculosis of the Epididymis, Vas and Seminal Vesicles*—James R. Dillon, M. D., 516 Sutter Street, San Francisco.

   A review of the literature would indicate the primary focus of tuberculosis in the above organs to be in the epididymis. Recent investigation by a few urologists doing the radical operation of epididymectomy, vasectomy, and vesiculectomy has shown the seminal vesicles to be the most likely primary lesion of tubercular epididymitis. Gross pathology. Brief case reports. Conclusions. Lantern-slide demonstration.
4. *A Congenital Diverticulum of the Posterior Urethra, With Some Remarks on the Modern Methods of Investigation and Treatment of Seminal Vesiculitis.* Illustrated with Lantern Slides—Martin Molony, M.D., 1056 Sutter Street, San Francisco.

   A detailed description of a congenital diverticulum of the posterior urethra in a patient with chronic seminal vesiculitis. Illustrated with lantern slides showing various views of the orifice, and with radiograms of the injected sac showing both seminal vesicles opening into it. Part Two. Seminal Vesiculitis: Some remarks on the complication that may arise in the course of the investigation and diagnosis of a case; the advantages and disadvantages of some methods of treatment, with a comparison of the modern method of injecting the seminal vesicles.
5. *Spinal Anesthesia in Urology*—J. C. Negley, M. D., Haas Building, Los Angeles.

   Length of time in use, reason for spinal anesthesia, drugs used and their preparation for injection, method of injection, the immediate and remote effects, depth of anesthesia, number of cases used by us and summary.
6. *The Godino Twins*—R. H. Van Denburg, M. D., Merchants National Bank Building, Los Angeles.

   Joined together since birth, manners, characteristics, adaptability of locomotion, study of their urogenital tracts, with view to separation. Photographs of different poses. Diagram to illustrate their lower intestinal tracts. Conclusions. Lantern slides.
7. *Surgical Anatomic Consideration of Male Perineum* (lantern slides)—C. Latimer Callander, M. D., 240 Stockton Street, San Francisco.

COUNTY NEWS

ALAMEDA COUNTY

Alameda County Medical Association (reported by Pauline S. Nusbaumer, secretary) — The February meeting of the Association was held on the evening of the 18th, President C. L. McVey in the chair.

Patients were presented and case reports given by W. B. Allen, Sumner Everingham, and Howard Parker.

The following program, arranged by G. G. Reinle, was given:

Lower Urinary Tract Obstructions.—E. Spence DePuy. Discussion opened by A. M. Meads.

Pyelography.—A. C. Siefert. Discussion opened by W. H. Sargent.

Constitutional Effects of Lower Urinary Tract Obstruction.—Charles L. McVey. Discussion opened by Fletcher B. Taylor.

Those participating in the general discussion were: P. N. Jacobson, Q. O. Gilbert, Raymond St. Clair, W. B. Palamountain, and A. T. Piercy.

C. A. Dukes offered a memorial to our late colleague, Stephen Wythe, which was ordered spread upon our minutes and a copy forwarded to his family.

The clinic conducted by George Dock of Pasadena on February 29 was most interesting. Considering the short notice, the meeting was well attended and thoroughly appreciated by all. Those who could not attend felt that they had missed an opportunity.

The annual banquet of the Merritt Hospital staff, held March 5 at the Hotel Oakland, was a delightful affair. The decorations, mostly of blossoms, were unique and beautiful. Sixty guests were present and listened to a rare program. Prof. John Adams of the University of London was the guest of honor. His address will be long remembered. George Rothganger, chief of staff, presided.

The regular monthly meeting for March was held on the 17th, President C. L. McVey in the chair. The program was presented by the Fabiola Hospital staff, as arranged by E. W. Goodman.

Demonstrations

Post-appendical Subdiaphragmatic Abscess.—G. H. Liliencrantz.

Leprosy.—A. M. Meads.

Bilateral Osteomyelitis of the Mandible.—A. E. Sykes.

Pathological Specimens.—Gertrude Moore.

Radical Frontal Sinus Operation.—F. M. Shook.

Papers

Observations in Vomiting of Pregnancy.—J. W. Sherrick.

The Place of Surgery in Brain Injuries.—E. W. Goodman.

Radium in Gynecology.—E. N. Ewer.

These papers were discussed by E. N. Ewer, F. M. Loomis, W. B. Allen, M. L. Emerson, W. H. Sargent, and Dudley Smith.

The following outline of plan for standardization of Wassermann reaction in accordance with a resolution adopted at the regular meeting held November 19, 1923, as submitted by the committee, was unanimously adopted:

"First—A commission consisting of five members shall be appointed from the Alameda County Medical Association, who shall serve for a period of five years, one term expiring at the end of each year. The duties of this commission shall be to certify laboratories for the performance of the Wassermann reaction, and to delegate the technical duties to proper authorities. A certified laboratory is defined as—

"1. Being one under the direction of a clinical pathologist. (Note—A clinical pathologist is a doctor of medicine, devoting at least one-half of his time to laboratory practice and having had at least one year's experience in laboratory work under the direction or supervision of a clinical pathologist.)

"2. Doing all Wassermann reactions in duplicate, with at least one set according to the method of Kolmer.

"3. Using technicians who are graduates of recognized universities, having majored in a science allied to medicine, and who have had at least six months' post-graduate serological experience.

"It is desirable to have one of the antigens used in the test in a certified laboratory, a common antigen made after the method of Kolmer.

"Laboratories desiring standardization shall make application to the commission, and upon demonstration of a proper equipment, medical director as above outlined, technicians with proper qualifications and experience, are entitled to receive certification. In order to maintain certification, a laboratory must live up to all the rules laid down by the Commission, including a proper check on Wassermanns at regular intervals."

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary)—The regular monthly meeting was held at the Abbott Emergency Hospital, Richmond, Saturday, February 23, 1924.

Doctor Southard of San Francisco, eye, ear, nose, and throat specialist, lectured on "Headache." He gave a very exhaustive analysis of the cause and symptoms of the malady. His conclusions were that 80 per cent of all headaches are caused by eyestrain. The others by various infections in other parts of the body. A free discussion followed the lecture.

The committee of censors reported on the free use of the County Hospital at Martinez for patients that were able to pay for private care, both for medical and hospital service. The secretary was instructed, by a motion of the members, to take the matter up with the clerk of the Board of Supervisors, advising them of the wishes of the Contra Costa County Medical Society.

A representative of the Aetna Life Insurance Co. was present and explained the "Group" method of medical defense. He will write an explanatory letter and mail to each of the members.

After the meeting the members adjourned to Martin's Grill for lunch. The following members were present: P. C. Campbell, J. T. Breneman, H. L. Carpenter, W. E. Cunningham, C. R. Leech, J. Emmett Clark, F. Lisle Horne, John Beard, Hall Vestal, L. St. John Hely, Southard, San Francisco.

FRESNO COUNTY

Fresno County Medical Society (reported by T. Floyd Bell, secretary)—The regular meeting of the Fresno County Medical Society was held at the Nurses' Home of the General Hospital of Fresno County on the evening of March 4.

Thirty-six members and five visitors were present, as follows: Members — Doctors James, Newton, Thompson, Kjaerbye, B. Petersen, Jamgotchian, Wiese, Couey, Miller, Tillman, Wahrhaftig, Willson, Pettis, S. M. Long, Morgan, Bell, Aller, Scarboro, Lamkin, J. R. Walker, G. W. Walker, Barrett, Wheeler, Montgomery, Craycroft, Vanderburg, Sheldon, Konigmacher, Anderson, Schottstaedt, Dearborn, C. A. Robinson, and Adams. Visitors—Doctors Jelalian, Meracle, Nedgerly, H. O. Collins, Skoonberg, and Take.

Hans Barkan of the Stanford Medical School of San Francisco gave a very instructive paper on "Ocular Headaches." He divided such headaches into (1) those due to use of the eyes, and (2) those due to diseases of the eyes. He emphasized especially the importance of refraction and the value of having it done by an oculist. Discussion by J. R. Walker, Kjaerbye, and Barkan.

W. F. Schaller, also of the Stanford Medical School, presented a paper on the "Present Aspect of the En-

cephalitis Situation." This was very interesting and instructive, covering the field from etiology to treatment as far as is known.

The Staff of the General Hospital of Fresno County held its annual dinner and election of officers at the Hotel Californian on the evening of February 12. T. F. Madden acted as toastmaster. Talks were made by D. I. Aller and C. O. Mitchell, and Dean MacDonald of the County Welfare Department. The following officers were elected for the coming year: President, A. B. Cowan; vice-president, F. B. Sheldon; secretary, C. A. James.

W. F. Schaller of San Francisco spoke at the noon luncheon of the staff of the General Hospital of Fresno on March 4, on the subject of the treatment of Neurosyphilis.

HUMBOLDT COUNTY

Humboldt County Medical Society (reported by L. A. Wing, secretary)—A meeting was held February 21 at Eureka, with an attendance of twenty.

Election of officers for the ensuing year resulted as follows: President, O. R. Myers; vice-president, Mabel A. Geddes; treasurer, John N. Chain; secretary, Lawrence A. Wing; delegate to State Convention, Carl T. Wallace; alternate, E. L. Cottrell; committee on program, Doctors Chain, McKinnon, and Marshall.

New members elected: Mabel A. Geddes, Matthew J. Beistel, and William Warren Styles of Blocksburg.

Meetings will be held the last Tuesday of each month.

The program of the meeting consisted in a discussion on Gall-bladder diseases by Doctors Quinn, Chain, Marshall, Beistel, and Wallace.

The meeting was followed by an excellent dinner and a very interesting evening, and adjourned to meet again on March 25.

LOS ANGELES COUNTY

Barlow Medical Library—The annual report of this library shows an increasing progress made during the year 1923. One of the great needs of not only the medical profession, but of the public in Southern California, is adequate library facilities. A splendid nucleus now formed by the Barlow Medical Library ought to have the very liberal and hearty support of physicians everywhere. Its importance should be brought to the attention of the public in such a way that it might have reasonable opportunity to secure annuities, endowments, and offerings of all kinds.

The trustees of the library are: T. C. Lyster, M. D., 1924 (December), to January, 1925; George Kress, M. D., 1924 (December), to January, 1925; Carl Rand, M. D., 1925 (December), to January, 1926; William Duffield, M. D., 1925 (December), to January, 1926; H. E. Schiffbauer, M. D., to January, 1927; Henry H. Sherk, M. D., to January, 1927; George Dock, M. D., to January, 1927.

Trustees-at-large to serve for one year: W. Jarvis Barlow, M. D.; Norman Bridge, M. D.; Roland E. Skeel, M. D.; Granville MacGowan, M. D.; W. W. Beckett, M. D.; F. C. E. Mattison, M. D.; Mrs. Mary E. Irish, librarian.

SAN BERNARDINO COUNTY

San Bernardino County Medical Society (reported by E. J. Eytinge, secretary)—The Society met on March 4 at San Bernardino County Hospital, twenty members being present and ten guests.

E. Avery Newton of Los Angeles gave a paper on "Cardio-Renal-Vascular Disease," illustrated by lantern slides; followed by presentation of patients, who were examined and their abnormalities discussed by Dr. Newton.

A. L. Haenszel of San Bernardino and J. Hubert Smith of Victorville were received as new members.

Elgar Reed of Chino and J. W. Benners of San Bernardino have passed away.

J. A. Connell, formerly of San Bernardino, transferred to Riverside County.

SAN DIEGO COUNTY

San Diego County Notes (reported by Robert Pollock)—The regular meeting of the Medical Society of February 26 at Science Hall, Balboa Park, was one of extreme human interest. A discussion of the value of certified milk and its bearings on the local situation was staged by Doctor Wessels in connection with entry upon the local market of the New Esmeralda certified product.

Doctor Hileman opened a lively discussion from the floor by reading a paper entitled "Trachoma and Certain Cases of Conjunctivitis That Are Being Diagnosed as Trachoma." This paper touched practically upon the high spots of diagnosis and treatment and was received with great enthusiasm. The discussion following was participated in by Doctors Carrington, Dingeman, Banks, Grant, Hosmer, Lesem, Thornton, and Hileman.

Charles Brown, who has recently returned from a protracted tour of European clinics, gave a very interesting talk on some of his experiences abroad. Incidentally he highly lauded the activities of the American Medical Association in Vienna.

The new St. Joseph's Hospital, not yet completed, is already planning an extensive addition in the form of a wing with a capacity of seventy-five beds.

The new La Jolla Hospital expects to open its doors in July next.

A Mental Hygiene movement was recently organized in San Diego under the name of the Bureau of Child Guidance.

On Friday evening, March 7, many of the members of the County Society attended the lecture by Samuel G. Gant of New York City on "Local Anesthesia in Operations About the Rectum," after which adjournment was made to the refreshment room, where the company partook of the sociability and refreshments for which the medical staff of the Naval Hospital is noted.

SAN FRANCISCO COUNTY

Proceedings of the San Francisco County Medical Society—During the month of February, 1924, the following meetings were held:

Tuesday, February 5—Committee on Medicine: Some Observations on Pneumonia on the Pacific Coast—W. J. Kerr. Complications and Coincident Diseases of Pulmonary Tuberculosis—W. R. P. Clark.

Tuesday, February 12—General Meeting: Some Observations on Sacro-iliac Pain—Arthur L. Fisher. The Newer Aspects of the Diagnosis of Tabes Dorsalis—Charles E. Nixon.

Tuesday, February 19—Committee on Industrial Medicine—Osteo-Arthritis (Spine) in Industrial Injury: Etiology of Arthritis—H. H. Markel. Osteo-Arthritis of the Spine with Particular Reference to Protracted Disability—J. T. Watkins. Examination and Treatment—R. L. Dresel.

Tuesday, February 26—Committee on Eye, Ear, Nose, and Throat—Symposium on Headaches: Ophthalmology—Hans Barkan. Otorhinolaryngology—Wallace B. Smith. Neurology—Walter F. Schaller. Internal Medicine—LeRoy H. Briggs.

St. Joseph's Hospital Staff Meetings—On March 12 St. Joseph's Hospital staff of San Francisco witnessed a demonstration by Ethan Smith and Frank Lowe of a patient with extraordinary polyarthritic lesions.

A. S. Keenan spoke on "New Medical Ideas Noted in the Old World." Impressions on Italian, English, and German surgery and surgeons were given. European nurses were reported as doing but little of the immediate preoperative preparation of patients and laboratory work was generally done by the attending physician himself. Tying of the carotids in hydrocephalus and the expectant, eliminative treatment of eclampsia were giving satisfactory results.

F. H. Rodenbaugh spoke on "X-ray as an Aid to Early Diagnosis," illustrating with lantern slides. Gastro-intestinal and bone lesions of the head, trunk and extremities were demonstrated to show early and

accidental radiological findings of importance. P. K. Brown dwelt upon chest and abdominal radiograms as they aid the physician.

Case reports were presentcd by A. S. Musante; Pyloric Carcinoma and Gastro-enterostomy, William Quinn; Influenzial Meningitis, J. M. Stowell; Purulent Chest, and W. T. Cummins and C. H. Hoag, Parotid Malignancy.

The program for April 9 follows: "Avoiding Neurological Errors in General Practice," C. E. Nixon; "Blood Transfusion," Sterling Bunnell; and "Demonstrations of X-ray Plates and Pathological Secimens," L. B. Crow and C. E. Smith.

Southern Pacific General Hospital Staff Meeting (reported by W. T. Cummins, secretary)—The regular monthly staff meeting was held at the Southern Pacific General Hospital, Huntington Hall, on Wednesday, March 5.

The scientific program was as follows:

Our Urological Department and an Illustrated Presentation of Interesting Cases (Roentgenologic Demonstration)—G. L. Eaton.

The Incidence of Perforated Gastric and Duodenal Ulcers in 4000 Admissions—J. H. O'Connor and J. A. Guilfoil. Presented by Guilfoil. Discussed by O'Connor and P. K. Brown.

Case Report of Angiosarcoma of Liver, with demonstration of gross specimen—J. D. Humber.

Case Report of Cerebellar Tumor, with demonstration of gross specimen—P. K. Brown.

Roentgenologic Demonstration—L. B. Crow.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by Alex C. Soper Jr., secretary)—At the meeting held March 10 at the Cottage Hospital, there were present twenty-one members and four internes. President Robinson in the chair.

Report being made by the secretary on the cause of the printer's failure to get out notices on time, it was moved and seconded and passed that the business with him be forthwith terminated, and transferred to the Pacific Coast Publishing Co.

Discussion on the charter, constitution and by-laws caused a motion by Ullman, seconded by Bagby, and passed, that the Chair appoint a committee to draft a constitution in accord with the requirements of the State Society. The Chair appointed Stevens, Henderson, and Ryan.

The matter of J. C. Thorpe and his projected therapeutic gymnasium was discussed at some length, and the Chair requested that the members read the letter addressed to them by Mr. Thorp, and be prepared to vote on the subject at the next meeting.

Five-minute case reports, as follows: "Extraperitoneal Cesarean for Placenta Previa," by H. F. Pierce.

"Thyroidectomy in the Diabetic," by Rexwald Brown.

"Appendiceal Retention," by Henry J. Ullmann.

The paper of the evening was on "Brain Surgery," by Edward Bancroft Towne of San Francisco, illustrated with lantern slides. Discussion was participated in by Ullmann, Campbell, Nuzum, and Stevens.

Meeting duly adjourned at 10:20.

SONOMA COUNTY

Sonoma County Medical Society (reported by N. Juell, secretary)—The Society met at Santa Rosa February 21, with seventeen members present and eighteen absent.

New members: Clara Pratt Sparks, Santa Rosa; Rosco E. Hamlin, Santa Rosa; Herman W. Covey, Eldridge.

Resigned: A. R. Graham of Tomales.

Delegates elected to annual meeting of C. M. A. were as follows: Henry S. Rogers, Petaluma; alternate, F. O. Pryor, Santa Rosa.

The meeting was devoted to discussion of advertising and relation to the cults.

At the last meeting a complaint was entered against one member for unethical conduct and advertising. The board of censors sustained the complaint. The member explained that he realized his error, but that he had no intention of violating medical ethics, to which he fully subscribed. He offered his apology, and the complaint was dropped. The result of the discussion was that the best way to meet the cults was to maintain a high standard of efficiency and ethics.

On Thursday, March 13, the Society held another meeting at Santa Rosa, with eleven present and twenty-four absent.

Alfred C. Reed of San Francisco delivered a very interesting address on "Vitamins and Food Deficiency Diseases."

The plan of the Child Hygiene Bureau for preschool examination of children was adopted, and S. Z. Peoples of Petaluma appointed to represent the Society on the central committee.

Resolution of regret for the death of W. B. Hays of Sonoma was adopted.

STANISLAUS COUNTY

Stanislaus County Medical Society (reported by E. R. McPheeters, secretary)—On January 11, the Society held a meeting at Hotel Modesto, beginning with a banquet. Meeting called to order by President R. E. Maxwell.

Members present: F. R. DeLappe, John C. Cooper, R. S. Hiatt, H. M. Presler, F. J. Peters, N. G. Chipman, C. E. Finney, B. F. Surrhyne, E. F. Reamer, John K. Morris, J. C. Collins, L. D. Mottram, J. E. Hosmer, R. E. Maxwell, C. E. Pearson, E. R. McPheeters.

Committee appointed to arrange for next meeting night, Modesto High School, E. R. McPheeters and B. F. Surrhyne.

Committee appointed for March meeting in Turlock, J. C. Collins, F. J. Peters, C. E. Pearson, N. G. Chipman, and H. M. Presler.

Board of censors appointed as follows: C. I. Bemis, F. R. DeLappe, and A. J. Young.

A paper by A. C. Reed of San Francisco, on "Heart Diseases in Every-Day Practice," was very attentively listened to and discussed by the members present.

A vote of thanks was extended the speaker, and the meeting was dismissed by the president.

The February meeting was held at Modesto high school auditorium, beginning with a banquet served by the culinary department of the Domestic Science class. President Maxwell presided.

After the banquet the medical society and the ladies were entertained for a short time by folk-dancing, after which the ladies played Ma Jongg and bridge, and the medical society listened to a paper read by Frank L. Kelly of San Francisco. Twenty doctors and their wives were present.

F. W. Didier and C. H. Griswold were accepted into the Society.

A plan was accepted whereby the Health Department is to furnish toxin-antitoxin to the doctors at $3 per.

Arrangements were made to hold the March meeting in Turlock.

TULARE COUNTY

Tulare County Medical Society (reported by Norman C. Paine, secretary)—At the meeting held January 20, the following officers were elected for the ensuing year: President, A. W. Preston (re-elected); vice-president, I. H. Betts; secretary, Norman C. Paine; censor, J. C. Paine.

The Society is planning greater activity during the coming year than in the past, and a closer relationship with the State association.

YOLO COUNTY

Yolo County Medical Society (reported by Lela J. Beebe, secretary) — The regular quarterly meeting was held March 11 at Red Cross rooms at County Courthouse, Woodland. Present: Drs. Bates, Beebe,

Blevins, Cooper, C. H. Fairchild, Lawhead, Newton, Ward, Abrent, Bransford, F. R. Fairchild, Harbinson, Keith, King, Lawson, McManus, Parsons, Poage, Rathbun, and Salter.

Program: "Report of seven recent cases of influenza with unusual symptoms"—H. J. Blevins. "Report of cases of gastro-intestinal influenza"—W. E. Bates.

Doctor Blevins' paper dealt with a group of cases occurring in Woodland, presenting the usual signs and symptoms of influenza, added to which were marked eye symptoms of sclera, photophobia, some protrusion of eyeball in most severe cases, and very severe pain in eyes and head. Five of these cases occurred in a boarding-house.

Doctor Bates' group consisted of children under six, all of whom showed severe constipation and vomiting as outstanding symptoms. The discussion of these papers brought out many interesting points in diagnosis and treatment.

Election of officers resulted as follows: President, Charles Keith, Williams; vice-president, Thomas Cooper, Davis; secretary, Lela J. Beebe, Woodland; assistant secretary, John D. Lawson, Woodland.

The Woodland Clinic has held programs as follows:

February 19—Symposium on focal infection, including medical, dental, and X-ray diagnosis and treatment.

March 18—Symposium on chronic indigestion.

The Society voted its endorsement of the effort of the State Board of Health and State Board of Education to encourage the examination of pre-school children this spring, and many of the individual members are volunteering time for this service.

Under the County Health Officer, H. D. Lawhead, a campaign for education on the value of immunization against diphtheria has been started, and the county health service is arranging clinics for such immunization in some parts of the county.

Notice of Resurrection — Soon after P. B. Wing came to California in 1918 from Tacoma, he began to be haunted by his own ghost, as it were. First, the Board of Medical Examiners informed him, when he sent them his annual tax, that he had died, and they tried to prove it by giving him the name of his school, date of graduation, former residence, etc. However, the doctor refused to believe even so official a record, and finally convinced the board that the report had been "slightly exaggerated." However, this did not seem to "lay the ha'nt," for as late as the A. M. A. convention last summer a number of his old friends seemed very much surprised to see him alive. Finally, the doctor decided to run the rumor to its source, and learned that in the September, 1911, issue of this Journal (seven years before he had come to California) there had appeared a notice that P. R. Wing had died at Arroyo Grande, whereas it should have been C. E. Wing.

We, of course, like to believe in the power of our Journal, but we had hardly hoped that a two-line notice published more than a dozen years ago could extend its influence so widely. Be that as it may, we are very glad to say that P. B. Wing is, and has been for many years, a member in good standing of the San Diego County Medical Society and the California Medical Association, as we hope and trust he will continue to be for many years to come.

Phi Chi Fraternity Luncheon During State Convention—The Los Angeles Alumni Chapter of the Phi Chi Medical Fraternity have arranged for a luncheon during the convention of the California Medical Association, in Los Angeles. The Chapter has made elaborate preparations for the entertainment of the visiting members at the University Club, Wednesday, May 14, from 12:30 to 2 p. m. It is requested that the members make themselves known at the registration bureau at the Biltmore Hotel.

Board of Medical Examiners, State of California (reported by C. B. Pinkham, M. D., secretary)—At the meeting of the Board of Medical Examiners held in Los Angeles, February 18 to 21, 1924, approximately 200 applications for reciprocity were considered, about 50 oral examinations were conducted, and 54 applicants wrote the three-day examination, most of whom were applicants for a physician's and surgeon's certificate.

A number of legal hearings were conducted, which resulted in the following penalties being imposed:

Heinz George A. Hummel, M. D., illegal operation; license revoked.

August Stone, M. D., illegal operation; license revoked.

George E. Thwaites, M. D., narcotic conviction; license revoked.

Several petitions were presented for restoration of licenses heretofore revoked.

The special investigation committee appointed to check up on the diploma-mill exposé, presented a comprehensive report of about sixteen pages, incorporating certain suggestions for legislation whereby the activities of the diploma-mills and their products may be curbed. The committee was directed to continue its activities and investigations.

Reports of various committees, as well as the investigation and legal reports were submitted, showing the activities of these departments, always summarized in the annual report of the secretary, and printed in each annual directory.

Utah State Medical Association

Salt Lake County Medical Society (reported by M. M. Critchlow, secretary)—A regular meeting of the Salt Lake County Medical Society was held at the Salt Lake County Hospital February 25, President A. A. Kerr presiding. Seventy-six members and twenty-four visitors were present.

Guy Van Scoyoc read a paper on the "Treatment of Tuberculosis by a Calcium Preparation Administered Intravenously," going into the metabolism and physiological action of calcium, the chemistry of the preparation used, and therapeutic effects. He presented cases which showed marked improvement in their pulmonary condition following administration of the preparation. This paper was discussed by Straup, McHugh, Vico, Groesbeck, Jellison, and Behle.

W. C. Cheney presented a case of Spastic Diplegia in an infant six months' old, and a case of Chronic Adhesive Pericarditis in a boy of eight years.

Roy Groesbeck presented a case of Empyema following Pneumonia treated by the closed method, with apparent cure but later recurrence. This was discussed by Straup and Behle.

Doctors Maddison and Miller presented a patient who had had Trichiniasis thirteen years ago. The patient recently developed appendicitis, and on operation a piece of abdominal muscle was removed, and cysts containing trichinae were found in the muscle. These were demonstrated under the microscope.

F. J. Curtis presented a case of Epilepsy Petit Mal Type, With Psychic Equivalents, which was very interesting from a medico-legal standpoint. He also presented a case of General Parcsis with simple deterioration.

J. E. Tyree presented a case of Perthe's disease. This patient had several brothers and sisters with the same disease. He discussed the pathology, treatment, and differential diagnosis. Discussion by Tyndale and Straup.

L. N. Ossman presented a case of Tuberculosis of the Spine With Paraplegia with complete relief of the paralysis, following immobilization of the spine.

F. E. Straup presented a case of gunshot wound of the liver. George Roberts showed an interesting chart of a patient with measles and erysipelas.

Application for membership by Newton Miller was read and referred to the Board of Censors. Burtis F. Robbins and S. H. Besley were unanimously elected to membership in the Society, sixty-two members voting.

Doctor Calderwood reported for his committee, which was appointed to investigate institutions caring for charity patients. He recommended that the City Board of Health be petitioned that the Baby Clinic be discontinued until a better plan could be adopted, after which reorganization might be effected. He also recommended that the president be authorized to appoint a committee of three to plan the new organization of the clinic. Doctor Galligan moved that the report be accepted, seconded by J. Z. Brown, and carried.

John Z. Brown spoke of the effort to have the Harrison Narcotic laws modified and the physicians' income tax reduced, and made some suggestions to the physicians in filling out their income tax returns.

A. J. Hosmer reported for the committee appointed to confer with the Civic Center relative to a course of instruction in home nursing, and recommended that the Society endorse a schedule of lectures to be given. He also recommended that another committee be appointed to investigate the feasibility of having introduced into the local hospitals a shorter course of training for the preparation of nurses' aids, or practical nurses. Doctor Calderwood moved the adoption of the report, seconded and carried.

After adjournment at 10:15 p. m., refreshments were served by the hospital nurses.

Minutes of Meeting Held March 10—The Salt Lake County Medical Society met at the Commercial Club, Salt Lake City, Utah, March 10, with sixty-six members and five visitors present, President Kerr presiding.

The minutes of the previous meeting were read and accepted without correction.

Clarence Snow reported three children immunized against measles by injection of serum from a convalescent case.

Doctor Holbrook presented a very interesting clinical case of osteitis fibrosa involving many bones. X-ray films of the case were presented by Mr. Thody. Discussed by Llewellyn and S. H. Allen.

Doctor Schulte reported a case which died of general carcinomatosis, the original tumor involving the bladder. Pathological specimens were shown.

The first paper on the scientific program was entitled "Diagnosis and Treatment of Peptic Ulcer," by George A. Cochran. Physiology of the stomach, symptoms, complications, and Sippy treatment for ulcer were dealt with. Discussed by S. H. Allen and W. L. Lindsay.

The second paper was "Diseases of the Cornea," by F. M. McHugh, in which he set forth clearly the anatomy of the cornea. He gave a classification of the ulcers of the cornea, symptoms, complications, and treatment. He also dealt on wounds of the cornea and the treatment of some of the complications by injection of foreign proteins. This interesting paper was discussed by E. M. Neher and L. W. Snow.

Transfer card recommending J. W. Henderson from the Weber County Medical Society, and his application were read. Doctor McHugh moved that the Society vote on his application for membership by transfer at this meeting. Seconded and carried. Doctor Henderson was elected to membership by transfer, forty-eight members voting.

Newton Miller was elected to membership, forty-eight members voting. The applications for membership of Eskelson and Jones were read and referred to the Board of Censors.

A letter from Chief of Police Burbidge, requesting physicians to pay their annual fee of $5 for the three-hour parking privilege, was read.

Doctor Calderwood reported for his committee that they had decided that the best method of handling the baby clinic was to turn it over to the community clinic, so that proper investigation of the patients could be made, the clinic to be under the care of pediatricians in rotating services. He recommended that the community clinic take over the baby clinic. This report was discussed by Helmina Jeidell, who said that, in her opinion, if this were done, it would pauperize the patients, so that many babies who, under the old system were being taken care of, would not be brought to the clinic, and felt the clinic should be continued as heretofore. Doctor Scott moved that the report of the committee be accepted. Seconded by J. Z. Brown. Carried.

The editor wishes the secretaries of the other County Medical Societies in Utah would furnish as excellent reports of their meetings as those furnished by Critchlow for the Salt Lake Society. Also any other items of interest. California and Western Medicine is your official publication, and should reflect your activities fully, as it will do if you will co-operate to the extent of sending the material.

Annual Meeting to be Held June 19, 20, 21—The officers and committee on Scientific Work of the Utah State Medical Association have set the date for the next annual Convention, which is to be held in Logan, Utah, for June, 19, 20, 21, 1924. They have secured three very excellent speakers, and expect others. The complete program will be published in a later issue of this Journal. It is anticipated that our annual convention this year will be equal to any we have had in the past.

Proposed Change in Amendment of the Constitution and By-Laws of the Utah State Medical Asso-tion—It is proposed to amend the constitution and by-laws of the Utah State Medical Association, so that the calendar year shall be the fiscal year. As the amendments now read, the fiscal year ends March 31, and it is proposed to have it end December 31. This will mean that all dues for the calendar year must be paid January 1 for that calendar year, and all dues not paid by that time will constitute a suspension of the members on the rolls of the Association. The members may be reinstated by payment of dues at any time during the calendar year. The present by-laws provide that a member shall not be suspended before March 31, so that members are carried on a three months' period of grace. The American Medical Association has adopted the calendar for its fiscal year, and has advised the various State associations to do the same. This matter was referred by the last meeting of the House of Delegates to the council for consideration and recommendation. The council has considered, and now recommends to the Association that such action be taken. If the proposed amendment is adopted, it will change the words in Chapter 9, Section 11, from March 31 to January 1., and in the same paragraph, Section 13, the words, "on or before March 31" to "on or before January 1," in two places, namely, line 7 and line 13.

Increasing Complexities of Medical Science—In an address before the Cincinnati Academy of Medicine, Ray Lyman Wilbur said, among other things (Cincinnati Jour. Med.): "Medicine fifty years ago was a simple personal relationship between the patient and the doctor. But the minute the laboratory became essential, medicine changed materially. Commercial medical schools had to drop out and university training came in. We have been trying to obtain a combination of the laboratory on the one side, bringing in new facts, and the art of medicine, or the application of those facts to the individual, on the other side. We have seen the most interesting period we will ever see in medical education.

"What results have obtained? I will say quite frankly that I think we have gone too far in the process of bringing the laboratory into the undergraduate medical school; too far in our standardization of medicine, until we really are in some danger.

" . . . We have gorged the medical curriculum. There has been an enormous growth of medical knowledge and with it a marked increase in the time requirement of the medical curriculum. There has been an increase in the time of premedical preparation, and also constant acquisition of an increased number of professorships and specialists within different departments, each one crowding in until in one of the oldest medical schools in this country there is required 5967 curriculum hours in the four-year course. Think of the absurd position in which the medical student is placed. He is like a young bluejay who sits with his mouth open for something to be poured in. With 5967 hours of work, think of the ingestion; think of the digestion required; in some in regurgitation lies his only safety.

" . . . There is no one so charitable as the physician, and no one more foolish in his charity. He is still in the state of handing out quarters to beggars. It does not help the recipient fundamentally, and it does not help the community, but he does it out of the goodness of his heart. Sometimes it is the wise way to do, but usually not.

" . . . The greatest mistake the doctor can make is not to put his hands on the patient. The laboratory is for service and not to stand between the doctor and his patient. Human sympathy is not developed and faith is not generated by studies of the urine and sputum. The doctor must make a real and thorough physical examination."

Nevada State Medical Association

Our next annual Nevada State Medical Association meeting is to be held at Bowers Mansion, Friday and Saturday, September 12 and 13. And on Sunday the 14th, we are to take an automobile or airplane ride to Lake Tahoe or some other nearby famous, beautiful and interesting place or places. Saturday, beginning about 8 p. m., we will have a cabaret dance at Bowers Mansion, twenty miles south of Reno, on the highway to Carson City. Ample transportation from the Golden Hotel or the M. D.'s offices in Reno will be provided.

This is to be our best year in attendance and program. If you fail to come, you know you will be sorry. If you come, you will always be glad for several reasons. It would strengthen our State and National organizations and be a local help to some physicians and their patients as well, if you who are not organized would form county or community medical societies composed of one or more counties. The fundamental essential qualifications for thorough organization are membership, scientific interest, and money.

We already have enough papers offered to keep us busy both days, Friday and Saturday, the 13th and 14th.

Usually we have had offers of papers galore a few weeks before our meeting when too late to accept the offers. This year we are early in completing our list, so the program is finished unless someone notifies us he cannot come. However, we might squeeze in a clinical case or two during program hours. And those who have offered papers are urged to present clinical cases during their alloted time.

On the night of our business meeting (Friday at the Chamber of Commerce Hall, in Reno), we will have a reel of movies showing something of value and interest from a noted surgeon from Illinois.

Governor Scrugham has appointed the following people for the Board of the Child Welfare Division of the State Board of Health: Horace J. Brown, M. D., Reno; A. J. Hood, M. D., Reno; Mrs. W. A. Shockley, Reno; Mrs. Frank E. Humphrey, Reno; and Mrs. Sarah George, Sparks. This department functions under the Sheppard-Towner Act.

The Military Affairs Committee is maturing rapidly. The Government wants all who are eligible to join the Reserve Corps. Our State president is re-enlisting, although years ago he swore off.

The Surgeon-General has sent us a list of seven Nevada M. D.'s who are now members of the Medical Officers Reserve Corps. He is very anxious to secure membership in the Reserve Corps from all eligible M. D.'s in our State. If you want an application blank, let your secretary know and it will be mailed.

If your dues are not paid before April 1, you will be reported to the A. M. A. as a non-member.

M. H. Crocker has moved from Winnemucca to Oakland, Calif., with offices in the Hutchinson building.

Washoe County Medical Society (reported by Vinton A. Muller, secretary)—A regular meeting of the Washoe County Medical Society was held at the Commercial Club, Reno, Nev., on Tuesday evening, March 11, with an attendance of over fifty members. President R. H. Richardson presided at the meeting. The Society was honored with the presence of Howard C. Naffziger, clinical professor of neurological surgery at the University of California, who presented to the Society two very interesting papers. The first paper explained in detail the results obtained by ventriculography, and was illustrated with lantern slides. Following this, Naffziger presented a motion picture reel of peripheral nerve injuries among the war veterans treated at the Letterman General Hospital. All other business was dispensed with except the voting on an amendment to the Constitution and By-Laws, providing that our regular meeting night be changed from the first Tuesday of each month to the second Tuesday of each month, which was carried.

The applications for membership from Alice Thompson, Reno, and W. H. Riley, Gold Hill, were voted upon and both elected to membership. The applications of Ira J. Sellers and Frank L. Barrows, both of Reno, were submitted to be voted upon at the next meeting.

A letter from Mrs. George McKenzie, expressing appreciation for the floral offering and words of sympathy sent by the Society, following George McKenzie's death, was read.

Medicine and Physicians in Europe — "It is customary in France for the different faculties to take turns in delivering the address at the reopening exercises of the university each year. This year at the University of Strasbourg, the honor fell to the medical faculty, and Prof. G. Weiss, dean, was selected to give the address," writes the Paris correspondent of the Journal of the American Medical Association. "He took as his subject, 'Medicine and Physicians.' He spoke first of popular misconceptions in regard to medicine and the peculiar opinions that one frequently hears expressed about physicians. Speaking then of patients, Weiss expressed astonishment over the frequent lack of confidence in the men who have devoted their lives to acquiring the knowledge of their predecessors and to developing new knowledge in the field of medicine, and the trust that is placed in ignorant charlatans, whose influence is based on idle gossip, on man's love for the mysterious, and on his feeling of contempt for a man who frankly admits that there is no absolute certainty that he can prevent a mortal from dying. To judge from the conversations one hears on street-cars and trains, one might suppose that everybody was versed in medicine except the physician. The public is at times fascinated by the empiricist, who claims to have secret remedies for all diseases, in spite of his clumsiness and often absurdity. The remarkable thing is the tenacity of his faith, which persists in spite of the occurrence of disappointments and accidents. Every day our clinics are thronged with unfortunate men and women whose condition is hopeless because some charlatan promised to cure them at a time when the disease was still amenable to treatment, and keeps them from the hospital until the condition is hopeless; he then sends them only to avoid being held responsible for his misdeeds. The credulity of the public is such that some physicians —the apaches of our profession—actually conceal their doctor's title and carry on what appears to be an illegal practice, and beg the police not to divulge the fact that they hold a medical diploma, for fear they will lose some of their clients who are destitute of sense."

Metabolic Mechanism in Beriberi — William D. Fleming (The Philippine Journal of Science, November, 1923) says, in concluding his research upon this subject:

1. In a series of beriberi patients the basal metabolic rate was found to be the same as in normal controls. The respiratory quotients were normal. With the percentages of heat obtained from the combustion of protein, of fat, and of carbohydrate, they point to a normal utilization of the food eaten. No evidence of the high carbohydrate intake as a disturbing factor was found.

2. Blood-sugar values were against the high carbohydrate intake causing a "diabetic tendency."

3. No evidence was found of damage to the excretory power of the kidney in beriberi, either in patients with oedema or in those without this symptom.

BOOK REVIEWS

Pediatrics. By various authors. Edited by Isaac A. Abt. Vols. 1 and 2. Illustrated. Philadelphia and London: W. B. Saunders Company. 1923.

The publication of the first two volumes of Abt's "Pediatrics," the first American system since Keating's Encyclopedia (1889), is a medical event of the first importance. If the promise of the first two volumes is carried out in the remaining six, there can be no doubt that Abt's "Pediatrics" will fill the need better than any similar work in English.

Of the many excellent monographs, only a few can be mentioned here. Garrison s History of Pediatrics is the most complete thing of its kind with which the reviewer is familiar, embodying a wealth of interesting material on the hygiene, pathology, and therapeutics of childhood from the earliest times to the present day, and a very complete bibliography which will be of great value to those who wish to review special phases of the history of medicine.

The review of predisposition and heredity by Little of Cold Springs Harbor presents in detail the present-day knowledge of a subject which is fundamental to an understanding of physical and mental development, and which, unfortunately, is not always directly accessible to study and appraisal in the current medical literature.

To the medical man wishing to acquaint himself with the many important differences between the anatomy of childhood and that of adult life, Scammon's chapter will be most useful. The subject is presented with the greatest thoroughness, but is so arranged as to make reference easy.

The chapter by Murlin on Metabolism is, likewise, an excellent compend of knowledge on a subject to which so much fruitful research in modern times has been devoted. Robertson presents his studies and views on the principles of growth and development, elaborating his well-known conception and formulation of growth as an autocatalytic reaction. McClendon gives a brief chapter on the relation of physical chemistry to the physiology of childhood, and there are three articles on the hygiene of the home, of the school age, and of infants in general.

In the second volume, Bolt presents much interesting material on infant mortality; Levinson describes the examination and characteristics of the cerebrospinal fluid in health and disease without, it seems to us, quite exhausting the subject. Rodda has a chapter on Roentgenology, with special emphasis on fluoroscopy, giving many illustrations. The chapter on peculiarities of disease in childhood could well be omitted. DeBuys reviews prophylaxis and treatment, with good illustrations of technical procedures. The chapter on heliotherapy is largely a resumé of Rollier's work. Pearce's section on diseases of the new-born will be found valuable for reference, and Julius Hess' chapter on premature infants is excellent. One of the best articles in the second volume is Heineman's "Chemistry and Biology of Milk," in which practically all the knowledge on this subject that is likely to be of value to the medical man is presented. It is fortunate that Sedgwick lived to complete his article on breast-feeding and nutrition, giving the results of his study and experience of a subject to which he had devoted so large a part of his life, with such fruitful results. The medical world has been waiting a long time for an exposition of the subject of artificial feeding which will be correct, authoritative, complete, and practically useful. It cannot, unfortunately, be said of Brennemann's discourse on the subject—in spite of the great amount of useful knowledge which it contains—that it fills the requirement.

The introduction of insulin has caused a complete reorientation of the treatment and prognosis of diabetes. The paragraphs on this subject in Strause's chapter on diabetes have apparently been introduced since the preparation of the original manuscript, and insulin is accordingly not given quite its proper emphasis. In other respects the chapter is an excellent one. The chapters on diabetes insipidus, sea-sickness, beri-beri, obesity, and pellagra are adequate. That on acidosis, by Howland and Marriott, is admirable. Alfred Hess covers scurvy and rickets authoritatively, in two particularly well-written papers. Wesson has a careful description, with an excellent colored plate, of acrodynia.

In general, it seems to us a pity that the loose-leaf style of publication was not adopted for this monumental work. In fixed binding it will be long before plates can be changed and a new edition published. In another edition a few of the chapters will undoubtedly be omitted, while many should be changed either to eliminate duplication of subject matter in different chapters on closely related subjects, or to admit new discoveries as they are made, or to alter opinions no longer tenable. Medical progress is so rapid that unaltered texts cannot have authoritative value or reasonable exhaustiveness for many years. We wish, however, to reiterate that there is at present no other work in English on pediatrics which has the scope or completeness of Abt's "Pediatrics."

H. K. F.

Lectures on Endocrinology. By Walter Timme. 123 pages. 27 illustrations. New York: Paul Hoeber. 1924. Price, $1.50.

A good, short review of clinical endocrinology, reprinted from the Neurological Bulletin.

The author emphasizes the interrelationship of the various endocrine glands. As in all works on endocrinology, there is much theory based upon what seems a shaky foundation. A more comprehensive bibliography would be useful. L. E.

A Manual of Clinical Diagnosis by Means of Laboratory Methods. By Charles E. Simon. Tenth edition. 1125 pages. Illustrated. Philadelphia and New York: Lea & Febiger. 1922. Price, $9.

Simon is the pioneer author on clinical pathology in this country, and the tenth edition of this standard work hardly needs comment.

The previous form, in dividing the book into a part on laboratory methods and a part on findings associated with various diseases and morbid conditions, is followed.

The entire field of laboratory diagnosis is thoroughly covered. Blood chemistry methods are standard, and the chapters on blood and stool parasitology are especially noteworthy. In serology, the author gives only his own and Noguchi's Wassermann methods. It is regretted that other and superior methods, especially that of Kolmer, are not included.

Gastric and duodenal content examinations are presented in detail together with Lyon's bile studies.

While the book has grown considerably in size, it it gratifying to note a gradual deletion of obsolete and unsatisfactory methods. E. A. V.

A Treatise on the Diseases and Injuries of the Rectum, Anus, and Pelvic Colon. By J. Rawson Pennington. Illustrated. Philadelphia: P. Blakiston's Son & Co. 1923.

It is a pleasure to review a volume on diseases and injuries of the rectum, anus, and pelvic colon that is not merely a reiteration of what has been better said before, but a work that is a real addition to proctologic literature. It is the first American book that approaches the lofty standard set by Tuttle eighteen years ago. The subject matter makes easy and entertaining reading, a short history of proctology introducing the volume and a brief historical sketch introducing each chapter, thereby lending interest to what is ordinarily a rather dry subject.

The author has expended much labor and energy in collecting and sifting all the literature on rectal diseases up to the present time. The various subjects

are all dealt with in masterly fashion by one experienced in what he writes.

As a frontispiece, the author presents an original map of anal and rectal diseases, a bird's-eye view, as it were, of the entire field. It shows at a glance those affections that arise from the anal region and those that arise from the rectal region, and will be very useful for purposes of instruction. Pennington is the first author who explains so that all can understand, the difference between internal and external hemorrhoids.

The chapters on anatomy are among the best that have been incorporated in any proctology. The chapters on injuries of and foreign bodies in the rectum make very interesting reading, particularly the latter, which mentions some astonishing articles that have been inserted into the human fundament—merely to mention one, a Rhine wine bottle, quart size.

Under neuralgia and pruritus are two chapters, short, but full of information.

Under hemorrhoids, the author gives all the time-honored methods of treatment, only to reject them in favor of his open method, which consists in cutting away the internal pile first and catching the bleeding vessels afterward. While this operation may be very satisfactory in Pennington's hands, it is bound to be very bloody when done by those less experienced, where the best rule to follow is: first tie, then cut, as in the ligature operation, which at present seems to have the preference with the majority of rectal surgeons. Whether the open operation will make a place for itself, time will tell.

Finally, there are chapters devoted exclusively to technic, where the various operations are mentioned and described, those preferred by the author being given more in detail.

While there are points where we may differ from the author, we do not hesitate to affirm that Pennington's work is by far the best that we have had the pleasure of reading in many a year, and is a decided addition to medical literature. A. N.

Montaigne and Medicine. Being the essayist's comments on contemporary physic and physicians; his thoughts on many material matters relating to life and death; an account of his bodily ailments and peculiarities and of his travels in search of health. By James Spottiswoode Taylor. New York: Paul B. Hoeber. 1921. Price, $3.75.

As its title indicates, this book gives an account of Montaigne's observations and ideas on the subjects of disease, remedies, physicians. He draws his opinions from his own experience, as he was for many years a sufferer from stone in the kidney and bladder. A considerable portion of the book is taken up with an account of Montaigne's travels from watering-place to watering-place, where he went in search of relief. The reviewer found this book a little difficult to read, as he continually had to jump from one style of writing to another. For example, there would be a few observations by the author, then a quotation from Montaigne, and then a footnote of considerable length, a quotation from some other author. In this way, the continuity of the subject matter is broken, and requires the closest attention on the part of the reader to follow. The book is well printed on good paper, and the illustrations are clear and interesting. A. L. F.

Exercise in Education and Medicine. By R. Tait McKenzie. Third edition. 601 pages. Illustrated. Philadelphia: W. B. Saunders Company. 1923. Price, $5.

This edition gives the reader comprehensive and reliable information presented in a scientific manner concerning an essential feature in medical practice. As a general thing, in the treatment of disease and disabling conditions, not sufficient attention is given by the medical profession to the many available physical measures that might be applicable in restoring or improving bodily function. Especially is this true in cardiovascular conditions, and McKenzie has given us much valuable knowledge that can be utilized for better treatment. Greater emphasis, however, should have been made on the essential importance of medical supervision or exercise in education, and exercise in medicine should have been published in separate volumes. In so doing, there would be less probability for the non-medical adviser to venture in a field necessarily controlled by the physician. The injudicious "Exercise Treatment," which is universally observed, has done much to place disfavor on indicated physical therapeutics. H. L. L.

Duties of Public Officials in Protection Against Quackery — When all public health officials realize that the scope of their duty lies in protecting the folks of their community from the wiles of the incompetent, irregular and the patent medicine concerns, as well as enforcing quarantine and sanitary regulations, then and then only will there be marked progress in present-day public health programs.— Editorial Ohio State Medical Journal, March, 1924.

Obituary

MEMORIAL
STEPHEN WYTHE
1874-1923

Classmate—Friend—Scholar

By Charles A. Dukes

As Christmas was passing, and Stephen was sitting by the fire with his family, he fell asleep. Sleep has been defined as preparation for greater work. Though we must let him sleep for this greater work, we will miss our Fellow, classmate, and friend.

The medical history of Alameda County and the State of California are closely linked with that of Stephen Wythe. His grandfather, J. H. Wythe, was the first professor of Bacteriology of Cooper Medical College, and belonged to that group of teachers composed of Lane, Cushing, and others who made medical history for California and the world. His father, also a graduate of medicine and a teacher, died when Stephen was very young.

It was in our student days at Cooper that I began to know the sterling qualities and wonderful character of Stephen, and, after his graduation, those of us who were closest to him knew of his love for his widowed mother and his wonderful care of his grandfather in his invalid days of old age; then his splendid years as husband and father and his example of fine manhood and a Christian gentleman. His service to his country during the Spanish-American War was in the navy, where he made an enviable record. During recent years he has practiced the specialty of eye, ear, nose and throat, and he will be missed by his large number of private patients, his clinic patients at the Health Center, and at the Merritt Hospital, where he was a member of the staff and gave so generously of his talents.

No man was more universally beloved and respected than Stephen Wythe, and no man more deserving.

The Alameda County Medical Society has lost a valued member, and those of us who have been near to him in his busy and active career will miss a scholar of rare qualities, always ready to help the sick and suffering with his advice.

We extend to his family our sympathies in this hour of sorrow.

HEALTH SERVICE ISSUES ANNUAL REPORT

While stressing the need for new Marine Hospitals and the difficulty of securing medical officers for the regular corps of the Public Health Service, the Surgeon-General states in his annual report that sanitary reports indicate that general health conditions throughout the United States have continued as satisfactory as in recent years. An increasing interest in public health improvement has been noted. In these reports, year after year, it is interesting to note the shifting of emphasis, which is due in part to progress in medical science." The present report for 1923 shows that the plague work, which has heretofore been the subject of much consideration in the annual reports has, temporarily at least, practically faded from the picture. Both human and rodent plague appears to have been eradicated in the United States except for infected ground squirrels in California and all anti-plague measures in other States have been discontinued.

We are warned, however, that, owing to the difficulty of completely exterminating rats on board vessels and the present widespread dissemination of plague, geographically, there is constant danger of the introduction of this disease at all seaports engaged in foreign trade.

While typhus, plague, and yellow fever have been reported from countries with which the United States has been in constant communication, because of the enforcement of international sanitary agreements and the maintenance of national quarantine systems, no cases of major, quarantinable diseases have gained access to this country within the year covered by the report.

Twenty-five hospitals are now operated by the Public Health Service, including the National Leprosarium at Carville, La. Great advancement in the hospital standards of the Public Health Service is noted. At the same time, there has been a reduction in the per diem cost.

DEATHS

Benners, James Wemyss. Died at San Bernardino, February 10, 1924, age 63. Graduate of the University of Louisville Medical Department, 1893. Licensed in California in 1915. He was a member of the San Bernardino County Medical Society, the California Medical Association, and the American Medical Association.

Bloch, Herbert Isaac. Died at San Francisco, March 4, 1924, age 50. Graduate of Cooper Medical College, San Francisco, 1894. He was a member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Easterday, George Spalatin. Died at Watsonville, March 10, 1924. Graduate of the Eclectic Medical College of Cincinnati, 1878. Licensed in California in 1900. He was a member of the Santa Cruz County Medical Society, the California Medical Association, and the American Medical Association.

Hays, Wilfred Bertram. Died at San Francisco, March 5, 1924, age 52. Graduate of the University of California Medical School, 1906. He was a member of the Sonoma County Medical Society, the California Medical Association, and the American Medical Association.

Thompson, J. Goodwin. Died at Oakland, February 19, 1924, age 59. Graduate of the University of California Medical School, 1894. He was a member of the Alameda County Medical Society, the California Medical Association, and the American Medical Association.

Hospital Service in the United States—According to the Council on Medical Education and Hospitals of the A. M. A., there are now 830 hospitals which have a total capacity of 755,722 beds which are occupied on the average by 553,133 patients. Of the 6830 hospitals, there are 1324 which have over 100 beds each, 1072 hospitals have between 50 and 100 beds each, and 1632 hospitals have between 25 and 50 beds each. This makes a total of 4028 hospitals or more than twenty-five beds each with a total capacity of 715,729 beds, which are occupied on the average by 531,024 patients. There are 2112 hospitals that have from ten to twenty-five beds each, with a total capacity of 36,514 beds occupied on the average by 20,269 patients, and 619 hospitals that have less than ten beds each, with a total capacity of 3479 beds, which are occupied on the average by 1846 patients.

Altogether there are 1736 hospitals under Government control, followed by 465 county hospitals, 415 city hospitals, 220 hospitals under Federal control, and 35 under joint city and county control.

The capacity of hospitals under governmental control is 471,948 beds, or 62.4 per cent of the entire bed capacity in the United States. Furthermore, the average number of beds occupied by governmental hospitals is 374,754, or 67.8 per cent of the total average number of beds occupied in all hospitals. It must be remembered, however, that Federal, State, and County hospitals include most of the institutions which provide largely or entirely for the custodial care of incurable patients, or those having chronic diseases. Many of the patients in these hospitals also are either indigent, or are employes, or otherwise beneficiaries of the Government. The large majority of patients having acute diseases are cared for in the non-governmental hospitals.

Of the 3066 counties in the United States, there are only 361 that maintain hospitals at county expense. These 361 counties are supporting altogether 465 hospitals, with a total of 46,571 beds which, on the average, are occupied by 32,789 patients. California has 56, the largest number of hospitals controlled by counties, followed by New York with 50.

Of the 6830 hospitals of the United States, 5094, or 74.6 per cent, are controlled by non-governmental agencies. These hospitals have only 283,774 beds, or 37.6 per cent of the total bed capacity.

The largest proportion of hospitals, 2196, or 32.2 per cent, are those maintained or controlled by independent associations or corporations not for profit, non-governmental, non-fraternal, and non-sectarian. These hospitals have a total of 149,341 beds, of which 95,674, or 64.1 per cent, are constantly occupied.

The next largest group of non-governmental hospitals is the 1762 maintained or controlled by individuals and partnerships. This group has altogether 45,719 beds, of which 27,393 are constantly occupied. These private institutions are frequently the only hospitals in the community, and are sometimes the only institutions that survive. There are 348 counties in the United States in which there would be no hospitals, excepting those which are private property of physicians and nurses.

The third largest group, but the second largest in bed capacity, is that of hospitals under Church control. Counting the hospitals that are under direct control of the Church, as well as those that bear the name and have some certain degree of connection, there are 893, with a total capacity of 77,941 beds, which care for an average of 49,046 patients.

There are now 97 hospitals financed or controlled by fraternal organizations which have a total capacity of 5043 beds.

In 1923, of the 3066 counties in the United States, 1521, or 49.6 per cent, had some kind of a hospital, as compared with 44 per cent (of the 3027 counties), in 1920.—Journal of American Medical Association, January 12, 1924.

What is S. M. A.?

S. M. A. is an adaptation to breast milk which resembles breast milk both physically and chemically.

S. M. A. in addition to giving excellent nutritional results in most cases, also prevents nutritional disturbances such as rickets and spasmophilia.

S. M. A. requires no modification or change for normal infants. As the infant grows older the quantity is merely increased.

S. M. A. requires only the addition of boiled water to prepare.

(Orange juice, of course, should be given the infant fed on S. M. A., just as it is the present practice to give it to breast-fed infants.)

Why was S. M. A. developed?

Because there is a real need for an adaptation to breast milk which will give satisfactory nutritional results in the great majority of cases, which includes the preventive factors, and which is, at the same time, so simple to prepare that the physician can rely on the mother to follow his directions accurately.

How is it possible to feed S. M. A. to infants from birth to twelve months of age without dilution or change?

The answer to this question sounds the keynote of the success which thousands of physicians are having with S. M. A. It is not necessary to modify S. M. A., for *the same reason that it is not necessary to modify breast milk:*— for S. M. A. resembles breast milk not only in its protein, carbohydrate and salt content, but also *in the character of the fat.* Since the very young infant can tolerate the fat, as well as the other essential constituents in S. M. A., it is possible to give this food in *the same strength,* to normal infants *from birth to twelve months of age.*

As the infant grows older, therefore, it is only necessary to increase the *amount* of S. M. A.

Samples and literature to physicians on request.

S. M. A. is to be used only under the direction of a physician. For sale by druggists.

FRACTURES OF THE SPINAL COLUMN *

A REPORT OF FIFTY-TWO CASES

By E. W. CLEARY, M. D., San Francisco

Neither the incidence of fractures of the spinal column nor the difficulties of diagnosis are sufficiently appreciated. The pertinence of this statement is justified by a study of the fifty-two cases which forms the basis of this paper. Twenty-six, or 50 per cent of them came undiagnosed to the orthopedic surgeon, after intervals ranging from five weeks to fifteen years from the date of fracture. Five of the twenty-six undiagnosed lesions were from one to fifteen years old. The average age of the injury in the remaining twenty-one was three and one-half months. Fourteen of the undiagnosed fractures were in the region recognized as most susceptible to fracture, namely, the lower dorsal and upper lumbar region. Three were fractures of the twelfth dorsal, eight were of the first lumbar, two were of the sixth cervical vertebra.

Reference to the tables show that twenty-five out of fifty-two fractures were the result of falls from a height ranging from six to seventy feet. Relatively short falls were responsible for some of the severe fractures. Eighteen injuries were caused by heavy masses falling upon the patient and crushing him forward. Several of these resulted in so-called "jack-knifing" of the patient, that is to say, forcing the spine into such acute flexion as to cause it to buckle. Four patients were struck upon the shoulders or upper part of the back by heavy objects in such a way that the impact, rather than the weight of the mass, caused the injury. In four instances, low lumbar fractures were associated with heavy lifting and twisting strains.

Four patients gave clear histories of previous injuries, at least three of which were old undiagnosed fractures, more or less completely recovered from, and discovered when a recent more trivial injury attracted attention to the region of previous fracture.

DIAGNOSIS

Most missed diagnoses may be credited to one or more of the following causes:

1. An erroneous conception that every broken neck or broken back presents symptoms and physical signs so unmistakable as to practically diagnose itself.
2. Inadequate x-ray examination.
3. Concentration of attention upon some more apparent complicating lesion.
4. Failure to get a clear history of the nature and violence of the force or forces which the accident brought to bear upon the patient's spine.
5. Failure to make a thorough physical examination.

Many non-medical members of the public believe that a broken neck or a broken back means either instant death or, at least, paralysis. Careless physical examination lends support to this popular fallacy.

In my series of patients, less than 30 per cent were correctly diagnosed early.

A clear history of the circumstances attending the injury is first aid to a correct diagnosis. Falls from a height and crushing into forward flexion by impact of force upon the head, neck or shoulders are so frequently the cause of compression fractures of the vertebral bodies that it is wise, with such a history, to assume that a fracture has occurred until or unless such a lesion has been ruled out by physical and roentgen ray examination.

Compression fractures rarely, if ever, occur as the result of lifting strains. A history of a previous fall or a crushing injury, with a resulting fracture, which may not have been diagnosed at the time, will explain many of the vertebral distortions noted after sudden disability from lifting strains. The lifting strain, then, has simply broken up, in greater or lesser degree, the repair after the old fracture. Pos-

*Presented to the Section on Industrial Medicine and Surgery at the Fifty-second Annual Session of the California Medical Association, San Francisco.

sible previous injury is one essential reason for taking a complete history.

Thorough examination would reduce the large number of undiagnosed spine fractures to a relatively insignificant minimum. In examining an injured patient who has no paralysis or obvious deformity, the physician should ascertain whether or not the patient can use his back normally. If he is able to stand, he should be examined stripped and standing. Deformities, limitations in motion, muscle spasm, and discolorations of the skin are all more easily noted in the standing position. If, without other conspicuous reason, the patient is unable to stand, this fact, in itself, should arouse a strong suspicion of possible spine fracture. Guarded motions of the body as a whole and rigidity of the injured and adjacent segments are characteristic of spinal fractures. Marked limitation in range of motion of the injured region of the spine is the rule in recent fractures.

If, as is rarely the case, the patient manifests no marked disability to ordinary movements, the attempt to lift even a relatively small weight with the arms, will, invariably, disclose the disability and result in localized pain and muscle spasm in the area of the lesion if it is below the seventh cervical, frequently even in the cervical segments. Downward pressure upon the head or a very light tap upon the head with the palm of the hand almost always causes severe pain in cervical fractures.

Manual examination frequently reveals a board-like spasm of the erector spinae muscles. Sometimes, however, the spasm is so slight that the vertebral spines may be palpated and even an abnormal mobility of the spine, at the level of injury, detected. Manipulation usually causes pain and muscle spasm sufficient to push the palpating fingers off the tips of the spines.

Failure to get a positive response from these tests must not be accepted as conclusive evidence that no fracture exists. In one instance, a relatively severe lower dorsal fracture, complicated by a fractured extremity which compelled recumbency, was almost overlooked because there was no marked muscle spasm and no tenderness manifest on light palpation or percussion.

In Case No. 48, recumbency was necessitated on account of paralysis of the left lower extremity, and the history indicated spinal fracture, yet muscle spasm was not at all marked and no tenderness was manifested by light palpation or percussion. A relatively light tap with the closed hand, over the sole of the heel of the extended leg, caused sharp pain at the point of fracture and immediate marked muscle spasm. Local pain and muscle spasm were also elicited by a light blow with the closed fist over the suspected area.

Where there is good reason to suspect a spinal fracture, I no longer consider clinical examination negative after less vigorous tests until I have gotten negative results from a definite blow upon the heel of the extended leg or with the closed hand upon the back over the suspected area. Please note that I do not recommend these tests or employ them except where less strenuous tests have been negative.

Reliance upon the negative evidence of inadequate x-rays has been responsible for many missed diagnoses. Anything less than clear stereo, anteroposterior negatives and a single lateral, centered on every suspected area is an inadequate x-ray examination upon which to make a negative diagnosis.

While taking a history, and considering x-ray evidence, the possibility of a previous fracture should always be in mind. Patient No. 33 denied any possibility of a previous injury. Excellent x-ray negatives, however, gave unquestionable evidence of a fracture older than his recent injury. Confronted with this fact, he admitted a fall from a height twelve years previous to his recent injury, and admitted two years of total disability as the result of spinal fracture at that time. In another instance, the recent accident had not been characterized by a sufficient degree of violence to account for the severe compression fracture present. I asked the patient, "When were you hurt the first time?" He then confessed a severe injury over a year antedating the recent accident. The first injury, and not the second, was the cause of the fracture.

TREATMENT

Rest, in the recumbent position, the first essential in treatment of a fractured spine, is usually enforced by necessity, whether the diagnosis has been made or not. Unfortunately, rest in bed is not, as a rule, all the treatment required and even rest and recumbency are likely to be terminated too soon.

Occasionally, as in patient No. 42, a remarkable degree of recovery takes place, after apparently severe spinal fracture, where no other treatment than rest in bed, over a few weeks, is given. This is exceptional. There was no evidence, either clinical or roentgenographic, that any considerable callus developed. Recovery apparently resulted through adaptation of the adjacent structures to the abnormal positions and stresses occasioned by change in shape of the compressed vertebral body, without fusion of any articulations, either intervertebral or zygapophysial. Such recovery, without fusion of the injured to adjacent segments, is rare except in the cervical spine, where fusion is the exception.

Secure and early fusion of the injured segment or segments to the immediately adjacent segments above and below is the result to be sought after the average severe vertebral fracture.

Rest in a favorable position, with immobilization sufficiently complete and prolonged to facilitate early and perfect fusion, is essential. This holds good whether fusion is expected by callus from the trauma or by fusion operation.

Head traction, special fracture beds, collars, splints, plaster-shells, jackets, and various other devices are used to secure immobilization of injured spines. The particular device used depends largely upon the choice of the surgeon. In most cervical fractures, I prefer a plaster paris dressing, including the shoulders and coming high enough on the sides and back of the head to secure perfect immobilization. To completely enclose the head in plaster, leaving only an aperture for the face, adds unnecessarily to the patient's discomfort. After the first four to six weeks, the plaster may be replaced by the Thomas leather collar. An initial period of

traction from the Sayre head-sling is necessary in some severe cervical fractures.

Eight to twelve weeks is the shortest time which any fracture of the spine should be kept immobilized. After this interval, the need for and degree of further immobilization must be determined by the reactions of the individual patient. Return of definite local pain and muscle spasm shortly after removal of immobilizing appliance, indicates the need for further prolonging the period of fixation.

If a case of severe fracture is not a good surgical risk, or, for other good reason, the plan is to immobilize until fusion occurs without operation, then six to eight months of brace-wearing is usually necessary to secure a reasonably strong fusion. It is often eighteen months or two years before the patient is able to work. As a rule, the convalescence in this type of patient can be shortened a year or more and a better final result secured by a good fusion operation. The purpose of fusion operation is to accomplish, with rapidity and precision, fixation of the injured segment or segments to the contiguous segments above and below. A thorough fusion operation, after Hibbs' method, enormously increases the tendency for the laying down of a bony bridge over the area where that bridge will make for the greatest strength and, at the same time, be least likely to encroach upon nerve roots.

Albee's operation, to secure fusion by inserting a tibial graft between the halves of the split spinous processes of the segments to be bridged, has the advantage of being a relatively quick and simple procedure, but in my opinion it does not, in the average case, give the assurance of a strong fusion afforded by the Hibbs operation.

In the Albee operation, two factors only operate to complete fusion, (1) the tibial graft making contact with three or more spinous process, (2) the outpouring of callus about the bodies of the vertebrae as the result of injury.

In the Hibbs operation, stripping of the cartilages from the zygapophysial articulating surfaces is a very important factor. This operation, in fact, makes for a strong fusion by establishing six different lines of bony contact, which may be summed up as follows:

Arthrodesis of the two series of zygapophysial articulations	2
Overlapping series of laminal shavings on either side	2
Central bridge of spinous processes	1
Contact of denuded bony surfaces with overlying periosteal tube	1
Tendency to formation of callus as the result of injury (present whether or not operation is done)	1
	7

Specimens, secured by Hibbs in several instances where death has occurred subsequent to convalescence after his operation, show an uninterrupted bony bridge extending practically from the zygapophysial articulations on one side to those upon the other.

Although I favor the Hibbs operation in the average case, in lumbar fractures and in patients where a preceding laminectomy had to be done, I have several times used a procedure which might be termed a modified Albee. In this operation, after splitting the spinous processes of the injured segment and the two contiguous segments, I drive the chisel laterally through the laminae on either side, out well across the zygapophysial articulations. Then, with an Albee saw, I cut two tibial grafts, each in cross-section, like a thick wedge and long enough to extend across the segments to be fused. These grafts I slip into place, with their thick edges toward the midline, under the lifted laminal shavings on either side. I drive the grafts out laterally until they lie directly across the series of zygapo-

FIGURE II

(A), Case No. 48 — Compression of first lumbar vertebra with total paralysis of left lower extremity and motor paralysis of right from knee down. (See Figure I, (A) and (B).) Paralysis recovered, except marked permanent atrophy and loss of function in both calf groups.

(B), Case No. 48—After double graft fusion. The area of laminectomy is still visible.

(C), Case No. 50—Lateral view taken two years after compression of first lumbar. Complete recovery after Hibbs' operation. (See Figure I, (C) and (D).)

physial articulations and bend the spinous shavings down over them, forcing fragments of the shavings between the grafts in the midline, so as to keep both grafts in their lateral positions. Over them I suture the soft tissues.

Figure III is a diagrammatic illustration of the grafts in position, in this instance bridging three sets of articulations, thus fusing together four vertebrae. This was the operation done on patient No. 48 (see tabulation). This man has had an apparently complete recovery of back function and no pain in his back since three months after operation. He is, however, incapacitated for hard labor, due to permanent paralysis of both calf groups. Figure I-b shows the degree of spinal flexion recovered, notwithstanding unquestioned fusion of four vertebral segments (twelfth dorsal, first, second and third lumbar). Paired grafts have been used by many other surgeons in spinal operations, notably by S. J. Hunkin of San Francisco. Gray has described a double tibial graft fusion, but it is possible that the technique of inserting grafts across the zygapophysial articulations after splitting of the articulating facets in the manner illustrated in Figures IV (A and B) is original with the author of this paper. A further report upon the results of this procedure will be made at a later date.

Figure I-d shows flexion recovered in patient No. 50, after a Hibbs fusion of first dorsal, first and second lumbar, in a case of severe compression of the first lumbar still disabled two years after injury.

It seems to me obvious, notwithstanding the recovery of a wide range of spinal flexion after fusion of four, or even of a greater number of segments, that a fusion operation should not lock up any more joints than are necessary to bridge the injured area. In the case of simple compression fracture of the body of a single vertebra, this result is accomplished by fusion of the fractured vertebra to the one immediately above and the one immediately below. This means locking up only two pairs of zygapophysial articulations. Additional lesions, such as fractures of laminae in adjacent segments (often not discovered until operation reveals them) may necessitate a further extension of the bridge. The shorter the extension of the fused area, either up or down the spine, the more secure, other factors being equal, will be the central area which is presumably the weakest point. This is but an instance of the physical principle, the longer the lever the greater effect of a force applied at its extremity.

The function of spinous processes as levers, through muscular and ligamentous attachments is important. The loss of this function, where a radical Hibbs operation is done, causes some additional difficulty in adaptation during convalescence. On this point, the Albee method scores a decided advantage. To obviate this disadvantage in the Hibbs operation, I frequently leave a portion of the spinous processes at either extremity of the fused area intact. I have already intimated that I consider the spinous process bridge a factor of relatively lesser importance in the success of the Hibbs operation.

Following a fusion operation, it is my practice to keep the patient in a plaster jacket, on a Bradford frame, seven to eight weeks. I then remove the jacket, take measurements for a modified Taylor brace, and keep the patient recumbent for ten days or two weeks while the brace is being prepared. The brace is then put on in recumbency and the patient begins sitting, standing, and walking for gradually increasing periods. As a rule, I do not permit the brace to be discarded during activity for at least four months. It is always removed during recumbency. The average patient returns to light employment eight months to one year after operation, if recovery is uncomplicated by other factors than the spinal lesion.

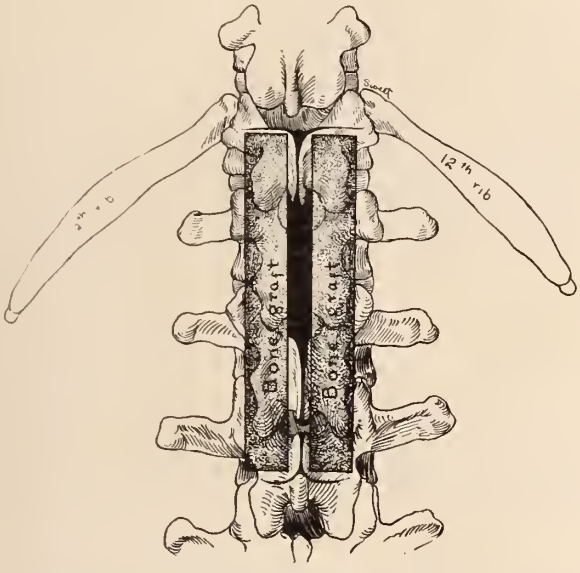

FIGURE III
Diagrammatic illustration showing position of tibial grafts in the double graft fusion operation.

During convalescence, we put spine-fracture patients through a carefully planned and graded course of physiotherapeutic exercises. The details of this plan of treatment are given in a paper on the "Physiotherapy of Back Injuries," not yet published. I am sure that such a physiotherapeutic course shortens the time and increases the degree of recovery.

PROGNOSIS

The prognosis in the average severe case of compression fracture of the spine is for a period of eight to twelve months, total disability, where thorough fusion operation is done early. Permanent potential weakness of the spine, such as to handicap the injured in undertaking heavy labor in the average of these cases amounts to 30 to 40 per cent disability. This weakness is manifest in a tendency to tire more easily and to get a backache after prolonged standing, rather than in an initial lowered capacity.

The prognosis, in the average case of severe compression fracture of the spine treated by prolonged rest, immobilization and support, without operation, is for eighteen months to two years of total disability. In the final result, permanent, potential weakness, following the non-operative course of treatment, is at least 10 per cent higher than in the average of cases operated early. Some patients, treated extensively by conservative means, have to come later to operation and, in these, the results are less sure and convalescence is longer.

In severe compression fractures, where neither operation nor adequate conservative treatment have been given, the prognosis is for continued total, or nearly total, disability, often with increasing pain and discomfort and, possibly, late development of paralytic symptoms. Operation in this type of case is worthwhile, but usually gives a relatively lesser degree of recovery even than operation after failure of conservative treatment. Rarely a case of definite compression fracture recovers without treatment other than a few weeks' rest in bed.

CONCLUSION

Fractures of the spinal column occur, with relative frequency, as the result of falls from a height, or of weights falling upon the head or shoulders. These fractures escape early diagnosis too often. The physical signs and symptoms of fractured spine are not as obvious as they are often considered to be. Care in history-taking, thorough physical and adequate x-ray examination would insure correct diagnosis in most cases.

Adequate fusion operation shortens convalescence and gives a higher degree of recovery than conservative treatment in the average patient. The Hibbs operation is, on the whole, more efficient than the Albee graft fusion. A special type of double tibial graft operation has been found advantageous in difficult cases of lumbar fracture. Carefully directed physiotherapy is an essential part of treatment. After thorough fusion by early operation, industrial patients return to employment in eight months to one year, with an average permanent disability rating measured by the standards of the rating department of the California Industrial Accident Commission of 30 to 40 per cent, or less. Similar patients, treated conservatively, take approximately twice as long to get back to work and show an average permanent disability rating of 40 to 50 per cent or more, measured by the same standards. Similar patients having no adequate treatment are likely to have indefinitely continuing total disability and may develop late paralytic symptoms. The result of later operations on such patients is an improvement,

31	52	Crushed under auto	4 lumbar	None	None	3 years	Rest in bed	Complete recovery
32	32	Crushed under auto	1 lumbar	Partial blindness	Skull fractured	3 months	Rest in bed	Total disability
33	29	Fell from height	1 lumbar	None	None	Few hours	Rest in bed	Complete recovery after 2 years reported
34	41	(Same patient) Fell 8 feet	1 lumbar	(Questionable refract.)	None		No significant treatment	Very slight signs of disability 2 months after
35	40	Fell 40 feet	1 lumbar	Fract. femur, tib., fib., mand., clav.		14 years	Rest in bed	Complete, after 18 months reported
36	54	Strained back lifting heavy bale	1 lumbar (old) no new fract.		Hyper. arth.; cardio-renal disease	Few hours	Rest in bed	Unknown
37	45	Fell 6 feet	2 lumbar	None reported			Rest in bed	Unknown
38	22	Crushed in cave-in	5 lumbar	None reported		15 years	Rest in bed	Unknown
39	37	Lift. strain with twist	Old fracture	None reported				
40	71	Crushed by falling mass	2 lumbar	None	Hyper. arth.	4 months	Rest in bed	(Approximately) 60% disability
41	49	Fell 45 feet	3 and 4 lumbar and lamina 4th	None	Fract. 7, 8, 9 ribs, left	Few hours	Rest in bed	89% disability
42	41	Crushed by falling wall	1 lumbar	None	None	1 month	Rest in bed	Complete
43	41	Crushed by caving earth	1, 4, 5 lumbar	Trans. paraplegia	Disloc. 12 rib; fract. all lumbar trans. proc.	2½ months	Rest in bed	80% per. dis. estimated
44	38	Fell 70 feet in elevator	3 lumbar	None	Fract. both os calces	1 year	Rest in bed	75% per. dis.
45	56	Fell 20 feet	3 lumbar	Trans. paraplegia	None	Few hours	Rest in bed; cast; Hibbs fus. operation	61¾% rating
46	35	Fell 20 feet	11 dorsal	Girdle of hyperesthesia	None	1 month	Hibbs fus. operation	20% per dis.
47	26	Crushed by caving earth	3 lumbar	None	Cont. left hip, knee and ankle	2½ months	Hibbs fus. operation	27% est. rating
48	26	Fell 45 feet	1 lumbar	Trans. paraplegia; perm. paraplegia; calf groups	Infection G. U. tract	Few hours	Double graft fus. oper	Complete recovery back function
49	48	Fell 18 feet	3 lumbar	None	Arth. and lues		Hibbs fus. operation	Unfin. est. 60% disability
50	38	Crushed by falling mass	1 lumbar	Part bladder paral.	Infection G. U. tract	2 years	Hibbs fus. operation	Complete recovery
51	52	Fell 20 feet	12 dorsal and 1 lumbar	Part paralysis rt. glut.; both peroneal and calf groups	Fract. rt. tib. and fib.	Few hours	Hibbs fus. operation	Est. recovery from spinal lesion 90%
52	25	Crushed in street car accident	12 dorsal	Complete permanent paraplegia	Infection G. U. tract	Few hours	Laminectomy	Complete perm. disability

but the factor of permanent disability is likely to be high even after operation. Complete recovery of patients suffering from severe fractures of the spine, without extensive treatment, occurs but rarely.

As the technique of fusion operations becomes perfected and the choice of operation best suited to the individual patient becomes more discriminating, a definite further improvement in the time and degree of recovery may be confidently predicted. Immediate diagnosis of a larger percentage of vertebral fractures will, by making early operation more often practicable, still further lessen the average of permanent disability.

In attempting to estimate disabilities and recoveries in percentages, only a relative degree of accuracy is possible with the data at hand. Not a few cases show apparent complete recovery of range and strength of painless motion after fusion operation, but it is apparent that cases estimated as complete recoveries by less conservative judges will be found to possess a definitely ratable degree of permanent disability under the careful and experienced scrutiny of such investigators as the permanent rating department of the California Industrial Accident Commission. In the author's opinion, an industrial accident commission is justified in exercising a large degree of conservatism in passing upon such cases. Compression fracture of a vertebra is so severe a lesion that it is doubtful if, under any circumstances of apparent return to normal, it can be said that no potential permanent disability is present.

177 Post Street.

DISCUSSION

Ellis Jones (Brockman Building, Los Angeles)—This paper is a valuable contribution to the literature of spinal fractures, and is by far the best paper I have read so far on the subject. Cleary's statement, that 50 per cent of his patients came to him with a missed diagnoses in spinal fractures, is disturbing indeed, but is commonly corroborated in orthopaedic practice. The burden of proof in diagnosis rests upon the roentgenologist, and we are accustomed to ask for at least three views—an anterior-posterior, lateral and oblique radiographs, including a stereograph. It should be an established rule in general practice to regard every back injury as a potential spinal fracture. A clear history and a careful clinical examination will not necessarily make the diagnosis, since an acute infectious spondylitis, a traumatic or infectious myositis, as well as many other conditions may simulate the symptoms of spinal fracture.

Persistent conservative treatment by cast or brace fixation undoubtedly will give good results when skillfully used and when time is no object and the persistent co-operation of the patient is obtained. We are satisfied to return the laborer to active work in from twelve to eighteen months. We have found, however, that internal fixation, whether obtained by the Albee graft or the Hibbs method, is far more satisfactory than any conservative method. In an experience in over three hundred cases of spinal fixation obtained in tuberculous spondylitis, spondylolisthesis and spinal fractures, we have found the Albee method eminently satisfactory. The Hibbs method is undoubtedly equally effective and is, at least theoretically, better applied in the cervical and dorsal regions, especially when the spinous processes are thin and apparently inadequate to insure graft fixation. The operation described by Cleary seems mechanically sound and of especial value when the condition is complicated by laminectomy. Adequate operative spinal fixation, however obtained, certainly shortens convalescence by from six to twelve months, and in the hands of a competent surgeon must be the method of choice in the treatment of spinal fractures.

George J. McChesney (Flood Building, San Francisco)—This is a very timely paper on a timely subject. The author emphasizes common errors in diagnosis and gives us valuable ideas in the operative methods of treatment. Fusion operations are just now obtaining proper recognition for fractures of the vertebrae, although long used with success for the crushing due to tuberculosis.

I heartily agree with his requirement for a proper physical examination: viz., the patient should be stripped and standing whenever possible, but proper x-rays are absolutely essential and the lateral x-ray is all-important. I have seen good antero-posterior x-rays quite fail to indicate a fracture that the lateral shows clearly especially when the crushing involves only a small portion of the body.

As regards treatment, the conclusion reached several years ago by the commission of the American Orthopedic Association for the study of end results of fusion operations for spinal tuberculosis, should also apply to fractures. This conclusion was that the older methods, recumbency and immobilization, are not made unnecessary, but their periods of use are shortened by the fusion operation. This point is well brought out in this paper, and their comparative values from an industrial standpoint well contrasted.

The fusion operations themselves have been used since 1912, and hence are far beyond the experimental stage, especially as they sought to control much more difficult problems such as a larger kyphosis in progressive disease, a sickly child, etc. That they have stood this test of time, with careful follow-up of cases, etc., is more than sufficient recommendation of their efficiency for the simpler mechanical and medical problem of a compression fracture in a healthy adult. In fact, the only limitation of the fusion operation in spinal tuberculosis is that of age. (Young children below six years, owing to presence of cartilage instead of bone where fusion is desired, are not favorable subjects.)

As regards the relative merits of the Hibbs and Albee operations, operators differ partly because they become more proficient in one or the other. The Hibbs is more difficult, tedious, involves more loss of blood, and not infrequently leads to some shock. It is easiest done in the dorsal spine.

The Albee is easier, quicker and comparatively little loss of blood leads to no danger and shock, and has the mechanical advantage, as pointed out in the paper, of having the fusion at the end of a longer lever than the other method. The lumbar and cervical spine are better adapted to it.

The combination of the two, as described in the paper, is certainly ingenious, and in some cases, as stated, should have a definite value.

I had recently the opportunity of examining and x-raying an Albee fusion done on a man in the lumbo-sacral region by the late Doctor Sherman and myself eleven years ago. The man had no vestige of his fifth lumbar tuberculosis, the graft was both palpable to the finger and visible in the radiogram, showing conclusively the permanence of the result. Neither was the slight loss of spinal flexibility an industrial handicap.

The after treatment is all-important, as the author states. I feel that every case should be judged on its merits and no set rule should be laid down. When in doubt, to immobilize a while longer is a safe rule to follow.

This paper should help greatly to put the treatment of a very serious fracture upon a more scientific and efficient basis than it now possesses.

Maynard C. Harding (Timken Building, San Diego)—Doctor Cleary's interesting and well-balanced paper has stimulated me to review the records of thirty cases of my own. My experience leads me to endorse his conclusions in almost every particular. I wish to commend his stand for the operative fixa-

tion of a larger number of these cases than has heretofore been attempted.

There are certain features in the immediate treatment of acute cases which will bear emphasizing. We have two distinct divisions of spine fractures: (1) Those of the spinous process or of the transverse processes, displacement of which cause no cord damage. (2) Those of the body, articular processes, and laminae, displacement of which may injure the cord.

The first type may be moved and manipulated with impunity. Recumbency in a fracture bed, or fixation by a jacket or brace is proper treatment. There are definite limitations to what may be safely done to the second type. Often the damage to the supporting structures is so complete in cervical or lumbar fractures that fresh hemorrhage is easily started up or further pressure on the cord is produced by even the most skilful lifting. Unless open surgery is to be done, the patient should not be moved from his bed. A fracture bed with a smooth, firm mattress can be made to do all that casts, shells, braces, or Bradford frames can do and do it more comfortably.

In fractures of the lumbar and eleventh and twelfth dorsal vertebrae, the desired posture is hyperextension with control of rotation and side-bending. Hyperextension is secured by a firm blanket roll under the mattress, and lateral stability by long sand bags. In dorsal fractures, varying degrees of hyperextension are required, rotation and lateral bending being prevented by the ribs. In cervical fractures both types of fixation are required plus traction, since cervical fractures are prone to telescope. Hyperextension is secured by a firm pad of Turkish toweling or felt. Lateral bending and rotation are controlled by square sand bags, bedded snugly down on the shoulders and reaching above the ears. Ten pounds of traction, applied intermittently, by a Sayre sling is enough, with the head of the bed raised one foot.

The Thomas collar, the plaster jacket and the Taylor brace, in my opinion, are for ambulatory use after healing is well advanced.

Thomas A. Stoddard (291 Geary Street, San Francisco)—I have read E. W. Cleary's excellent article with a great deal of interest. I would like to emphasize that among the early essential factors of diagnosis is a good history of the nature of the accident, and subsequent symptoms, then proper x-rays. The average x-ray technician has not the ability to make proper x-rays with the usual equipment found at most doctors' offices, in the usual hospital plants, or in the average commercial x-ray establishments. Most of the cases that suffer fracture of the vertebrae are of the heavy, muscular type, and therefore require better than the average equipment, particularly to make a differential diagnosis of fractured laminae, and articular processes, and to get proper lateral pictures to show the crushing injuries in the bodies of the fractured vertebrae. It has been my observation that one of the principle causes of failure of early and proper diagnosis has been the lack of proper merit in the x-rays taken.

The average medical man seldom meets with more than two or three of these cases in all his practice, consequently he is not suspicious enough of the nature of the man's injury to make him exhaust all the diagnostic assistance possible before being satisfied that the man has not sustained a fracture. In passing, after examining many hundreds of backs, I have been unable to find a single case of dislocated vertebra which was not accompanied by some congenital deformity or a fracture, and I have found none of the so-called osteopathic or chiropractic subluxations.

Doctor Cleary has confined the scope of his paper to a discussion of compression fractures of the vertebrae. It has been my experience that about 50 per cent of the fractured spines, uncomplicated with nervous symptoms, were compression fractures. I get a large percentage of fractures of spinous and transverse processes and have been fortunate enough to early recognize, both clinically and by x-ray assistance, six fractures of articular processes within the last two years.

All the fractures of articular processes that have come into my hands have been in men doing heavy work and through muscular strain, and not through violence of other types.

Treatment of the last three types of cases is, of course, non-operative. Their period of disability, if diagnosed early and cared for with proper fixation in plaster casts, is much less prolonged and their recovery usually complete.

I believe in early operation in all compression fractures, and use Hibbs' technique as the operation of choice. My post-operative treatment differs from that mentioned by Cleary, in that I keep my patient in bed in a plaster jacket one month, then get him up and about for two months, after which time he wears a Taylor brace for about three months, depending upon the location and severity of the injury, and the nature of his normal duties.

The last three operative cases I had in young men all got back to their normal duties within six or seven months from the time of the initial injury. Recognizing the basic principle that function tends to strengthen the parts, whether soft or hard tissues, I believe these excellent early results were due to the fact that early normal function was instituted in a guarded position without other physiotherapy. I am opposed to long-continued physiotherapy in most of these cases, on account of the dependent psychology which attends such persistent treatment.

Lionel D. Prince (Flood Building, San Francisco)—E. W. Cleary deserves great credit and certainly is to be complimented on having presented in such an excellent and comprehensive manner a paper on so difficult a subject as fractures of the spinal column.

This is an extremely important subject, and too much emphasis cannot be placed upon it. Of the major types of bone injuries there is none, probably, so frequently overlooked and consequently neglected as fractures of the spine. This tendency to overlook fractures of this type is growing less for the reasons that, firstly, spinal fractures have of recent years been given extensive consideration in medical journals and, secondly, the majority of fractures of this type come under the care of industrial and orthopedic surgeons who through experience have become more mindful of their frequency.

The diagnosis is not difficult, and even where clinical manifestations are masked or are not sufficient to warrant a diagnosis, satisfactory x-rays can always be relied upon. Lateral x-ray views are especially valuable and should always be taken. I have on several occasions seen cases where the diagnosis has been overlooked owing to the fact that anterio-posterior views, which were the only ones taken, did not show sufficient pathology to suggest a fracture. Lateral views subsequently taken made the diagnosis indisputable. All spines which have been subjected to trauma warrant an x-ray examination.

Probably the most frequent cause of fractures of the spine, from a mechanical point of view, is the forcible buckling forward of the spinal column—the so-called jack-knife position. Frequently, in falls from a height the patient is jack-knifed. The application of force or blows, as pointed out by Cleary, produces the same effect. In three cases that I recall offhand, one received his injury as the result of a barn door falling and striking him on the shoulders; the second, a miner, was buckled forward as the result of a cave-in in a tunnel; the other, while on his knees under a truck which he was repairing, the supporting-blocks gave way and his spine was jack-knifed when the weight of the truck fell on his shoulders.

I am of the opinion that early operative interference is indicated in most cases of fractured spines. Statistics show that the ultimate outcome, as regards the degree of permanent disability, is very much less in the operative cases, and, as pointed out by Cleary, the period of convalescence is materially shortened. In old patients and in patients with arthritic changes

in the spine, the prognosis is not so good. Arthritic spines often mask, owing to the symptoms due to the arthritis, the advantage of operative interference. These cases in industrial work often get eventually very high ratings. Arthritis, on the other hand, occasionally reacts to the advantage of the patient, and one not infrequently sees cases of old fractures of the spine where a spontaneous cure has resulted from a complete pathological ankylosis of the fractured vertebra.

The accepted Hibbs and Albee methods of interference have given excellent results and, when properly performed, satisfactory results may be expected. The site of ankylosis in the Hibbs operation is mechanically better than that in the Albee. The Hibbs operation is a more difficult one and, in addition, it is tedious and time-consuming except in the hands of the most skilled. The paired graft operation emphasized by Cleary offers a distinct advantage, in that it produces a firm ankylosis at the most advantageous site and precludes the possibility of a fracture of the graft, a complication which is most annoying and which occasionally is experienced in cases operated on by the Albee technique. Cleary's method of insertion of the tibial grafts gives additional insurance of a more adequate ankylosis. I do not quite agree with him, however, that the fusion of one vertebra above and one below the lesion is sufficient to insure the best results. Probably traumatic lesions do not require the same degree of stabilization as diseased lesions of the spine, but I use the same technique in both types of cases. It has always been my policy to fuse two vertebrae above and two below the lesion. This insures greater stability, and I do not believe adds materially to restricting motion in the spine. With the increased accommodative motion in the uninvolved spine very little restriction may result, and I have in mind a case in which I performed a Hibbs for a fracture of the twelfth dorsal vertebra, fusing five bodies. The patient could eventually practically touch the floor with the tips of his fingers.

Physiotherapy, as emphasized by Cleary, is a most important therapeutic adjunct during the period of convalescence. Careless post-operative observation and treatment has in many cases protracted the period of disability. There is too much tendency for the surgeon to lose interest in the case after he has performed the operation. Physiotherapy is equally important in cases where the conservative treatment of spinal fractures has been instituted, though in cases treated by immobilization only there is not infrequently too great a tendency to institute physiotherapy too early. This overenthusiastic and misdirected judgment may easily undo the beneficial effects resulting from the immobilization and eventually bring the patient to the operating-table.

Doctor Cleary (closing) — In closing, I wish to thank the discussants for the very generous commendation given my paper. Increasing experience and study of lesions of the spinal column heightens my appreciation of the sentiment put by Tennyson into the mouth of Ulysses: "Yet all experience is but an arch where through gleams that untraveled world whose margin fades forever and forever as I move."

I am glad Jones stressed the limitations of history and clinical examination as means of making a diagnosis. The revelations from a carefully conducted history and clinical examination both warn the examiner to take the precautions for the patient's protection, ably outlined by Harding, and fortify his resolution to proceed to the exact diagnosis through a thorough x-ray examination, always more or less expensive, and sometimes distressing to the patient.

McChesney and Prince have done well in reminding us that a slight loss of spinal motion is not necessarily an industrial handicap. Good function depends, not so much on preservation of a complete range of motion, as upon the ability to use, without disabling distress, even a considerably restricted range of motion.

I agree with Prince that a fusion operation is an undertaking for the specialist in bone surgery.

I am particularly interested in Stoddard's experience in getting patients upon their feet four weeks after operation. I quite agree that it is desirable to shorten the period of immobilization and recumbency as much as is safe. I believe that, for every week safely cut from the immobilization-in-recumbency period, ultimate recovery is advanced by two to three weeks.

It gratifies me that the importance of physiotherapy in these cases is so generally conceded. I believe we are all agreed that, in discussions of problems of restoration of joint function, co-ordination should be spelled with capitals.

There are over one hundred joints either directly or very intimately associated with the spinal column. I do not know that anyone has been found with the temerity to announce the exact number of muscles concerned in the functioning of this vast aggregation of joints. The disability due to failures and disturbances of co-ordination after severe spinal injuries often seem proportionate to the complexity of the joint and muscle system involved. After the necessary measures to restore skeletal support have been taken, properly applied physiotherapy is our greatest aid to recovery in the restoration of muscular strength and co-ordination.

Hydrochloric Acid Therapy in Rickets—Those infants having relatively little hydrochloric acid in the gastric secretion may develop normally when breast-fed, but, says Martha R. Jones, San Francisco (Journal A. M. A., February 9, 1924), if the diet is changed to foods having a higher potential alkalinity, the amount of acid present may be insufficient for normal mineral metabolism. Individual differences in hydrochloric acid secretion may also explain why one of a pair of breast-fed twins is rachitic and the other not. It is conceivable that the beneficial effects derived from cod liver oil, sunlight and improved hygiene may be due to the stimulation of general metabolic processes, and indirectly the readjustment of the acid-base balance in the body. For the latter theory there is some foundation in an athreptic infant, age three months, in whom the gastric contents after a test meal of oatmeal gruel showed complete anacidity. Hydrochloric acid was added to the milk formula, and not only was there prompt and striking improvement in the general well-being of the infant, but the gastric tests made during the acid therapy showed a curve well within normal limits. When the infant's condition warranted a discontinuation of the hydrochloric acid, gastric tests still showed the presence of considerable acid, although the curve was not so good as that during the acid therapy. Apparently, in this case, the increase in hydrochloric acid secretion was the result of general improvement which was initiated by the addition of acid to the diet. Furthermore, the fact that inanition greatly retards the rachitic process can also be explained in the foregoing hypothesis, since the products of catabolism of body tissue are acid in reaction, and may help to restore a normal acid-base balance. Having succeeded in producing rickets in apparently normal puppies on a well-constituted diet with the addition of an alkaline salt mixture and to cure this condition with no changes in environment or diet other than the addition of hydrochloric acid, Jones decided to try out this therapy on rachitic infants. The result was very satisfactory. The cases are reported.

Notice to Motorists Planning to Drive to Annual Meeting at Los Angeles—Various and conflicting reports are current of difficulties incurred by people traveling thoughout the State. Those who desire to motor down to Los Angeles, would be wise to get in touch with the California Automobile Association, and see what the actual conditions are before starting.

DEEP X-RAY THERAPY *

By JAMES P. KERBY, Salt Lake City, Utah.

Deep x-ray therapy is a relative term. Treatment of any condition beneath the epidermis is, therefore, deep therapy.

However, by the term "deep therapy," as used by radiologists of the present day, is meant the treatment of conditions by rays produced by transformers generating 200,000 or more volts, which have been filtered through copper or zinc. As a matter of fact, copper is the agent which is almost universally used as a filter in this country. Rays generated by a current of this voltage, filtered through copper, approaching the gamma rays of radium in physical properties, are known as hard rays. These hard rays may be used in the treatment of superficial lesions; for instance, epithelioma. One of the most startling results I have ever seen was in the case of an epithelioma involving the nose and upper lip, with large metastasis to the glands of the neck. This condition was pronounced inoperable by two competent surgeons. Nine months after completion of deep x-ray treatment he is apparently well, with no evidence of original lesion or metastasis.

At a meeting of this society last spring, in a preliminary report, I suggested the term "high voltage, heavy filter, x-ray therapy" as a descriptive term for this method of treatment.

This method of treatment is the subject of so many articles in general and special journals that a detailed account of its historical aspect is unnecessary. Suffice to say, it is not really new, for experimentally it was used nearly twenty years ago, and has been in use in German clinics for ten years.

Its use in this country is comparatively new. The first machine to be built in the United States was used by Millwee of Dallas, Texas, less than three years ago.

It is interesting to note, in observing the strides made along this line, that during the discussion of a paper by this same title read about two and a half years ago before this society, mention by me of the fact that this new type of x-ray therapy was being utilized in Europe was passed with scant acknowledgment and apparent questioning of its efficacy by the essayist of the evening. During the past two years the apparently greater success achieved by its use as compared with the results with the older therapy, which, for distinction, I will call 9″ therapy, in contra-distinction to the newer, so-called 20″ therapy (though, as a matter of fact, the tubes which are now commercially available will stand only a voltage equivalent to a 16″ spark gap) has resulted in its widespread adoption. However, I fear this widespread utilization may prove a temporary hindrance to a true appraisal of its value, because it will undoubtedly be used by some men without sufficient knowledge of the dangers inherent in its usage. For it cannot be disputed that it is not safe to employ such a powerful agent without due consideration of the destructive factors difficult of disassociation from it.

In the consideration of any therapeutic agent it is important that its modus operandi be determined, if possible. The manner in which radiant energy inhibits or destroys living tissue is a moot question. Of course, an overdose destroying all tissue can be understood. But the manner in which it acts when used therapeutically is not definitely known. By some, it is believed that the—if I may use the term—cellular growth-producing hormones are destroyed. Possibly a larger percentage of investigators believe it due to some alteration in the permeability of the cell membrane. In a general way, the more nearly a new growth approaches the primary embryonal tissues, the more likely it is to be affected by radiation. Vascular and lymphatic endothelium are very susceptible to radiant energy, so tumors composed largely of this type of tissue offer a favorable field for x-ray therapy; hence the encouraging results in Hodgkins' disease and lymphosarcoma. Intercellular connective tissue is relatively highly resistant, therefore tumors made up largely of this type of tissue are less favorably affected. From this it will be seen that the type of tumor rather than its location determines the degree of success which may be anticipated. This statement, while practically axiomatic, is subject to definite limitation, because of the problems involved in delivering the necessary dose to the growth. If it were possible to expose the neoplasm to the direct action of the rays we would be able to destroy it by radiation therapy; incidentally, it could be removed surgically. The problem is to pass the rays through the intervening structures in such quantity as necessary to effect the desired result and at the same time not do these tissues an irreparable damage. In addition to the destructive action exerted on malignant cells it is believed that the obliterating endarteritis, the round cell infiltration and scar tissue formation wall off more resistant malignant cells and prevent their entrance into the blood and lymph streams. Many observers believe that, in addition to the local changes produced, a constitutional reaction ensues which may be compared to the formation of antibodies following bacterial invasion. Results of animal experimentation, however, show such varying results that this cannot be stated positively.

The essential factors in this form of therapy are:

1. The utilization of short-wave x-rays, heavily filtered. The short-wave rays are obtained by using a high voltage current, 200,000 or more volts, and employing heavy filters which shut out a very large percentage of the rays which are injurious to the skin.
2. A great increase in the distance between the patient and the tube.
3. The use of large treatment areas.
4. Long treatment periods.

In the beginning of this form of treatment, a great deal was heard of carcinoma doses, sarcoma doses, etc., as if a malignancy could be cured by simply turning on a current and letting it play the resulting rays on the involved region. In my opinion, practically every case is a law unto itself. The same skill and judgment must be utilized in attacking a cancer problem by radiant energy, cautery or knife, the weapon used in the attack depending upon the given case. This brings up the actual methods of treatment. It is not my plan to discuss this tech-

* Read before Salt Lake County Medical Society, November, 1923.

nically, but to give you an idea of the factors involved. Before deciding on the plan of attack, it is well, so to speak, to make a reconnaisance. The patient's general condition must be evaluated—i. e., blood, urine, heart, lungs. Would this patient be a good surgical risk and would you be willing to operate if operation were indicated? Is there evidence of metastasis? Examination of the points where metastasis is most likely to occur must be made. The various tests necessary in determining these facts—x-ray, laboratory, clinical—must be utilized. To cite a few instances, a carcinoma of the prostate may extend to the seminal vesicles, to the rectum or bladder, the aortic glands, the spine, hips or pelvis. Carcinoma of the breast may extend to either axilla, either side of neck, the opposite breast, the lungs, spine or pelvis.

This survey having been completed, the next thing, of course, is to undertake the treatment. And this is usually no easy matter in cancers involving the abdominal and pelvic cavities. There has been some discussion about how much exposure the intestinal mucosa will resist. Recent investigation tends to show that it is not improbable that this membrane is at least as susceptible to x-ray exposure as the skin. It has been observed that at a distance of 10 cm. beneath the surface a certain percentage of the x-rays reaching the skin is delivered. This percentage varies according to the factors involved in the treatment, but with the majority of machines used in America utilizing the treatment factors usually employed, it is somewhere between 40 and 50 per cent. In a general way, from 75 to 125 per cent of the amount of radiation which will produce an erythema of the skin is believed necessary to destroy malignant cells. By an erythema in this case is meant a slight reddening of the skin, followed by a deep tanning which vanishes in from ten to twenty-one days. It is thus seen that if a certain quantity of rays will produce skin reaction varying from erythema to ulceration, a similar reaction might be produced in the intestine if the same amount of radiation reached it. It seems reasonable to me to believe that most of the nausea, vomiting, diarrhea, and prostration sometimes associated with this form of treatment, are due to damage to the intestine, as these symptoms are much more noticeable after abdominal than after thoracic or extremity radiation in much larger quantity.

One of the most, if not the most, difficult problems in modern deep x-ray therapy is dosage. It is my opinion that there is no hard and fast dosage for any one condition. Two neoplasms of apparently the same type in the same organ in two different individuals, as nearly as possible to determine of approximately the same size, have given entirely different results. I have treated in two cases what I believed to be approximately the same condition in the same organ, with exactly the same technique, as accurately as I was able, with considerable difference in the end results. This would certainly seem to emphasize the truth of the dictum that every case is a definite entity in itself and must be regarded as a distinct biologic and physical problem.

Before going further, I wish to state that it is my opinion that every operable malignant tumor should be operated on; that uterine and mammary carcinoma should be x-rayed from eight to fifteen days before operation; that in every case operated on there should be post-operative radiation of essentially the same type as that case would have received had it been inoperable; that all areas to which lymphatic drainage occurs should be radiated; and, unless there is a definite contra-indication, the areas to which metastasis most commonly occurs should be radiated. I believe that supplementary radiation of this type will materially increase the percentage of three and five years' operative cures. There is convincing evidence that more sarcomas, especially lymphosarcomas, will respond more favorably to radiation than to surgery.

Always bearing in mind that I place operation first where there is reason to anticipate favorable results from operation, x-ray therapy is indicated in malignancies of the brain, malignancy of the thyroid, prostatic hypertrophy, benign and malignant, malignant conditions of the breast, lymphosarcoma and lymphogranulomatosis, tuberculous adenitis, fibroids, chronic non-malignant endometritis, keloids, peritoneal and genital tuberculosis. In hypernephroma, it is beneficial in relieving pain, but the danger of destruction of adrenal function must be guarded against. Encouraging reports of the palliative value of x-ray in malignancy of the esophagus are being received. When we consider that the number of cases of definitely diagnosed cancer of the esophagus which have been cured can be counted on the fingers of one hand, the further use of x-rays in the hope of securing a cure is warranted. An increasing number of cases of gastric malignancy considered unsuitable for surgery are being reported, with apparently encouraging results, from high voltage x-rays. However, the treatment has not been used generally. In cancer of the sigmoid and rectum, striking palliative results have been observed and apparent cures secured.

This paper is not presented with the idea of establishing a therapia magna sterilisans for the treatment of malignancy. It does not have for its purpose to propose radiant energy treatment of all malignancies. It merely reviews the advances made in the line of x-ray therapy as an adjuvant to or as a substitute for medical or surgical treatment of disease. Surgery, endocrinology, internal medicine, radiology are all branches of the healing art, and no one of them can stand alone.

Boston Building.

Immunization Against Typhoid — Ordinarily typhoid vaccine is administered at intervals of seven days. It is said that if the interval is less than seven days the immunity may be less than after longer intervals. It is asserted also that the maximum response follows when the intervals between the injections are lengthened to eighteen or twenty days. No definite statement can be made as to what the optimal intervals really are. Immunity after antityphoid inoculation is not absolute. Army medical officers express the opinion that immunity from inoculation begins to decline in from two to two and one-half years; but even after four and five years, the typhoid rate of inoculated troops has been estimated at about one-fourth that of uninoculated troops.—Journal A. M. A., February 2, 1924.

SOME TYPES OF CHRONIC RECURRENT PYELITIS AND THEIR TREATMENT*

By FRANKLIN FARMAN, M. D., Los Angeles, Cal.

Women are more subject to pyelitis than men. This fact has been explained by the peculiarity of feminine body form, and by the anatomical shallowness of the lumbo-renal recess in women as compared with men, which permits of greater mobility of the kidneys, and which subjects the kidneys to many forms of internal and external traumata.

Congestion of the kidney is regarded as the actual important factor in the production of renal infection. Mobility of the kidney, occasioning either slight torsion of the vascular pedicle, or slight retention by kinking of the ureter, the trauma of slight bruises and wrenches, straining, lifting and flexions of the body, and toxic influences all lead to congestion of the kidneys. Congestion of the kidney is even more important than the type of bacterial invasion, for it is well known that a normal kidney will excrete and destroy bacteria and that no infection results unless the dose of bacteria reaching the kidney is deposited in congested tissue. About 90 per cent of renal infections are caused by the colon bacillus, and another 5 per cent are caused by one of the pyogenic cocci. In this discussion tuberculosis of the kidney and the rare forms of pyelitis are not considered.

Renal infection in the female may appear at any age from childhood on, but there are certain periods of life in which the recurrent types are more apt to become activated. For instance, pyelitis in young adult women occurs more commonly after marriage than before. The so-called "defloration" pyelitis occurs at this age. Women around the menopause age are particularly subject to urinary disturbance. The trauma of repeated childbirth and the strain of heavy household work are factors which lead finally to congestion and infection of the kidney. Elderly women, too, are prone to the chronic recurrent types of infection. A chronic urinary infection may remain dormant for years until suddenly activated by some indiscretion, or general lowering of vitality.

In young adult women attacks of pyelitis are frequently precipitated by marriage or make their appearance during the early months of pregnancy. Some extra strain, overexertion, chill, "cold," intestinal upset, menstrual irregularity, or the like may be the immediate exciting cause. Careful questioning frequently reveals a history of some previous urinary disturbance occurring during childhood or youth, often not recognized or considered as a definite entity. So often urinary symptoms in the young are considered lightly and ascribed to gastrointestinal disorders or nervousness. Many patients will tell you that they had "weak kidneys" early in life or were subject to enuresis.

The typical attack of acute pyelitis in young women comes on suddenly with symptoms of urinary disturbance. Frequency, burning, and marked urgency are predominate symptoms. The presence of chill and fever are not constant, and do not occur unless there is urine retention with toxic absorption. The leukocyte count generally is low, under 15,000. Pain in the region of the kidneys frequently is absent in uncomplicated pyelitis. A catheterized specimen of urine contains pus cells, occasionally red blood cells, epithelial debri, and bacteria. Mild attacks of pyelitis often subside quickly and spontaneuosly, but the more severe cases tend to run a protracted and relapsing course extending over a period of weeks.

Pyelitis attacks occurring in middle-aged women may be similar to those occurring in younger women, but there are certain added factors which frequently change the clinical picture and alter the course. Many women, apparently in good health, "carry on" for years, experiencing occasionally mild transitory periods of urinary disturbance with indefinite backache or abdominal pain, until a sudden, sharp attack of urinary distress, kidney area pain, chill and fever, directs attention to the actual condition of pyelitis.

Women of this age are more apt to be suffering from nephroptosis, from strictures, kinks, or angulations of the ureter, from cystocele, pelvic tumors, and from chronic infections of the abdominal viscera. We should mention especially the close relationship of gall-bladder disease, and colitis, to renal infection. Definite experimental and clinical tests have shown that the constant elimination of bacteria and toxic material brought to the kidney by the blood stream from distant sources of infection (teeth, tonsils, sinus) finally result in irritation, destruction, and infection of the kidney itself.

Due to the above complicating factors, chronic renal infections occurring in middle-aged women frequently run a varied and atypical course. Kidney area pain is a more constant and prominent symptom. The bladder symptoms oftentimes are mild, but, on the other hand, may be of the greatest severity. Associated digestive and nervous symptoms are misleading. The urinary findings are similar to those in other forms of pyelitis, but we more often find mixed infections. The functional capacity of one or both kidneys will be found greatly diminished, as indicated by the phenolsulphonphthalein test.

It is in this period of life that most surgical conditions arise. Attacks of pyelocystitis are not at all uncommon following operations. I recently treated a woman for a severe renal infection, which followed a simple hemorrhoidectomy. The frequent occurrence of vesical irritability and loss of bladder function following major surgical operations, especially of a gynecological nature, is known to all surgeons. The treatment of this condition will be mentioned later.

The symptoms of renal infection in elderly women are of bizarre character. The symptoms are less acute, patients acquire a high degree of tolerance for pain and urinary irregularity. Also a certain immunity against the infecting organism is established. So-called "urethral chill" with fever occurs when there is sudden renal or vesical retention. Often there is loss of weight, cackexia, and anemia, the resulting picture being that of cancer. The urine generally is highly colored, offensive from ammoniacal decomposition, and heavily loaded

* Read at annual meeting of the Nevada Medical Association, Reno, September 28, 1923.

with pus, mucus, and bacteria. The clinical course is slow and irregular, with periods of slight exacerbation.

Treatment—I offer nothing experimentally new in regard to the treatment of pyelitis, but wish to call attention to certain details and modes of therapy which have proven successful in our work. Acute attacks are treated symptomatically and later treatment is directed toward correction of the accessory causes of renal infection.

Absolute rest in bed is an important factor in the quick relief of the acute inflammatory symptoms of the urinary tract. In the absence of chill and fever, patients are inclined to keep up and about their daily duties, even pain not being sufficient to cause a patient to voluntarily confine himself to bed. For this reason we aim to hospitalize patients at the onset of an attack, so that absolute control of the clinical course may be maintained. For economical reasons, I do at times attempt to direct teatment of a case of pyelitis by home and office visits, but find that such cases tend to run a more protracted and relapsing course.

Diet is another important and often neglected factor in the cure of renal infections. Proper emphasis has been placed upon diet in the treatment of nephritis, but in renal infections which are more of a surgical nature, the importance of diet therapy has been overlooked. A diet which puts the kidney at rest, which reduces the acidity of the body, and which keeps the urine neutral or alkaline is desired. The so-called "basic nephritic" diet as advocated by Sansum does this. In general this diet includes mostly vegetables, fruits, and sugars, and excludes meats, eggs, and cereals. All foods which are essentially basic or neutral in nature may be allowed. Orange juice is very potent in rendering the urine rapidly alkaline. One glass at each meal is advised. Contrary to popular impression and taste, orange and lemon juice are not acid, but basic in nature. I have found this diet of the greatest help in relieving the distressing urinary symptoms of an acute attack. The basic diet, with exceptions, should be followed until the inflammatory lesion of the kidney and pelvis have healed.

In addition to the "basic diet," we administer drugs at the onset of an acute attack to further insure alkalinity of the urine. The citrates, acetates, or carbonates are the usual drugs employed. I find a combination of sodium bicarbonate and calcium carbonate in large doses useful. It is well to ascertain the degree of alkalinity of the urine frequently by determining the hydrogen-ion concentration or for clinical purposes the ordinary litmus test is sufficiently accurate.

Following subsidence of the acute symptoms of pyelitis, the administration of alkalies may be discontinued, and an urinary antiseptic given. Hexamethylenamin, better known by the trade-name of urotropin, is the most effective of all urinary antiseptics. Care should be exercised in its administration, and I wish to emphasize that generally hexamethylenamin should not be given for acute urinary symptomatology. The physiological effect of hexamethylenamin is due to the antiseptic action of the formaldehyde liberated in acid solution. A more uniform effect of urotropin is noted when the urine is made acid by the associated administration of acid sodium phosphate. The latter drug has no influence on the general body reaction or the alkalinity of the kidney tissues as maintained by a basic diet.

Experimentally, it has been found necessary to give large doses of hexamethylenamin in order to recover free formaldehyde in the urine, but for practical purposes, small doses in 5 to 10 grain amounts often are sufficient to control a chronic pyuria and bacteruria. Larger doses up to 60 or 90 grains per day may be used to render the urine sterile following an acute infection. It is best to give urotropin at intervals and for periods not longer than five to ten days. The untoward effects of hexamethylenamin are indigestion, aggravation of urinary symptoms, and renal irritation up to the point of hematuria.

A pyelitis which does not subside readily under medical management, or which tends to recur, should then be treated surgically. By surgical we mean direct kidney and bladder treatment, and investigation and correction of the accessory causes of infection. Our greatest success in the cure of the chronic types of pyelitis has been through the use of "pelvic lavage." Many patients experience their first relief from urinary distress following drainage and lavage of the kidney pelvis. We employ a silver nitrate solution in 1 per cent to 2 per cent strength, injecting through ureteral catheters amounts depending on the size of the renal pelvis. The pelvis should be allowed to drain thoroughly before lavage is carried out. It is better to use a warmed solution, making the injection slowly, and taking care not to distend the pelvis. In this way after-pain and colic are avoided. We repeat "pelvic lavage" once or twice per week, depending upon the clinical improvement and urinalysis. We aim to continue treatment until the separate urine specimens from each kidney are negative for bacterial growth and free from pus cells. This, however, is not always practical or necessary, as the clinical improvement following one or two treatments may not warrant further instrumentation.

Mention should be made of the value of "pelvic lavage" in the treatment of pyelitis of pregnancy. No other form of treatment gives uniformly such satisfactory results. It should be remembered that bladder symptoms occuring during pregnancy are rarely caused by pressure of the gravid uterus alone, but that a pyelitis more often is the responsible factor.

The important mechanical accessory causes of renal infection commonly found are varying degrees of nephroptosis, strictures and angulations of the ureters, and vesical retention or cystocele. Oftentimes it is difficult to correctly interpret mobility of the kidney. Palpation alone is not reliable, but should be combined with roentgen visualization of the kidney and pyelography. When it is determined that abnormal mobility of the kidney exists, a properly fitted abdominal belt or corset is recommended. Occasionally, it is necessary to correct sagging of the kidney by operation, in order to secure free drainage of the kidney pelvis.

In elderly women I encounter often marked tor-

tuosity of the ureters, strictures, and stenosis of the ureteral openings. In these cases the mere passage of an ureteral catheter often is sufficint to relieve an attack. Dilatation of a stenosed, pinpoint, fibrous ureteral opening gives prompt and permanent relief in many instances, and is fully as important as dilation of an urethral stricture.

Curtis has called attention to the frequency of urine retention found in post-operative and pregnancy cases. He holds this as a responsible factor in the production of pyelitis. In the routine examination of women complaining of urinary symptoms, we always look for and determine the presence or absence of residual urine. Sometimes it is necessary to examine for residual urine on successive occasions, as nervousness or sphincter spasm may prevent complete evacuation of the bladder, and then in the early stages of vesical relaxation it may be possible to empty the bladder completely by extra voluntary effort. Much can be done in this type of case to prevent retention and ascending infection.

The Curtis plan of management of the female bladder after operation and during pregnancy depends on two cardinal principles: 1. Catheterization is avoided if possible, but no patient is allowed to suffer from distention; 2. If the catheter has been employed, it is thereafter used once a day until the patient has regained the power of complete evacuation. The catheter is passed once a day, immediately after urination, until residual urine disappears. Before withdrawal of the catheter a few cubic centimeters of one-eighth per cent silver nitrate solution are instillated.

Renal infection occurring secondary to gallbladder, appendiceal, pelvic disease, or tooth, tonsil or sinus infection will spontaneously disappear following surgical relief of these foci. I wish to emphasize the importance of the removal of these chronic sources of bacterial and toxic formation, for I have previously pointed out that the constant excretion of these products by the kidney may finally result in infection of that organ itself.

Before dismissal of a case of pyelitis, we instruct our patients in what we have termed "bladder hygiene." They should avoid overexertion, fatigue, chilling, and exposure to inclement weather. Many of my cases during the past summer have come on following ocean-bathing, with sudden chilling of the body surface. They should be cautioned against inattention to proper bladder function. Neglect and voluntary suppression of the desire to urinate is a frequent cause of urinary disturbance. Women especially are prone to accustom themselves to overdistention of the bladder on occasions of long automobile trips and social gatherings.

Diet and careful regulation of the bowels are important. The "basic" diet serves admirably to alkalinize the urine at intervals. We generally advise a patient, subject to chronic renal infection, to take a course of alkaline powders once a month followed by a course of hexamethylenamin and acid sodium phosphate. Such a regime, if closely followed, favors complete healing of certain types of kidney infections.

(1501 South Grand Avenue.)

UNIQUE TRANSPOSITION OF ABDOMINAL VISCERA FROM HYDROTHORAX

By A. W. MEYER
Division of Anatomy, Stanford Medical School

Although I have made an earnest effort to learn of cases similar to the present one, my search has been unavailing so far. I have seen some very pronounced displacements of the liver caudally and also of the diaphragm cranially, in connection with various thoracic or abdominal conditions, but I have never seen anything, even roughly approximating the displacements of the liver and stomach, in the present case. Indeed, as an anatomist, I would have questioned whether anyone could endure such changes in position, no matter how gradually they occurred. That the hydrothorax in question must have been of rather long duration seems self-evident, for any abrupt displacement of the respective organs, even roughly approximating the conditions which obtained in this case, undoubtedly would have led to sudden exitus.

The body was that of a man, aged 57, who had given a history of night sweats beginning four and one-half months before admission. At this time he had been run over by an express wagon, a wheel of which passed over his left thigh, abdomen, and chest. It was noted in the clinical history that upon admission he was found too ill for a complete examination. Although the aggravation of the symptoms resulting from the accident brought him to the hospital, it was noted that he had felt weak for about eighteen to twenty months before admission, and that he tired easily. He had suffered from frequent colds since nine months before admission, at which time his cough had grown worse and was accompanied by expectoration of "four or five mouthfuls of blood at a time." Following the accident, he became progressively weaker and was shorter of breath. "A slight irregularity" of the right pupil was noticed. The cervical glands were enlarged and the clavicular fossae were very deep. Tachycardia was present.

Upon dissection the body was found to be in fair condition of nutrition. Inspection revealed fullness and particularly increased firmness in the whole epigastric region, suggesting the presence of a very greatly enlarged liver. The right side of the thorax seemed a little more prominent and rounder than the left. This thoracic asymetry became more evident upon removal of the upper extremities.

Upon opening the abdominal cavity in the course of dissection, the unusual position of the liver at once attracted attention and suggested the presence of a partial situs inversus. However, upon further inspection the right dome of the diaphragm was found protruding far below the right costal margin. The abdomen contained no evidences of adhesions, and, as shown in the figure, the apparently large, oddly shaped but otherwise normal liver occupied the greater part of the ventral portion of the cavity, being dislocated very far to the left. The right lobe seemed greatly enlarged, but the surface was smooth, although marked with a fine vascular relief suggesting possible congestion. A very shallow sulcus extended obliquely to the left from the um-

bilicus along the ventral surface of the right lobe of the liver, and very plainly resulted from pressure of the ligamentum teres hepatis, which made an angle of approximately 75 degrees with its normal position, extending to the left instead of to the right of the midline. The omentum lay entirely on the left side, and the liver as a whole seemed to be enlarged about one-fourth. It extended 5 cm. below the umbilicus, the caudal border of the right lobe lying 7½ cm. to the left of the midline and its diaphragmatic surface 3 cm. below the right costal border. The gall-bladder notch lay about 2 cm. below the umbilicus and 7½ cm. to the left of the midline. The ligamentum teres crossed the left costal border at the tip of the ninth costal cartilage, 9 cm. from the midline, and an equal distance below the level of the caudal extremity of the xiphoid. The dorsal surface of the right lobe of the liver was moulded to fit the vertebral column, and the entire diaphragmatic surface of the right lobe was occupied by a broad, deep impression made by the inverted right dome of the diaphragm.

The pylorus lay at a level 2 cm. cranial and 8 cm. to the left of the umbilicus. The small intestine was crowded into the pelvic cavity in the hypogastric region, a few coils only extending upward a short distance beneath the thick, rounded border of the right lobe of the liver. The right colic flexure was located immediately above the crest of the right, and the left flexure 5 cm. above the crest of the left ilium. The coecum, with a retrocoecal appendix, lay in the right iliac fossa quite in normal position.

The hepatoduodenal ligament formed a very prominent fold with a slightly crescentic border to the left, and was fused with the mesocolon. It extended a little to the left of the midline, had a width of 3 to 6 cm., and was entirely free from adhesions to the peritoneum behind it. It formed a large pouch with an opening approximately 7 cm. long and 4 cm. wide, facing in the direction of the spleen. The line of attachment of the mesentery was displaced caudally several centimeters.

The stomach, the left border of which was barely visible in the opened abdominal cavity, lay to the extreme left, occupying the upper portion of the left hypochondrium. It lay in a vertical position and was firmly contracted into a tubular form as is not rarely the case in dissecting room cadavers. The fundus lay directly over the spleen, which was enlarged somewhat and rotated 90 degrees. It was displaced obliquely to the right, its diaphragmatic surface having become dorsal in position, and being deeply grooved by the ribs.

The abdominal portion of the oesophagus turned sharply to the left from the diaphragmatic hiatus, the cardia lying 7 cm. to the left, approximately in a parasternal line. The duodenojejunal junction lay directly dorsal to the pylorus in the left hypochondrium, having been displaced caudally, and to the left far less than one might have expected in view of the greatly changed position of the pylorus.

The right kidney was somewhat displaced and rotated about 60 degrees, the caudal pole lying opposite the third lumbar vertebra, but the left was in about normal position.

The right dome of the diaphragm was totally inverted and depressed until its lower convexity reached 3 cm. caudal to the costal border in the right mammary line. It remained 2 cm. below this border from here to the median line, where it met the left dome approximately 2 cm. to the right of it. The inverted right dome was stretched until it lay 7½ cm. farther caudal than it is possible to move the normal specimen.

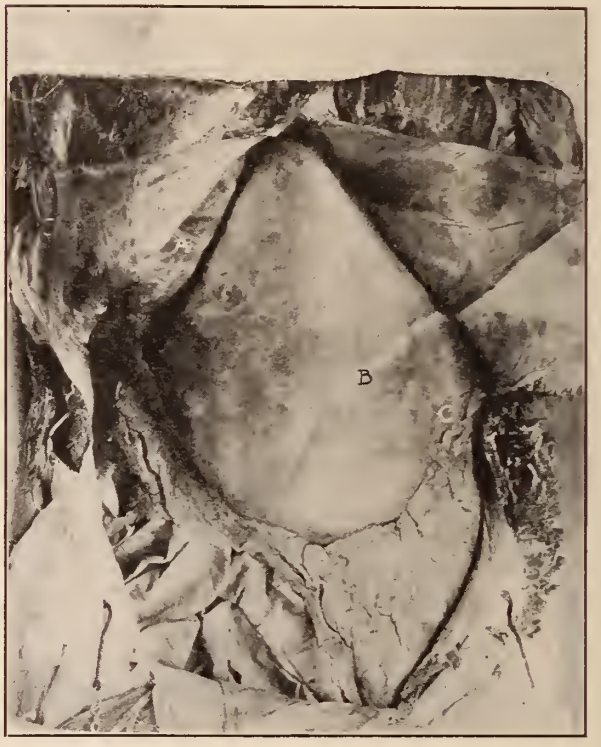

Figure 1—Abdominal wall reflected to expose viscera in situ. (A) Inverted right dome of diaphragm. (B) Sulcus on liver from ligamentum teres hepatis which is plainly visible on the interior surface of the reflected left rectus abdominis. (C) Location of the gall-bladder. The pylorus lies directly dorsal. The displacement of the transverse colon and the unusually large area occupied by the liver are plainly evident.

In spite of the astonishing displacement and rotation of the liver with consequent tension upon the vena cava and compression of the liver, there is no evidence that ascites was present, for the increase in abdominal tension from inversion of the right dome of the diaphragm may have been responsible for rather prominent peritoneal fossae in the femoral and inguinal regions.

Upon removal of portions of the right ribs the parietal pleura was found only very slightly thickened, though somewhat more opaque than normal. Though remarkably enlarged, the right pleural cavity contained no coagulum. Only a few fibrin strands and small remnants of old adhesions were found dorsally. The extent of the effusion, as shown by the volume of the pleural cavity, was 3300+ cc. The right lung, which was covered by a thickened visceral pleura, was markedly compressed, lying very largely in the upper third of the pleural cavity and being pressed firmly against

the vertebral column. The narrow tip of the lower lobe extended down to the diaphragm, to which it was adherent in the midline. The upper lobes formed a small, flat, triangular mass, the apex of which extended to the level of the sixth rib, occupying an axillary position against the ventral thoracic wall. A large vomica with somewhat fibrous walls occupied the upper third of the adherent, collapsed and compressed upper and middle lobes. The superior mediastinum was displaced about 4 cm. to the left of the median line at the fifth chondrosternal junction. The posterior mediastinum was displaced approximately to the left border of the vertebral column, with the heart lying entirely to the left of the median line. The azygos vein was not evident upon inspection, in spite of the very marked displacement to the left, of the posterior mediastinum. The oesophagus was displaced to the left, especially in its upper portion. The inferior vena cava crossed the vertebral column approximately in the midline, but turned obliquely to the left to join the heart.

The left costal pleura was normal except for a few small adhesions of the upper lobe to the pericardium and to the fourth rib in an axillary line. Although the entire upper left lung was studded with numerous nodules, apparently tubercular in character, the lower lobe was wholly free.

Although the hydrothorax in this case was very large, its volume alone does not account for the remarkable rotation of the liver to the left, amounting to almost 95 degrees. In another cadaver in which the hydrothorax was almost as large and in which the right dome of the diaphragm was also partly inverted, the liver was merely displaced caudally. That the intrathoracic pressure was very considerable also in this other case of right-sided hydrothorax is shown by the fact that the trachea was displaced markedly to the left, entering the thorax at the left sternoclavicular junction. The anterior mediastinum was displaced 7 cm. to the left of the midline, the right atrium and superior vena cava decidedly compressed, and the heart dislocated very far to the left. A large diverticulum of the posterior mediastinum extended caudally between the crura of the diaphragm to the second lumbar vertebra, lying directly dorsal to the omental bursa. Yet there was no rotation of the liver in this case.

It seems probable that the extent to which the mediastinum yields, the extent of the depression of the right dome of the diaphragm, and especially the rate of the effusion, may largely determine whether or not the liver is rotated to the left in cases of right-sided hydrothorax. Nor does it seem unlikely to me that the strength of the abdominal wall may be an important factor.

The extreme extent of the displacement, especially of the stomach and liver in the case here reported, implies that the effusion and the resulting displacement probably were very gradual. In individuals with relaxed abdominal musculature the direction of least resistance from intrathoracic pressure naturally would be mainly downward. In right-sided effusions, as in the present case, with an unyielding mediastinum, the right dome of the diaphragm would necessarily have to yield more. If the mediastinum more nearly maintains its normal position the heart and the left lung are more undisturbed. Consequently, it would seem that survival for a longer period of time would be more likely, permitting a gradual displacement of the liver and pylorus to the left. It is also likely that the presence of a large left hepatic lobe, held in position by its attachment to the left dome of the diaphragm which maintains a practically normal level, also might facilitate rotation of the liver. Nor is it unlikely that the habitual posture of the individual may be a factor, although it would seem that the nocturnal posture naturally assumed in right-sided hydrothorax would militate against rather than for, a rotation of the liver such as observed in this case. I have not been able to find any satisfactory explanation for the marked hepatic and gastric displacements in this case of hydrothorax, and as far as I have been able to learn, no such corresponding transposition of the liver and stomach are mentioned as a possibility in contemporary works on physical diagnosis. They merely speak of a change in liver dullness, and do not mention the possibility of rotation at all.

"More and Better Dentistry"—Under this slogan, the California State Dental Association will hold its fifty-third annual session at the Civic Auditorium, San Fancisco, June 11 to 15, inclusive.

The very complete and excellent program contains discussions of subjects of the greatest interest to physicians as well as dentists. The whole program has been so constructed that it constitutes a real five-day course in intensive graduate instruction. Clinics, scientific and commercial exhibits are well arranged, and the social program is—well Californian.

The officers and chairmen of the committees are: John D. Millikin, president; D. H. Leppo, president-elect; B. Frank Gray, secretary; Robert E. Keys, treasurer; Frederick T. West, editor; Guy S. Millberry, chairman Educational Committee; F. V. Simonton, chairman Research Committee; John E. Gurley, chairman Interstate Relations; D. H. Leppo, chairman Membership Committee; W. P. Heaney, chairman History and Necrology Committee; Fred J. Seiferd, chairman By-Laws Committee; Arthur M. Flood, chairman Legislative Committee; Charles Zappettini, chairman Dental Science and Literature; T. A. Vogel, chairman Insurance Committee; Robert E. Keys, director Exhibit Committee.

Fat-Free Tincture of Digitalis (Propaganda for Reform)—Roth found that fat-free tinctures of digitalis had no advantages over the U. S. P. tincture of digitalis. On the contrary, he found some of these fat-free tinctures were so unstable that he advised manufacturers not to market them without stating the date of their manufacture on the label. "Fat-free" tincture of digitalis was introduced under the belief that the fat from the leaf produced gastric disturbance; but Hatcher and Eggleston fed the fat to cats and found that it had no emetic action whatever. After an investigation of the subject, the Council on Pharmacy and Chemistry concluded that there is no essential difference in action between "fat-free" tinctures of digitalis and the product official in the U. S. Pharmacopeia.—Journal A. M. A., March 16, 1924, p. 911.

Digifolin (Propaganda for Reform)—The claim is made for digifolin that it keeps indefinitely. The available scientific evidence indicates that all digitalis preparations deteriorate with age.—Journal A. M. A., March 15, 1924, p. 911.

ESOPHAGEAL DIVERTICULA*

By JOHN HUNT SHEPHARD, M. D., San Jose, Calif.

The rarity of any pathological condition varies inversely as our familiarity with it increases. Judd reports that prior to 1917 there had been twenty-five cases of diverticulum of the esophagus diagnosed in the Mayo Clinic, while in the year 1917 there were ten. Rokitansky, in 1840, gave a clear description of esophageal diverticula and pointed out that they were of two different types, both as to their origin and anatomic structure. The most frequent type encountered at autopsy, though rarely seen by the clinician, he named traction diverticula, and later Schmorl reported their occurrence in 3.5 per cent of autopsies. They result from contracting tissue following a peri-esophageal inflammation, usually of the tracheo-bronchial lymph glands, although they have been found as sequelae to vertebral caries, strumitis and mediastinitis. Their sac is composed of all the coats of the esophagus. They rarely attain one centimeter in diameter, and the communication with the esophagus is usually their largest diameter. When their base lies lower than their esophageal opening, food will lodge in them and they may become converted into traction-pulsion diverticula, of which Tetten has reported six cases. Probably on account of the surrounding denser fibrous tissue following the original inflammatory condition they rarely attain sufficient size to produce symptoms. They may occur in any portion of the esophagus, although their most frequent location is near the left bronchus.

The type that is of most interest to the diagnostician and surgeon develops from pressure from within the esophagus and are known as pulsion diverticula, occasionally erroneously referred to as pulsating diverticula. They are constant in their point of origin; always arising on the posterior surface of the esophagus at the pharyngeo-esophageal juncture, through Laimer's triangle, sometimes referred to as the Linnier-Hackerman area. They are in reality a hernia of the mucosa and submucosa of the esophageal wall through the weakened longitudinal muscular fibers, no muscle fibers being found in their walls. The only possible exception to the above statement of their point of origin may be three cases reported by LeCount, originating in the cavum broncho-aorticum, a small area where the esophagus is unsupported by any adjacent organ, to which Brosch first called attention in 1900. While there was no peri-esophageal inflammatory tissue adjacent to any of these, and therefore no contracting bands, there was no microscopical study made of the walls to determine the presence of muscular fibers. They were all small and had given rise to no symptoms during life.

On account of the anatomical relations of the esophagus in its upper few inches, the vast majority of pulsion diverticula burrow to the left and when developed to sufficient size present as a tumor mass just above the clavicle and lateral to the sternomastoid muscle.

Seventy-five per cent of the reported cases were in males. The average age of the patients at the time of their recognition was 56 years, and the average duration of dysphagia was 5½ years. Many patients stated that they had had slight trouble in swallowing, or a sensation of something wrong in their throats, or too-frequent coughing spells while eating, as long as they could remember. In all probability if careful attention had been paid to the date of the first symptom, the average duration of symptoms at the time of recognition would be much longer than that reported.

The first two symptoms complained of by practically all of these patients are the sticking of food in the throat, and coughing spells during eating. Dysphagia gradually develops, until nutrition becomes impaired and unless relieved death results from some intercurrent infection or starvation.

A study of the schematic serial diagrams of a gradually enlarging diverticulum explains the symptoms better than words.

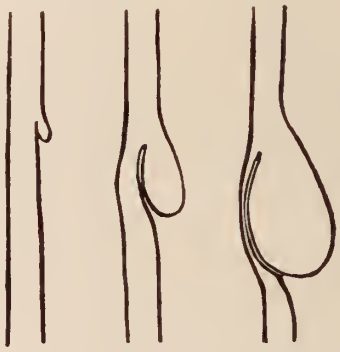

Figure 1 Figure 2 Figure 3

Schematic representation of the development of an esophageal diverticulum. Note how obstructive symptoms develop as the sac enlarges.

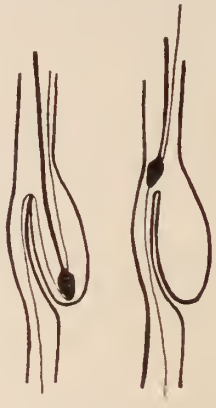

Figure 4

Showing how the bougie enters the diverticulum on a loose string, and how it is elevated and directed down the esophagus when the string is drawn taut.

Figure 1 shows a very small diverticulum and only a very slight amount of food can lodge therein; it becomes easily dislodged by coughing or a few attempts at swallowing. Figure 2 shows that when the pouch is filled the esophagus is sufficiently compressed to cause a partial stenosis. In this stage the patient soon learns that, by moving the head in certain directions or by pressure over the lower neck or upward stroking along the margin of the sternomastoid muscle, saliva and food will be forced into the pharynx and deglutition temporarily relieved.

* Presented to the Section on Surgery at the Fifty-second Annual Session of the California Medical Association, San Francisco.

Figure 3 shows a large pouch which, when filled, causes practically a complete occlusion of the esophagus. When the opening of the sac is large—and some are as large as the diameter of the esophagus—it fills readily, and these patients may have to spend the greater part of their waking hours in alternate eating and emptying the pouch in order to get enough food into their stomach to sustain life. When the opening is small and the pouch large, complete emptying is practically impossible and the retained food undergoing fermentation produces a very fetid breath. Ulceration may occur in these cases resulting in inflammatory adhesions surrounding the sac, making its removal very difficult.

The diagnosis in the larger types of diverticula can usually be made from the history of food lodging in the throat and being eructated free from the acrid taste of stomach contents, and the finding of a fluctuating swelling in the neck which enlarges on the drinking of water and diminishes upon pressure with the simultaneous expulsion of liquid into the pharynx. Not infrequently the forceful emptying of the sac is accompanied by a gurgling sound, which I believe is found in no other condition.

In the smaller types the diagnosis is made by the x-ray and the esophageal bougie. The shadow cast by a diverticulum after the swallowing of a mucilage-of-acacia and barium mixture outlines the lower portion of the sac, or perhaps the entire sac. Unlike the shadow cast by a dilatation of the esophagus above a stricture, in which there is usually seen a tail of the barium trickling through, that cast by a diverticulum shows a smooth regular outline. However, the shadow cast by a dilatation above a typhoid stricture may be indistinguishable from that cast by a diverticulum. The final and absolute diagnosis is made by the Mixter silk string technique and the esophageal bougie, as pointed out by Plummer in 1910. The patient is instructed to swallow ten to twenty yards of buttonhole twist at the rate of one foot per hour. A considerable portion of the thread will coil up in the pouch, but, eventually, which may be three or four days, a loop will find its way down the esophagus, through the stomach, and after traversing several loops of the intestine becomes firmly anchored. A perforated olive tip, on a whalebone staff, threaded on the string, and passed while the string is loosely held, will enter the diverticulum and become arrested on the bottom of the pouch. The string is now drawn taut while the bougie is steadied by the other hand, and when further traction on the string causes the bougie to rise, the level of the incisor teeth on the staff is marked. The string is then drawn until the bougie no longer rises and the position of the teeth again marked. Now, with the string held taut, the bougie is readily passed down the esophagus. The distance between the two markings on the staff gives the depth of the diverticulum. By substituting various-sized olives, the diameter of the opening into the pouch can be determined. I cannot too strongly recommend the string guide whenever an esophageal bougie is to be used, and it will find its way through any incomplete stenosis.

Partial relief may at times be secured by repeated sounding and dilatation, but the condition is primarily surgical and its early recognition will reduce the operative risk incident to the high degree of undernourishment found in too many of these patients.

Some surgeons recommend gastrostomy for those patients suffering from undernourishment, as a means of building up their strength and resistance. This procedure is practically never necessary and may of itself result fatally. The string will pass in all these cases and can be used as a guide for introducing a feeding tube. A nurse, or even the patient himself, can readily be taught to pass the tube on the string, as one of the patients, herewith reported, did for six months prior to his operation, during which time he used over 400 yards of thread, daily cutting off that portion which came through the anus.

When feeding patients through a gastrostomy opening or by the method here advised, it is very beneficial to introduce a reasonable quantity of saliva with each feeding. The physiological reason for this I will not attempt to discuss, but from a practical standpoint it is of great value.

Less than 200 cases of diverticula of the esophagus are reported in the literature though undoubtedly many more have been operated. The operative technique is simple, and if the patient has received the proper pre-operative treatment the risk is very slight, the chief danger being the development of infection, which is usually the result of soiling of the field from the contents of the sac at operation, and on account of the absence of any limiting fascia quickly descends into the mediastinum.

A liberal incision along the anterior border of the sterno-mastoid muscle permits the carotid sheath to be retracted laterally and the thyroid gland toward the midline. At times it may be necessary to ligate the inferior thyroid artery; the recurrent laryngeal nerve is usually not exposed, it being retracted with the lower pole of the thyroid. Since the sac is devoid of muscle fibers, it is easily torn and must be handled with care. After the sac is isolated, it may be dealt with in one of several ways. If one decides to do an excision, with closure of the opening with two rows of suture, it is well to introduce the first row as excision proceeds, for if the sac is completely removed before suturing is commenced it may be found quite difficult to pick up the margins as they seem to unduly retract, and the danger of soiling the wound is great.

The Sippy-Bevan reefing or tucking operation obliterates the sac without opening it, and completes the work at one operation. For the smaller type of diverticula, it is the method of choice and may be employed even though the sac be large. For the large sacs extending below the sternum a two-stage operation, as suggested by C. H. Mayo, seems to be the safest. After carefully isolating the neck of the sac it is twisted once on itself and a ligature of chromic gut applied. The wound is closed with the skin margins sutured to the neck of the sac, the sac left lying on the skin to be removed eight or ten days later. This secondary operation can be done without an anesthetic. A fistula may develop after the second operation, but this readily closes.

Immediately prior to the operation the sac should be carefully emptied to prevent the possibility of

forcing its contents into the throat, which may be aspirated, resulting in pneumonia, abscess or gangrene of the lungs. The silk thread should be left in for several days following the operation, as it may prove useful in passing a bougie for the identification of the sac during operation, and serves as a guide for passing the feeding tube while the wound is healing.

I wish to add to the already reported cases two cases seen within the last year.

Mr. B., carpenter, 62 years old. Past and family history of no bearing on present trouble. For past twenty-five years has been troubled by dry toast, lettuce, and cold slaw sticking in the throat. Past five or six years other kinds of food occasionally lodges just above the clavicle. Past three years has spit up a little food following each meal, and at times has had to wash out the throat during a meal. Weight normal. General health good.

Examination negative apart from throat. Immediately after drinking water, pressure over the left side of the neck causes about two drams of fluid, chiefly water, to be forced into the pharynx and expectorated. X-ray taken after administering a thin mixture of barium and mucilage-of-acacia shows a rounded shadow with regular margins two centimeters in largest diameter, just below the level of the cricoid cartilage. He was unable to spare the time for further examination and promised to return later, but has failed to do so. Diagnosis small esophageal diverticulum.

Mr. H., painter, 73 years old. Past and family history of no bearing on present trouble. Has always had trouble with food sticking in throat. Has always considered his throat was unusually small. About eight years ago a piece of cold slaw lodged in the throat, causing considerable coughing before it was dislodged an hour later. Following this occurrence, every few days food would lodge in the throat, to be released by coughing or drinking water. This condition gradually grew worse. About three years ago he discovered that, by rubbing upward over the left sterno-mastoid muscle, food could be dislodged from the throat with relief of the discomfort. Gradually the condition grew worse, and for the last six months he has had to spend four to six hours each day alternating eating with emptying the accumulation of food from the neck. He has lost forty-two pounds during the last ten months. Present weight eighty-two pounds.

Examination shows a markedly emaciated man. Skin exceptionally dry and parchment-like; blood pressure, 130-90; hemoglobin, 65 per cent; erythrocytes, 4,100,000; leucocytes, 6700; Wassermann, negative; twenty-four-hour urine, 200 cc. sp. gr. 1036; small amount of albumen. Physical examination negative except for the throat and moderate enlargement of the prostate. On drinking a glass of water, a tumor mass appears on the left side of the neck just above the clavicle. Pressure over this mass forces fluid into the throat with a gurgling sound, and 400 cc. was expectorated. X-ray picture taken after administering a mixture of barium and mucilage-of-acacia shows a shadow extending from just below the level of the cricoid to within one-half centimeter of the aortic arch, and seven centimeters in its transverse diameter. The margins are smooth and regular.

He was sent to the hospital and given a 10 per cent glucose in 5 per cent sodii bicarbonate solution by the Murphy drip method. He retained three quarts the first twenty-four hours. He was started swallowing a silk string as soon as he was put to bed. Being curious to see how fast he was accomplishing his object, he pulled out the string three times the first two days. On the fourth day the string was anchored in the intestine, and feeding was commenced by passing a large catheter, in which a hole had been punched from the tip to the eye, over the string. He was given fruit juices, tomato soup, broths, milk, and eggs. The glucose solution was continued per rectum for one week. The urine rapidly rose in quantity, and on the third day after feeding was started he passed 1800 cc.

Mr. H., 72 years old. Large diverticulum of the esophagus. Cured by two-stage operation.

which showed only a trace of albumen, but was heavily loaded with granular and hyaline casts. Two days later there was only an occasional cast, and the phthalian output was 45 per cent in two hours and fifteen minutes. At no time since have we found more than an occasional cast in his urine. His general condition rapidly improved. In two weeks he had gained eight pounds and, having

Mr. B., 50 years old. Small diverticulum of the esophagus. Refused operation.

learned to pass the tube himself, was sent home. This method of feeding was so superior to what he had been used to for two years, that he was inclined to let well enough alone. Three months after first seeing him, he developed influenza. Ran a temperature for ten days, and his convalescence was rather slow. Six months after coming under observation a two-stage operation was done. Ether

anesthesia being used for the first stage and no anesthesia for the second. Four days after cutting off the sac a small fistula developed, but at no time did more than two drams of fluid escape in twenty-four hours. The fistula healed in four weeks. It is now five months since he was operated. His weight is 126 pounds, a gain of forty-four pounds. He has no difficulty whatsoever in swallowing.

Growers' Bank Building.

DISCUSSION

Daniel C. Crosby (Twentieth and Webster Streets, Oakland) — Doctor Shepard is to be congratulated upon the presentation of a paper replete with information about a condition so seldom encountered that, when we do come in contact with it, we are prone to overlook it.

In the matter of diagnosis, perhaps our first and greatest resource is the x-ray, and for the making of this examination, if the patient be placed in a position on the right side analogous to the Simm's, the stomach end of the esophagus is slightly higher than the pharyngeal end and the process of swallowing is somewhat slower. Then if the patient be permitted to take a thick barium mixture through a tube or have it fed to him with a spoon, the progress of the bolus can be watched with somewhat greater ease.

After the x-ray, we should probably place the esophagoscope and then the silk twist and the tube. By the use of the esophagoscope, the size and character of the opening may be determined. In the examination with the tube, or sounds, or with the esophagoscope, great care must be taken else the diverticulum may be punctured.

In the matter of treatment, surgery stands as our first resource for cure; but it sometimes is necessary to render palliative service before doing surgery, and then experimenting in change of position or by lavage with the twist and tube, the patient can be rendered very comfortable and some improvement made while waiting for radical cure. The hollow tube with the silk-twist guide means certainly a better expedient for feeding than is gastrostomy.

Insulin as an Investment for the Patient With Diabetes Mellitus—Reginald Fitz and William P. Murphy, Boston (Journal A. M. A., February 9, 1924), point out that a broad-minded physician conserves the money as well as the health of his patients; in a sense, he is a trustee both of their bodily welfare and of their finances. In other words, a physician is not justified in prevailing on sick people to go to a great expense for diagnostic tests or therapeutic procedures which are unnecessary or of theoretical interest; rather must he advise those measures which are as safe and certain as possible and which offer the prospect, through relieved symptoms, of a good return for the financial investment involved. This point of view is particularly sound when applied to the insulin situation. The authors have followed a small group of typical cases, in an endeavor to measure what insulin has accomplished for them in terms of dollars and cents. The result of this work is reported in this paper. The material selected for this study consists of five cases chosen to represent the various types of severe diabetes most commonly seen in general practice. These cases are illustrative of the economic results in the treatment of diabetes with insulin which are being obtained in many cases throughout the country, and tend to show that, on the whole, the money spent by patients in buying insulin and in learning how to use it has been well invested and has purchased a satisfactory gain in strength and efficiency.

CLINICAL ASPECTS OF RICKETS IN SOUTHERN CALIFORNIA *

By ROBERT EWART RAMSAY, M. D., Los Angeles

Rickets is more prevalent in Southern California than is generally supposed by the medical profession. This categorical statement is my own opinion, but I have reason to believe that it is also the opinion of most of the physicians who are limiting their practice to diseases of children. The opinion of the average physician may be typified by the reply of the secretary of the medical association of one of our southern counties, who, when I suggested rickets as the subject of an address, said: "We never see any rickets. Please talk about something that we are more interested in." Now the fact is, that rickets is present in an appreciable number of patients and should be recognized. It is possible that the manifestations of the disease are not so striking as in other parts of the country, and that we need to study rickets as we find it among us in order to enable us to recognize it early enough to prevent the sequelae, which are just as serious here as elsewhere.

It is only natural to suppose that rickets should be less prevalent and of a milder sort in California. Many of the factors which have been thought conducive to the rachitic state are not of such serious import here where the sun shines practically every day, where green vegetables are available the year round, where fruits are abundant, and where the climate naturally encourages an outdoor life, and well-lighted and ventilated homes. That we should under these reasonably ideal conditions still find rickets to be present constitutes in itself a contribution to the study of this disease. I am of the opinion that a study of rickets in California will yield worthwhile results.

The clinical observations which I shall present are easily open to criticism, and the figures deduced from them are even more assailable; yet, since it is the clinical aspect which really interests us, I have considered it worthwhile to venture to gather some data on the prevalence of rickets, and its symptomatology as exhibited in recognized cases. I consider the etiology of rickets a question to which clinical observation can be only contributory. We must await results from the many trained workers who are busy in this research.

My material was obtained from two series of cases from the records of the Los Angeles General Hospital, and one series from the Anita M. Baldwin Hospital for Babies, Children's Department of the California Lutheran Hospital of Los Angeles.

The first series comprised twenty-eight cases diagnosed "rachitic" during the period from November 8, 1912, to June 1, 1920, a period of seven years and seven months. Of these, twenty were under two years of age, four between two and three years, and one of ten years. Nineteen were males; nine females. Thirteen were of American extraction, six Mexican, two negro, and one each were Italian, Jewish, Russian, Japanese, Filipino, Spanish, Austrian, and French.

The second series comprised thirty-eight patients

* Presented to the Section on Pediatrics of the California Medical Association at the annual meeting in San Francisco, June 22, 1923.

diagnosed "rachitic" during the period from June, 1920, to December 31, 1922. Of these, thirty-seven were two years of age or under, and one of eight years. Twenty-five were males, thirteen females. Twelve were American, sixteen Mexican, two each Jewish, negro, Japanese, one each Swedish and Italian, and two unknown.

The third series comprised fourteen patients from the out-patient department of the Anita M. Baldwin Hospital for Babies, representing the number of cases of rickets recognized among the first consecutive one thousand patients under twelve years examined. Eleven were two years old and under; this out of a total of 242 children of two years and under received in the clinic. Nine were males, five females, nine were American and one each Mexican and Italian, and three Jewish.

Observation on the nationality of these patients is interesting, in that out of a total of eighty patients thirty-three are American, twenty-three are Mexican, six are Jewish, four are negroes, three are Italian, two Japanese, and the rest scattered. The sex incidence was males, fifty-three; females, twenty-seven.

I attach considerable value to the figures deduced from the third series, small as it is, because every child was examined by a pediatrician. In this series, the cases of rickets discovered among the children of two years and under was 4½ per cent.

In the following table, I show the signs and symptoms upon which the diagnosis rests, and the number of times each was mentioned.

	First Series 28 Cases	Second Series 38 Cases	Third Series 14 Cases	Total 80 Cases
Rosary	17	24	6	47
Groove	3	9	8	20
Pigeon breast	2	2	1	5
Bosses prominent	10	19	7	36
Fontanel	1	5	3	9
Epiphyses enlarged	6	15	1	22
Bowing of legs	1	4	2	7
Dentition delayed	3	2	2	7
Cervical adenopathy	12	5	3	20
Abdomen large	15	13	11	39
Muscles weak	3	1	1	5
Liver enlarged	2	5	4	11
Spleen palpable	1	3	0	4
Sweating of head	0	4	0	4
Constipation	3	2	0	5

By way of comment, it is interesting to note that the diagnostic helps in the order of their occurrence are (1) beading of the ribs; (2) enlarged abdomen; (3) prominent parietal and frontal bosses; (4) enlarged epiphyses; (5) cervical adenopathy; (6) Harrison's groove. The emphasis here placed on the first three mentioned is quite in keeping with established practice. The rosary is perhaps the earliest and best of the accepted signs of rickets. The enlarged abdomen, together with a rosary, is of great value, while these two with enlarged parietal bosses constitute sufficient evidence that we are dealing with rickets. The enlargement of the costochondral junctions is known to occur in scurvy, but as this can be easily differentiated if it is borne in mind, the presence of a rosary should always suggest rickets. The enlargement of the epiphyses involves too much of the personal equation to be a satisfactory sign. The groove is a sign of progress in a well-established rachitic process. Cervical adenopathy is also a secondary manifestation. Delayed dentition, as also delay in sitting, standing and walking, are only of value as confirmatory signs. It is interesting to note the infrequent mention of sweating, which is often the cause of a parent bringing a child to the physician. Digestive disturbance also plays too small a part. As I have considered the result of this study and also the general problem involved in the need for better and earlier diagnosis of rickets, I have been forced to conclude that, as long as we are content with signs which may be classed as results, we are not going to be able to make the diagnosis early enough. Results even with similar processes are variable. If we can fasten our attention on the rachitic process rather than on the rachitic result, we shall make progress.

To be specific, I can consider the beading of the ribs only as nature's attempt to buttress a weak point, which she does by overgrowth of tissue. Why is this particular point so in need of help? Because of the peculiar breathing process of the rachitic child which is a definite process and peculiar to it and worthy of being given the dignity of a sign of rickets and the name rachitic breathing. Watch such a child and you will see that the upper chest does not move normally with inspiration and expiration, that the lower chest falls in during inspiration instead of during expiration, and that the part which moves most is the abdominal wall below the attachment of the diaphragm. An inquiry into these peculiarities so antagonistic to the normal act of breathing is very instructive. The diaphragm is the great breathing muscle, which by its contraction enlarges the capacity of the chest and provokes negative pressure within it. But the muscles of the chest wall are accessory muscles of respiration. Their action lifts the chest anteriorly, distends it laterally, and in its lower portion where the diaphragm is attached holds it tense and counteracts the pull of that strong muscle. But in the rachitic child we see a feeble lifting of the chest, an actual failure of the lateral widening, and at the region of the diaphragmatic attachment an inability to withstand the inward pull of the muscle. Hence, the peculiarities of the rachitic breathing are susceptible of explanation as a phase of muscular inability. Whatever our construction of the relation of this breathing act to the deformed chest, which is its result, I am sure that we should do well to concentrate our attention more upon the act which is so characteristic than upon the results which are so variable. Infrequently shall we find rosary, flare, pigeon breast, lateral flattening present in the one patient, but practically always do we see the peculiar rachitic breathing.

One factor involved in respiration I have not mentioned, namely, the size of the upper respiratory air passages. Obstruction here is not to be overlooked. The depression of the lower part of the chest in laryngismus stridulus, acute or diphtheritic laryngitis or in chronic enlargement of tonsils and adenoids must be borne in mind.

The effects of this faulty respiratory act are most disastrous for the health and growth of the child.

To bring in sufficient air to refresh the blood stream is difficult and attended with unusual effort. The resulting pallor and anaemia are characteristics of rickets which, therefore, need not surprise us. Again, the insufficiency of the respiratory act predisposes to respiratory infection to which the rachitic child is especially liable. Seldom do we find a rachitic chest free from signs of bronchial irritation. This can scarcely be otherwise when we consider the faulty aeration of the lungs. The grave prognosis in bronchopneumonia and whooping cough is notable in rachitic children.

Again, the labored respiratory act may be held responsible in part for the inactivity of the rachitic child. Where just to breathe at all is reasonably hard, why should the child by moving about make itself miserable.

There is still another aspect of the respiratory act which I trust will not be considered fanciful. As I have watched the anxiety, weariness, pitiable cry and distress of the child with pneumonia, who must breathe so rapidly and so steadily in order to use what little air space is available, I have recalled the rachitic child who, in his chronic unfevered condition, is working so rard to get enough air into his lungs to maintain life. I am not surprised that an effort so prolonged, so fruitless, should result in restlessness, long considered a sign of rickets, and periods of consequent reaction characterized by sweating and exhaustion.

There is another characteristic of the rachitic child, which is of extreme clinical importance, namely, the atony of the abdomen, which produces a chain of symptoms which can be recognized as diagnostic of rickets, if we give proper consideration to that characteristic of rachitic muscular tissue which I shall venture to call rachitic flabbiness. As is well known, the rachitic child may be above normal in weight, but he is always flabby. This lack of muscular tone is in marked contrast to the condition of the atrophic and marasmic infant in whom we may find decrease of tissue, but tonicity intact.

Rachitic flabbiness of muscular tissue has disastrous effects on the abdominal organs and their functions. Under normal conditions, the muscles of the abdominal wall, by virtue of their pressure on the abdominal contents, are accessory factors in the movement of the contents of the intestine, and assist in the act of defecation. When this counter-support is decreased or reduced to a minimum, as in the condition known as potbelly, the weakly condition of the intestinal musculature itself is aggravated. For this lack of muscular tone is probably as marked in the intestinal wall as in the abdominal wall. An early sign of rickets is constipation, characterized by small, yellow, pasty stools. Occasionally the evacuations become loose and offensive. This alternation of constipation, with periods of diarrhoea so characteristic of early rickets, is understood when considered in the light of rachitic flabbiness in the intestinal musculature. Thus we have lack of peristaltic force, slow and inadequate movement of the intestinal contents, incomplete bowel evacuations, accumulation of waste matter, fermentation, putrefaction, and gaseous distention, all resulting in occasional crises when the body arouses itself to a supreme effort of evacuation resulting in loose movements.

To sum up the symptoms and signs which I believe will help us to arrive at an earlier diagnosis of rickets, I would place them in this order: (1) Rachitic flabbiness of muscular tissue; (2) rachitic breathing; (3) the atonic abdomen of rickets; and would repeat my statement, that we must consider the working out of the rachitic process rather than its results. If some sign of an unmistakable character must be added to these three, let us add beading of the ribs, the earliest and best and most frequently noted indication of bony change in rickets.

Since we are convinced that bony changes are going on coincidently with other manifestations of rickets, it is cause for regret that the x-ray is not dependable as an aid in early diagnosis. Once the diagnosis has been established, the x-ray is useful in measuring progress under treatment.

The attention of the medical profession must be directed to the damaging after-effects of unrecognized and untreated rickets. For instance, the effect of rickets on the bony pelvis of the female results in a deformity which affects the adult and endangers the life of the child. In rickets, the weight of the body causes the sacrum to sink forward, so that the promontory tends to approach the symphysis, producing a shortening of the antero-posterior diameter of the true pelvis. Where lateral curvature complicates the problem, an oblique deformity is produced. In the very regions where rickets abounds, namely, in the temperate zone, dystocia, craniotomy and Caesarean section are most frequent.

Again, softening of the bone of the upper maxilla which occurs in rickets is largely responsible for the arched palate, deflection or buckling of the septum and the consequent irritative phenomena which are contributory to hypertrophy of adenoids and tonsils. The adenoid facies, without question, should suggest a deeper lying cause than difficult or obstructed breathing. An unusual pliability of the bone should be presumed.

The permanent teeth are affected by rachitic disease as early as the second year, while they are being laid down in the jaw. The teeth affected are those whose calcium metabolism is impaired while the disease is most active, namely, the central and lateral incisors, tips of the canines, part of the crown of the first molars. Defects of the enamel are also seen in malnutrition and acute diseases of childhood such as measles and whooping cough, producing pitting of the surface and early caries, which is different from the hypoplasia of the rachitic teeth.

Early rickets is a considerable factor in cases of faulty posture. In the adolescent, perhaps as the result of increased rapidity of growth and disordered metabolism; in the school child, perhaps because of the unaccustomed confinement; in the boy or girl with hypertrophied tonsils and adenoids, probably due to obstruction and toxic causes, we see the development of rounded shoulders, scoliosis, flattened chest, prominent abdomen, knock-knees and flat feet. In the third series, three cases of over two years of age were cases of this kind in which persistent signs of rickets were discovered.

Undoubtedly, this factor in faulty posture has not been given due consideration.

I have indicated only a part of the reasons why more attention should be given to the early diagnosis of rickets. As I have proceeded with this inquiry, my interest has changed from that of merely trying to ascertain to what extent rickets is clinically prevalent among us. This is very difficult to ascertain, at least in the present stage of apathy on the subject, and in view of the questions which naturally arise with regard to what shall constitute a diagnosis of rickets. How many of the accepted signs, which are many, must be present in any one case before it shall be considered a case of rickets? And when we have reached this point there arises the more fundamental question of how to recognize the rachitic process in its early stages, before the appearance of the bony and structural changes, which are its result. It is to this interesting and difficult question that I invite attention.

1026 Marsh-Strong Building.

DISCUSSION

Dudley Smith (Medical Building, Oakland, Calif.)—Doctor Ramsay's paper is of interest and his argument is ingenious and suggestive. If his experience and inferences are supported by other observers and by his own further experiences, then certainly his observations of respiratory peculiarity will bring a definite and valuable sign of early rickets to the aid of the practitioner. His observations on the incidence of rickets in California can be confirmed by anyone who deals much with children, and they are quite in line with the growing experience of clinicians everywhere.

Minor degrees of the disease are common in all regions, under all circumstances of life, and with all methods of feeding. The writer's explanation of the beading of the ribs in rickets is ingenious, but I think improbable.

Robert Hutchinson years ago stated that the bony changes in rickets could be epitomized in a phrase: "Overpromise and underperformance of bone growth"; that is to say, excessive production of cartilage which fails to become adequate bone. The explanation would seem to be as true for the rib epiphesis as for the long bones, and explains as well the bossing of the flat bones about their centers of ossification.

Langley Porter says that it always seemed to him possible, in many cases of rickets, to identify the very early stages of the condition with that of the clinical picture described by Finkelstein as "balance disturbance," but that the identification ought to rest on radiographic and chemical proof rather than on clinical, for there are many symptoms commonly ascribed to the rachitic process which are very often, if not always, due to some other agency. This is especially true of the Harrison groove, of curved tibia, and of cranio tabes.

Doctor Ramsay is to be congratulated for his painstaking and stimulating attitude in the study of rickets in California.

Doctor Ramsay (closing)—I have called attention to the prevalence of rickets in California. I have sought to emphasize certain early clinical signs of diagnostic value. In keeping with the spirit of preventive medicine, we should endeavor to recognize and to treat rickets early in its course, in view of the costly deformities and incapacities which are the result of neglect.

THE CORRECTION OF EXTERNAL NASAL DEFORMITIES

By J. PAUL de RIVER, M. D.
(From Eye, Ear, Nose, and Throat Section, United States Marine Hospital, San Francisco)

In approaching the subject of corrective rhinoplasty, the essential point to be considered is the anatomical variance from the normal that warrants surgical correction. This clearly understood, together with a thorough knowledge of the structural anatomy and the application of rigid surgical technique are important factors. Having taken care of these essentials, the result in a large majority of instances will be all that can be hoped for, as in any other branch of surgery.

The deformities encountered are varied: the hooked nose, the overhanging tip, the saddle-backed nose, the African nose and lateral deformities. Each in itself presents a distinct mechanical problem to tax the ingenuity of the surgeon, who, before attempting operative procedure, should examine the case from all angles, not only as to the mode and method of attack for the correction of the deformity, but should thoroughly search for the etiological variation from normal. Anatomical variations due to traumatism should be separated from those changes resulting from constitutional disease, such as syphilis, for by so doing much can be hoped for as to prognosticating the ultimate result. Diseased conditions of the para-nasal sinuses should be sought for, and rigid treatment carried out before undertaking operative procedure.

The choice of the anesthetic is of no great importance. Local or general may be used with equally good results. However, I frequently am in the habit of leaving this question to the decision of the patient. For brevity I will outline the operation as performed under local anesthesia. The operative technique is applicable to all forms of deformities. The patient is placed in a semi-recumbent position, and draped for operation. The cilia at the nasal vestibule are clipped with fine scissors. The mucous membrane of the nose is painted with 10 per cent solution of cocain, to which is added a few drops of adrenalin chloride. The external nose is then painted with tincture of iodine, which is carried well over both cheeks, up between the eyes, and down over the upper lip, and the excess removed with alcohol. The next step is the cleansing of the interior of the nose. A swab of pure alcohol is inserted into each nostril and passed over the mucosa. The injections are then made, a one-half of 1 per cent novocain solution is injected subcutaneously beneath the mucous membrane covering the septum. This is done first on one side of the septum, and then on the other. The needle is then inserted in the region of the lateral cartilages, where further injections are made. The attention is next turned to the anesthetization of the external nose, where four injections are made: No. 1 directly over the bridge of the nose; No. 2 directly on the tip; No. 3 and 4, respectively, on either side of the nose, well out over the maxillary bones.

Having completed these steps the surgeon begins

by making an incision along the pyriform opening of the nose. Beginning at the nasal bone the incision is carried downward and outward through the mucous membrane and chondro-osseous junction. A periosteum elevator is passed through this incision and inserted between the periosteum overlying the nasal and maxillary bones, and the bones are swept mesially and laterally separating periosteum, subcutaneous tissue and skin from the bone. This freely liberates the entire area extending from the root of the nose over the nasal bones and superior maxillae. A second incision is then made, beginning at the lower end of the nasal bone; it is carried downward and forward along the anterior edge of the septum to the tip of the nose. This incision is parallel to the bridge of the nose, and is carried through the cartilage up to the perichondrium overlying the nasal bridge; then by means of dissection the perichondrium and soft tissues over the bridge of the nose and lateral cartilages are separated from the underlying bony and cartilaginous septum and lateral cartilages. A third incision is made from one nostril to the other. Starting at the tip of the nose at the end of the second incision, it is carried backward along the lower border of the quadrilateral cartilage to the nasal crest of the superior maxillary bone and through the mucous membrane and cartilage. The fourth incision is made through the lower lateral cartilage at the point where the cartilage bends upon itself. Having completed these incisions, one is able to correct all types of nasal deformities.

SADDLE-NOSE OR FALLEN BRIDGE

The operative procedure in this case depends upon the elevation of the nasal bones, together with the filling in of the depression with a graft of either rib cartilage trimmed to the desired size, or a portion of a turbinate bone. A chisel is introduced into the nose, and the nasal bones are detached freely from the frontal process of the superior maxillary bones and from the nasal process of the frontal bone. Elevation is then made sufficiently to raise the bridge of the nose. A piece of turbinate bone, denuded of all save its periosteum and trimmed to the proper size, is then inserted between the anterior edge of the bony septum and nasal bones, and is maintained in place by means of a padded metal splint and adhesive plaster. Within three or four days the graft becomes fixed, and in four weeks complete organization as a rule.

Humped or crooked nose is corrected by means of the saw and rasp operation. The nasal bones are shaved down to the proper level, and the protruding bony and cartilaginous septum trimmed off with scissors or scalpel. The overlying skin is then moulded into position to overcome the widening which frequently results after the removal of the hump. By means of forceps the remaining portions of the nasal bones, with the frontal processes of the superior maxillary bones, are forced inward into the desired position; the splint is then applied externally to maintain them in place.

LATERAL DISLOCATIONS

Before attempting to correct this type of deformity a resection of the anterior part of the bony septum should be performed. This accomplished, the nasal bones, together with part of the frontal processes of the superior maxillary bones, can be dislocated by means of a chisel and then swung into the median line. Great care should be taken in exerting side pressure for fear of possible fracture of the cribiform plate of the ethmoid.

In concluding I wish to say that the post-operative care in these cases is of great importance. The results achieved will depend largely, not only upon the proper observance of asepsis during operation, but also upon the care of the nose during the convalescent period. Much has been said for and against this type of surgery, but to quote the sayings of a well-known European authority: "While outer deformities, like blindness and lameness, arouse our pity, a misshaped nose arouses ridicule."

DISCUSSION

William J. Mellinger, M. D. (San Marcos Building, Santa Barbara)—The correction of external nasal deformities is a very important subject and one that requires a great deal of highly developed surgical skill and artistic ability. In the first place, I always make a cast of the entire face and stereoscopic photographs of different poses. These can be studied even though the patient is not present, and they serve as an exact record of the case which can be compared with the end-result. If a nose requires more than one operation, as is often the case, the pictures are taken at various stages to show the progress by steps. If the deformity is an acquired one, a photograph taken before the injury is of great advantage in judging what is required.

De River makes the statement: "The choice of anesthetic is of no great importance." I am greatly in favor of a general anesthetic, as the introduction of needles and solution in or near the field of operation without doubt increases the danger of infection. A rib graft, if necessary, is accomplished more satisfactorily under general anesthesia.

The interior of the nose should be made as nearly as possible surgically sterile, then packed beyond the incision line with iodoform gauze, which is left in the nose for several days.

Concerning the graft—I first make a model of the proposed graft, of metal, which can be sterilized and inserted after the bed is prepared; by so doing the graft can be trimmed to the proper size. It is particularly important that the graft be not introduced more than once; in other words, it should not be withdrawn after it is once in place. Forceps should always be used in handling the graft. The most ideal material is an autogenous graft from the rib. I am opposed to the use of the turbinate bone for the following reasons: (1) A normal turbinate should not be removed; (2) difficulty in preparation of the graft; (3) greater danger of infection.

In humped noses, if the hump is not too sharp, a wedge of bone removed from the frontal processes of the superior maxillary, and the dorsum depressed to the proper level, gives the best result. This does not disturb the width of the dorsum.

George Warren Pierce, M. D. (Flood Building, San Francisco)—In cases of humped nose with broad bridge, and this is the commoner type, I prefer to make an incision through the membranous septum, bringing the knife out through the base of the columella. The columella is then deflected upward and a periosteal elevator is passed between the mucous membrane of the two sides of the septum and up over the nasal bones. After the subcutaneous tissue in this region is freed, narrow right-angled retractors are inserted and the operator obtains a direct view of all the structures to be attacked. With a

narrow sharp chisel a triangular section of the nasal bones, with the base down, is removed from the median line, and as much of the upper border of the septum as is necessary to obtain a corrected line of the bridge. The nasal bones are then fractured medialward, using a broadnosed hemostat. The above procedure accomplishes two things—the hump of the nose is removed, and the bridge is narrowed, avoiding the undesirable flattening and broadening of the bridge obtained by the rasping operation and which is especially noticeable with an already broad nose. Moreover, the operation is accomplished in a thoroughly surgical manner, as all work is under the operator's eye and, most important of all, the danger of infection is minimized, as the nasal cavity is not entered at all. This avoids the necessity of packing, which is most uncomfortable to the patient and is attended with some danger, as it may favor a sinusitis. The resulting scar at the base of the columella is practically negligible.

A suggestion regarding cartilage for transplant which some of you may have folowed, but which will bear repetition, is to bury the spare cartilage in the subcutaneous tissue of the abdominal wall. It remains there unchanged and obviates the painful reoperation for obtaining a new piece, if by any chance the first graft should fail.

For maintaining the alignment of a laterally dislocated bridge after correction, I prefer to use a cap splint on the upper incisors with a strong, springy wire extending outward and then upward and terminating in a flattened vulcanite pad. The amount and direction of the pressure applied can be accurately controlled and can be easily and quickly changed. The apparatus is light and comfortable and, in my experience, is superior to a plaster mold or an ordinary metal splint, from the standpoint of both the patient and surgeon.

Doctor de River (closing)—The technique used by Pierce I think is very good. A similar technique, I believe, has been described by Major Gillies of England, and more recently by J. D. Lewis of Minneapolis in a recent number of the "Annals of Otology, Rhinology and Laryngology." The burying of cartilage in the abdominal wall in cases where there may be future use for the cartilage is advisable and is a custom that I have followed many times. Mellinger mentions the fact that he always makes a cast of the face before operating; this, too, has been a routine procedure that I follow in all cases. I endeavor to make a replica of the entire face before attempting any operative procedure; this enables me to study the case from all angles. On completion of the operation a recast is made.

As to the choice of anesthesia I have not considered this question of great importance, perhaps because I have done such a large number of cases under local anesthesia and feel that I can secure perfect anesthesia by the local method with a minimum of shock and risk to the patient. I quite agree with Mellinger regarding the withdrawal of the graft after it has been introduced; the avoidance of the practice lessens the chance of carrying infection back into a sterile field. Forceps should unquestionably always be used when handling a graft. Too much cannot be said regarding the avoidance of digital manipulation of the graft.

Conclusion—In all cases surgical judgment, coupled with an artistic temperament and an anatomical familiarity with the parts to be corrected, is the sine qua non of success. Whether using grafting bone, cartilage, or using celluloid as a supporting bridge, as suggested by some operators, matters not, provided the operator possesses the skill and patience required of all undertaking this type of surgery, for when the curtain falls at the grand finale the success of the performance is judged by one word, and that is—results.

INFLUENCE OF PILLOW HABITS ON THE DEVELOPMENT OF THE UPPER JAW*

By HARVEY STALLARD, D. D. S., San Diego.

INTRODUCTION

A common facial deformation, due principally to pillow habits, is marked by a narrow upper jaw, a large mandible, a contracted palate, a narrow nose, and a deflected nasal septum. Since the dental arches and jaws form a great part of the face, this type of deformity has been designated by dentists as "narrowed upper jaw," "Gothic arch," "V-shaped" or "church roof" palate, etc. Faces having such oral features are referred to as "dished," "bell," or "urn" faces. When the deformity is confined to one side, the cheek is flattened or depressed, making the face seem twisted or "lop-jawed." The compression of one maxilla makes the jaws appear to close crosswise, hence the malocclusion is called a cross-bite.

OCCURRENCE OF THESE DEFORMITIES

"Dished" and "twisted" faces are often associated with impeded speech and disturbed nasal respiration so that they were probably noticed by observers of early times. However, earlier descriptions of oral or facial deformations have been so brief and indefinite that it is impossible to determine whether ancient writers refer to these two types of prognathism. Their greatest frequency has been in the colder parts of the north temperate zone, occurring more often among those of English descent. They are found among Italians, Brazilians, Australians, Chinese, Filipinos, Russians, and to a more limited extent, perhaps, in all other civilized peoples.

THEORIES OF THEIR CAUSES

Idiocy and Heredity—The first medical writers to discuss causes of these two malformations believed they were symptoms of idiocy (Downs: 1871; Ireland: 1874). This assumption was combated by Kingsley (1879), who after examining many idiots of different nationalities, said that idiots had no more irregularities of teeth than any other class, and concluded that their oral deformities were due to family traits.

Such malformations have been attributed to heredity because they are often traceable back in families and in members of the same household may be strikingly similar. The most popular doctrine taught is that, through mixing of many races, a child would inherit large teeth from one parent and small jaws from another, or a small palate from one and a large mandible from the other. Another belief, once regarded as the most scientific, was that contracted palates and jaws result from disturbed innervation, neurosis, and evolutionary reversions (Talbot: 1903; Ballenger: 1911).

Rickets, Trauma, Mouth-breathing, and Endocrine Disturbances Suggested—Rickets has been suggested as a cause by many writers (Bosworth: 1889; Ballenger: 1911), but it was early denied by Shaus (1887). Bosworth believes many contracted palates were due to mouth-breathing, which, he imagined, was caused by partly occluded nostrils resulting

* Read before the San Diego County Medical Society, May 22, 1923.

from inflammation following accidental trauma. Wallace, enlarging upon the influence of mouth-breathing and poor mastication, stated that constant mouth-breathing allows the tongue to lie in the floor of the mouth, away from the palate, so that its lateral influence is less than that of the cheeks; this, he claimed, atrophies the upper jaw and overdevelops the lower, so that with poor mastication and infrequent closure, the upper teeth and their alveolar processes developed downward unrestrictedly, resulting in long teeth and the high, narrow palate. Recently, disturbed endocrine organs have been held responsible for oral deformities.

Mechanical Explanations of Their Development —Farrar (1888) believed a cross-bite was due to one of the following causes: (1) incorrect antagonism of teeth, (2) a too short ramus of the mandible on one side, and (3) a faulty location of the glenoid fossa. Angle (1911) attributed the beginning of these deformations to the child sucking the cheeks habitually, but the development (1907) to the perverted forces transmitted through the teeth.

Pillowing on the Face in Infancy Suggested—Marshall (1913), reporting correction of a badly deflected nose, so often characterizing "twisted faces," suggests pillowing on one side of the face in infancy as a cause. Case (1921) attributes development of cross-bites to infants lying and nursing too much on one side of the face.

The writer's attention was called to cross-bites in 1918 by John C. McGuire, D. D. S., who suggested that they were caused by pillowing always on the same side in infancy. In 1920 Angle suggested as the cause the child's habit of pillowing its cheek on a hand. The same year Spencer Atkinson, D. D. S., reported a case in which he had observed this method of pillowing to be a causal factor.

INVESTIGATION OF PILLOW HABITS

Location of the Work — This account is based upon studies of several hundred subjects of Southern California which were found in schools, preschool clinics, industries, hospitals, homes, asylums, streets, private practices of Los Angeles and San Diego.

Method of Investigating—At first the writer relied on what the patients said about their method of pillowing. Among the first patients examined was one having a much contracted palate. His mother said he always slept on his abdomen, keeping his fists under the pillow with the knuckles upward and resting his cheeks alternately on the mounds made in the pillow. On each side, the arrangement of his upper teeth showed the imprint of his knuckles. Other patients having cross-bites admitted pillowing their cheeks most of the night on a hand or arm. When a parent did not discover the habit, a visit was paid the child's bedside. The most convincing evidence was obtained by studying sleeping children. Subjects having nearly normal jaws do not have these pillow habits.

General Evidence—The main fact to interest the writer in these two types of malformations was their frequent return to former conditions even when treated by the best of orthodontists. Corrective treatment is often prolonged by the orthodontist working unaware of the habit; when it is discontinued treatment is rapid. No matter how well treated and mechanically retained, the teeth will return to their former alignment if the habit is not stopped, but where it is broken the treatment is successful.

It is possible to identify these malocclusions by the contour of the faces, to diagnose pillowing habits by the arrangement of the teeth, and to predict the kind of deformity by knowing the habitual malposition of the face during sleep.

Origin of Wrong Pillow Habits—Many histories show that a child, when compelled to lie for a long time on one side, on account of an abscess, injury or burn on the other side of the body, will vary his position to obtain rest and will occasionally put the hand between the cheek and pillow. Some began the habit during long attacks of pneumonia and pleurisy. The habit is sometimes associated with sucking of thumbs or fingers. A patient having a bilaterally constricted palate started the habit after becoming bedfast through infantile paralysis. A woman suffering in early childhood from conjunctivitis, procured most comfort during the day by burying the forehead and eyes in a large pillow; by resting the cheeks on her hands, she prevented smoothering, but started the habit.

Its beginning cannot always be traced to an illness, abscess, burn, or injury, or even to a change in bedding or position of the bed. Some attribute its commencement to face-pillowing initiated by parent or nurse. The following shows how open to suggestion a child is: One day a child was shown some photographs of children pillowing their faces on their hands; she was impressed and began the habit, which her mother stopped only by determined efforts.

It is impossible to find a constant relation between the effects of these habits and rachitis and, conversely, evidence that rachitic children are predisposed to such habits. When they appear in members of a family, those affected have similar pillow habits. It seems reasonable that the habit is handed down by instruction or imitation, rather than through heredity.

Observations on the Development of the Habit—Some infants who habitually sleep on their bellies have shown marked effects of pillowing on the hands. Older children and many adults, among them several dentists, with more pronounced malformations, observed while asleep, were found pillowing on their hands or arms. The most typical V-shaped palate found was in a physician who sleeps on the abdomen, resting his cheeks alternately upon mounds in the pillow made by his arms, one of which he keeps under the pillow at a time. When he was a child a dentist tried to expand his upper jaw by transverse jackscrews, but so much pain was caused at night that treatment was abandoned. Men of 65 or more having cross-bites were found pillowing on one side as in infancy. These habits originate early in life amid many different conditions, continue often through adolescence and into advanced age; in only a few did the habit start after the twelfth year.

The Inertia and Nature of the Habit — Many

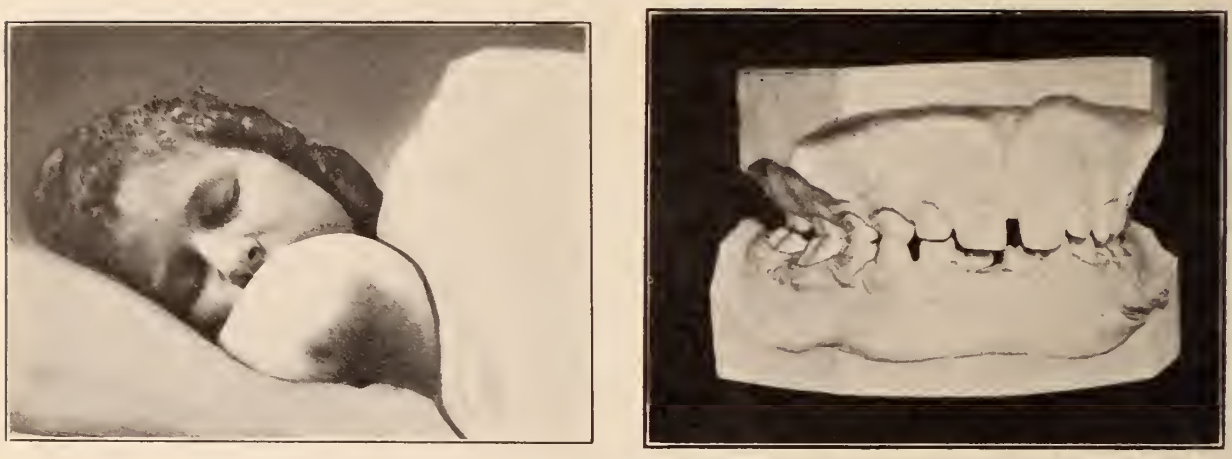

Figure 1—A typical cross-bite, unilateral constriction of the upper jaw.

times while studying sleeping children the writer tried to make them rest directly on the pillow, but no matter how sound asleep, they resist change and replace the hand to its habitual position. When told, while awake but unaware that they are being experimented upon, to lie first on one side and then on the other, their habitual pillowing habits dominate. Patients lying on the normal side, when told to turn over quickly, usually select the habitual pillowing method, automatically placing beneath the deformed cheek the preferred arm or hand. Comfort for these patients is obtained by indulging the habit; on requiring discontinuance of the habit, discomfort and a few sleepless nights will be experienced before they become adapted to new positions. Since pillowing is comfortable and habitual, it has great inertia.

Amount of Force and Length of Time It Acts—Children are in bed fully half of their lives; if they lie on their faces much, development of the jaws will be repressed. Any small constant external force will in time produce damaging imbalance in such a complicated organ as the mouth. But we have here a force, derived from the weight of the head, acting on the plastic bones of childhood throughout the greater part of each twenty-four hours, and, as case histories show, many children suffering from these deformations have been confined to bed for longer periods during which the force has continued for a greater time. It is well known that a letter-carrier's spine becomes deformed by carrying bundles constantly on the same shoulder. Similarly, facial depressions may be developed by pillowing the face habitually upon hard objects.

Normal Breathing and Vigorous Mastication Insufficient—If a normal breather pillows alternately on his right and left arms, he may have both dental arches narrowed, or if infants rest habitually on just pillows, their deciduous dental arches will be narrowed and their permanent anterior teeth will be rotated and "bunched." Parents have been known to give their children hard foods, remove their tonsils and adenoids, taking every precaution to avoid malocclusion except preventing face-pillowing, yet their children have narrowed dental arches and crowded anterior teeth, due principally to pillow habits.

When teeth are fully erupted and interdigitate normally, the tongue, filling the mouth cavity, presses outward on them, the alveolar processes and the palate, while the lips and cheeks bind the structures on the outside, preventing too great expansion. If the mouth be closed most of the time, or during swallowing, so that the opposing cusps interlock, the muscles of mastication and the hyoid muscles keep the lower jaw in position, indirectly protecting the upper dental arch against pillowing. While pillow habits damage the normal arrangement of teeth,

Figure 2—A typical bilaterally constricted upper jaw, a Gothic arch.

Figure 3—Effect of pillow force on the upper incisors.

even when breathing and swallowing are normal, greatest damage is done to a mouth-breather before the age of six, since worn, deciduous teeth, by not locking firmly, afford the jaws very little intermaxillary bracing.

Relation of Mouth-breathing to the Deformities —Masticatory forces are responsible for the main development of the face; if not suspended for long intermissions by mouth-breathing they protect the face from being indented. The unexhausted boxer keeps his jaws firmly clenched, for it requires only a slight jar on a depressed jaw to cause discomfort or to stave in upper teeth when the mouth is open. Breathing through the mouth at nights, so common among children of congested cities, suspends the protection afforded the upper jaw by occlusion; if during sleep the head's weight presses the cheek upon a hand, the alveolar process will be deformed. In mouth-breathers, the mandible moves to one side in pillowing, but the upper jaw being immovable and unsupported by any muscle cannot escape the pressure. Children having this habit often do not close their teeth in swallowing, but tuck their tongues out between the front teeth to effect air-tight closure necessary for deglutition. In this the tongue cannot maintain the normal width of the upper jaw, and even where there is no perversion of tongue forces, the palate is contracted by the pressure.

Variety of Wrong Pillowing Habits. — There are numerous varieties of wrong pillowing habits. Perhaps the most common is illustrated in Figure 1, where the wrists and forearm are placed between pillow and cheek. This habit presses in all the upper teeth from the canine back, producing the typical cross-bite. When the hand alone is employed, the malocclusion is limited to fewer teeth, principally molars and bicuspids. In rare cases the child may suck the thumb or finger of one hand and rest its face on the back of the other, which produces constriction of the upper jaw on one side and an arrangement of incisors to accommodate the thumb. Figure 2 shows a child who lies on the abdomen and pillows on the back of one hand and an arm; when she turns over she assumes a similar position; the arrangement of the teeth shows the effect on the upper jaw. A child may lie on the abdomen, keeping one hand on top and the other underneath the pillow, with the cheek on the one above, and on turning over exchanges hands. In such a case one side is usually favored. In simple oral deformities where the hands are kept under the pillow or where the pillow is rolled, both dental arches are narrowed as in Figure 3. Figure 4 shows the effect of a pillow habit on the arrangement of incisors. Thus, the hands may be kept under the pillow or under the cheek or one in each place. The variations in breathing habits, together with those in pillowing, make the descriptions, classifications, and diagnoses of sleeping postures complicated.

CONCLUSIONS

The writer would like to emphasize from a dental standpoint the sound advice given by careful pediatricians, namely, that infants invariably rest more contented on the cool, straight hair mattress than on or in a hot depressed, ill-ventilated feather bed and pillow, and that constant turning is conducive to the highest cranial symmetry. So far as

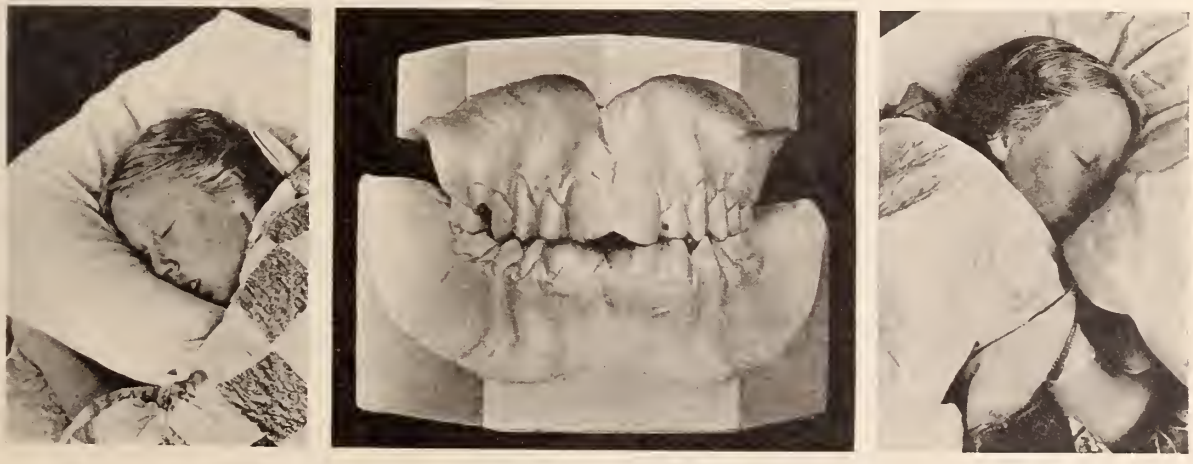

Figure 4—The upper jaw is more pointed and narrow than the lower, the child uses two pillows, breathes through the mouth and while lying on the stomach turns from side to side.

the denture is concerned, various postures can be safely assumed if pressure is not applied to the face, if breathing is normal and both hands and arms are kept away from the head. It is best to make a child lie straight, first on one side, then on the other, pillowing on the cranium, health permitting. The highest oral symmetry may be obtained by the baby resting part time on the back, then on the sides, and seldom on the face, in the absence of pillow or its substitutes. Pillow habits originate in many different impulses and amid many different conditions of child life. Whatever habit is acquired in infancy is apt to be continued indefinitely and be reflected in the various upright postures. Any sort of facial pillowing is to be discouraged, for it is responsible for at least 20 per cent of oral deformations, the most marked malocclusion being the result of pillowing on parts of the upper extremities.

Spreckels Building, San Diego, Calif.

DISCUSSION

Robert G. Sharp (Watts Building, San Diego)—Notwithstanding the fact that careful pediatricians habitually advise mothers to bed their infants on cool, straight hair mattresses without pillows, it behooves not only these careful pediatricians, but all medical men who give advice to young mothers to carefully read and make use of the investigations and conclusions set forth in this paper. I heard Stallard give his original paper on this subject and have followed his work with interest and enjoyment. There is no question but what this is a very much worthwhile piece of research. Doctor Stallard's investigations have extended over a long enough period of time, and he has considered enough cases to make his conclusions of real scientific value. These conclusions with a modified terminology should be so impressed upon every mother before pillowing habits are formed, that she will see to it that there takes place no facial deformations in her offspring. While there is no doubt but what other factors enter into the productions of facial deformations, the writer has emphasized not only one of the important ones, but what is more to the point, one which lies entirely within our control.

Of particular interest is the truly scientific spirit in which Stallard has pursued his researches. Far into the night has he stolen upon his unsuspecting victims and observed them all unaware in their natural habitats.

Arteriosclerosis in Thyroid Deficiency—Arthur M. Fishberg, New York (Journal A. M. A., February 9, 1924), asserts that various anatomic, experimental and clinical findings point to loss of the thyroid secretion having among its consequences injury to the vascular system. This connection seems to be definitely demonstrated in the case reported by him. The patient presented two seemingly discrete symptom complexes, an anatomic equivalent for each being found at the necropsy: (1) A hypertensive syndrome with a diastolic blood pressure of 135, cardiac hypertrophy and cerebral hemorrhage; corresponding to this there was found at the necropsy generalized arteriosclerosis and beginning primary contraction of the kidneys. (2) Sudden onset of adiposity of a peculiar distribution with retardation of skeletal and more particularly genital development, as well as abnormal distribution of hair. These phenomena point unequivocally to an endocrine disturbance, and at necropsy there was found a very extensive atrophy of the thyroid gland, with no other evident anomalies of the endocrine organs. In this case not only were the larger vessels atheromatous, as in the ordinary senile arteriosclerosis, but also the arterioles in the various organs were thickened.

TOXIC DERMATOSES

By O. V. SCHROETER, M. D., Los Angeles.

The term toxic dermatoses would embrace all lesions of the skin caused by toxic matter. I shall confine my remarks to but a certain group of these affections which are of an endogenous nature. In such the changes in the skin are, therefore, but imprints on that outpost of the organism, the cutis, of a turbulence within the same. These manifestations are really as much an affliction, yea more so, of the whole organism than of the skin itself. These dermatoses are the pictures on the skin produced by toxic substances in the blood, the result of pathology in the terminal circulation which finally gives up to the light of day an evidence of the organism's reaction.

As with surgery, much that now finds place in dermatology by virtue of pre-eminent symptomatology and location, as well as by virtue of our ignorance of the finer changes in the highest realm of pathological chemistry and anatomy, will, with a later day become a part of mother medicine herself. We must remove what we cannot cure. Urticaria is but a symptom, as is asthma, as is purpura, as are the exanthemata. The latter, too, are toxic dermatoses, but belong more to clinical medicine.

The group I desire to consider here is one of very great interest. There are two or three ways of grouping its members. A simple and practical way is by that of degree.

The Urticarias—This is the mildest dermic toxic manifestation. Its characteristics are familiar to all of you. There is a classic entity called the wheal—a pinkish or pinkish-white, irregular, more or less hard, elevation with the subjective symptom of itching and the marks of skin insult by scratching. There is no inflammation in the complete sense. Suddenly there has come into the terminal circulation a toxic material which has caused an angioneurotic condition. Recent investigation goes to show that, contrary to former belief, the capillaries have the ability to contract, become smaller on high internal pressure and take on various abnormal shapes, uneven dilation and contraction in angioneurotic conditions. This ability to contract is now found to be by virtue of fine branching muscle cells which encircle the tube and which, on contraction, tend to close the lumen; these are the Rouget cells. Formerly, capillary contractility was explained in terms of endothelial swelling. It is found the Rouget cells receive fibres from the sympathetic—stimulation causing contraction, and section—dilation. Dilator fibres run along the posterior route which explains, by reflex, the phenomena of herpes zoster.

The histo-pathology of urticaria is simple. I quote from Ehrmann: "The histologic examination of a wheal gives as the basis of the process an edema. The lymph vessels are widened. The fine fibrillary striping of the connective tissue disappears. The tiny vessels of the superficial plexus appear contracted, and those of the lower plexus widened and filled with blood. The epidermis is normal and the interspinal spaces show no widening."

There we have it—an anaphylactic reaction acting on the sympathetic innervation of the terminal vascular system causing localized dermic edemic

spots. In the morning they are gone. Toxemia has here its mildest manifestation. Anaphylaxis, Rosenau defines as "a condition of unusual or exaggerated susceptibility of the organism to foreign proteins." We see the reaction of urticaria after the injection of the various serums and after absorption of certain food products. The dark curtain falls when we seek to understand the finer chemistry of these substances swept by the plasma into the terminal circulation of the skin.

In the urticarias we have, therefore, as Auspitz states, a dermatosis with the character of a widespread disturbance of vascular tonus, together with more or less pronounced inflammatory raising of the skin surface. When from bacterial or other toxins we have a severer reaction, we enter the acute inflammatory stage characterized in a general dermatologic way by the term:

Erythema—Scarlet fever might be called generalized erythema, an erythema caused by the toxins of a group of the pus cocci as yet not definitely isolated. There are flat red patches as the simplest manifestation, often caused by drug or food poisoning. In the type known as erythema multiforme there is conglomeration of papules, wheals, and vesicles localized on the hands, the feet, the mouth—in other words, the more distant areas of the terminal circulation.

The histopathologic picture now passes from simple angioneurotic swelling to actual inflammation. There is a dermatitis. The reaction is more severe, ergo, the toxin was greater in severity. There is edema, the intercellular spaces are widened, the epithelial cells swollen and enlarged. About the vessels of the rete subpapillare, as well as about the capillaries in the papillae, there is an inflammatory infiltrate.

Symptomatically, we will find itching and burning; the patient will or will not have, depending on the character of the offending toxin, fever, malaise, joint pains.

There will not be an overnight amelioration. We have no longer simply angioneurosis; we have vascular insult, infiltration-exudate and through days or weeks of a nuance of red, purplish coloration, an eruption of this character will gradually subside. If it is seasonal, the toxemic manifestation will return periodically. We have more than a problem in dermatology; we have a problem, and a deep one, in internal medicine. What and where is the toxin? I confess, at times, the problem has been baffling. A recent case in a husky truck driver defies solution as to source of the bacillary or protein or chemical toxin.

Beyond angioneurosis and inflammation, there is conceivably one further degree of histopathology in this classification of toxic dermatoses. In the urticarias, we have shown the existence simply of loss of vessel tonus and some edema, and in the erythemas we have shown vessel congestion, exudation and vessel-wall insult, but with good repair in both cases in reasonable time. Let us step a grade further in the inflammatory category, and we have the serious pemphigus type—the inflammatory edema raising the upper surface of the skin.

But beyond actual inflammation, there is a further grade of actual hemorrhage into the skin, a total breaking down of the vascular wall as a barrier between the tissue of the skin and the vessel itself. This type embraces the

Purpuras—The day has passed when purpura has been conceivably of a neurotic etiology. It is always, except in the simplest types, gravely toxic, even if it does not eventuate in death. To this class belong peliosis rheumatica, the purpuras following the septic fevers, and purpura hemorrhagica, that fatal condition which defies solution as to etiology.

Clinically, the patients present a serious, sometimes terrifying picture. Purplish red spots appear on the extremities only or all over the body, and with or without bleeding from the gums, the kidneys, and even into the brain. Although the latter, as if nature would conserve, is almost always spared. The systemic disturbance may show fever, arthritis, the symptoms of a grave septic infection, or the patient may appear with a widespread purpura in a state of surprising well-being, save for the weakness attendant on loss of blood.

The histopathology is simple. There is the picture of exudation of the blood itself into the tissue. Between the connective tissue fibers we find red blood cells and the broken-down products of the hemoglobin which, of course, accounts for the nuance of red, yellow, and green in the spots on the skin. Endarteritis and thrombosis is seen, and in some cases an actual rupture of the vessel wall. The picture gives, of course, no clue as to cause.

Sternberg has recently among many others made studies of the blood pictures which have focused interest in this type of skin disorder. He has divided the purpuras into (1) those with fever and anaphylactic manifestations and a normal proportion of blood platelets, and (2) purpura without fever, but with thrombopenia. Much attention has been given the role of the blood platelets. Their possible role with regard to the coagulability of the blood in these cases has been gone into, and with the result that we find we still are ignorant as to the finer changes which eventuate in this phenomenon. It is stated that the blood platelets are an important source of prothrombin which is required for the formation of thrombin. Coagulation equals a combination of fibrinogen and thrombin.

Now, strange to say, in purpura hemorrhagica, the coagulation time of the blood is not prolonged or is prolonged very little. Prolonged clotting does not run parallel with reduced platelets. While the normal platelet count is 200 th to 400 th, it may be reduced to as low as 60 000 in severe pur hem. The amount of bleeding, too, is not always paralleled by the reduction. But the characteristic thing about the clot in purpura hemorrhagica is that it does not retract in the normal manner. While the factor common to all cases of prolonged bleeding, hemophilia and the purpuras, is not known, a diminished platelet count is nearly always present in purpura hemorrhagica. Thrombopenia alone does not explain the hemorrhages, but there is another factor—anaphylactoid, toxic and, as in scurvy, deficiency diet as the basic cause. What is the blood chemistry here? What fine changes occur in the constituting substances of the plasma or what mystic

toxins elusive to our touch and present powers are swept into the finer circulation to make this grave dermatologic picture? These are questions yet to be solved. When they are solved the purpuras will know a different name and will have joined mother medicine.

1002 Union Bank Building.

DISCUSSION

Moses Scholtz (Brockman Building, Los Angeles)—The subject presented is of great interest both to the dermatologist and to the internist. I wish to acknowledge a splendid presentation of the pathology of various grades of skin reactions to toxins. I am in thorough accord with the basic idea of the paper, that various toxic dermatoses are merely skin reactions to some systemic irritant or toxin, infectious or metabolic in origin. I heartily endorse the attitude of the writer emphasizing this special point of view over merely technical morphologic differential diagnosis of various clinical types of dermatoses belonging to this class.

I am particularly glad to have the author advance the idea that scarlet fever dermatologically is not an independent entity but merely a generalized infective erythema caused by a specific but as yet not identified micro-organism—the idea which I had advanced in 1918 in a paper written on this particular subject. While I fully realize the great clinical importance and enormous clinical domain occupied by toxic dermatoses, I wish to say, in the light of my experience, that the general practitioner is inclined to overrate the frequency of occurrence of systemic dermatoses over the local, and is often tempted to see systemic dermatoses in skin lesions purely local in origin, such as parasitic dermatoses, streptococci infection, various types of tinea, particularly of eczematoid type, insect bites, etc.

Kendal P. Frost (831 Pacific Mutual Building, Los Angeles)—Doctor Schroeter has struck a very important point in drawing attention to the general medical aspects of dermatology as a specialty. His examples of the toxic groups are the outstanding ones. There is, however, with the exception of the new growths and the dermatoses which are recognized of external origin, a profound influence from internal sources. Dermatology is a branch of internal medicine and can exist only as such, and its existence is fully justifiable with the tremendous growth of our knowledge and the tremendous detail which every man must hold. To intelligently follow the science of medicine now we must limit ourselves to one field, otherwise it cannot be done.

Thus, Mother Medicine has a number of children, all of them intimately related and interdependent and all dependent on the mother herself, but each one should be strong enough to stand alone.

Albert H. Rowe (119 Thirteenth Street, Oakland)—Doctor Schroeter emphasizes the fact that skin diseases are often manifestations of fundamental bodily disease. It is true that these general disturbances are vague and difficult to understand. This fact, however, emphasizes the great outstanding challenge to dermatologists, which is the true basic etiology. As dermatology exists today, many of the diseases are merely catalogued according to symptoms and empiric treatment only is suggested. Investigations which will yield basic and scientific information as to etiology are tremendously needed. Allergy as it has unfolded itself in the last few years is certainly shedding light on the etiology of some of the syndromes of dermatology. Most of this information has come through the investigations and clinical researches of internists, which again shows the immediate relation dermatology bears to internal medicine. Today dermatology cannot be practiced successfully without the aid of allergic skin-testing and desensitization. Thus a dairyman recently came complaining of a severe eczema during all the year except the winter. This was localized to his face and hands. Skin tests with animal hair proteins were negative. However, testing with some sixty different pollens to which he was exposed, showed positive reactions to bermuda and barley pollens. His cows were eating bermuda grass in the pasture, and barley hay in the barn. Desensitization to these pollen proteins has afforded complete relief.

Ernest H. Falconer (Fitzhugh Building, San Francisco)—Doctor Schroeter's paper is conceived along broader lines than those of anatomical distribution and morphology. This broader conception is due to advances along the lines of biochemical research and studies on sensitization and anaphylaxis. It brings into the foreground suggestions that must be worked out and translated into facts by groups of workers composed of physiologist, pathologist, biochemist, and bacteriologist. Their isolated facts and observations must then be collected and correlated by the internist and the dermatologist and the collected data applied to the problems of etiology. This means a large order for dermatologist and internist, for it demands a broad training, constant study and the development of a critical faculty for using information that will be of help in solving their problems. In the matter of the purpuras, for example, it has been suggested by recent data at our disposal that idiopathic purpura hemorrhagica is a true platelet deficiency disease, or a thrombopoenia. It was thought that the spleen took on the aberrant function of destroying the platelets in an abnormally rapid manner. The suggestion for splenectomy was obvious. Yet after such an operation, the platelets were found to rise first to a nearly normal number, but gradually to fall again until they reached a point at which we expect hemorrhages to recur. Apparently, however, they do not recur. An explanation which seems tenable is that the spleen elaborates some toxin or substance which acts on the capillaries, making them abnormally permeable. When the spleen is removed, the capillaries again return to a condition capable of holding the formed elements of the blood sufficiently intact so that red corpuscles do not permeate into the skin and mucous membranes. We are, however, just arrived at a point where the pathologist, the physiologist, and the biochemist must take up the problem. For the present, however, is the dermatologist prepared to make a diagnosis of idiopathic purpura hemorrhagica and on the basis of that diagnosis to advise his patient to seek relief in splenectomy? If he should shift this responsibility to the internist, is the latter prepared to make the necessary platelet counts and blood studies to prove the diagnosis and assume the responsibility of advising a splenectomy? These questions are worth thinking about and should stimulate our enthusiasm to study disease as applied to the body as a whole and not to isolated portions.

Doctor Schroeter (closing)—Of the specialties, none is so closely bound to general medicine in some of its aspects as is that of dermatology. No specialty is more ruthlessly abused and less understood by the general profession. Many diseases are cutaneous because the outstanding symptom is written on the skin, like pellagra, but many skin entities are the outstanding symptoms of as yet unknown diseases. Progress in the discovery of these pathological conditions lies in the direction of a study of the finer disturbances of metabolism and blood chemistry. . . . The dermatologist should be more frequently consulted as to the character of a particular eruption, with a view to ascertaining, first, if it really has an internal basis and, secondly, if so, the probable source. Recently a case of harmless pityriasis rosea, a type of exogenous skin disease, and likely to be overrated by the general man as Scholtz points out, was put in a room with cases of infectious exanthemata.

A dermatosis is a very important matter to the patient and always means a disturbance. Medically, the types of dermatoses here mentioned are very important and offer a fertile field for research. Fal-

coner's citation of effect of splenectomy on blood platelets is very interesting. Barrow of Los Angeles recently called my attention to the discovery of certain intestinal protozoa in two cases of erythema multiforme. Frost and Rowe have both emphasized the intimate relation of internal medicine to these dermatoses.

SKIN SYPHILIS ASSOCIATED WITH INFLAMMATORY SKIN DISEASES *

(A REPORT OF THREE CASES)

By KENDAL P. FROST, M. D., Los Angeles.

The factors underlying active syphilitic processes have been much discussed of late. Moore and others have added considerably to the spirachete strain idea. Klauder has written concerning the determination of late syphilitic lesions by trauma. It has long been recognized that trauma plays a large part in localizing syphilitic process. This is true of the skin as well as the organic manifestations of the disease. Inflammatory processes directly preceding syphilitic processes are not uncommon.

Three cases have come under observation in which an inflammatory skin condition closely preceded and apparently excited the development of cutaneous syphilis and seemed to a certain extent to determine the type of the syphilitic lesions.

Case I—Miss N. K., 26 years of age, white. Had had trychophytosis corporis and was cured except for one lesion on the chin which had not yielded to treatment. She was referred for a diagnosis of this lesion. It was a somewhat boggy, inflammatory node about 2 cm. by 3 cm. on the side of the chin. The Wassermann reaction was negative. There was no history of previous manifestation of lues, and the history otherwise was negative. Soothing applications were made to this lesion, and after about two weeks it assumed the appearance of a typical circinate nodular syphilide. Three-tenths gms. arsphenamine was given, and a week later the lesion was healed.

Case II—Male, age 35. This man had been diagnosed as luetic about a year previous on the basis of a weak positive Wassermann reaction. He received a small amount of treatment then. Under our observation, the evidence did not seem sufficient for a diagnosis of syphilis, repeated Wassermann reactions being negative, and no signs were found on physical examination. He had a troublesome herpes progenitalis, and during treatment for that developed an epidermophyton infection on the sole of the foot, from which fungi were demonstrated microscopically. He was given a Whitfield ointment and returned a week later with a small, punched-out ulcer at the site of each group of vesicles in the infected area. The Wassermann reaction taken then was positive. The ulcers and the herpes healed rapidly under antisyphilitic treatment.

Case III—Mexican woman, age 28, married. Good history not obtainable on account of language difficulties. The skin trouble had been present for several years and occupied the bridge of the nose and the upper cheeks. The lesion on first glance was a typical lupus erythematosis of the butterfly type. On closer observation small nodules and deep pitted scars were seen, especially in the margin. Her Wassermann reaction was positive. Under treatment the nodular portion quickly healed and the inflammatory part remained active to a slight degree for some time, although it eventually healed under no other medication or treatment than the anti-luetic. In this case there is some possibility that the entire process is syphilitic, but the fact that it healed over a period of some months lends strength to a diagnosis of lupus erythematosis associated with syphilis.

As short a series of cases as this proves nothing. They are presented merely for the purpose of recording them and drawing attention to the fact that local inflammatory processes may produce a locus minoris resistenciae wherein latent syphilis may become active.

Pacific Mutual Building.

* Read at Section of Dermatology, State Medical Society, San Francisco, 1923.

DISCUSSION

Ernest Dwight Chipman (391 Sutter Street, San Francisco) — The cases recorded by Frost are extremely suggestive. They agree with what all of us must have observed, viz., that traumatism may undoubtedly be the determining factor in the outbreak of lesions in syphilitic subjects.

I have recently treated a serpiginous ulcer of the leg in an individual who, for twenty years, has had an infection with no clinical signs, but in whom a blow on the shins caused typical syphilitic lesions.

The doctrine that traumatism may evoke specific reactions is probably capable of extension to include non-specific reactions as well. It seems possible that certain dermatoses classed as eczema, dermatitis, etc., sometimes occur more readily in subjects with a specific history, the determining causes probably being those trivial traumata of every-day wear and tear which would give rise to no reaction in one with no underlying syphilitic taint.

Harry E. Alderson (240 Stockton Street, San Francisco) — Frost's case reports and observations are most interesting and bring up questions of great practical importance. As Chipman well says, we often see late syphilides occurring at the site of traumatism. And these traumata need not always be severe, but repeated often they have their effect.

Where lues is acute, that is, in the earliest stages with extensive generalized distribution of the treponemata pallidae, local heat or chemical or other irritation may produce intensification of the secondary eruption in local areas. These cases and the late cases where local infection or trauma excite the appearance of syphilides in situ bring up questions of importance from an industrial standpoint. One occasionally has to decide whether or not a late syphilide occurring at the site of trauma sustained by a worker entitles the victim to care and compensation by the insurance carrier.

Analogous to this effect of local impaired resistance in favoring the development of syphilides is the apparently selective action of the treponemata pallidae in producing visceral complications. This is seen in the common occurrence of cerebrospinal lues in the mentally active Caucasian, as compared with its rarity in the native African; in nervous and cardiovascular syphilis in alcoholics, in cardiovascular involvement in those who indulge in hard physical labor and in tobacco to excess.

Roentgenologic Examination of the Gall-bladder—Preliminary report is made by Evarts A. Graham and Warren H. Cole, St. Louis (Journal A. M. A., February 23, 1924), of a new method utilizing the intravenous injection of the calcium salt of tetrabromphenolphthalein. No untoward effects have been observed in the human subject with the concentrations used. A dose of 0.1 gm. per kilogram, when injected into a human subject, was found sufficient to cast a shadow. At present, 6 gm. has been the largest dose used. Six grams of tetrabromphenolphthalein is mixed with 1.2 gm. of calcium hydroxid, ground in a mortar with a few cubic centimeters of water, and dissolved in from 325 to 350 cc. of distilled water. Addition of calcium lactate was found to produce a more stable solution and slightly increase its solubility. Therefore, a solution of 2 gm. of calcium lactate in a few cubic centimeters of water is added.

COCCIDIOIDAL GRANULOMA IN SOUTHERN CALIFORNIA

By ROY W. HAMMACK, M. D. and J. MARK LACEY, M. D., Los Angeles.

So far as we have been able to determine, only two cases of coccidioidal granuloma observed in Southern California have been reported in medical literature. Brown, in 1906, reported two cases seen in Los Angeles. Both of these had apparently acquired the infection in the San Joaquin Valley. While in the majority of all cases reported the infection appears to have been acquired in the San Joaquin Valley, in recent years an increasing number of cases undoubtedly infected elsewhere has been recognized. In our series about one-fourth of the cases appear to have originated in the San Joaquin Valley. Of the others, one is attributed to Mexico, one to Texas, one to Arizona, one to New Mexico, and the remainder to Southern California.

Our acquaintance with the disease dates from 1916, when the first case of the series was seen at the Los Angeles County Hospital. Since that time a total of nineteen cases has been recognized at that institution. In addition to these, we include four cases which occurred in the private practice of physicians in Los Angeles and Pasadena. In these the laboratory studies were carried out in the laboratory with which one of us is associated.

Our report thus includes twenty-three cases. Of these, eleven were Mexicans, three negroes, and nine Caucasians. Nineteen were males and four females. The ages range from 2 to 83 years.

Occupation seems to be a factor in the etiology of the disease, since those who worked on farms far outnumbered those of any other occupation; yet the series included a clerk, a student, an electrician, and a retired business woman. In no case could the portal of entry of the infection be demonstrated, but in several cases the findings suggested that infection was through the respiratory tract.

In Case No. 1 (see table) there was found in the anterior wall of the esophagus, a little above the level of the bifurcation of the trachea, an ulcer one centimeter in diameter. Imbedded in the ulcer was an oat kernel. Sections from the ulcer showed a granulomatous base containing a few parasites. Infected lymph nodes lay adjacent to the esophagus over the ulcer. It was suggested that the oat kernel might have been the carrier of the organism, and the esophagus the portal of entry. Unfortunately, animal inoculation with this foreign body was not performed.

CLINICAL FEATURES

Cutaneous lesions were not common. They occurred usually as reddish papules which broke down, forming discharging ulcers. They were found on various parts of the body. Subcutaneous abscesses were very common, occurring on all parts of the body. These were prone to break through the skin and discharge pus for a long time, but occasionally such lesions healed, others appearing on other parts of the body. Bone lesions were very common, occurring in twenty-one of the twenty-three cases. Many different bones were involved, those most commonly affected being the bones of the foot and the vertebrae. The involvement of the foot was always in the ankle region, and the joint was usually affected. Nearly all of these cases gave a history of injury to the ankle, such as sprain, followed soon after by swelling, suppuration and sinus formation after spontaneous or operative evacuation of the pus. Such a lesion was present in eleven of our cases, in nine of which it was the first lesion to be recognized, in five the only one found. We have been able to follow only two of these latter for a period of over two years after amputation of the affected part.

Infection of other bones was usually followed by suppuration of the surrounding soft parts which eventually reached the surface of the body.

Lung involvement was frequent, producing physical signs indistinguishable from tuberculosis.

Involvement of cervical lymph nodes was seen in two of the four children and in two adults.

The temperature range was from normal to 103 degrees Fahrenheit, according to the severity of the disease and the regions involved. The pulse was increased in frequency in proportion to the elevation of the temperature. The leucocyte count varied from normal to high polymorphonuclear leucocytosis, depending upon the extent of the lesions and the secondary infection present.

PATHOLOGY AND BACTERIOLOGY

Autopsy was performed upon the eight who died at the County Hospital. Material was also obtained at surgical operation in several cases. While a wide variety of lesions was found, there was nothing strikingly different from what has already been described by other investigators. Lung involvement was present in some degree in every autopsy and the lesions were very similar, both grossly and microscopically, to tuberculosis. In two instances active tuberculosis was also present, as shown by demonstration of the bacilli. Very striking was the freedom of the gastro-intestinal tract, liver, spleen and the genito-urinary tract from the infection. In only one instance were lesions of the genito-urinary tract found, a few miliary nodules in the kidneys. The bone lesions were usually markedly destructive. In a few instances, notably in Case No. 18, there were proliferative changes in the cortical portions. Roentgenological studies of some of these cases have been reported by Bowman and Taylor. In only one case was involvement of the nervous system found. Here there was a small granulomatous nodule in the cerebral cortex, in which the organisms could be demonstrated.

In every case in the series the organism has been demonstrated either in pus or in tissue, and has usually been cultured.

Animal inoculation has been performed in some instances. Blood cultures have been negative. At autopsy one and a half hours after death in Case No. 9, cultures from the blood in the right auricle yielded streptococcus hemolyticus and coccidioides immites.

TREATMENT AND PROGNOSIS

Various forms of therapy have been tried, but no drug has been found of value. In two cases subcutaneous lesions apparently responded to x-ray treatment, and these patients are well five and nine

No.	RACE	AGE	SEX	OCCUPATION	PROBABLE SOURCE	RESIDENCE IN CALIF.	LOCATION OF LESIONS	TOTAL DURATION	TREATMENT	OUTCOME
1	Mexican	25	Male	Farm and R. R. Laborer	So. Calif.	6 years	Ankles, lungs pericardium, subcutaneous abscesses	4 months	Drainage	Death
2	Negro	83	Male	Gardner	So. Calif.	25 years	Left ankle	2 months	Amputation	Well 5 years
3	Mexican	54	Male	Teamster	Mexico	1 year	Right groin, vertebrae Left wrist	1 year	None	Death
4	American	28	Male	Teamster	San Joaquin Valley	Life	Fingers, knee joints, subcutaneous abscesses	11 months	Amputation	Death
5	Mexican	48	Male	Farm laborer	Imperial Valley	4 years	Right ankle	8 months before observation	Refused amputation	Unknown
6	Negro	44	Male	Laborer	So. Calif.	8 years	Abscess lumbar region, lumbar vertebrae	5 months	Drainage	Death

21	American	53	Male	Veterinarian and farm laborer	Tulare Co.	14 years	Subcutaneous abscesses, wrist (metacarpals)	4 years before observation	Drainage	Living. Several lesions healed.
22	American	23	Female	Student	So. Calif.	Life	Lung, cervical glands. Subcutaneous abscesses	20 months	Arsenic, X-ray	Well 5 years
23	American	23	Male	None	So. Calif.	2 months	Ankle, subcutaneous abscesses	1 month before amputation. Abscesses 4 months later	Amputation of Ankle X-ray	Well 9 years

years, respectively, after their lesions healed. In one of these the subcutaneous lesions appeared after amputation of an affected ankle; in the other after what was clinically a long continued broncho-pneumonia. Ten of our cases are known to have died of the disease, one of another cause. Three have been lost sight of. Only four have been free from symptoms for a period of two years or more. Three of these have had amputation of an affected foot, and are well, two, five, and nine years later, respectively.

The duration of the disease in the fatal cases has been short, from one month to one year after the first symptoms were noticed. That some infected individuals may live for a period of years with little extension of the process suggests the existence of strains of low virulence or the power of the body to develop resistance against the infection.

CONCLUSIONS

Infection with coccidioides immites not infrequently occurs in Southern California. X-ray therapy appears to have been of value in two cases, and we believe that it should be given thorough trial. No other therapeutic measures except surgery have proved of value.

Note—Since this report was made, nine additional cases have been encountered. These we hope to include in a subsequent report.

Pacific Mutual Building.

DISCUSSION

William B. Bowman (Brockman Building Los Angeles) — It was my good fortune to have made a thorough Roentgen study of five of the cases reported in this paper, all of which showed definite bone lesions. The following bone changes were noted at the time of their examination.

Case I — As listed in their table, revealed a small irregular area of necrosis involving the inner two-thirds of the articular surface of the tibia. There was also an irregular fuzzy thickening of the periosteum of the internal malleolus.

Case II—Left ankle. The articular surface of the tibia was irregular, showing beginning destruction of the joint surface. There were also a few small areas of rarefaction on the posterior surface of the tibia.

Case III — Left wrist. Roentgenograms revealed marked destruction of the articular surface of the radius, the bone having a punched-out appearance such as seen in cases of tuberculosis. The outer border of the radius showed a roughened, irregular, fuzzy thickening of the periosteum not seen in tuberculosis of the bone.

Case IV—Roentgen examination of the chest and spine of this patient was negative for any definite bone lesion. Left hand—All carpal and proximal ends of the second, third, fourth, and fifth metacarpal bones were poorly defined. The joint surfaces were practically destroyed and the carpal bones had practically lost their identity. There was a marked thickening of the soft tissues. These changes were identical with those found in tuberculosis. Right knee showed practically the same changes except that the patella was missing, it having been removed prior to the roentgen examination.

Case V—Right ankle. There were small areas of rarefaction in lower end of fibula. The tip was denuded of periosteum, with slight bone destruction. The internal malleolus showed marked bone destruction with considerable irregularity, and fuzzy thickening of the periosteum.

Summary — In practically all of these cases, the findings were typical of bone tuberculosis, with the exception of a peculiar roughening and fuzzy thickening of the periosteum which seems to be peculiar to this disease. These periosteal changes were not present, however, in Case No. IV.

From my limited experience I am of the opinion that these cases are not as rare as is generally supposed, and that most of these cases are diagnosed as cases of tuberculosis.

Raymond G. Taylor (Hospital Good Samaritan, Los Angeles)—It was my privilege to see most of the cases mentioned in this report, and make a roentgen study of the bone and chest lesions. A detailed roentgen report was made by me of eleven of these cases in 1922 and published in July, 1923. No attempt will be made to go into detail in this discussion, as anyone who is interested can find the details in the published article.

I do not believe that there is any uniform, constant roentgen finding that is characteristic of this disease. Practically any of the lesions that we have seen would justify a diagnosis of bone or lung tuberculosis when viewed from the x-ray standpoint alone. There are one or two points which make one suspicious of a diagnosis of coccidioidal granuloma, but nothing that is sufficiently definite to warrant an unsupported diagnosis. The suspicious points referred to are the rather unusual, circumscribed, large areas of soft tissue density that precede the bone lesions in the extremities and the unusually marked proliferative changes seen most frequently in the younger patients. Neither of these are sufficient to rule out tuberculosis, but they are, apparently, much more often found in the cases of coccidioidal granuloma than in tuberculosis.

The bone proliferation may be observed in a most unusual and marked degree after some operative interference, in the young, such as an attempt to clean out the diseased bone by curetting. In one case in which this was done, before a diagnosis was made and before the patient came under observation, a diagnosis of probable sarcoma was made. The proliferation was more rapid and intense than any the writer has ever seen in any type of lesion.

The fuzziness of the periosteum mentioned by Bowman has apparently been present in some of our cases, but only those which affected the bones about the ankle-joint.

So far as treatment is concerned, cases which have been radiated are among those which are still alive after some years. My opinion is that any benefit that may be derived from this type of treatment must, undoubtedly, be due to a stimulating of the natural defensive mechanisms in the tissues, rather than any direct action of the ray on the organisms.

Philip King Brown (909 Hyde Street, San Francisco)—The search for cases of coccidioidal granuloma is possibly responsible for the recognition of such a large number of cases in the period of eight years covered by Hammack and Lacey's report. I presume we are overlooking these cases all the time, and such reports as this should awaken us again to the fact that in all our large hospitals there must be such cases constantly. I should agree with the others that the portal of entry was the respiratory tract, although the skin cases may have been direct inoculation. I do not think that any case in a large hospital of a suppurating superficial lesion suggesting tuberculosis should be treated without cultures being made. It is hopeful that cases have apparently recovered where what seemed to be primary foci were extirpated surgically. Gardner has two in his Southern Pacific Hospital service where the amputation of a foot in one and the excision of an elbow-joint in the other resulted in apparent cures.

False Diverticula of the Jejunum — False diverticula of the intestine constitute a rare anomaly. A study of the literature reveals only twenty-seven cases. Three additional cases are reported by William M. Sheppe, Wheeling, W. Va. (Journal A. M. A., April 5, 1924), occurring within four weeks.

KIDNEY AND URETERAL CALCULI *

By J. C. NEGLEY, M. D., Los Angeles

These cases were collected from the records of the Los Angeles County Hospital, and are only those cases definitely proven by x-ray or other means to be calculi.

They were compiled for the purpose of trying to determine whether there were any definite symptoms, clinical and laboratory findings, and operative results upon which we might base conclusions in the future management of such cases. The paper represents statistical findings, and the summary and conclusions are based on these rather than on the personal opinion of the writer.

There were twenty cases of stone in the ureter, of which six were on the right side and fourteen on the left. There were thirty-seven cases of stone in the kidney, of which twenty-one were on the right side and sixteen on the left. There was one case of stone in the right kidney and right ureter and one case with stone in the left ureter and left kidney. There were two cases of stone in both kidneys. As to sex, there were thirty-five men and twenty-seven women, As to age, the youngest was 17 and the oldest was 80. Of the ages between 17 and 27, there were fourteen cases. Between 27 and 37 there were nineteen cases. Between 37 and 47 there were nineteen cases. Between 47 and 57 there were five cases. Between 57 and 67 there were three cases. Between 67 and 77 there was one case. Between 77 and 87 there was one case.

SYMPTOMS

Duration—Twelve cases came into the hospital with their first attack. One case had symptoms for three days, and another one for eight days. One case had symptoms for two weeks, three cases had symptoms for three weeks. One case had symptoms for two months, three cases had symptoms for three months, eight cases had symptoms for from six to eight months, two cases had symptoms for ten months. Seventeen cases had symptoms lasting from one to three years, eight cases had symptoms lasting from four to seven years, five cases had symptoms lasting from ten to twenty years, three cases had symptoms lasting for thirty years or longer.

Character of Symptoms—In forty-two cases there was bladder disturbance, ranging from a mild degree of dysuria to tenesmus and pain that required an opiate. Frequency both night and day was the most prevalent symptom.

Nine of the series had frank hematuria. Another marked symptom was pain. All but seven of the cases complained of pain in some degree and in many locations. Some of the cases were unconscious or to near a state of collapse to register much pain, which accounts for a relatively large number of cases that presented no pain.

Location of Pain—Nineteen cases manifested typical kidney pain which radiated from the lumbar region along the course of the ureter, and in some cases to the thigh or the testicle on the same side. Twenty cases presented abdominal pain. In five cases the pain was limited to the left lower abdomen, in eight cases to the right lower abdomen, four cases to the left upper abdomen, and three cases to the right upper abdomen. Most all the cases of pain on the right side was found a little lower and more lateral than McBurney's point. In sixteen cases there was pain in the back, mostly in the lower part of the back in the lumbar region. The cases of renal pain, of course, were in the back, but are not included in these sixteen cases.

Physical Findings—The tenderness corresponded to the side in which there was renal pain in every instance. The abdominal pain did not always show tenderness, but there was rigidity in every case of abdominal pain. The physical findings were negative in seven cases. There was a palpable mass in the kidney region in eleven of the cases.

Urine Findings—The bladder urine in three of these cases was entirely negative. In fifty-two cases red blood cells were found. In fifty-six cases pus cells were found. The urine was frankly infected in twenty-six cases. Albumin was found in forty-seven cases.

Cystoscopic Findings—Every case had some degree of cystitis, varying from a mild degree of trigonitis to a very virulent or ulcerative cystitis. The bladder capacity was impaired in only five cases, that is, to any marked extent. Of the thirty-two cases operated on, eleven had both pus and bacteria; ten had pus alone and no bacteria, and one had albumin alone and no pus or bacteria.

Pthalein Output — A twenty-minute period was used in all cases. In those cases in which the urine was obtained from the kidney or ureter on the side affected, there were eight cases in which the pthalein did not appear at all. There were eight cases in which the pthalein was normal. There were seven cases in which the pthalein appeared between ten and fifteen minutes. There were three cases in which the output of pthalein was between 15 and 25 per cent. In one case the time of appearance was twenty-eight minutes. With another patient the pthalein did not appear for forty-five minutes.

Percentage of Pthalein—There were eleven cases in which the pthalein did not appear in a sufficient quantity to estimate. There were eight cases in which the pthalein ranged between 2 and 7 per cent. There were seven cases in which the pthalein ranged between 7 and 12 per cent. In two cases the pthalein output was normal.

Of this series of cases, thirty-two were operated on, nine in which the left nephrectomy was done, eight in which a right nephrectomy was done. There were eleven cases in which the stone was removed through a pyelotomy incision and in which the stone was either in the kidney, pelvis, an accessible portion of the kidney tissue, or was drawn with forceps from a lower portion of the ureter. In four cases there was simply an incision in the ureter, and the stone was removed through this incision.

The average post-operative stay in the hospital was twenty-four days. The shortest period in the hospital was fourteen days, and the longest period was three months. This case was one in which a sinus leading from the kidney had opened into one of the larger bronchial trunks so that injection of bismuth into the end of the sinus opening out

* Presented to the Section on Urology at the Fifty-second annual session of the California Medical Association, San Francisco.

through the skin brought some of it through the bronchial tubes. Of these thirty-two operative cases, there were four women who had had some pelvic operation, three men who had appendix operation, one man and woman who had had a gall-bladder operation.

SUMMARY AND CONCLUSIONS

Location of the stone in ureter seems to be more frequent on the left side; in the kidney it was more frequent on the right side. In all these cases there were only two with bilateral calculi. If this series of cases alone were to be considered, may we not tell our patients that the danger of formation of stone in remaining kidney is rather remote—about one chance in thirty-one, according to these statistics.

Age — It seems that no one from 17 to 80 was exempt, but more cases were found between the ages of 27 and 47.

Duration of symptoms would go to show that the greater number had symptoms lasting for over a year, but this factor varies so with the individual that it is hardly important in the question of diagnosis, particularly so in this series, as most of them were of low intelligence and not accustomed to noting any minor disturbance of bodily health.

Findings in Bladder Urine—This is a factor of prime importance, because only three or a very small percentage failed to show signs of pathology in the urinary tract.

The cystoscopic findings are also conclusive, in that every case had some degree of cystitis. Practically 100 per cent of the cases showed diminution of pthalein output, either as to time of appearance or percentage or both in the affected side.

The bladder symptoms are also conclusive, in that over 85 per cent of the cases had some bladder disturbance, most marked of which was frequency. Hematuria, the often-quoted symptom of calculi, was present in only 7 per cent of these cases—a relatively small percentage. Red blood cells were present in practically every case, however.

Pain was probably the most important symptom, as all the cases except the ones that were unconscious complained of pain in some location. Not all—in fact, only 18 per cent—showed the typical renal pain. The greater number showed abdominal pain in widely varied locations.

Physical findings were also conclusive, in that 100 per cent showed tenderness on the side affected, and there was rigidity in 100 per cent of the cases with abdominal pain.

A relatively large percentage (18) showed a palpable mass in the kidney region. These cases, of course, showed obstruction of ureter with infected hydronephrosis.

CONCLUSIONS AS TO ADVISABILITY OF OPERATION

It would seem from this small series that operation is the method of choice in all these cases showing derangement of kidney function. The reasons for advocating operation are, first, the element of time consumed. These patients averaged only twenty-four days in the hospital, which is a relatively short time; second, it is not a serious affair to operate on these cases, as all of our deaths were from causes far removed from the operation, but were from outside influences—in fact, only the death from septic erosion of the pedicle can in any way be called an operative death; third, manipulations for the non-operative removal of the stone, if too often repeated, do more harm than good and certainly cause the patient more suffering, more inconvenience, more loss of time, more expense, and more chance of destruction of kidney tissue with abscess formation if condition is allowed to remain for a long time. However, every case should have at least three attempts made for the non-operative removal of the stone before they are subjected to operation. The safety of the operation is illustrated by a few selected cases, namely, one done by Rosencranz on a woman, age 62, who had a large hydropyonephrosis, with the mass so large as to extend from the ribs to the sacrum. The kidney was removed, and the patient left the hospital in fourteen days.

Two cases operated by Day, one a girl age 17, with a right pyonephrosis in which kidney was removed. In the left ureter just below the kidney was a small stone, which caused obstruction and suppression of urine. Twenty-four days after right nephrectomy she was operated on, and through a pyelotomy incision the stone was removed and she left the hospital in forty-eight days with a functioning kidney. Second case of a boy with several stones in right kidney and right ureter full of stones. He also had active pulmonary tuberculosis and a heart lesion. Day did a nephrectomy under para vertebral anesthesia, with complete recovery, gain of weight, and cessation of all kidney symptoms.

From this small series of cases one would be led to believe that stone in the kidney or ureter was a relatively uncommon occurrence. If we consider the aggregate number of cases that pass through the County Hospital in a period of three years, only a small number are affected by urinary calculi.

We find opposite to other observers, in that only nine of these cases had been subjected to operation for other condition while showing evidence of kidney trouble, and as these operations were done outside of the hospital, we have no way of telling whether they were unnecessary operations or not. In fact, in only one case, a gall-bladder operation, did we find that a mistaken diagnosis had been made. Therefore, we have no criticisms to make such as are all too often made of the other fellow's diagnosis and treatment, which criticism not only hurts the surgeon in question, but the profession as a whole. Some day one of the cults will seize upon a paper in which some member of the profession has enlarged upon his colleagues' mistakes mainly for self-glorification, and make such paper an issue to the general detriment of the profession at large.

219 West Seventh Street.

DISCUSSION

R. L. Rigdon (291 Geary Street, San Francisco)—The report of Negley confirms for the most part other similar reports of kidney and ureteral stones; such differences as occur may be attributed to the variations that must be present in relatively small series of cases. It is rather striking that no patient among the sixty-two was under 17 years of age. Cabot reports more than 20 per cent occurring within the first two decades of life.

The frequency of bladder symptoms is another

striking observation. It is rather commonly thought that stone in the kidney does not cause vesical reactions, but that these symptoms result from ureteral stones. In this series, with only twenty-two instances of stone in the ureter, bladder disturbance was noted in forty-two. It is probable a closer analysis might elicit the fact that causes other than the calculi were operating to produce these symptoms.

Pain is a symptom that is very common and may be very misleading. It was complained of in forty-seven instances, and in a considerable proportion of the cases might have been produced by lesions in other organs.

In this connection, it is well to recall that, in nearly all of this series, some change was found in the microscopic appearance of the urine. Taking these two symptoms together, pain and changes in the urine, we may be justified in hesitating to incriminate the upper urinary tract, if pain is present and the urine persistently negative upon microscopic examination.

The percentage of tenderness and rigidity is striking. These observations are not borne out in the routine experience of some other observers. It has been our experience not infrequently, that neither tenderness nor rigidity is demonstrable.

With reference to treatment, the doctor's statements are so brief as to seem misleading. He contrasts operative and non-operative methods, and makes out a good case for surgery. There is a rather large percentage of stones in the lower ureter that should be treated by means of ureteral dilatation. Indeed it is sometimes possible to follow the descent of a ureteral calculus, under ureteral manipulation, from the upper portion of the ureter until it is delivered in the bladder, from which it can be voided or removed by an evacuating instrument. I believe that practically every ureteral calculus that is not too large should be given every opportunity to deliver itself, or be delivered without cutting. The patient who has escaped the knife is the grateful patient and, like the woman in labor, the pains are forgotten as soon as the child is born.

H. A. Rosenkranz (Story Building, Los Angeles)—The careful and painstaking work of Negley has been of interest to me from several standpoints. I have been impressed with the fact that he has not encountered any cases of reno-renal reflex. That red corpuscles were found in only 52 per cent of cases must, I believe, be attributable to the fact that the period covered by Negley's statistics included that of the World War, during which time hospital standards were inadequate. I can recall cases of ureteral calculus at the County Hospital in cases younger than 17 years of age, but they had other complications or refused operation, so were not transferred to the Urological department. I once extracted a stone the size of a small lima bean from the urethra of a babe about one year old.

As regards technique: I have found those calculi most difficult to remove that lie in the lower portion of the ureter just posterior to the bladder. About a year ago I bought a ureteral stone crusher fitted with a woven silk tip. Several months later I had occasion to use it on a patient who entered the office with quite a severe Dietls' crisis. He gave a history of having passed a number of stones, and had had one operation upon the side in question. Manipulation of the instrument after the administration of an H. M. C. tablet was not painful. I suspected that I might have caused considerable trauma to the patient, but was surprised when he walked into my office on the following morning entirely free from his ureteral symptoms, and he remained so during the several months following, during which I kept him under observation. I believe that if this instrument were given a fair trial the percentage of major operations for ureteral calculi would be considerably diminished.

I may add that, during the nine years of my service at the Los Angeles County Hospital, the percentage of renal calculi that have been diagnosed has increased several hundred per cent due to the fact that all cases having urinary symptoms are x-rayed. It has been noteworthy that we have diagnosed many cases of kidney calculi in patients who had not had any necessarily leading complaints that would make the general practitioner suspicious of renal calculus. I regard this routine roentgenography as of prime importance in cases complaining of backache, symptoms of cystitis and abnormalities in the urine.

Doctor Negley (closing)—Answering Rigdon, first, in reference to the large number of cases showing vesical reactions: Our cases are mostly terminal cases that have been suffering from renal or ureteral calculi for a sufficiently long time to cause infection of the upper urinary tract to a grave extent. Naturally, vesical infection follows in a very large proportion of these so-called terminal cases.

Second. In regard to pain in this series of cases, being due to lesions in other organs, will say that all patients (unless in a critical condition) are first admitted to the diagnostic wards, where they are examined by the internist, the gynecologist, the general surgeon, the radiographer, and a very complete examination is made, so that by the time they reach the urologist there is very little probability of any grave lesions elsewhere that are overlooked.

Third. In reference to tenderness and rigidity, most or all these cases seem to have had some degree of tenderness, but only those cases that showed marked abdominal pain had any degree of rigidity.

Fourth. In regard to the advisability of operation, or attempts at removal through the cystoscope: Of course, these cases, as any other surgical case, must be considered on their individual merits, and neither of the above methods should be advocated for all cases.

I have said that every case should have at least three attempts made for non-operative removal of the calculi, and after these three attempts if no progress has been made, then operate. Again, we must remember that these cases were ones that had had their calculi for a long time; had plenty of opportunity to pass and in many cases had cystoscopic manipulations on the outside.

We have adopted the plan of explaining both methods to the patient and allowing them to decide, and most of them choose an operation, particularly those who have already had one or more cystoscopic examinations.

Answering Rosenkranz, in regard to red corpuscles in the urine: Probably a word of explanation as to that would be that I considered only those cases that had not had the urine removed by instrumental means, i. e., by catheter or cystoscope; for all these cases have more or less blood, and I only considered those cases that had voided the urine before examination.

Estimation of Blood Sugar by the Folin-Wu Method—A simple and accurate micromethod for the determination of blood sugar, using only 0.1 cc. of blood, with a new method of collecting the blood, which is described, is recommended by F. S. Randles and W. K. Grigg, Albany, N. Y. (Journal A. M. A., March 1, 1924), for routine examinations when only small amounts of blood can be obtained, as in the case of babies and small children, or for the study of blood-sugar curves of adults from whom samples must be taken at short intervals. Tests showed that 0.5 cc. of blood filtrate would suffice for an accurate blood-sugar determination by the Folin-Wu method. By centrifugating instead of filtering in the preparation of the protein-free blood filtrate, it was found that 0.1 cc. of blood would easily furnish 0.5 cc. of the filtrate. In order to make the procedure as simple as possible, the authors have adopted Haden's modification of the Folin-Wu method of preparing the protein-free filtrate. Small, wide-mouthed, homeopathic vials (14 by 25 mm., 2 cc. capacity) are used for collecting the blood. The blood may be taken from the ear or finger following puncture. The puncture should be deep enough to insure a free flow of blood, if possible.

EDITORIALS

WHO IS VIOLATING THE MEDICAL PRACTICE ACT?

Section 17 of the Medical Practice Act provides a penalty for treating, diagnosing or prescribing for any ailment of the human system without having a license issued under the laws of this state.

It is a matter of common belief that some medical officers of the state, county and municipal governments, and technicians of a variety of species, are constantly violating this law.

DETAILING THE DOCTOR BY MAIL

The doctor's mail is beginning to look like the advertising sheets of some of our "careless" newspapers and magazines. Some of the publicity is well written, informative, and from legitimate firms who advertise in good medical journals. But fully 95 per cent of it is the worst form of medical piffle. Much of it is not even cleverly done, and lots of it frankly appeals to the physician's cupidity at the expense of his honor.

Doctor, did you ever stop to think what an insult to your intelligence and how cheaply many of these advertisers regard your integrity, as expressed in the expensive "stuff" they load your mail with? They further show how cheaply they expect to buy you, by trying to buy space in your medical journal and when they are turned down, they resort directly to your mail.

Do you know that some of these people grade their "literature" into three classes? One kind goes to doctors who are members of their medical societies; another grade goes to those doctors who are not members *and* to the various groups of cultists. The final grade is for public consumption.

Some of our members supply their state officers and CALIFORNIA AND WESTERN MEDICINE with all their mail of questionable character in original wrappers. We wish more physicians would do so. Original wrappers are necessary for the postoffice people with that class of rot covered by postal laws.

We also have facilities for getting some of the class sent to nurses, clinics and the public, but we want more from different localities. These fakirs often send one class of mail to one locality and another class to some other county.

The reasons for all these customs are, of course, obvious. We have no hope of destroying these pernicious influences, but it is quite a pleasure to help keep them on the move.

PAY CLINICS

Doctor, if you are interested in the greatest problem of our profession, which consists in making the best that scientific medicine has to offer available to everyone at the lowest possible cost consistent with good service, read the abstract of the discussions about "pay clinics" published on page 15 of this issue.

The July, 1923, number of Hospital Social Service is practically all devoted to the subject. There are several good articles dealing with its various phases. We have taken abstracts from some of the papers and reduced the matter for your convenience.

The pay-clinicers are a very busy lot of people. A few of them are educated practicing physicians, but most of them are non-medical with a sprinkling of "swivel-chair" men of our profession who have long since gotten out of touch and out of step with medicine as a great altruistic human service to sick people. To some of them medicine, whether preventive or curative, is now a cold-blooded game based upon "statistics" and other actuarial figures, with human beings as pawns. We must not lose sight of the fact that the 150,000 physicians of the country are themselves part of the public, and whatever steps and movements are made to limit or treat disease should not imply the complete pauperization of physicians. They have the same human desires and requirements as other citizens and are entitled to the same consideration given to others. Destructionists may criticize them all they please, but the fact remains that they are the best we have. They are the chief agents of civilization in controlling disease, relieving suffering and extending intelligent sympathy to those most in need of it.

Following promptly upon the introduction of pay clinics, we have the movement to change many former "free clinics" to "pay clinics," and this movement already has traveled far. What do you want done about it, and who shall do it?

DO YOU WANT THAT TWO-DOLLAR TAX ABOLISHED?

Many of our members are urging that the League for the Conservation of Public Health be asked to promote legislation to abolish the two-dollar-a-year Board of Medical Examiners' tax. A bill to this effect is now in course of preparation, which will be submitted to medical organizations and, as endorsed, will be introduced at the next Legislature.

We have yet to meet the first physician who is not opposed to this tax; most of them even decidedly resentfully opposed to it. This is not because of the amount of the tax, which is small, nor so much the nuisance connected with its payment. The objections are those of principle. It is probably the best, or the worst, example of class legislation to be found anywhere and, of course, is therefore unfair, unjust and repugnant to honest men.

In the enforcement of the Medical Practice Act by the Board of Medical Examiners, for which the two-dollar tax was supposed to supply funds, physicians are placed in the anomalous position of paying a special tax for the support of laws which, in some instances, are injurious to the only group of people who pay the tax. Some of the money collected by that exclusive, select and special class tax was, and presumably still is, used to pay a committee of doctors to prosecute violators of the medical practice laws. It is generally and correctly believed by both physicians and the general public that the prosecution of quacks, fakers, and the general unlicensed mess of so-called "doctors" by a board of doctors causes great injury to the good name of the medical profession. In spite of this well-known fact, physicians, and physicians only, are specially taxed

to add further injury to themselves and the cause they espouse. The enforcement of the laws governing the practice of medicine should, of course, be carried on by the law-enforcement machinery of the State. It is their business and it is not the doctors' special business.

It is not possible to enforce the miserable makeshifts of law governing the practice of medicine for which California is notorious. Attempts to do so are about as popular as attempts to enforce the Volstead Act. So long as human nature continues as it is, any attempt to enforce the law by a committee of doctors who are paid in part by special taxation of other doctors will continue to be the failure it has been, is, and should be.

Some of that two-dollar special class-legislation tax presumably goes to pay for the preparation of a directory published annually, and sold for more than the tax. This directory may be occasionally useful to an occasional physician, and the general public rarely sees it. It is chiefly interesting and of the greatest value to all sorts of honest, but particularly dishonest, vendors of services and things sold to cure disease. Many copies of this directory could be sold at $100 a copy as easily as they are for two or three dollars. If California is going into the game of selling "prospect" lists to all sorts of fakers, why not get real money for the "service"?

If you want this law repealed, write to the secretary of your medical association, the executive secretary of the League, or to the editor, and express your views.

SHOULD PUBLIC HEALTH DOCTORS BE LICENSED?

Publication in the newspapers of a statement that the State Board of Health does not want their doctors to be licensed has resulted in considerable discussion of the subject by other doctors and in not a small amount of criticism of the board's action.

The reason given for the attitude of the board is, that they desire their doctors to give all their time to their work and not be engaged in preparing themselves to engage in private practice.

The criticisms that have come to the Journal, with requests for a public discussion of the subject, have covered several lines of argument. It is stated that the practice of public health or preventive medicine is just as intimately a part of medical practice as is the diagnosis and treatment of appendicitis. Some physicians believe that the fact that much of a health officer's work is among the poor constitutes all the more reason for his being a law-abiding physician. This not only for the protection of the public and himself, but also that the legal responsibilities and privileges of the physician provided by the State license may not be avoided.

Others less kindly disposed believe this action to be but part of a general scheme now widely commented upon in many places to separate public health medicine from the work of that profession as doctors see it. It is stated by some that to allow public health doctors to practice medicine without a license opens possible avenues for incompetents to practice public health medicine, if the personnel of the State board were ever to be of the class that it is easy to make it under our laws.

And, probably most important of all, the decision results in keeping an important group of physicians largely imported for special work out of touch with other physicians whose co-operation they must have in order to render the better service so much to be desired. It is our impression that all members of the State board are themselves not only licensed to practice, but are members of their county medical societies and thus identify themselves, as is fitting, with medical progress. Adequate reasons for not extending to and insisting upon a similar status for all official public health doctors have not been advanced. In the absence of convincing reasons, people are liable to supply other reasons, and some of them probably unwarranted ones.

We discuss this question openly, because we believe the board of health is making a serious mistake, which no physician wants to see them do, in the interests of better medicine, including public health medicine for all the people.

GOING "CHRISTIAN SCIENCE" ONE BETTER

Whatever one's opinions of the adequacy of the medical education or of the methods of "doctors of Christian Science" in their treatment of the sick, it must be admitted that, from a business standpoint, their organization is effective. Their publicity; discipline of their own followers, as well as of their enemies, and particularly their power to get money, are outstanding. To them belongs the credit of teaching a philosophy and a religion that all sickness is error and not only securing followers, but making these followers pay for their tuition, as it were, and for the cure of those things their teachers said they had not.

Christian Scientists have for some years held the center of the stage against all comers in the field of mental and spiritual healing. Many groups of various kinds have attempted to break in on this profitable activity, but few of them have prospered over any extended period of time, and it is said that the great Christian Science organization helped in their decline. It has, of course, been recognized for some time by thinking people, and probably by the Christian Scientists themselves, that their position was precarious and could be held only at the price of well-organized and financed publicity, and an administration with disciplinary power. It has been equally obvious for some time that the social, sociological, psychological, sex and philosophical unrest being so widely propagandized among people was liable to swing many away from fundamental Christian Science and into some one or another of the camps of the other mental and spiritual healing groups. The signs have seemed clear that "weak sisters" were probably being so swung away from the "mother church" and the danger of possible successful combinations of several of these groups probably has had the serious attention of the Christian Science authorities.

Some thoughtful watchers of things, as they pass by, are beginning to wonder if the combination known as the "Christian Philosophers" or the

"Christian Philosophical Institute," with headquarters in Oakland, may not have attained a popularity where they are menacing the "Christian Science" movement; at least, in their most lucrative field of, what physicians claim to be, the practice of medicine. The head of the "Christian Philosophers" is one quoted by himself as "Bishop Wilbert, Le Roy Cosper, D. D., Ph. D." The "Bishop" and his cohorts also apparently have a good business organization. They have an expensive publicity organ; a legal department, and an "Institute" which seems to be a sort of a college which awards degrees that appear to be all that the student needs to prepare him to treat the sick. Thus, through the "Institute" and what is called a "Watch Tower," they seem to have an organization that places, supports, and promotes their rapidly growing group of graduates in a chain of *health centers* which they are locating at strategic points.

As "doctors" these "Christian Philosophers" make claims of cures that make Christian Science practitioners look like pikers. This new crowd publish names and addresses of "testimonialists" and they are not at all bashful. They also publish broadcast a statement presumably prepared by their "legal" department declining all responsibility for possible happenings to patients, including death; a statement not unlike the one a passenger signs relieving the steamship company from responsibility while he goes sailing the seas.

Then, too, this new group of "prayer doctors" have a "Luther V. Bates, M. D." on their staff. Luther V. Bates is an osteopath with a state license or political title of "physician and surgeon." The precaution of having someone on the staff licensed by the state to sign death certificates and certain other medical papers is a wise provision, as is also that of having a strong legal department.

Several varieties of inadequately "educated" "doctors," including Chinese herbalists, have attractive advertisements in the "Christian Philosophers" magazine. In other words, they appear to have capitalized the fundamental psychology behind cultism in any and all of its forms, and the attempt appears obvious to bring them all together under one banner. If they can succeed, the pre-eminence of "Christian Science" is at stake, and the war should be interesting.

We are very much afraid that most people are not artistic and idealistic and religious enough to see the innocence, or the Christian elevation "The Philosopher" implies he intends to portray in the pictures of the more or less disrobed women who are featured in the magazine. If a choice must be made between "Christian Science" and "Christian Philosophy," Oh Lord, give us Christian Science!

"THE NEXT GENERATION"

Most of us are guilty of often giving utterance to that stupid platitude, "the next generation," when we mean nothing of the sort. Calculated from rather generous minimums, there is one generation started by birth every day of every year. Those of us who are living are, therefore, contemporaries of a sort with just as many generations as we are days old. Generations, therefore, may mean the same thing only to those of us who are the same number of days old.

Toward the end, any generation become quite frazzled. Many of them have gone prematurely, and many of those of former generations have lived on, so that the older we are the greater the number of generations about us, and therefore the more confusing the babble of thoughts and the greater the difficulty of drawing deductions from "averages" that are not. Then, too, senescence is liable to produce minds that jump backward over many generations and interpret them all as yesterdays.

When we speak of generation, therefore, even the best of us, in reality, have in mind groups of generations.

"COMPETENT PHYSICIANS NEED NO PROTECTION; INCOMPETENT ONES DESERVE NONE"

This title is worth reading, pondering over, and filing in that handy file in our minds to which we all refer frequently in the working out of the day's problems. This phrase constituted the slogan of the New Jersey Medical Society, in their campaign for an adequate educational basis for all who would practice the limitation and treatment of disease.

The goal of a satisfactory medical practice act was reached after many years, only to be destroyed again by a legislative act which made it possible for persons without any medical education whatever to practice healing. The medical society is again on a campaign to restore the practice of public health to its logical position of a specialty of medicine. Their slogan for this campaign is "Medical Men for Health Problems."

In announcing their entry into politics to bring their desires about, they do so "not as office seekers, but as physicians, to help guide and direct the state in health questions for which we alone, by our education, by our lives of service, by our standards, experience and associations are fully qualified."

In commenting upon their problem, the leaders of the movement say: "Of course, there will be conflict with those who deny the existence of communicable disease; with those who would tear down the educational barriers which have been built up for the protection of the public only after years of labor; with those who would treat health matters as subservient to other interests; with those who in health matters would regard the medical profession as clerks to command, not as directors to execute. To all such, of course, the medical profession, as a unit, is opposed, as they cannot regard persons holding those views as qualified to properly represent the people of New Jersey."

As noted in California and Western Medicine recently, the board of education of New Jersey is making a tremendous fight to have their own special health board for school children. In other words, they want the schools set up so that the children are completely under their control in health as well as in most other matters—the whole child for the school. New Jersey is not alone in having to face this problem. California physicians would do well to follow the movement with some care.

SPIRITUAL HEALERS

The horde of crusading ministers of the gospel, and other necromancers who live by traveling over the country proposing to cure disease by prayer, laying on of hands, and what not, are encountering some rocky places on their road to prosperity. They are being investigated and the findings are being published.

One of the latest is the rather notorious Rev. C. S. Price "healer." Recently, in Vancouver, he stirred up things so much that the general ministerial association appointed a committee of eleven ministers representing all churches, eight doctors of medicine and a few other scientific men to look into Price's methods and results. This perfectly fair committee asked Price for his co-operation in an attempt to arrive at the facts, and, of course, were refused. Nevertheless, the committee was able to get track of a considerable number of his patients and follow them. Their findings are expressed in these figures: "No organic lesion or defect had been helped, and the only successes had been in cases of functional disturbances. Five cases of typically functional disorders were cured; specific or general improvement, due to improved mental or spiritual outlook of the patient, was found in 38 cases; no change since anointment was recorded in 212 cases, while 17, mainly through neglect of proper scientific treatment, had become worse; 10 seemed to have a better mental outlook; 30 had developed marked depression; 39 had died; and 5 that were anointed and 4 members of families of anointed persons had become insane."

California has had and now has more than her share of these healers who contribute to poor health, insanity, and death among our citizens.

SHALL A PARDONED MEDICAL CRIMINAL HAVE HIS LICENSE RESTORED?

According to the Los Angeles Herald of February 20 "The State Board of Medical Examiners has under consideration today the application of William S. Card, former Oakland physician, for license to practice medicine in the State of California. Card's license was revoked seven years ago, when he was convicted of a criminal operation and sent to the State penitentiary on a charge of second degree murder. He was pardoned by Governor Stephens after serving a sentence of four and one-half years, on condition that he leave the State, which order was rescinded by Governor Richardson in January of last year, when he was granted a full pardon."

We do not know the reasons which actuated Governor Stephens in granting this man's conditional pardon. Nor are we accurately advised as to why, when the conditions were not fulfilled, Governor Richardson converted the conditional pardon into a full pardon instead of returning the man to prison for not living up to the conditions.

However these things may be and whatever the governing motives and influences, it is to be hoped, in the interest of decent medical protection for our citizens, that they won't be effective with the Board of Medical Examiners.

PUBLIC MEETINGS OF MEDICAL ASSOCIATIONS

It ought to be interesting to physicians engaged in public promotion of health meetings to know of the many kinds of meetings now being tried.

The Ontario Medical Association has what is called "The Lay Conference of the Ontario Medical Association." This public organization is promoted and fostered by the committee of the Ontario Medical Association on the "Inter-Relations of the Public and the Medical Profession." The conference has held three annual meetings. The first two meetings were held at the same time as that of the Ontario Medical Association, but the last one was held by itself and independent of the meeting of the Ontario Medical Association. With a program committee made up of both medical and lay persons which provided attractive addresses by prominent speakers, they were able to secure and hold the attention of large audiences. The good and bad features of this movement ought to be studied by other medical organizations. Persons interested in this work will find a full discussion on page 262 of the March issue of The Canadian Medical Association Journal.

ANNUAL SESSION OF UTAH MEDICAL ASSOCIATION

Preliminary program of the Annual Session of the Utah Medical Association is published elsewhere in this number of California and Western Medicine. It is a particularly attractive program with important discussions opened by prominent members of our profession from different parts of the country. The movement by which medical meetings are becoming more and more really short courses of graduate instruction in the various principal topics of medicine is deserving of the highest commendation.

The sessions of the Utah meeting will be held at Logan, June 19, 20 and 21.

The relations between the California Medical Association and the Utah Medical Association are very close and the spirit of co-operation is splendid, this being fostered by the fact that California and Western Medicine is the official publication of the Utah Medical Association.

It is our purpose, if copy is received in time, to publish the complete program in the June issue of California and Western Medicine.

What is Exhaustion—"An animal or man who has first been exhausted by exertion, emotion, hemorrhage, asphyxia, anesthesia or loss of sleep succumbs more readily to infection, and an animal or a man exhausted by infection succumbs more readily to trauma, emotion, anesthesia, exertion, loss of sleep," says G. W. Crile (Arch. Surg., March, 1924). "It becomes of value, therefore, to determine whether the exhaustion, which is one of the phenomena of either an acute or a chronic infection, is essentially different from exhaustion from other causes—emotion, exertion, physical trauma, insomnia." Crile, who has worked for many years on the problem, has just published an exhaustive, experimental study of this question, particularly as affected by blood poisoning, and concludes that exhaustion is an "end-result" of changes located primarily in the brain. The liver and the suprarenals are associated in some curious way in bringing about exhaustion.

Medicine in the Public Press

What Will Be the End Result When We "Educate Everyone in Medicine"?—Some of the editors of our metropolitan newspapers and magazines are beginning to wonder where we are going in our industrious attempt to "educate the public in medicine." Editorially the San Francisco Call recently had this to say:

"It's very easy to get the idea nowadays that you are not normal.

"If you read a book on insanity you will begin to doubt your own sanity. You remember that, back in your childhood, you didn't like to step on a crack for fear it would break your mother's back, and that you used to count everything in sets of three, or couldn't go by a telegraph pole without touching it. Sure signs of abnormality, of course, that could easily be aggravated into insanity. And that's where you are wrong, since a certain amount of insanity seems to be normal.

"A garrulous doctor or a medical case book, meant for the profession, can also introduce doubt into your mind. Reliable doctors know about that and are very careful about suggesting symptoms of disease to their patients. We seem to insist on being sick, regardless of the doctor's efforts to make us well. If the doctor tells a certain type of patient the symptoms of a disease, the patient will do his best to comply with the medical specifications.

"A little reading in the apparently new science of psychoanalysis disturbs many people. They learn that repressions and little fears in childhood may disturb one for a whole lifetime, so they become bundles of walking worries, of 'neuroses,' 'complexes' and such things. And this little knowledge makes them fancy themselves abnormal—poor, extraordinary folk adrift on a miserable sea of normality."

The "White Soap" Snowball—It's amusing how important a little well-directed propaganda will make an unimportant subject. The merry little white soap controversy now making its way along in eastern centers is a good example.

We don't know just how it started, but probably some advertising manager "got sore" because the soap people did not "come through" to suit him, so he started a destructive campaign against any and all soaps except those pure white in color and free of perfume. He based his propaganda—as they all do—upon the alleged fact that any coloring matter, or a few drops of perfume, immediately changes a valuable toilet preparation into a dangerous disease-producing, life-shortening agent. The campaign went swimmingly and secured the endorsement of one school and uplift group after another until the list of endorsers was quite overpowering. Then the doctors were tried and a few of them "fell for it," but most of them poohpoohed the idea quite correctly, of course. It is said that one surgeon told the proponents that he had scrubbed his hands before operating several times a day for forty years with what is called green soap, and that he was still going strong both in medicine and golf.

Of course, it is well known that "white soaps" are good and bad, and so are all other kinds. It is also generally known that a soap good in one water may be hopelessly bad in another water. Thinking, educated people must know that neither a little wholesome coloring matter, nor a small amount of perfume has any determinative action on the quality of a soap.

If this propaganda goes much further, just watch what the soap people will do in the advertising columns and reading matter also of our good newspapers and magazines.

Advertising Clinics and Health Centers—Advertising of clinics and health centers is getting bolder, as attested by the following, copied exactly in wording but not in set-up from the Visalia Times:

"Tulare County Health Center, West Main Street, Visalia. Clinics Dental (School and Adults)—1 to 5 p. m. Children (under 12 years)—Mondays, 9 to 11 a. m. Well Baby Clinic—First and third Tuesdays of each month, 1 to 3 p. m. Medical—Thursday, 8:20 to 10:30 a. m. Surgical-Gynecological—Thursdays, 8:30 to 10:30 a. m. Eye, Ear, Nose and Throat—Tuesdays, 8:20 to 10:30 a. m. Patients will be expected to report during first hours of each clinic. A charge of 10 cents per visit and a small charge for drugs, etc., is asked of those who can pay."

"Cheap" medicine, cheaply provided for by nonmedical people. Some of these agencies claim to be free. Absolutely none of them are. In a very few of them the patient is not charged anything. In most of them the patients pay in accordance with their ability to pay. In most, the doctors donate their services. Practically all others, people serving in these "centers" are paid salaries, and usually good salaries, from funds either collected as taxes or donated. All of the very considerable "overhead" and other expenses are paid from similar funds, plus what is collected from the poor patients or those—who constitute the majority—who, although able to pay, are willing that the state should pauperize them.

All of these places must depend upon advertising for their ability to "get business." Usually they advertise by circulars, personal letters, telephones and through visiting agents. They also manage to get considerable of their advertising matter over to the public as "news" which costs them nothing. It is at least more open, frank and honorable to advertise, like Tulare and some other places are now doing, by buying space in the newspapers.

No Standard Man—Are we giving too much attention to nutrition standards and not enough attention to malnutrition?

This question is raised, says the Porterville (Calif.) Messenger, editorially, by the Medical Journal and Record, which concedes that there are so many variations in physical makeup from the average that it is difficult, if not well nigh impossible, to fix a standard which a general body of persons could beneficially follow.

Not less than a dozen standards have been worked out in Europe and in this country, the journal states, and none of them agree. Proponents of the standards are seeking a "vital index" which would measure the nutrition needs of mankind as a whole. Yet what two persons in the world are identically alike in physical construction and mental capacity? There are none. It is this divergence, physical and mental, which goes to make up evolution. If there were no divergence from the "average," man would never grow. He would always be just "man," "toiling, rejoicing, sorrowing," incapable of mental expansion or physical progress.

The study of what is best and what is not best for his appetites is a worthy study, but it should not be overstressed.

"Physical and Health Education" Expanding in Minnesota—The educational authorities in Minnesota have issued some interesting instructions to teachers, of which the following are examples:

"Require all teachers to give careful attention to children's health and the maintenance of hygienic and sanitary classroom conditions."

"Have teachers co-operate with parents in the remedy of physical defects which may be discovered in children, and with physicians or nurses who may have such cases in charge."

An interesting sidelight in the development of this new medical edict is that local colleges and at least one great university are establishing courses for teachers that will "prepare them to meet these new requirements."

The Rathbone Serum Bill—It is assumed that all fair-minded persons, whether they believe in medicines

or not, endorse movements calculated to insure purity of medicines and the protection of those who do use them against imposition and fraud.

What is called the Rathbone Serum and Vaccine bill, now before Congress, proposes to improve our safeguards as to purity of serums and vaccines and to prevent exaggerated or fraudulent claims in the promotion of these medical agents. The bill is by no means guaranteeing the safety that the public should have, but it is an improvement upon present laws and is a step, however short, in the right direction.

The Federal Pure Food and Drug Act of 1906 and the serum law of 1902 require proper labeling of medicines, including serums, drugs and foods, but names are easy to create. The existing law also provides against the use of "any statement, design or device regarding the curative or therapeutic effect of such article or any of the ingredients or substances contained therein, which is false or fraudulent." Rules and regulations are made by a committee consisting of the Surgeons-General of the Army, Navy, and Public Health Service. Enforcement is by the Treasury Department. Present rules provide for license and revocation of license. Cracks in the fence of the present law are too numerous and of too great variety to discuss here.

The new law places all responsibility for regulation and enforcement in the hands of the Secretary of the Treasury. Why it is taken from the hands of persons of technical training is not clear. The new law also provides that serum vaccines and antitoxins that have not been duly accepted by science shall bear the label "No U. S. Standard of Potency."

Altogether the Rathbone bill steps forward in a halting and somewhat hesitating way in a movement all physicians endorse. The line-up of forces against the bill is its best endorsement. They are practically the same much-interested group that have persistently and somewhat effectively opposed adequate food and drug legislation.

Grape Seeds and Appendicitis—Physicians will be amused to know that "eminent dietitians" are in controversies in some places as to whether grape seeds or "inactivity of the bowels" is most important in causing appendicitis. Just wait until everyone is "educated" in medicine and "public health" and this will constitute a serious topic compared to what we are destined to hear.

Periodic Examination Clinics—A movement is getting under way in some centers for the operation of clinics where complete examinations only are made. They are being operated by this or that welfare organization, and a few by-groups of physicians. Nearly all of them charge fees from 50 cents to $5, and claim they are not practicing medicine because they only make diagnosis and do not give treatment.

Goiter-Iodine Clinics—The hysteria about the prevalence of goiter and the specificity of iodine in curing it has grown to astounding proportions in certain parts of the country.

It is reported that "surveys" of the school children in some places show that more than 50 per cent of them have "the beginnings" of goiter. Some enthusiasts are demanding that the school departments establish goiter clinics, and one of them already has planned a "pre-goiter clinic."

One school in an eastern state has a slogan that "a drop of iodine a day will keep the goiter away." In some places they put iodine in the drinking water; in others they feed it to "suspects" or "pre-goiter" persons in tablet form; in some schools the teacher gives a tablet to each child on Monday mornings between 9 and 10 o'clock, and in places grocery stores are selling table salt mixed with the "normal" amount of iodine.

The next thing we know suicide by drowning will be indecent unless the water contains iodine.

Physician as Editor Needed—A number of commendable efforts are being made in several great centers to bring about closer working arrangements between newspapers and physicians in the praiseworthy cause of bettering the public health.

A particularly significant meeting was held recently in Brooklyn, New York, at which some 400 members of the medical society and the editors of all Brooklyn newspapers met and discussed what could best be done. Mr. Arthur Brisbane advocated short, well-prepared articles as being the only ones that would get wide reactions or that would be extensively read. The statement of H. Sherman Baketel, chairman of the meeting, that every great newspaper should have a medical editor, as it had for sports, society and what not, was generally endorsed by the editors present. The editors, however, wondered where they would be able to find physicians who were also experienced in the pitfalls, problems and methods of publicity. A committee of doctors and editors was endorsed and instructed to try to work out a practical plan whereby the press and the physician might co-operate for the common good.

Philosophizing About Uplifters—"There have always been in the world persons who think they are their brothers' keepers, who would like to be, and who strive to be," says Joseph Collins (The Bookman). "There have always been others who are convinced they know more about matters that are unknowable —such as destiny and how to prepare for it—than their fellows of equal original endowment and of greater opportunity for enlightenment; and they deem it their mission to make us, by exhortation or legislation, conform to their beliefs. They parade their honesty, praise their sincerity, preach their purity and pretend their efforts are for the public welfare.

"One of their beliefs is that they know good and bad, proper and improper, salutary and pernicious literature, and they are constantly striving for legislation that will force their judgment upon the public. The most naive reason they give for their activity and ardency is that they want to protect their children. To make the state share the parent's responsibilities may lessen the burdens of parenthood, but it is unlikely that it will improve the child's chances."

The Hazards of Beauty-Specialty Surgery—The press in many places, including California, is recording an unusual number of malpractice suits against plastic surgeons, as well as quack beauty doctors. We are not interested in the quacks, but we are interested in plastic surgeons and particularly in patients. The first thing an educated physician should do before he enters this field is to protect himself and those dependent upon him by a safe policy of at least $50.000. Patients, of course, understand the possibility of accidents and failures, and it is better to have witnesses to these understandings than it is to have a waiver agreement in writing.

Our Local Taxes—Recently published figures about our county and municipal taxes, when reduced to figures that mean something to average people, show that we are paying for the operation of county and municipal government an average of over 25 cents a day for every man, woman and child in the state. If state and federal government taxes are added, the figure is more than doubled, and if income and inheritance taxes are added—but what's the use?—the first figures are enough.

We are not going into a discussion about taxes further than to state that they are important in the causes of unhappiness and of sickness. We also want to state that not enough of tax money is expended for legitimate better health service, and too much is wasted in health luxuries and the promotion of health fads.

Should Criminals be in Hospitals, Prisons, or Hospitals in Prisons?—One of those traveling health experts who give "intensive health courses" of one or two evenings recently secured first page headlines by

stating that eight out of ten of our state prisoners should be in a hospital. This man, like all such, was a "world authority," a "savant," a "specialist," and of course a "doctor."

It is reported that this "specialist" held a lecture clinic in a hotel, at which he "challenged the active interest of a group of prominent San Francisco physicians and surgeons with the statement that chronic bronchitis, chronic deafness, rheumatism, earache, stiff neck, nervous debility, melancholia, neuralgia, infantile paralysis, tonsillitis, lumbago, congestive headache, menopause, varicose ulcers, high blood pressure and numerous other ailments would yield to electro-therapy. Only through electrical stimulus, he urged, can torn muscles and nerves be restored to normalcy."

Some challenge!

Dishonest Slogans—A health slogan that is truthful or that definitely implies may be of value in constructive health work. Conversely, one that implies what is not a fact unquestionably does harm to the worthy cause it proposes to help.

Of the seemingly endless variety of the widely quoted health slogans, a substantial percentage are definitely untrue in fact, imply the false, and what is perhaps even more harmful, they state or imply indefiniteness and ambiguity. One of these now before the public is particularly untrue and is constantly being challenged. It is to the effect that "a physically handicapped child cannot be properly educated."

The medical record of the leading men in all walks of life of this or any other period will show that a quite substantial percentage of them have now and have had from their early school days definite recognizable and understood physical handicaps. Of course, life's promises and opportunities are improved by the removal or amelioration of handicaps wherever and whenever possible, but to make a slogan definitely calculated to discourage the thousands of youths who have incurable handicaps and which at the same time is an insult to many of our leading citizens, is unwise and reprehensible.

An American "College" of Plastic Surgery Organized—Another national "college" of a specialty of medicine was recently organized with headquarters in Chicago. T. Floyd Brown of Los Angeles is president and J. Paul Fernel of Chicago is secretary of the new organization. The first purpose of the new college, according to reports, is to establish a graduate school.

It is said that this new organization will not follow the international association of the same group recently formed in London and include the work of "beauty specialists" in their field.

Campers Carry a Spade—Under this title the Bulletin of the California Health Board carries a sane brief article that ought to be read and re-read by every vacationist.

The Chicago Session — Local Committee of Arrangements—The Local Committee of Arrangements for the Seventy-fifth Annual Session of the American Medical Association, to be held in Chicago, June 9-13, 1924, consists of: Chairman, J. W. Van Derslice; treasurer, John S. Nagel; secretary, Hugh N. MacKechnie, and Isaac A. Abt, Archibald Church, D. J. Davis, Ludvig Hektoen, C. E. Humiston, Frank Morton and J. H. Walsh. Mrs. Charles Spencer Williamson will serve as chairman of the Ladies' Entertainment Committee. The office of the Local Committee of Arrangements is located in Room 1522, Marshall Field Annex, 25 East Washington street, Chicago. This committe is ready to extend any assistance within its power to physicians who expect to attend the Chicago Session. The committee has held a number of meetings, and great progress has been made in arranging the important details of the session. The committee may be addressed as indicated above by any who desire information.—Journal A. M. A., February 9, 1924.

COUNTY NEWS

ALAMEDA COUNTY

Alameda County Medical Association (reported by Pauline S. Nusbaumer, secretary)—Providence Hospital staff held its annual banquet April 8, at the Hotel Oakland. Some sixty-five members gathered around the festive board. The guests and speakers of the evening were J. Wilson Shiels of San Francisco, Ezra Decoto and W. H. L. Hynes of Oakland.

At the regular monthly meeting of the staff of the Alameda County Hospital, the following papers were presented: "Hydronephrosis," by A. M. Meads. "Brain Surgery in Case of Post-traumatic Epilepsy," by E. W. Goodman.

At the staff meeting of the Samuel Merritt Hospital, pinicillium infection of the lung was discussed by Charles McVey. Sumner Everingham gave an analysis of the cases of intestinal obstruction in this hospital during the year 1923.

The following case reports were presented at the Fabiola Hospital staff meeting, March 25: Carcinoma of the stomach, with pathological specimens—E. G. Simons. Radiographs of the same case, showing development of the lesion over a period of six months—Charles E. Peters. Electrical burn of the elbow and gluteal region, with presentation of case. Osteomyelitis of femur, with radiographs. Foreign body in the bronchi, with x-ray pictures—E. A. Majors.

Papers on "Late Pulmonary Hemorrhage, Following Fractured Ribs," by W. L. Bell, and "Caudal Anesthesia," by A. M. Meads, were also presented.

The staff meetings of the hospitals are well attended, and the discussions are interesting and instructive.

Alameda County Institutions' Commission — The membership of this commission has been increased from six to nine, and three physicians were elected to fill the newly created positions: George Rothganger, G. G. Reinle, and Guy H. Liliencrantz. As O. D. Hamlin and R. G. Legge are already members, this gives five out of the nine positions to the medical profession.

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary)—The regular monthly meeting was held at Crockett March 29.

The lecture by Hans Lisser of San Francisco discussed the subject of ductless glands. This lecture was illustrated by lantern slides. The doctor covered as much of the pathology and treatment of the ductless glands as the time would permit. The value of this lecture is hardly appreciated until it is digested. The average physician, whether practicing in large or small communities, is groping in the dark, in regard to the treatment of ductless gland disturbance. This lecture would certainly enlighten them; so at least was the expression of the members who were fortunate enough to be present at Crockett. There is a wish among the members to have Lisser deliver a series of at least three lectures along this subject to the society.

The lecture was held at the Crockett auditorium, from whence the members were invited by mine host, J. M. McCollough, to a luncheon and picture show at the Crockett Hotel.

The following members were present: Clara and J. B. Spalding, William A. Rowell, John Beard, F. Lisle Horne, H. L. Carpenter, Hall Vestal, J. M. McCollough, L. St. John Hely.

FRESNO COUNTY

Fresno County Medical Society (reported by T. Floyd Bell, secretary)—The regular meeting of the Fresno County Medical Society was held at the

Nurses' Home of the General Hospital of Fresno County on April 1, 1924. Twenty-three members and six visitors were present. Members—Adams, Aller, Barrett, Bell, Brown, Dearborn, Goldberg, Jamgotchian, James, Jorgensen, Kjaerbye, S. M. Long, Manson, Mordoff, Milholland, Newton, Pettis, Pomeroy, Schottstaedt, Sheldon, Scorboro, Tillman, and Tupper. Visitors—H. O. Collins, Cook, Gregory, Burk, Victor Randolph, and Harry Robertson.

Doctor Kjaerbye reported for the Crime Commission on the advantages of using county prisoners for common labor on the county roads. Tillman moved, Couey seconded, that the Fresno County Medical Society endorse the recommendation of the Crime Commission for the use of county prisoners on the county roads.

W. R. P. Clark, director of the Bureau of Tuberculosis, San Francisco Board of Health, gave an interesting talk on tuberculosis. He first dwelt on the work being done in San Francisco, the need for further work, and the immediate plans for the future in the care of tuberculous patients. He next exhibited some x-ray films of the chest, discussing the differential diagnosis of tuberculosis.

James T. Watkins of San Francisco presented a paper on the "Diagnosis and Treatment of Back Injuries." He took up also the static troubles of the back. He considered strains, and slips of sacro-iliac and lumbo-sacral joints; also fractures of the vertebrae and their treatment in detail. Discussion—Adams, Aller, and Watkins.

The application of H. M. McNeil of Big Creek was read and referred to the proper channels for action.

The application of G. C. Nedry was reported on favorably by the state association and the board of censors, and he was unanimously elected a member of the society.

After adjournment a buffet lunch was served.

Burnett Sanitarium—The twenty-fourth annual graduation of nurses of the Burnett Sanitarium of Fresno took place April 1, 1924, at the Y. M. C. A. The exercises were preceded by an alumni dinner at the Burnett.

Mr. David Ewing gave the address of the evening to the graduating class. Rev. G. W. Fletcher offered the prayer and gave a short address. Miss Little, superintendent, and D. H. Trowbridge, secretary, gave talks to the graduates.

A wrist watch was presented to Miss Grace Von Volkinburg, the gift of Trowbridge, for the best practical work during the course of her training. Miss Maries Sievking received a diamond pin, the gift of Maupin, for the highest marks in theoretical work. Miss Dorothy Waag and Miss Annie Olsen received honorable mention for excellent work in practice and theory. Many of the staff doctors and their wives were present, besides the relatives and friends of the graduates. The evening was concluded by a dance.

MARIN COUNTY

Marin County Medical Society (reported by J. H. Kuser, secretary)—The society met March 27 at Jones' office, San Rafael.

Members present: President Dufficy, Jones, Mays, Kuser.

The invited guest of the evening was Thomas Addis of Stanford Medical School, who gave an interesting talk on nephritis, which was of great interest to all those present.

Owing to a previous meeting during the same week, but few members were present.

SAN BERNARDINO COUNTY

San Bernardino County Medical Society (reported by E. J. Eytinge, secretary)—On April 1 the society held its regular meeting at the County Hospital, San Bernardino, with thirty-five present, forty absent, ten guests.

The program consisted in "Observations in Surgical Pathology," by C. G. Hilliard; discussion opened by E. J. Eytinge. "Prophylaxis and Treatment of Non-Toxic Goiter," by D. C. Mock; discussion opened by K. L. Dole. "Treatment of Toxic Goiter," by Joseph K. Swindt of Pomona; discussion opened by Phillip Savage.

R. L. Alexander of Ontario has transferred his membership to the Pomona Valley Section of the Los Angeles County Society.

J. A. Connell, formerly located at San Bernardino, is now located in Riverside, and has been transferred to that society.

SAN DIEGO COUNTY

San Diego County Notes (reported by Robert Pollock)—Quite a group of the San Diego County members motored to Santa Barbara to participate in the spring meeting of the Southern California Medical Association, held in Santa Barbara early in April. They enjoyed a splendid program.

Hospital activities in San Diego are rapidly assuming definite form. The new Mercy Hospital, of the Mercy Sisterhood, to replace their former building, which has served its purpose so long under the name of St. Joseph's Hospital, has its roof completed and in a few days will permit of my sending the Journal a photograph of the finished product. The new La Jolla Hospital, of fifty beds, has reached a similar stage, and being a smaller structure, will probably be completed, furnished and opened to the public in about ninety days. These two hospitals, added to the splendid Naval Hospital, present a group of modern structures for the care of the sick of which San Diego may well be proud. The proposed new McCullough Hospital, a private enterprise which has in the past thoroughly demonstrated its utility, has its plans completed, its ground selected and will undoubtedly enter its new quarters before the first of next year. Renewed activity is also in evidence to build a community hospital, a magnificent site overlooking the park having recently been donated for that purpose. This movement, which has been feeling its way carefully for some time, will take the form of a modern hospital, built by all the people for all the people and expressive of the modern idea of helpful citizenship.

The county society, to the number of twenty-five, recently visited the Imperial County Society at El Centro and presented a symposium on our views of the value of insulin after our first year of experience with it. Papers on the subject were presented by L. H. Redelings and Robert Pollock, and liberal discussion was entered into by Burger, Burton, Harding, Howard, Rees, Stealy, Thornton, Redelings and Pollock. H. P. Newman at the same meeting made a strong appeal for the support of the Gorgas idea, while Councilor Carrington made an interesting talk on what the state council has recently been doing for the profession it represents. At the conclusion of the meeting Kinney, on behalf of the San Diegans, extended a cordial invitation to the Imperial County Society to furnish a scientific program in San Diego, Saturday, June 28, and enjoy such hospitality as that city wishes to extend.

At the regular meeting, held in Science Hall, Balboa Park, April 8, Mott H. Arnold presented a terse and well-constructed paper on Pyloric Obstruction in Infancy. As a model of briefness, conciseness of statement and thoroughness in covering the subject, his paper left little to be desired. Discussion, like the paper itself, was brief and to the point, and at its conclusion Charles R. Ball of St. Paul, Minnesota, responded to an invitation from the chair with an extremely interesting discussion of Syphilis in Relation to the Nervous System.

SAN FRANCISCO COUNTY

Proceedings of the San Francisco County Medical Society (reported by J. H. Woolsey, secretary)—During the month of March, 1924, the following meetings were held:

Committee on Medicine—March 4. The interest of the general man in neuropsychiatry—M. B. Lennon;

Tryparsamid therapy in neurosyphilis—H. G. Mehrtens.

General Meeting—Tuesday, March 11. New Constitution and By-Laws adopted; Observations on ovarian auto-transplantations—F. R. Girard; Testicular substance implantations—L. L. Stanley, San Quentin.

Committee on Surgery—Tuesday, March 18. Diagnosis of intracranial injuries—H. W. Fleming; Treatment of intracranial injuries—H. C. Naffziger.

Committee on Eye, Ear, Nose and Throat—Tuesday, March 25. Clinical meeting at Stanford University Hospital.

Southern Pacific General Hospital Staff Meeting (reported by W. T. Cummins, secretary)—The monthly staff meeting of the Southern Pacific General Hospital, San Francisco, was held on April 2 in Huntington Hall. Program: "Backache," by Walter I. Baldwin; discussions—Stanley Stillman and W. B. Coffey, Surgical; G. J. McChesney, Orthopedics; Fred W. Lux, Medical; W. F. Schaller, Neurological; G. L. Eaton, Genito-Urinary; M. P. Burnham and L. B. Crow, Roentgenological.

Franklin Hospital Staff Meeting (reported by Adolph Rosenthal, medical director)—The monthly staff meeting of the Franklin Hospital was held on Monday, March 24, J. Wilson Shiels presiding.

The speaker of the evening was M. P. Burnham, who delivered an interesting lecture on "Dyspepsias, Reflex to Chronic Infective Lesions of the Liver and Its Distributing System," illustrated with typical x-ray plates. The subject prompted more than the usual discussions by Guilfoil, Harder, Ingber, Rodenbaugh, Yoell and Shiels.

All felt that they owe a debt of gratitude to Burnham for his masterful presentation of the subject.

St. Joseph's Hospital Staff Meets—On April 9 St. Joseph's Hospital Staff met and heard case reports from C. O. Southard (mastoiditis), A. S. Musante (pancreatic carcinoma and cholecystectomy), E. T. Krebs (cerebral embolism), and C. E. Smith (chronic bronchitis).

C. E. Nixon spoke on "Neurological Errors in General Practice," demonstrating that nervous diseases simulated many other conditions, on account of the distribution of the nerves. Syphilis is the most common imitator, especially as exemplified in the early gastric, laryngeal and bladder crises of tabes dorsalis; and spinal fluid examination is needed to differentiate. Encephalitis, obesity, hysteric symptoms, numbness, brain and cord tumors, cervical ribs, and peripheral neuritis were described and the prognostic importance of an early diagnosis shown. Sterling Bunnell spoke on "Indications and Methods for Blood Transfusion." Effects of this procedure are an increase of volume pressure, antiseptic and hematopoietic properties of blood. Indications are acute and chronic bleeding, shock, anemia, especially secondary, cachexia, even of infants, chronic and acute sepsis, the latter debatable; burns, operations on icteric patients, hemophilia and hemorrhagia neonatorum, purpura, leucemia, lead poisoning, pellagra and gas poisoning. Reactions from the citrate method and pure blood were compared. Typing of bloods and the Kimpton-Brown technique, and accidents and their prevention were explained by demonstration of the apparatus.

L. Crow showed radiograms of pulmonary infract, hypernephroma bone lues, abdominal aneurysm, and pericarditic effusion. C. E. Smith presented pathological specimens of brain, liver, heart and abdomen.

The program for May 21 follows: "Specific Obligations of Physicians Under the Law," by Mr. Hartley F. Peart; "Local Police Regulations Affecting Doctors," by Captain Duncan Matheson, and "Plastic-Surgery," by G. W. Pierce.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by Alex C. Soper, secretary)—The society held its regular meeting April 14 at the Cottage Hospital, President Robinson in the chair. Present, twenty-two members, four interns and one guest.

The matter of the proposed Therapeutic Gymnasium was again tabled, due to press of other business. Correspondence was read, with the State HQ., regarding Industrial Medicine Questionnaire, regarding Medical Defense, with the A. M. A. regarding "Hygeia" magazine, and notice again made of society dues payable.

The secretary brought to attention the character of the patent medicine ads being carried over the names of leading drug stores in town, as being inimical to the interests of the ethical medical profession; and it was moved, seconded by Pierce, that the president appoint a committee to investigate the matter and to draw up a letter to be approved by the society, protesting against such ads. Passed unanimously. Pierce, Stevens and Soper were appointed.

Case reports followed, each five minutes: "Bone metastasis in carcinoma of the prostate"—Henry Ullmann; "Acute suppurative mastoiditis treated conservatively"—Henry J. Profant; "Parotitis following general surgery"—Horace F. Pierce; "Aphagia"—Hugh Freidell.

The main address of the evening was on "Surgery of the Hand," by Sterling Bunnell of San Francisco, illustrated with lantern slides and with types of splints and apparatus used. This very thorough exposition of technique was much appreciated by the members, and discussion was participated in by Pierce, Schurmeier, Ullmann, Nuzum and Stevens.

SONOMA COUNTY

Sonoma County Medical Society (reported by N. Juell, secretary)—The Sonoma County Medical Society met at the Santa Rosa Chamber of Commerce, Thursday, April 10, with twelve members and eighteen visitors present. There was a general discussion, led by Elizabeth Emerson, of the State Board of Health's plan for a medical examination of all children of preschool age entering school this fall, in which all doctors and dentists are expected to participate, the examination to take place between April 15 and May 15. Dr. Leppo, dentist, spoke on the dental problem. The idea was to decide on the chief points of child hygiene which we should attempt to impress upon the mothers who will be present at the examination.

Kristine Blickert Johnstone of Eldridge was admitted to membership.

The Seminal Vesicles in Arthritis—The necessity of examination and of immediate treatment in those cases of arthritis which are due to the seminal vesicles being the primary site of infection, as in extension of a gonorrheal infection is urged by Daniel E. Shea, Hartford, Conn. (Journal A. M. A., January 26, 1924), and attention is directed to cases in which the seminal vesicles are presumably the site of secondary infection from teeth, tonsils or some other area of infection, and in turn become the focus that supplies toxins to the synovial membranes in arthritis even after the primary area has been destroyed. Cases are cited in which every one of the patients had had arthritis for some period of time, and many of them had had other foci of infection removed with no effect on the arthritic condition. Among the areas previously treated were the tonsils, teeth, colon, and skin. In several of the cases the same organism was found in the original area of infection as was found in the seminal vesicle. Organisms other than the gonococcus found were: Micrococcus catarrhalis, Staphylococcus albus and aureus, Bacillus coli communis, Streptococcus viridans, hemolytic streptococcus and diphtheroid bacillus. Treatment consisted, as a rule, of non-surgical methods; namely, massage of the seminal vesicles and prostate, heat to the parts and vaccines. Direct medication to the seminal vesicles was used in several cases. Surgical intervention, consisting of vesiculectomy, was used only in very acute conditions in which the contents of the vesicles could not be expressed; also, in one case of hard, fibrous, indurated vesicles that were producing much discomfort.

Utah State Medical Association

About the Annual Meeting (reported by William L. Rich, secretary)—The program for the annual meeting of the Utah State Medical Association, to be held in Logan June 19, 20, 21, is now being prepared. We are assured of the following speakers: Dean Lewis of Chicago will be with us and will probably give us a series of talks. L. G. Rowntree of the Mayo Clinic has consented to give two or three lectures. E. V. McCullum of Johns Hopkins will give the following papers: "The Present Status of Our Knowledge of Vitamins"; "Nutritional Aspects of Preventive Dentistry"; "Present Status of Our Knowledge of the Etiology of Rickets." John B. Doyl of the Neurological Department of the Mayo Clinic will speak on "Clinical Manifestation and Treatment of Encephalitis Epidemica," and probably two other subjects not yet announced. We are also expecting Professor Alfred S. Warthin of Ann Arbor, Mich., and R. C. McClain of Detroit, Mich., and possibly W. G. Anderson of Yale University.

We anticipate an excellent program and a good attendance. The visitors who arrive in Salt Lake will be taken in automobiles to Logan Thursday morning. It is planned to have the scientific session begin Thursday, June 19, at 2 p. m. There will be a meeting of the Council and House of Delegates at 10 a. m. on Thursday preceding the opening of the scientific session. The annual banquet will be held at the Hotel Eccles, Thursday evening at 7 p. m., at which time we shall hear the president's address and the report of the advisory committee to the Medical Department of the University of Utah. Following this there will be toasts and a relaxation from the more serious aspects of medicine.

The ladies are invited, but will be entertained separately by the ladies' committee, who are making preparations for a very pleasant evening.

On one evening there will be a public meeting, to which the general public will be invited.

Salt Lake County Medical Society (reported by M. M. Critchlow, secretary)—The regular meeting of the Salt Lake County Medical Society was held at the Commercial Club, Salt Lake City, Utah, Monday, March 24, 1924, President A. A. Kerr presiding. Sixty-three members and one visitor were present.

The subject of the first paper on the program was "Encephalitis," by J. R. Llewellyn. He went into the history of the disease, its relationship to influenza, the bacteriology and the treatment by Rosenow's anti-streptococcic serum. He reviewed four cases which he had treated, from which conclusions cannot be definitely drawn as yet. This very interesting paper was discussed by F. J. Curtis and R. T. Jellison.

The second paper was entitled "Drug Eruption," by Clifford Pearsall, in which he clearly brought out symptoms, types and time of appearance of eruptions in parts of body involved. He discussed in detail eruptions caused by arsenic, copaiba, quinine, coal-tar drugs, salicylates, luminal, phenolphthalein, bromine, and iodine. This paper was discussed by W. L. Rich and E. L. Skidmore.

R. O. Porter's application for membership and his transfer card from the Cache Valley Medical Society, were considered and he was elected to membership.

F. G. Eskelson and Scott A. Jones were also elected to membership.

Communication to Rich from the secretary of the California Medical Association was read, inviting the Utah State Medical Association to send a fraternal delegate to the fifty-third annual meeting of the California Medical Association.

A letter from the executive secretary of the Bureau of Legal Medicine and Legislation, American Medical Association, addressed to Rich, secretary of the Utah State Association, was read. This letter urged the Utah State Association to request Senator Smoot to use his influence to have the Harrison Narcotic tax reduced and also to allow physicians to exempt from their Federal Income tax, money expended in post-graduate work. Kahn moved that a committee of three men who would have personal influence with Senator Smoot, be appointed by the President to offer suggestions as outlined in the letter and send them to Senator Smoot in the form of resolutions from this society as a component part of the Utah State Medical Association and that Rich request the State Association to take the same action. Rich suggested that all county societies take the same action. Motion was seconded by C. A. Broaddus. Carried. Tyndale suggested that all physicians who know Senator Smoot send him a personal letter in regard to this matter.

Calderwood reported for his committee that the city commission are considering transferring the Baby Clinic to the Community Clinic, but no action has been taken as yet. President Kerr told of his conference with the mayor in regard to the Baby Clinic. Kahn reported that the Liability Insurance Committee was not ready to give a final report as yet, but would give it at the next meeting.

Tyndale reported for the Library Committee announcing that the loan library would be locked up, the key in possession of the librarian. He reported several current magazines were missing and requested that they be returned at an early date. He also requested that members hand in a list of the books that they want purchased to any member of the Library Committee.

Calonge announced that he would be glad to receive any evidence of the activities of the so-called ambulance chaser lawyers, as a newspaper man was anxious to secure evidence against them. Hampton moved that the society purchase a blackboard. Seconded and carried. Straup announced that a clinical meeting would be held at the Salt Lake County Hospital on March 31, and invited all members of the society to be present.

April meeting of the Salt Lake County Medical Society at the Commercial Club, Salt Lake City, Utah, Monday, April 14, 1924, President Kerr presiding.

Fifty-eight members and three visitors were present.

J. F. Critchlow gave a preliminary report on a case of acute traumatic rupture of the diaphragm with herniation of certain viscera. He reviewed literature and described the operation under paravertebral nerve blocking.

H. C. Holbrook presented two cases of torticollis recently operated.

T. B. Beatty spoke briefly on the goitre problem of the school children of Utah and requested assistance fom the local physicians in the examinations of the Salt Lake City school children.

Professor George S. Snoddy of the University of Utah talked briefly about his stability test, its application in forecasting epileptic seizures and urged the physicians to make use of his tests in the treatment of epileptics.

F. F. Hatch read an extremely interesting paper on the "Diagnosis and Treatment of Diseases of the Prostate." He dwelt on the indications for prostatectomy, preliminary care, anesthetic and operative technique, complications and post-operative treatment. He reviewed his series of cases and demonstrated some x-ray films. His points were illustrated with views projected on the screen. This paper was discussed by F. A. Goeltz and Ernest Van Cott.

S. C. Baldwin moved that V. J. Clark's paper be

postponed until the next meeting. Seconded and carried.

Delegates for the annual meeting of the State Association were nominated and the following members were elected: A. A. Kerr, A. C. Behle, J. C. Landenberger, M. M. Critchlow, E. M. Neher, W. R. Tyndale, Ernest Van Cott, C. L. Shields, H. P. Kirtley, W. R. Calderwood, D. L. Barnard, V. J. Clark and F. B. Steele.

The following members were elected alternates: William F. Beer, T. B. Beatty, F. E. Straup, Clifford Pearsall and David Smith.

Sol Kahn read his report for the Liability and Insurance Committee. It was moved that it be adopted. Seconded and carried. A. A. Kerr read a letter from the Thompson Investment Company, describing its new building and the inducements it offered for physicians. The floor plan was also shown. This was referred to the Building Committee.

President Kerr read a report of the Necrology Committee by D. L. Barnard, chairman, relative to the death of our member, Dr. J. Lane.

Woman's Auxiliary, Salt Lake County Medical Society Organized (reported by Mrs. Lawrence Ossman) — The Woman's Auxiliary to the Salt Lake County Medical Society was organized March, 1924, with the following officers: President, Mrs. F. M. McHugh; first vice-president, Mrs. Spencer Wright; second vice-president, Mrs. J. C. Landenberger; secretary, Mrs. Claude L. Shields; corresponding secretary, Mrs. Lawrence Ossman; treasurer, Mrs. A. J. Murphy; parliamentarian, Mrs. Scott Keyting.

Nevada State Medical Association

HORACE J. BROWN, M. D., Reno.....President
CLAUDE E. PIERSALL, M. D., Reno.....
Secretary-Treasurer and Associate Editor for Nevada

Washoe County Medical Society (reported by Vinton A. Muller, secretary)—A regular meeting of the Washoe County Medical Society was held on Tuesday evening, April 8, at the Commercial Club, in Reno. President R. H. Richardson presided at the meeting, and there were twenty-two members present.

The minutes of the previous meetings of February 5 and March 11, 1924, were read and approved, after which the society listened to an extremely interesting paper given by Ernest H. Falconer, Associate Clinical Professor of Medicine at the University of California. Falconer spoke at length on the changes taking place in the bone-marrow in the anemias and the leukemias. The title of his paper was, "Can We Stimulate the Bone-Marrow in the Treatment of Anemias?" and he covered the subject in a very thorough and most interesting manner. His talk was illustrated with lantern slides.

The applications for membership of E. E. Hamer of Carson City, Nev., and W. M. Edwards, Mason, Nev., were read and given over to the board of censors, to be voted upon at the next meeting. The board of censors had not met to discuss the applications of Ira Sellers and Barrows; therefore, these applications cannot be voted upon until our next regular meeting in May.

Physical Factors Pertaining to Hay-fever — It is A. G. Gould's, Ithaca, N. Y. (Journal A. M. A., March 1, 1924), opinion that there are a great number of factors which have to do with the severity of hay-fever. Some of these undoubtedly are the amount and frequency of rainfall; the amount of growth of the plants responsible for the hay-fever, which is influenced by the amount and frequency of the rainfall, the temperature, and the amount of sunlight; the velocity of the wind; the amount of exposure to the pollen; the state of the anatomy of the nose, and the personal hygiene of the patient. There may be some cumulative immunity from year to year, but Gould believes that its importance has been exaggerated.

CORRESPONDENCE

Editor California State Journal of Medicine, Balboa Building, San Francisco, Calif.

Dear Sir—Enclosed find case report which some of us have considered rather interesting.

Very truly yours,
LINWOOD DOZIER, M. D.

Case Report (by Linwood Dozier, Stockton, Calif.) —J. J. R. Born 1885. Referred for treatment, August, 1914, by Fred Clark, with diagnosis of general paresis. The man acknowledged to a primary several years before. His reflexes were exaggerated and he had the usual inco-ordination of speech; confusion, etc. Wassermann in blood was ——; in spinal fluid +++.

The man received hydrotherapy, was put and kept on KI and Hg intramusc. and courses of 0.6 salvarsan intravenous.

By August, 1915, he had improved enough to leave the sanatorium and care for himself, but in October, 1915, the man suddenly had a severe headache; became dizzy and aphasic and with a little weakness of right side. He was seen by Moffitt and James Pressley, who concurred in diagnosis of general paresis. He soon recovered from this attack. From August, 1914, to October, 1916, he received continuously KI in large doses—Hg intramusc. and thirty-four doses of 0.6 salvarsan.

In August 1916, he had a epileptiform attack; got blue in face, etc., remained confused and then rapidly went into deep coma and remained semi-comatose for several days, with recurring convulsions. Under restraint a decubitus about 6 x 6 inches developed over and to depth of the sacrum. Moffitt in consultation, in October, 1916, advised against further anti-luetic treatment. The man left the hospital in six months with decubitus practically healed and was under care of nurse for another six months, but showed a gradual improvement for several years.

Before his trouble in 1914, the man had been athletic and had been in charge of a large and complicated business house, and popular socially. At present, 1924, he is in charge of one department of this former business house and is extremely exact in all transactions. Socially, he is fairly sure of himself; mixes moderately and enjoys old acquaintances, but seems to seek very few new ones.

This is reported as a case of general paresis of ten years' standing treated by intravenous salvarsan and now arrested. Search of the literature available shows no parallel cases of over five years' duration.

A New Test for Bile Pigments in Urine, Bile and Blood Serum — While investigating the relation of bile pigments and metabolism in dogs with complete obstructive jaundice, or with biliary exclusion in which the bile was eliminated through the urine by means of a cholecystonephrostomy, Robert Kapsinow, New Haven, Conn. (Journal A. M. A., March 1, 1924), examined the urines as a routine for evidences of intestinal putrefaction as demonstrated by the test for indican. He rarely found the indican test positive, but instead observed that the urine became deep green in every instance. The test for indican employed was the Obermayer test. It was found that all urines containing bile pigments when treated with Obermayer's reagent became a deep greenish blue at once. This color was not extracted by the chloroform, and therefore could not have been due to indican. Many urines from normal dogs did not give this reaction. The test was performed on many specimens of urine obtained from patients, and in no case was it positive except when bile pigments were present. None of the drugs used in medication were found to interfere with the test.

MEDICAL ECONOMICS

Hospitals and Real Estate Values—Hardly a week passes that the press doesn't carry doubly ludicrous stories of contests and controversies over the influence a hospital may have upon the value of surrounding real estate.

In the first place, a modern hospital should not and does not in most urban communities cause a depreciation of property—quite the reverse. For instance, two of the newest and finest hospitals in one great Eastern city were secured for the most prominent street in the city—or in the world for that matter—because the surrounding property owners made concessions to get it there. A modern hospital is just as much an asset to a busy street as is a hotel or department store. The objections of realtors is based not upon hospitals as they now are conducted, but upon their reputation during the lifetime of past generations.

In the second place, it is inconceivable to hospital executives that any group of people would want to build a hospital on down town business streets with their very high values, unless they propose to build the new and modern "hotel-hospital," now being constructed in so many places. With these "hotel-hospitals," the lower floors are used for hotel purposes and for stores, with rentals that offset the excessive values of real estate taxes and insurance. The upper floors are, of course, hotels. Few, if any, hotels even try to utilize more than a fraction of their ground floor space for hotel purposes. Nor could they afford to do so even at modern hotel rates which even a plutocrat would not call cheap.

Otherwise, every reason exists for locating hospitals farther out in cities where property is less expensive, noise not so great, and where there are better parking and breathing facilities. Most people who get sick do not live "down town," and there is no reason why they should be taken there when they need hospital care, unless it is felt that the noise, dust, hustle and bustle of a "down-town" section is considered good "medicine."

It is only a habit, and a very foolish obsolete one at that, that keeps doctors' office buildings "down town." Many cities are rapidly getting away from the custom, and as sure as the sun shines more of them will do so, once the movement gains a little more headway.

The primary and only interest physicians have in this question is because of its influence in the cost of good medical care, whether the patient is sick in a hospital, or walks to a doctor's office. "Overhead" is an important item of hospital costs, and it takes a good share of the doctor's office income. Good management, and with the elimination of some of the "luxury" features, would decrease prevalent hospital deficits, improve the doctor's net income, and help reduce the cost of medicine to the patient.

Too Many Official Health Units—It has been for some time an obvious fact that there are too many small, insignificant, ineffectively operated official health units in this and in many other states. Each county has a health unit—as it should have—and it would be all right if the division of authority and responsibilities stopped here; except possibly in some counties with more than one large city. The average county has from one to several small incorporate towns of from a few hundred to a few thousand inhabitants. Each of these has its own official health machinery. The border line between these towns and the rest of the county, of which they are a part, is often a quarantined zone where controversies about who's who and what's what between county authorities and city authorities go on indefinitely. A motorist passing through many of these little towns on the state and county highways can tell when he passes into the "township" and out again simply by the roughness of the road at the boundary lines. Much the same sort of roughness is apparent in health work.

More counties should do what some have done and others are trying to do by extending the county health board's responsibilities to include the incorporated townships of the county. San Luis Obispo County is now engaged in an attempt to bring this about. If they succeed and will then establish a strong county health board with a full-time executive officer, they can both reduce the costs of health work and have better service than is possible under the present plan of separate boards for each of the several small towns of the county.

Venice Emergency Hospital—The municipality of Venice has opened an emergency hospital next door to the police headquarters. According to the city manager, the hospital and clinic is conducted by L. L. Magee, city health officer, and is equipped to handle any sort of an emergency occurring at any time.

Glendale Municipal Clinic—A municipal clinic is being operated at the corner of Brand boulevard and Los Feliz road by the city health officer, G. Kaemmerling. The health department collects fees for "part-pay" patients and renders free service to others.

Health Center Work in Visalia—A health center or child welfare conference was conducted on West Main street by school and public health nurses recently. Miss Marion F. Horrocks and Mrs. Meta V. Keener were in charge. Mothers were invited to bring their babies for examination. Instead of a physician being in attendance, as in a clinic, the nurses weigh and measure the children and give advice on health problems. If defects are found, the mothers are referred to their private physicians or, if the occasion warrants, treatment will be given at the clinic.

Mothers' Helpers—There seems to be springing up over the country a new class of those who serve. They are called "mothers' helpers" or "home helpers." Some of them may be engaged by the day for as long as they are needed, while others are "visiting mothers' helpers" who spend so many hours at certain times of the day helping to hold the home together during sickness. In some places, these persons are being given instruction in practical home nursing. One New York City organization maintains a bureau, or register, for placing "mothers' helpers." The principal difference between "mothers' helpers" and maids appears to be in the title, and in placing the service upon a temporary basis.

An Interesting Health Development—The first chapter of an interesting controversy between the political powers and the county medical society in a New York county was recently concluded. The political body had decided to turn over a certain important phase of medical practice to the usual groups of technicians who were to practice medicine under the usual misleading names and were to get their salaries and protection from lay organizations supported by subsidies. The medical society took the problem to the public and won out to the extent that all classes of technicians' work was to be frankly labeled for what it was, and that all classes of these technicians were to operate under policies laid down by a committee of the medical society. All of the technicians' individual work must be carried out under the supervision of a physician.

School Board Dismisses Doctors and Appoints Nurses to Practice Medicine Among School Children—The school board of an Illinois community "fired" their school doctors and employed nurses to do their work. They claimed a saving of $900 a year by the change.

The comments upon this incident have shaken a

lot of physicians and other good citizens into complete wakefulness.

Clinics Conducted by Non-Medical People — Recently the medical society of a large Eastern county refused to further co-operate with a powerful, largely non-medical welfare organization who are conducting a chain of clinics and health centers in that city and in yours. The physicians insisted that they should have the say as to the professional work, who should do it, and that the credit be placed where it belonged. As usual, the welfare organization declined to adopt either of the suggestions.

Rotary Clubs Enter Medical Field—Recently, the Rotary Clubs of Illinois planned to conduct crippled children's clinics throughout the state. The council of the State Medical Association passed a resolution to the effect that the Rotary Club should not enter the practice of medicine, and that the physicians, many of whom were Rotarians, can more efficiently render the same service, the exact wording being as follows: "That the Illinois Medical Society, through its council, condemn and advise against such arrangements, and recommend that these crippled children's clinics supported by Rotary be conducted by the local medical and surgical men in the various counties where same are to be conducted."

The Legal Relation Between Physician and Patient —The relation between physician and patient is a personal one, says Medical Economics, February, 1924. It will be remembered that the able Thomas Linacre, who attended Henry VIII, King of England, made it a rule of the College of Physicians, which he founded, that no member of that body could practice in partnership or be engaged in selling drugs. This principle is more or less recognized by custom and the common law, and in some commonwealths of the United States, as in New York, the physician is expressly forbidden to hide his identity under a charter. In medicine, the corporation is permitted to have neither soul nor body. The doctor personally is responsible to his patient.

For the Family Physician—It is interesting and important and significant that a number of good medical schools and hospitals are opening up special courses for general practitioners of medicine. In the better schools these courses are separated into units of two or four weeks each, and the physician may take as many units as he desires.

The instruction is all directed toward developing a mind capable of collecting all the varieties of evidence of illness, weighing it accurately, and giving judgment in the form of diagnosis. Methods of improved craftsmanship in treatment are accentuated and the general physician's duties as the first and still most reliable and dependable health officer are considered most important of all. The teaching is all done by men in active practice.

What an opportunity is available along these lines for our three Class A medical schools, as well as some of our excellent hospitals.

Ousting of Chiropractic Board Sustained — The findings of the lower court which held that the appointment of Ray S. La Barre, Alden Peterson, James P. Compton, Joseph G. Edgerton, and W. A. Messick as a chiropractic examining board was illegal, has been sustained by the Supreme Court. These men had not legally practiced chiropractic in California for three years prior to appointment, as provided in their initiative law.

It does not appear certain that it will be possible to appoint a legal board. While there are members of chiropractors who hold licenses as drugless practitioners, it is stated that none has been legally licensed as chiropractors.

The Sickness and Hospital Problem of New York —Last year the hospitals and clinics of New York City served well over 3,000,000 people, exclusive of the well to do. It took 12,000 doctors and nurses to render the service, and over 90 per cent of the doctors' services were without pay. The fifty-eight hospitals from which, and in which most of this service is rendered, are assisted by the United Hospital Fund. The average daily applications for admission are about 8500.

Insurance Companies Getting Particular About the Education of Their Doctors — The only surprising feature of the new move among some insurance companies to check up on the education of their doctors is why they have delayed this action so long.

Every other feature of life, sickness and health insurance is relatively of minor importance when compared with the findings of the medical examiners. For many years insurance companies were unable to get enough of the best physicians to do their work for the fees they were willing to pay. The situation is not by any means what it should be today, and it will not be satisfactory until adequate education and experience become the basis of selecting and appointing physicians to insurance positions. The companies might and probably would be compelled to pay their doctors larger fees, but we suspect that the financial balance-sheet would reflect a saving for the company. In any event, it is encouraging to see some of the more reliable companies making a start in the right direction.

Michigan T. B. Association Conducts "Institute"— Short "intensive" educational courses in "institutes" teaching plants are becoming quite popular. Some of these "courses" last most all day, and others last about as long as it takes a chiropractic "college" to educate a "doctor." Many groups of technicians have useful and worthwhile places among the medical agencies, and if the "courses" offered them were calculated to make their work as technicians more effective, they would accomplish much good. Sometimes this is so. Much more often the courses are designed to produce "near doctors" out of good technicians. This is definitely harmful to the cause of better medicine.

The Michigan "courses" last two weeks. Such things as how to distinguish between malnutrition and tuberculosis; public speaking and public health topics; modern health crusades; public health research; why movies and automobiles are menaces to the "pre-tuberculous" and other similar subjects are included.

One physician speaker sounded a note of warning as to possible dangers on the road we are traveling in making everyone a "doctor." He even said that if public health work were to become more effective, it would be necessary to remove it from the emotional and place it upon an "intellectual" plane.

The Costs of Visiting Nursing Service—One great organization that spends large sums of money and carries a large staff of visiting nurses in New York has carefully tabulated the cost per visit of the nursing service, and it amounts to the sum of $1.05. Of this amount, 64 cents is staff salaries, 28 cents is supervision and general overhead, and 13 cents is for clerical help.

Simplifying Diphtheria Prevention—The New York health authorities are eliminating the Schick test in part of the diphtheria prevention work in children under six years of age. All the Schick test does is to determine whether or not the child is susceptible to diphtheria at the moment. Statistics show that such a preponderating percentage of those under six years are susceptible that it is proposed to give them all toxin-antitoxin without the Schick test. The test will be continued for those over six.

Question—How much nursing per patient is considered necessary in good hospital service, and what should it cost?

Answer—The correct answer depends upon many conditions. One is the arrangements provided by the hospital for prompt effective nursing. For example, a nurse in a good well-planned hospital with all the facilities she needs brought together in a central service station can render much more service than the one who must run all over the floor and often up and downstairs to secure the things she needs for any particular service. The time devoted to each patient is decidedly influenced by the physical provisions of privacy for patients. If the patient is in a private room with a noiseless swinging door, the nurse only has to walk in and render her service. If the patient is in a ward, from five to fifteen minutes of the nurse's time is required to secure the privacy necessary for most of her services before she is ready to actually render the service. After the service, more time is required to remove the screens, irrigating-stands and other paraphernalia she has used. This is a partial explanation of why adequate ward nursing is more expensive than private-room nursing.

Other factors that must influence the answer to your question are the classes of patients. Whether the patients are maternity, contagious, surgical, acutely sick, and what not, of course determines to a marked degree the amount of nursing time they should have.

Assuming a complete, well arranged, well managed hospital of 100 or more beds accepting all classes of sick people, the answer to your question still is at best little more than a guess. Several executives have studied and reported upon the problem, and their answers vary from one hour to six hours of required nursing service for each patient for twenty-four hours. The amount and quality of orderly and maid service supplied, the widely varying requirements of doctors; the presence or absence of students of nursing, the manner of nursing "shifts," and many other conditions contribute to the difficulties of answering your question.

Costs of Nursing—Many of the factors mentioned above as applying to the amount of nursing service are, of course, also operative in figuring costs.

Then, too, the compensation and the length of the nurse's work-day are important. In California, nurses have a twelve-hour day with a two-hour rest period. They are paid from $100 to $150 a month, with usually one day a week to themselves and two or more weeks vacation during the year. Private-duty nurses are paid from $5 to $7 for a ten-hour day and maintenance.

If we then say that the average patient requires four hours actual nursing care during twenty-four hours or two hours of the day nurse's and two hours of the night nurse's day, one day and one night nurse could take care of six patients at a total cost of $12 to $15 a day or $2 to $2.50 a day for each patient.

Further comment and suggestions are invited.

The Cults and the College of Surgeons—Under this title the Cincinnati Journal of Medicine, April, 1924, says in part, editorially: "The propaganda in behalf of the American College of Surgeons, so brilliantly begun in the Chicago daily papers in October, is supplemented by an article in Harper's Monthly by William G. Shepherd. Harper's editor says: 'This article has been read, carefully reviewed, and approved by several of the eminent surgeons of the United States, who are familiar, at first hand, with the conditions described therein, and with the objects and achievements of the American College of Surgeons.'

"The eminent surgeons that reviewed this article must be members of the College of Surgeons, because, surely, no one that had not an ax to grind would countenance such absurd statements as it contains. Therefore, we have a right to infer that this article was inspired by members of the College of Surgeons, who wish to use it is a club to drive within their fold those surgeons who have been recalcitrant to their persuasive powers. It is evidently intended to create a feeling of distrust by the laity in any surgeon who doesn't write F. A. C. S. after his name, regardless of the reputation he may have acquired by years of work of high quality, and by years of conduct that reflects credit upon his profession, as well as upon him as a man. Although the writer is not a member of the College of Surgeons, he has always had the most kindly feeling for it and has appreciated the fact that it has undertaken a tremendous task, has labored under difficulties, and has accomplished some good, especially in raising the standard of the hospitals. Therefore it is with genuine sorrow that we see the College of Surgeons adopt the methods they have. It will make enemies for the college.

"The leopard does not change his spots; a liar will not fail to lie because he has promised not to. Every lodge, every profession, every church, has rascals within its fold. Is the College of Surgeons the one exception to this general rule?

"If a surgeon, eligible for membership in the College of Surgeons, be asked why he does not join it, he will usually give one or all of the following reasons: The college in the beginning took in so many men of mediocre ability that he feels it would be no honor to him to have his name listed with theirs. Its law against the division of fees, like the Volstead Act, is not being enforced. The men constituting the 'inner circle' or the medico-political machine that runs the college are always 'browsing along the brink of impropriety' as regards advertising themselves. This should lead the College of Surgeons to assume an attitude of becoming modesty. Truly great men are always modest. Truly great institutions require no 'muckraking' correspondents to describe the depravity of the rest of the world, to furnish a dark background, that their virtues may be seen.

"'There will be other surgeons round the corner—in this new day of surgery—who will not stand by the old fogy code of not taking another man's cases who will help you' (Harper's, page 314). So that is the ethics promulgated by the College of Surgeons, is it? The eminent surgeons that read this article before publication approved this statement. No harm for a member of the College of Surgeons to steal from one who is not! Our author tells us the college received $90,000 from the Carnegie Foundation. Did the foundation impose the ethics of the market place on the recipient? 'To cut the greed glands out of surgery has really been the first step of the College of Surgeons.' Surely the operator got the wrong glands!"

Is This the Ideal County Medical Society?—The Idaho Falls Medical Society has all practicing physicians in its territory enrolled as members; does the medical work for its city and its county; has a meeting on the first Friday evening of each month, with a dinner before the scientific program; pays its secretary; pays the county and state dues for its members; pays the dues for its members as members of the League for the Conservation of Public Health, a statewide organization; provides a $5000 indemnity policy for each member; pays for narcotic licenses for members; pays for the state renewal license for members; pays for the dinners served at its regular meetings; has all members present at every meeting except when emergencies prevent attendance. The money paid by the city of Idaho Falls and the county for medical service is paid to the society.—American Medical Association Bulletin, March, 1924.

Medical Ideals to be Attained—In discussing this subject (West Virginia Medical Journal) Oscar B. Biern says in part: "The ideal of fraternalism must be kept alive. Jealousy, criticism and intolerance lamentably weaken medical influence. Much can be done to perpetuate the tradition of a brotherhood by earnest attempts to create a scientific unity. The gospel must be preached especially to those backward members of the profession who rarely attend county, city, state, or national medical meetings. Fraternalism with workers whose daily life is occupied not with the care of the sick, but with the scientific study of

conditions underlying such care, is quite as important. The benefits to be derived are equally reciprocal."

Physicians and Dentists of Hollywood to Have Million Dollar Office Building—Incorporation papers have been issued to "Medical Center Inc." of Hollywood. It is the purpose of the promoters to lease space only to doctors and dentists.

We would like to caution members of the California Medical Association to be sure that "doctor" and "dentist" is defined in a satisfactory manner in the articles of incorporation. And furthermore, that the authority to pass upon applications for lease be vested in safe hands. The history of alleged doctors' office building promotions justify these precautions.

"Health Surveying as a Favorite Indoor Sport"—There are more alleged surveys in California than there are in any other state and more than there are in any other country of the world. In fact, it seems to be one of our favorite occupations and is much vaunted as a stimulating research problem. It is customary for us to have from four to forty health surveys, local and general, going on all the time. They are sometimes by local surveyors, but most often by imported "one-night standers." Their survey reports are all voluminously filled with platitudes and propaganda. They are sometimes published, but more often they are "confidential" documents. No one pays much attention to any of them any more. They could not if they would, because a start is hardly made on any program until someone thinks of another survey and another surveyor, and we are off on a new line.

Milling around is at its height and chewing the cud of reflection is unpopular. Motion, motion everywhere without a place to go. Surveys cost money and imported surveyors demand good fees. There are instances in California where public-spirited influences asked for and received "expert" "surveyors'" opinions for quite reasonable fees, while the surveyor received Teapot Dome fees for service to those who always know what they want and how to get it.

Santa Barbara Doctors' Office Building—A new exclusively doctors' office building, to cost $90,000, is being promoted in Santa Barbara. It is proposed to locate the building away from the business section, and doctors are expected to be stockholders.

The movement to locate doctors' office buildings away from the congested downtown sections of cities appears to be growing. There is much to be said in favor of the movement and there are a few legitimate objections. It is to be hoped that doctors, planning to invest in the Santa Barbara or any other doctors' office building, will see that adequate provision is made for a satisfactory definition of "doctor," as well as satisfactory assurance that the definition will be lived up to. Some good doctors have lost money in promotion schemes for "alleged" doctors' buildings.

Apartment-Hospitals—There is a sound thought behind the new movement for apartment-hospitals now being experimented with. Certain disqualifying chronic diseases, deformities and certain classes of obstetrical patients among families who cannot bear the legitimate costs of modern medicine may utilize the apartment-hospital.

In these hospitals certain space is set aside for required technical service. All other space is given over to regular, medium and smaller-sized apartments. When prolonged disqualifying illness comes to a family operating close to the base line between solvency and insolvency, the whole family moves into a hospital apartment. They continue to do what they can for themselves, the wage-earners continue to go to their work, while the patient has just such additional care as is necessary over and above what the family can give. Members of the family become apprentices, as it were, in nursing and otherwise serving the sick. Medical, nursing and other technical services are available within limits at the apartment-hospital. For more highly skilled surgical and other services the patient may be placed temporarily in more fully equipped hospitals.

The Victoria Apartment-Hospital at 315 East 158th street, New York, was the first of these apartment-hospitals.

Board of Osteopathic Examiners Makes Interesting Ruling—In a letter to C. B. Pinkham, secretary of the Board of Medical Examiners, Lester R. Daniels, secretary of the Board of Osteopathic Examiners, says:

"Replying to your inquiries of March 8 regarding the cases of Frank E. Corwin and D. F. Hyder, will state that the board has very definitely ruled that an individual licensed on osteopathic credentials is not entitled to the suffix M. D., in spite of the fact that he may have legitimate medical credentials evidencing graduation from a college conferring the M. D. degree. Frank C. Corwin, however, has an osteopathic license only, and therefore is not entitled to hold himself out as a physician and surgeon.

"As regards individuals who illegally hold themselves out to practice osteopathy, the board is taking steps to prevent all such persons from thus misrepresenting themselves before the public. Tasker was empowered at the last board meeting to employ an inspector for this purpose, and it is to be hoped that prosecution of individuals of this character may be successfully carried out."

Reflections on "Medical Economics"—Twenty topics are mentioned by Edward H. Ochsner of Chicago in a recent article on "The Medical Economic Situation," says the Ohio State Journal of Medicine.

These are: 1, Federal aid laws; 2, Single standard for the practice of medicine: (a) Cults and cultists; (b) Quacks and quackery; 3, Medical inspection of school children; 4, Medical education: (a) Premedical; (b) Medical; (c) Interne; (d) Post-graduate; 5, Nurses' training; 6, Hospital and hospital management; 7, Group practice; 8, Medical charities; 9, State wards: (a) Penal; (b) Delinquent; (c) Insane; (d) Feeble-minded; (e) Blind; (f) Deaf; (g) Miscellaneous; 10, Venereal disease control; 11, Public health and sanitation; 12, Personal hygiene; 13, Periodic medical examination for all citizens; 14, The doctor's investments; 15, The business side of the practice of medicine; 16, The claims of the chemical foundation; 17, Narcotic drug control; 18, Lay control of medical affairs; 19, Compulsory health insurance, old age pensions, etc.; 20, State medicine.

It would be easy to increase this list by some eight or ten more important economic problems facing the medical profession and calling loudly for remedies.

Is This the Way it Should be Done?—The Bureau of Child Hygiene of the California State Board of Health and the State Department of Physical Education are conducting a month of physical examinations of children who are about to enter school. These examinations will be conducted by qualified physicians, dentists and nurses, and will be "free of cost" regardless of the patients' ability to pay.

They mean, of course, that the service will be "free of cost" to the patient. The costs will be paid for out of taxes and by the practicing physicians who give of their time and also help pay the taxes. This type of the practice of medicine is important for children and for all other persons, provided the examinations are well done by educated physicians; provided further, that accurate written records of all findings are made; provided further, that these records are placed in the hands of the patient or family for the information of the family physician; and provided further, that the patient and the family secure the remedial service they need from competent sources. Otherwise, such examinations are an expensive luxury which produces motion but not progress.

Chiropractors Protest Against Nurses Practicing Medicine—The California Chiropractic Society have

protested to San Francisco County Supervisors against school nurses practicing medicine by attempting diagnosis of disease and ordering surgical operations.

There is a grim sort of humor in a situation where one body of, for the most part, unlicensed practitioners of medicine protest against the competition of another unlicensed group. Neither of these groups is adequately educated or experienced to assume the serious responsibilities of life and death that both are being widely charged with assuming.

Commercial Exhibits at the California Medical Association Meeting in Los Angeles — The following advertisers carrying space in California and Western Medicine will have commercial exhibits at the annual session in Los Angeles:

The Vitalait Laboratory, Pasadena, Calif.
The Calso Company, 524 Gough street, San Francisco.
Horlick's Malted Milk Co., Racine, Wis.
The Medical Protective Company, Fort Wayne, Ind.
Hanovia Chemical and Manufacturing Company.
Scherer, Hospital Supplies, 728 South Flower street, Los Angeles.
Abbott Drug Co., Chicago, Ill.
Bush Electric Corporation, 334 Sutter street, San Francisco.
Ralph Sweet, Medical Illustrating, 235 Grattan street, San Francisco.
Parke-Davis, Detroit, Mich.

A new Alleged Spokesman for the Regents of the University of California and the California Board of Education—The editorial in California and Western Medicine of February, dealing with the establishment of a course in "optometry" by the physics department of the university has called forth many compliments, and it also drew fire from expected and anticipated sources. The only feature of the comment that was not anticipated was that one class of optometrists presumed to speak for the authorities of the university as well as for the board of education. This they do in an abstract of an editorial published in the April issue of "The Reflex," when they say:

> "The regents of the University of California and the State Board of Education have become aware of the constant and continued success that the optometrists are having in giving to the public that for which they have been especially trained—efficient ocular service. They have come at last to the realization that the really efficient method to examine the eyes is **without the use of drugs,** and that only the optometrist is qualified by **education and special examination** to give that kind of an examination to the public."

The reaction of the university and the board of education to the statement of their presumably self-appointed spokesman will be awaited with some concern by all persons interested in the question of adequate education for all persons who treat the sick, including the correction of deformities of the eyes, toes, heart, or any other part of the body.

Old Fractures of the Ankle—It is the belief of Emil S. Geist, Minneapolis (Journal A. M. A., March 22, 1924), that it is absolutely necessary to make liberal use of the roentgen ray in the treatment of ankle fractures, both before and after so-called setting. It is necessary to recognize a type of backward fracture dislocation of the ankle. When fresh, it is easy to treat; when old, it is a bete noire. Correct alinement of the bones comprising the ankle-joint is necessary in order to prevent later disability. Thorough and efficient after-treatment by massage, hot-pack applications, and active and passive motion are necessary. In these cases the Achilles tendon will shorten if it is not watched. In all ankle fractures, no matter of what type, the foot must be held at right angles with the leg.

Medical School News

University of California (reported by L. S. Schmitt, acting dean)—Reserve Hospital Units—The advisory board of the Medical School has recommended to the faculty the organization of a general reserve hospital unit and a surgical reserve hospital unit. Upon approval by the faculty, the commanding officers for each unit will be designated and the surgeon-general of the army requested to give numbers to each unit.

At the last meeting of the Association of Ameriman Medical Colleges, a motion was adopted to appoint a commission to include representatives of the Council on Medical Education and Hospitals of the American Medical Association and the Committee on Education and Pedagogics of the Association of American Medical Colleges to carry out a thorough investigation as to what should be the essential requirements for the degree of Doctor of Medicine.

At the same meeting a plan to establish examinations for admission to medical schools, similar to the plan now in vogue for admission to American universities and colleges, was discussed.

Ray Lyman Wilbur, president of Stanford University, was elected president of the Association of American Medical Colleges for the year 1924-25. L. S. Schmitt, acting dean of the University of California Medical School, was appointed a member of the Committee on Education and Pedagogics of the Association of American Medical Colleges.

Stanford University School of Medicine (reported by William Ophuls, dean)—The 1924 Lane Lectures —The following is the final program of the Lane medical lectures to be delivered by Professor Ludwig Aschoff, Professor of Pathology of the University of Freiburg, Germany, at Lane Hall, Stanford University Medical School, corner of Sacramento and Webster streets, San Francisco, for the year 1924, as reported by Dean William Ophuls:

May 26, 1924, 8:15 p. m.—Place of Origin of the Biliary Pigment.
May 27, 1924, 8:15 p. m.—Atherosclerosis.
May 28, 1924, 8:15 p. m.—Ovulation and Menstruation.
May 29, 1924, 8:15 p. m.—The Morphology and Function of the Adrenal Cortex.
May 30, 1924, 8:15 p. m.—Fatty Degeneration.

The medical profession and students of medicine are cordially invited to attend these lectures.

The subjects for this year's lectures are all particularly timely, and every physician ought to make an earnest effort to hear the subjects discussed by a truly great pathologist.

Pneumonia Simulating Appendicitis in Children—The acute onset of pneumonia with few or no clinical symptoms may simulate acute appendicitis, especially distention in children. Abdominal symptoms of pain, tenderness and rigidity may be present as in the cases cited by Paul A. White, Davenport, Iowa (Journal A. M. A., March 1, 1924). Difficulties in diagnosis are multiplied because of the tender age, lack of intelligence, or fear on the part of the patients. A severe chill at the onset, temperature over 102, and a leukocyte count near or over 20,000, should engender extreme caution and intensify efforts at differentiation. A careful urine examination should always be made.

The "mother instinct," helpful as it is, is not sufficient to cope with the responsibility which comes with motherhood. Children enter the world—little plastic creatures with so much natural force and for the rest blank, and life writes its own story on those blank pages.—Medical Woman's Journal, March 15, 1924.

BOOK REVIEWS

Local Anaesthesia Methods and Results in Abdominal Surgery. By Hans Finsterer. Illustrated. New York: Rebman Company. 1923.

Finsterer's book is more than a mere exposition of methods of local anesthesia. It might perhaps better be entitled "Abdominal surgery under local anesthesia."

The first hundred pages have to do with local and regional anesthesia in the abdomen; the remaining two hundred fifty treat of Finsterer's methods of gastric, intestinal and gall-bladder surgery.

The book contains much of value, although there are but few American surgeons who will entirely agree with the author's practice.

No doubt that splanchnic anesthesia greatly decreases the risk of abdominal operations in weak and unresistant patients when the choice lies between regional anesthesia and ether or chloroform. Gas anesthesia, however, which has come into such wide use in this country, and which almost entirely obviates the dangers of ether or chloroform, is not considered. One cannot help but feel that if gas were as much used in European clinics as it is here complicated injection methods would scarcely have reached the refinements and the development to which Finsterer has largely contributed. Finsterer's methods used together with gas give an almost ideal abdominal anesthesia—an anesthetic both of the pain-sense and of the psychic insult accompanying a major abdominal operation.

The book will be of especial value to beginners in local anesthesia, for it is quite true that the only way to perfect oneself in the methods of infiltration anesthesia is to use them alone without the supplementary aid of a general anesthetic. After one has mastered the technic, one may supplement the effects of novocain with gas; if the beginner immediately has recourse to gas or ether, he will never learn the imperfections of his infiltration anesthesia.

The book will be equally valuable to surgeons working in small hospitals without special anesthetists skilled in the use of gas. It is in the small hospital that pure infiltration methods will find their sphere of greatest usefulness.

The controversial and rancorous tone of the work is regrettable. This sentence from the opening chapter is a sad commentary on Viennese surgery:

"With the great number of surgeons in Vienna at the present time, it is certainly not necessary to state that the commercial side of such an important question is very much of a deciding factor, because we know that when a surgeon operates on all, even the minor cases, it is not in the interest of the patient, but principally in the financial interest of the operator himself."'

The translation is lame, involved, full of Teutonicisms and Teutonic turns of phrase. The book is full of typographical errors. The errors should be corrected and the translation might well be revised in future editions. In spite of these faults, the work is of much interest and its methods of great value. L. E.

Diseases of the Skin. By Richard L. Sutton. 5th ed 1214 pages. Illustrated. St. Louis: C. V. Mosby Company. 1923. Price, $10.

Richard L. Sutton's fifth edition of Diseases of the Skin is a praiseworthy text-book, with many features which make of it one of the best. Perhaps best of all is its completeness. The many excellent illustrations are a second notable feature.

The book is well printed and pleasing to read, and for reference it is not too large. It proves its worth in diagnosis. It is equally as helpful from a therapeutic standpoint.

Sutton's book, I feel confident, will be found to fulfill any praise that may be given it. G. D. C.

BOOKS RECEIVED

Applied Pathology in Diseases of the Nose, Throat, and Ear. By Joseph C. Beck, M. D., Associate Professor of Laryngology, Rhinology and Otology, University of Illinois College of Medicine. With 268 original illustrations, including four color plates. St. Louis: C. V. Mosby Co., 1923.

The Beaumont Foundation Lectures. Subject: The Antidiabetic Functions of the Pancreas and the Successful Isolation of the Antidiabetic Hormone—Insulin. By J. J. R. MacLeod, Professor of Physiology, University of Toronto, and F. G. Banting, Research Professor, University of Toronto. Series No. 2. Auspices of the Wayne County Medical Society, Detroit, Michigan, 1923. Published by the C. V. Mosby Co., St. Louis.

Methods in Medicine—The Manual of the Medical Service of George Dock, M. D., formerly Professor of Medicine, Washington University School of Medicine. By George R. Herrmann, M. D., Instructor in Medicine, University of Michigan; formerly Assistant in Medicine, Washington University. Illustrated. St. Louis: The C. V. Mosby Co., 1924.

International Clinics, a Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles. By leading members of the medical profession throughout the world. Edited by Henry W. Cattell, M. D., Philadelphia, with the collaboration of fifteen physicians. Volume I, Thirty-fourth Series, 1924. Philadelphia and London: J. B. Lippincott Co., 1924.

Diet for Children (and Adults) and the Kalorie Kids. By Lulu Hunt Peters, M. D., formerly Instructor in Infant Feeding, Los Angeles County and Clara Barton Hospitals, Los Angeles Medical Department, University of California, Los Angeles; Pediatrician Los Angeles County Hospital. New York: Dodd, Mead & Co., 1924.

National Health Series. Edited by the National Health Council, written by the leading health authorities of the country, and published by the Funk & Wagnalls Co. Price per volume, 30 cents. Complete set of twenty volumes (ready about May 1, 1924), $6. The first five volumes have been received, and are as follows:

Cancer—Nature, Diagnosis and Cure. By Francis Carter Wood, M. D., Director Institute for Cancer Research, Columbia University.

Man and the Microbe—How Communicable Diseases are Controlled. By C.-E. A. Winslow, Dr. P. H., Professor of Public Health, Yale School of Medicine.

Community Health—How to Obtain and Preserve It. By D. B. Armstrong, M. D., Sc. D., Executive Officer of the National Health Council.

The Baby's Health. By Richard A. Bolt, M. D., Gr. P. H., Director Medical Service, American Child Health Association.

Personal Hygiene—The Rules for Right Living. By Allan J. McLaughlin, M. D., Surgeon United States Public Health Service.

Rush Alumni Society Banquet (reported by W. H. Olds, secretary)—The Rush Alumni Society of Southern California held a banquet March 20, in honor of Arthur D. Bevan, Wilber Post, and Truman Brophy. The dinner was held at the Athletic Club. There were eighty members of the society present. Our old professors gave us some very good addresses regarding conditions as they now exist at Rush, and the plans for the future. We hope that more of the faculty will visit us before long.

NEW MEMBERS OF C. M. A. SINCE JANUARY 1, 1924

Alameda County—Marie A. Heinatz, R. L. Rupert, E. V. Sheafe, John W. Sherrick, Sydney Kinnear Smith.

Butte County—Mary W. Harris, William S. Lavy, Sydney V. West.

Contra Costa County—J. Emmet Clark.

Fresno County—Stephen M. Long.

Humboldt County—Mathew J. Beistel, William W. Styles.

Los Angeles County—John Waite Avery, Donald T. Babcock, Robert V. Baker, Frank S. Barnard, Harold D. Barnard, Joseph J. Bellin, Milton G. E. Bennett, George L. Blanchard, Oliver Bourbon, Gilbert S. Bovard, Robert J. Brown, William Thomas Cain, Kenneth A. Crismon, C. D. Dickey, George A. Fielding, Harry S. Fist, H. J. Friesen, C. E. Galloway, John P. Gilmer, R. Y. Glidden, Joseph Goldstein, L. Yuba-Sutter County—F. B. Lawton.

TRANSFERRED

F. Lisle Horne, Placer County to Contra Costa County.

Charles L. Ianne, Santa Clara County to Contra Costa County.

W. A. Rowell, Shasta County to Contra Costa County.

Mabel A. Geddes, Alameda County to Humboldt County.

R. Manning Clarke, Santa Barbara County to Los Angeles County.

Burton E. Paul, San Francisco County to Los Angeles County.

Irwin C. Sutton, Orange County to Los Angeles County.

Frank W. Yocom, San Francisco County to Merced County.

Henry W. Vollmer, San Bernardino County to Riverside County.

Archibald A. Atkinson, Siskiyou County to Sacramento County.

Walter F. Pritchard, Napa County to San Bernardino County.

Gordon F. Helsley, Santa Barbara County to San Francisco County.

Sidney J. Shipman, Placer County to San Francisco County.

Ernest C. Griner, Mendocino County to San Joaquin County.

M. F. Frandy, Kern County to San Bernardino County.

Henry G. Zanger, San Francisco County to Santa Clara County.

Frederick W. Didier, Shasta County to Stanislaus County.

Homer H. Beck, Siskiyou County to Tehama County.

Too Much Specialization—The earnestness of purpose among advocates of special lines of health activities is deserving of great commendation, but the policy of conducting campaigns each dealing with some particular problem regardless of its relation to other similar problems is productive of confusion. National and State legislative bodies are asked for appropriations in behalf of special programs of work, and it is not unusual to find in the communities themselves several persons, each representing a different health activity, vying with one another for local appropriations to carry on their work.

The usual result of this state of affairs is that the advocates with the most active support, or with the most attractive and convincing method of presentation, win the laurels. Few, if any, are given what they ask; and often the appropriations allowed, while making a fair-sized total, are so divided and apportioned that the results are far less than might be obtained from the expenditure of the same amount under a systematic plan of work.

The time is at hand when legislative bodies and the people themselves should thoroughly understand that no special line of health work can be complete in itself; that the whole problem of health and disease is so inter-related and complex that it is impossible to make satisfactory progress along one line unless it is conducted in a definite and proper relation with all others. . . .

An important part in the protection of the health of mothers and infants lies in the control of communicable diseases, especially venereal diseases, the provision of safe water and milk supplies, adequate methods of sewage disposal, and a generally healthful environment.—W. F. Draper, Journal A. M. A.

Obituary

WILLIAM MILLER STOVER
1867-1924

The medical profession of California suffered a severe loss in the death of William Miller Stover, which occurred on April 4, 1924, at his home in San Luis Obispo.

Doctor Stover was born in New Hope, Virginia, on the 10th of February, 1867. He received his preliminary education at the Augusta Military Academy of Fort Defiance, Virginia, and his degree of Doctor of Medicine was bestowed on him by the University of California in 1896.

In 1898 he was married to Miss Anne E. Mitchell in the city of Watsonville, California. Mrs. Anne E. Stover and two children, Mrs. Virginia Stover Williams and Beverly R. Stover, are left to mourn his loss.

After graduation Stover began the practice of his profession in Gonzales, Soledad, and Paraiso Springs, all in Monterey County, California. In the fall of 1900 he moved to San Luis Obispo, where he continued to practice until his untimely death. He was a Fellow of the American Medical Association and a member of the Council of the California Medical Association.

From the very beginning he showed an indomitable energy and love for his work that presaged the success that was his later in life. His work, medical and surgical, was of the very best and was his pride and joy.

The fact that he was twice elected mayor, twice a member of the school board, once president of the Chamber of Commerce, and was always prominent in civic activities in his home city, was testimony that he was not just an ordinary doctor in his community.

Doctor Stover had been ill for many months and had been advised that he must quit work and take care of himself. But to loaf was foreign to his nature. He did not quit. To serve had become a habit of his life and it may well be said that he forgot himself in service to others.

What greater epitaph could man ask?

Professor H. Finkelstein, Guest of the C. M. A.—H. Finkelstein, Professor of Children's Diseases in the University of Berlin and Director of the Kinderkrankhaus, is to be a guest of the C. M. A. during the Los Angeles session. He is scheduled to speak to the Section on Pediatrics on May 15, and interested physicians are invited to be present. Finkelstein is widely known for his work on diseases of the digestive system in children and especially for his classification of the summer diarrheas.

EXAMINATION DATES OF THE NATIONAL BOARD OF MEDICAL EXAMINERS

Part I—June 19, 20, 21, 1924.
Part II—June 20, 21, 1924.
All applications for these examinations must be made on or before May 15, 1924.
Further information may be obtained from the secretary, J. S. Rodman, 1310 Medical Arts Building, Philadelphia, Pa.

The Botany of Southwest Texas, With Reference to Hay-fever and Asthma—The article by I. S. Kahn, San Antonio, Texas (Journal A. M. A., March 15, 1924), is the result of a year's study of glycerin pollen plates exposed twenty-four hours, later stained with compound solution of iodin, and examined twice each week. The plates were exposed in both the residence and business districts of San Antonio; in addition, a number of plates have been studied from Houston, Dallas, Corpus Christi and smaller cities nearer San Antonio. The actual field botany work and identification of specimens were done in connection with Miss Ellen Schulz, professor of botany in the San Antonio high schools, and Mr. Wallace Butler of the local United States Agricultural Experimental Station.

DEATHS

Burchard, Edwy Adelbert. Died at Lodi, March 31, 1924, age 75. Graduate of the University of Wooster Medical Department, Cleveland, Ohio, 1877. Licensed in California, 1881. He was a member of the San Joaquin County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Butler, Fletcher Asbury. Died at San Diego, March 21, 1924, age 70. Graduate of Louisville Medical College, 1879, and of the Tulane University of Louisiana School of Medicine, New Orleans, 1881. Licensed in California, 1881. He was a member of the San Diego County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Hennessey, Edwin Zac. Died at Napa, April 3, 1924, age 60. Graduate of the Medical College of Indiana, Indianapolis, 1884. Licensed in California in 1886. He was a member of the Napa County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

O'Reilly, Thomas William. Died at Los Angeles, March 19, 1924, age 55. Graduate of Jefferson Medical College of Philadelphia, 1892. Licensed in California, 1906. He was a member of the Los Angeles County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Smith, Samuel F. Died at Bakersfield, April 4, 1924, age 59. Graduate of the University of Southern California College of Medicine, Los Angeles, 1895. He was a member of Kern County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Squire, Herbert A. Died at Los Angeles, March 16, 1924, age 64. Graduate of the New York University Medical College, 1886. Licensed in California, 1901. He was a member of the Los Angeles County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Stover, William Miller. Died at San Luis Obispo, April 4, 1924, age 57. Graduate of the University of California Medical School, San Francisco, 1896. Licensed in California, 1897. He was a member of the San Luis Obispo County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

"Vita-Pep" (Propaganda for Reform)—Vita-Pep is nominally put on the market by the Vitamine Products Co. of New York City, but actually seems to be put out by the Vitamin Food Co., Inc., of Westfield, Mass. The president of the Vitamin Food Co. is one Eugene Christian, who calls himself a food specialist. He has offered a "Course in Scientific Eating," in which he showed his monumental ignorance of the subject he wanted to teach. Later, he was interested in an obesity treatment, the "Vaco Reducing Cup." Then he tried to sell oil stock to those on the sucker list. Then came the Vitamin Food Co., Inc., with Christian as president, and those on the sucker list were asked to buy stock in this company. In the earlier advertising, the product mainly stressed was "Vegex," which, according to the advertising matter, was a name that the Vitamin Food Co., Inc., had given to a British preparation sold across the water as "Marmite." Now comes the crowning achievement of the Vitamin Food Co., Inc.—Vita-Pep. The circular for this contained the statement in large letters that the preparation contains alcohol 16 per cent. According to the label, Vita-Pep, in addition to containing wine with an alcohol strength of 16 per cent, also contains pepsin, rennin and a concentrate of vitamin "B." The advertising circular states that Vita-Pep is a "Zestful New Health Tonic" which "Restores Youthful Vitality." According to the advertising, "Vita-Pep is pleasant to the taste and delightful in its effect—takes away that tired, rundown feeling and makes one feel vigorous, healthy, and strong." What is the United States Revenue Department going to do about it?—Journal A. M. A., March 15, 1924, p. 907.

Said Anatole France—"Robespierre was an optimist who believed in virtue. If you want to make men perfect, you end, like Robespierre, by desiring to guillotine them. Marat believed in justice and demanded 200,000 heads."

Tryparsamid—A study made by Wade H. Brown and Louise Pearce, New York (Journal A. M. A., January 5, 1924), of the action of tryparsamid on the animal organism and on experimental infections produced by trypanosomes and spirochetes showed that, although the drug exhibits no unusual parasiticidal effect, it possesses properties of action which peculiarly adapt it to the treatment of trypanosomiasis and to certain classes of syphilitic infections, especially those that call for the use of drugs with high penetrability as well as those that might be influenced favorably by reinforcement of processes of natural resistance. From the practical point of view, the most important features of the action of tryparsamid are: comparative freedom from untoward effects, a moderate degree of trypanocidal action and slight but definite spirocheticidal action, an unusually high penetrability which enables it to develop a high actual as compared with its potential parasiticidal action, and a remarkable power of reinforcing processes of natural resistance and of promoting recuperation. Therefore, the use of the drug should be directed with a view to utilizing these resources and not from the standpoint of a powerful parasiticidal agent.

The Clean Inunction Treatment of Syphilis with Mercury—A further series of cases is reported by H. N. Cole, J. R. Hutton and Torald Sollmann (Journal A. M. A., January 19, 1924), which confirms their contention that mercurial inunctions are fully as efficient when the excess of ointment is removed with benzin, after thirty minutes of rubbing, as when the ointment is left on the skin. By either method, about half of the patients require from eleven to nineteen rubs before salivation occurs; about a fourth require a smaller, and a fourth a larger number. Pathologic conditions of the skin are important factors in the absorption of the inunctions.

What is S. M. A.?

S. M. A. is an adaptation to breast milk which resembles breast milk both physically and chemically.

S. M. A. in addition to giving excellent nutritional results in most cases, also prevents nutritional disturbances such as rickets and spasmophilia.

S. M. A. requires no modification or change for normal infants. As the infant grows older the quantity is merely increased.

S. M. A. requires only the addition of boiled water to prepare.

(Orange juice, of course, should be given the infant fed on S. M. A., just as it is the present practice to give it to breast-fed infants.)

Why was S. M. A. developed?

Because there is a real need for an adaptation to breast milk which will give satisfactory nutritional results in the great majority of cases, which includes the preventive factors, and which is, at the same time, so simple to prepare that the physician can rely on the mother to follow his directions accurately.

How is it possible to feed S. M. A. to infants from birth to twelve months of age without modification or change?

The answer to this question sounds the keynote of the success which thousands of physicians are having with S. M. A. It is not necessary to modify S. M. A., for *the same reason that it is not necessary to modify breast milk:*— for S. M. A. resembles breast milk not only in its protein, carbohydrate and salt content, but also *in the character of the fat.* Since the very young infant can tolerate the fat, as well as the other essential constituents in S. M. A., it is possible to give this food in *the same strength,* to normal infants *from birth to twelve months of age.*

As the infant grows older, therefore, it is only necessary to increase the *amount* of S. M. A.

Samples and literature to physicians on request.

S. M. A. is to be used only under the direction of a physician. For sale by druggists.

The Declaration of Rights of Children

As Adopted by
The International League of Child Welfare
at Geneva

IN THE declaration of rights of children, called the Declaration of Geneva, men and women of all nations should give to children the best gifts in their possession, and affirm their rights irrespective of race, nationality and religion.

1. Children should be placed in an environment in which they can develop normally, physically and mentally.

2. A child that is hungry should be fed; a child that is sick should be cared for; the backward child should be encouraged; the child that has gone astray should be reclaimed; the orphan and the deserted child should be given a home and their distress relieved.

3. Children should be the first to receive aid in time of distress.

4. A child must be put in a position to earn his living and should be protected against exploitation.

5. Children should be brought up to believe that their best qualities must be used in the service of their fellows.

ORIGINAL ARTICLES

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

The author of an article appearing in the CALIFORNIA AND WESTERN MEDICINE *is entirely responsible for all statements and conclusions. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the language and method of presenting their subjects. All manuscripts will be carefully read, but editorial privileges will be exercised only to a very limited extent. It is believed that the manner of presentation of any subject by any author determines to no small degree the value of his conclusions. Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented by the author as little disturbed as possible by the editors. However, the right to reduce or reject any article is always reserved.*

THE DOCTOR, AS HE WAS, IS AND SHOULD BE *

By THOMAS CLAY EDWARDS, M. D., Salinas.

To have been chosen president of a scientific body composed of the most unselfish men and women in the world is the crowning honor of my life. I wish to thank you for having conferred that honor upon me.

Our time is so taken up with our professional activities that the majority of us do not sufficiently interest ourselves in some very important medico-civic affairs. We often do not seem to realize that scientific medicine is menaced by the increasing propaganda by certain dangerous cults.

Many of the better non-medically educated men and women seem to appreciate this more than we do. Such influential persons as Professor Eliot of Harvard are so greatly concerned lest scientific medicine be crippled in its activities, that they are organizing for the purpose of informing the people of the danger to the human race if scientific medical investigation is limited or stopped. It, therefore, behooves us to be a little more careful to cultivate our personal relations with the public so that we, too, may do our part in placing the facts before the people.

Some of you have a picture hanging in your office —"The Doctor." Call it to mind. The father is standing in the background and the mother is seated at a table with her head resting on her arms. In the foreground you see the doctor, seated by the bed of his little patient. There is no nurse in white raiment, for this doctor was unaccustomed to the services of a trained nurse. Many, many times he would spend the whole night sitting just as you see him there. His, would be the hand that smoothed the pillow, making it softer for his little patient. His, the hand to administer a sip of cold water to parched lips. His fingers gently feel the pulse; his eyes watch the respiration, and his ears are very alert to catch the measured breath sounds that denote refreshing sleep.

Do you wonder that he was considered a comforter and friend as well as a doctor? It was this solicitude, this sacrificing personal service that made him so loved by his patients. Every time we delegate a service we are cutting a strand of the cord that binds us to our patient and thus damaging the value of our services to him.

Modern medicine, by the use of hospitals, laboratories, nurses, specialists, has delegated so much of the work once done by the old family doctor that the doctor of today is losing much of his patient's love. This is a great loss to medicine, because the family physician is the standard by which the average person measures our profession. Our relations to the community are such that what we do is of more importance than that which the average person does. We have been conceded a position of leadership because of the ideals that have actuated us. If we hope to retain the respect that we now claim, we may not with impunity break this, that or the other law. Our position in society is such that if we do so, we teach disrespect for law, bring reproach on our chosen profession, and trample under foot the ideals of our fathers. We are patterns for the young. The youth of today judges us by what we do, not by what we say. Keeping faith with ideals has been, is and always will be one of the big influences toward human progress. We all know that the idealist looks way beyond his own personal comforts or desires. He sees men and

* President's annual address, Fifty-third Annual Session California Medical Association, Los Angeles, May 15, 1924.

women enjoying pleasures denied him. This has been beautifully expressed by Emma Leutert.

Scorn not the dreamer! He it was who with bent back
Cut smooth the road for you and me,
That we might travel on from generation unto ex-generation,
In ease and luxury and sweet security.
What is this wondrous Present but the dreams, in ages gone,
Of those whose inner visions brought into their outer world
What We Now Gaze Upon?
It was the dreamers dauntless brain
That lifted us from out the sordidness of life;
Emancipated us from drudgery and bade us hope again.
And they, the dreamers of today, fearless and bold,
Who saw a great metropolis rise from her ashes Phoenix-like,
A greater, nobler, grander than the old.
It was in dreams men saw the desert crossed with rails of steel;
Its countless homesteads, bridges, cities rise;
Its wagon caravans give way to steam and wheel.
To break down barriers of creed and race,
The dreamer set aside as naught,
Such trifling things as friction, time and space.
He saw the bird-man fly from peak to peak;
The giant steamship ride the ocean wave;
The cable tie two continents and bid them speak.
Erase from history's marvelous page,
Such names as Edison, Morse, Fulton, Field,
And who would care to read the record of the age?
Let him without imagination say "It cannot be!"
"It can be done!" The dreamer cries, and lo!
In steel or steam or poet's verse comes the reality!
Oh, Emerson! you had prophetic vision of the world to come!
Now countless thousands, men and women, stand today
Where you once stood alone.
Confucius, Buddha, Socrates and He,
The Master dreamer of them all, saw in the coming man,
The perfect image of Divinity.
Oh, who would rob the poor of this divinest heritage of man,
The will to dream?
Then let him dream his dreams who can!

Those who have caught the dreamer's vision are ready to take it up where he put it down. Where he strove alone there may be a dozen or twenty or more who will work for it. To them it does not seem so much like a dream; it is more tangible, more workable. There will be more who will co-ordinate his dream and make it available for human needs. The advantages that we have in medicine, surgery, prophylaxis, hygiene, are dreams come true, bequeathed to us by our predecessors, and they were indebted to those who "in their turn preceded them." The foundations on which we stand were built a little higher for us, and we must add our quota so that those who follow may have a saner judgment, a safer rule of action. We must continue to steer true to the course mapped out for us. By doing this we have already made possible the eradication of diphtheria, lockjaw, typhoid fever, smallpox, and many other diseases. And now comes the assurance that scarlet fever, that treacherous thing that entails so many damaging sequelae, has been conquered by scientific medicine. I say that we have made possible the eradication of these and many other diseases, but this possibility will never be a fact if the people persist in ignoring that which painstaking investigation has proven to be true. The part that medicine has played in perfecting professional ideals is a story of unselfish service, untiring devotion to duty and of actual martyrdom.

Let me recall one outstanding example. After the American occupation of Cuba, it became evident that something must be done to stamp out yellow fever, which was causing such havoc to Americans and Europeans. Consequently, Surgeon-General Sternberg of the U. S. A. appointed a commission, composed of Doctors Walter Reed, James Carroll, Jesse W. Lazear, and Aristides Agramonte, to make a scientific study of it, and in case the cause were found to seek a remedy. When they began their investigation they found a dreamer in the person of Carlos J. Finlay, a Cuban physician, who believed that of the 700 species of mosquitoes found on the island, there was one, the stegomyia, that was the culprit. So persistently and insistently did he urge his theory that people called him a crank, a dreamer. After a few months devoted to investigating the more plausible theories without results, the committee turned its attention to the mosquito and found that Finlay was undoubtedly right. Gorgas, who had already done wonders in cleaning Havana, without decreasing the number of yellow fever cases, said that he would rid it of these pests. But Reed said it could not be done, that it was an unthinkable and impossible task. Gorgas exclaimed, "It shall be done," and it was. The result you know. That, whereas, the city of Havana, which had not been free of yellow fever for more than a century and a half, today boasts that there has not been a case reported there since 1905.

Let me draw you another picture. While the investigation was in progress, Carroll was taken sick and Gorgas was called to see him (Reed being absent in Washington on business). Gorgas found his friend and comrade critically ill with yellow fever, restless, tossing on his bed, and intermittently delirious. During his lucid moments, Carroll told of permitting an infected mosquito to bite him on his arm. His whole thought was on his task and not of himself. Before Carroll had recovered, Gorgas was summoned to the bedside of Lazear. He found him mortally ill; but, before he died, he, too, managed to give accurate details of being bitten by an infected mosquito. Was he thinking of himself? Not at all. His whole thought was of the service he had to perform; and faithful to this trust, he died a little over a week after being bitten. But this is not all. The committee completed its work in 1901. In 1902, Reed died after an appendix operation; but with health broken as a result of his work in Havana. Five years later Carroll died of a heart disease, which developed at the time he had yellow fever. Thus, three out of four members of the committee, true to their ideals, were martyrs to humanity's urgent needs.

Think of the glory of it all! On the meager salary of army officers, these, greater than heroes, laid down their lives that others might live.

"GREATER LOVE HATH NO MAN THAN THIS, THAT A MAN LAY DOWN HIS LIFE FOR HIS FRIENDS."

Members of the California Medical Association:

We may justly be proud of the legacy left us by these members of our chosen profession. Let us be true to the ideals they have established; *true to the* ideal that unselfish personal service pays best, that it is the real essence of living, and it is *this* that has written the names of our comrades in the hearts of grateful men and women.

ADDRESS OF PRESIDENT-ELECT *

By GRANVILLE MacGOWAN, M. D., Los Angeles.

The House of Delegates did me the high honor of selecting me as the presiding officer of the association for the year 1924. Lacking moral courage to refuse this gift of preference I did not seek and for which I was not prepared, it is accepted with grateful appreciation of the honor it confers.

It has been esteemed good form for the president, in assuming the duties of his office, to discourse upon ethics as observed among ourselves, as brethren and as affecting our relations to our clients; upon the desirability of an intensive training of the student of medicine so that he may be the better fitted when time and practice has ripened his judgment and trained his reason to give better service to the sick who may employ him, and be better able to defend the privilege and assert the right of the disciplined and scientifically competently drilled medical mind to act as guide and counsel in all legislative or executive proposals which have as their purport improving, safeguarding or regulating better health in the state or nation.

The president is not restricted in his choice of a theme for a dissertation. He may choose to write and present an essay upon the distinguished dead, who have held high the torch that has spread hope's rays into the beclouded foggy, brumous, cheerless chamber of the sick and made the world a better earth to live upon; or he may, out of his own experience, present his knowledge upon any subject, medical or surgical, the relation and presentation of which he believes will be of instructive interest to his audience.

With this rich cadre to choose from, I have selected a subject which is closer to my heart than any knowledge or surmise that may be gained from the seven major branches of medical science and which in these strenuous days, when the hebetudenous body politic, dulled from the continuous practice of the serious sin of hypocrisy, scarcely noting the prevalent disorder and lawlessness, sits benumbed while the undermining current of the stream of dissatisfaction and distrust of the things that are because they are, skillfully guided, to wash against the jutting foundation of our constitutional prerogatives and protective guaranties by wise, adroit and subtle men, who, having achieved places of authority, wait for the dyke to crumble, believing that out of the eddying currents of the swirling incoming waters of disturbance and destruction will to them accrue the benefit; the right to govern and provide the opportunity for the easy accumulation of great wealth, fame, and power without limit.

Were I a famed dissertator, with my facts and fancies arranged and indexed in the cubicles of my mind so that my facile tongue could, without error or confusion, produce them in orderly array, I would place dependence upon rhetorical skill to arouse in you reflexion and contemplation of the distance that we have wandered from the portals of our constitutional republic and the desirability of pausing before we become altogether lost, and urge returning before it is too late. I prefer the slower but more certain exposition of the written word.

In this century, almost from its beginning, have we, the people of these United States, cast off the moorings of our bark, the republic, from the safe anchorage of that constitution provided for us by that little band of thirty-seven patriots, and of whom seven—George Clymer, Benjamin Franklin, Robert Morris, Governeur Morris, George Reed, and Roger Sherman—twelve years before had signed the Declaration of Independence, mutually pledging "their lives, their futures and their sacred honor" to its upholding. In that interval, the Revolutionary War was fought, and finally won; a delayed agreement among the colonies was finally signed in 1781, as an article of confederation of perpetual union. But there was no union, not even for a day; bickerings, dissensions, exhibitions of faithlessness between the states were continuous. The end of the experiment in freedom seemed to draw near.

Impotence of a Congress, whose powers were flaunted at home and derided abroad, appeared to finally point to this end of the experiment of the rearing of the child of freedom upon the North American continent. The dissolution of the Union into thirteen governments, with divergent interests, different views, ceaseless jealousies, appeared unavoidable. Paralysis of industry, and exploitation by the powerful European kingdoms seemed straight ahead.

In May, 1781, the convention of delegates, charged with the duty of "rendering the federal constitution adequate to the exigencies of the Union," met in Philadelphia. These men, chosen from the states because of their erudition, good judgment, practical business ability, and political wisdom, were presided over by George Washington, then and until he died, the most prominent trusted man in America.

In an age and time when the only methods of communication were the stage coach, the sailing vessel, and the dispatch bearer, and when there was no telephone or telegraph; when the assistance of stenographers, typewriters, and statistical experts could not be availed of; when methods of illumination that make of the night a better time than the day for intellectual work were lacking, the members of the convention themselves, without external aid, did all of the rough drafting, correction after debate, and final shaping of the notes upon each and every measure, including the ultimate engrossment, before signing, working less than 100 days from May 14 to September 17. After much discussion and rancorous debate, by the end of 1788 this constitution had been ratified by all of the states of the Union, except North Carolina and Rhode Island, and the government was in motion before these two states agreed to go along.

* Presented at the Fifty-third Annual Session of the California Medical Association, Los Angeles, May 15, 1924.

Is it, as its socialistic and communistic detractors would have us believe, a damning evidence of its unfairness and incapacity, and its culpable capitalistic tyranny that, under its beneficent protection, in only twelve decades the Union expanded from the boundaries of its narrow strip, extending just a few hundred miles back from the shores of the Atlantic Ocean to cover the entire rich loin of the North American continent from the Bay of Fundy to Cape Mendocino and from the Rio Grande to the Lake of the Woods. Peopled by whom? By the direct and ultimate descendants of the 2,500,000 of the financially embarrassed and physically exhausted colonists who had won a bitterly contested prolonged war for freedom. These capitalistic autocrats, who spun their own clothes, ploughed their own fields, and drew their own nets. While they remained and had their natural increases which gave for many years the leaven to the mass of immigrants with whom they shared their inheritance, a horde of economically discontented artisans and peasants, of ambitious youths longing for a chance to rise above the positions in which they were born and forced to remain by the fetters of class, the politically oppressed, the restless of every branch of the Aryan races of the north of Europe, driven from their homes by adverse fortune, by war, by famine, but chiefly by the hunger for land, which might not be had at home, they came in millions up to the last decades of the nineteenth century, and as they came, spread out in all directions across the mountain ranges and the endless prairies, over the great divide to the Pacific slope. They paused as they went, breaking farms and building cities, establishing states, each with a republican form of government, and everywhere using the same tongue for communication. These children of the constitution, speaking English, the language of the charter-makers, the language of the people who fought for the privilege of the opportunity to found a government which for the first time in the history of the world gave security of individual rights, civil liberty, freedom of the press, religious freedom, popular education, extended suffrage, and freedom of speech. But not the right by speech to incite rebellion and destruction of the government itself, for their Declaration of Independence recites, "Prudence indeed will dictate that government long established should not be changed for light and transient causes."

Under no other form of government except that of a republic could this have been accomplished; but it was a task relatively easy by reason of the similarity of purpose and ultimate aim—the building of states like unto the thirteen originals, which not only furnished the model for government, but the habits and customs of daily life, and the language which makes for homogeneity.

With the exhaustion of the tillable soil, that might be had almost for the asking, we changed to a manufacturing country from an agricultural one, and from then on came, one by one, the changes in our government, insidiously at first, and then the flood. It was the colonist and the emigrant of the first century of our existence who pioneered; it was he who developed the country. It is he and his descendants who are its chief owners now. It is they who chiefly constituted the bourgeois against whom the flood of hate is let loose by envious communistic radicals of a late immigration who have brought their bitter, age-old, fierce struggle against all government. From the countries of Central and Southeastern Europe immigrants came, speaking many tongues, without any knowledge of the foundation of our government or of the opportunities it affords to the poor to cast aside their rags and crusts by industry. Ignorant of our customs, traditions and language, but avid of gain, willing to work for a pittance and able to live upon it, and accumulate for them comparative riches to send back to, or carry home with them to their natal villages, there to live in affluence was their object. Strangers in the land, concerned not at all about its government, living segregated in groups, speaking no language but their own, controlled by patrons, contractors, or bankers of their own race, their scent smelled good to the professional politician, who passed many of them by connivance through the melting-pot and made them citizens, their votes often controlling the destiny of states.

These people, in the closing decades of the nineteenth century, commenced to be diverted to the rapidly expanding industrial life of the mines and the great factories in the great cities, where but too often they had for masters iron-hearted men who, having been laboring men themselves, had lost the mental contact with their class. Men who, in the words of Benassis, "passing from the simple life of a laborer to an easy life of ownership grow unbearable, form a class, half-virtuous, half-educated, half-ignorant, which will always be the despair of governments," drunk with the power of new riches, mercilessly refused to treat with their employees who, incensed at the unfair division of the profits and led by a new class of intelligent and well-paid buccaneers, the labor union walking delegates staged strike after strike, which was met by these stubborn, shortsighted and rich peasant-minded employers by further importations of a flood of cheap—for a time at least—ignorant, debased labor to break the strikes.

Amidst this industrial strife in 1891, the Populist party was born at Cincinnati. This was designed to alleviate all of the wrongs, real or fancied, of the citizens of these United States, whom the goddess of fortune had treated invidiously, but more particularly unfortunate agriculturists and working men. It declared primarily for the free and unlimited coinage of silver, the issue of fiat money, the very issue which kept Rhode Island out of the original convention for the preparation of the constitution, public ownership, the prohibition of alien ownership of lands and the popular election of United States Senators. Late in 1900 the party demanded the election of the President, Vice-President, and Federal Judges, by the direct vote of the people. This party never had enough adherents to place anyone of note or ability in an elective office, but its tenets afforded the opportunity to that wonderful orator, its leader, the grand commander of the order of demagogues and perennial candidate for the presidency to infect the American public with its virus and to make himself the arbiter of

the Democratic party for a score of years. So deep was its benumbing influence that, in 1912, in the platform of the Progressive party, we find it demanding the direct election of United States Senators and the adoption of the initiative referendum and recall, and we even find the illustrious candidate, Theodore Roosevelt, advocating, in Arizona, then as now a radical state, the recall of judges.

I dwell upon these matters because the adoption by the American politicians of all parties of these socialistic measures has insensibly almost completely changed our form of government. Nearly every measure proposed by the Populist party has been erected into a statutory law through one or other of our political parties from reasons of pure expediency. The few who have known what our constitution stands for have feared to oppose the oncoming wave of democracy, or their selfish interests have been served by silence.

This constitution which provided for the election of:

First—An executive.

Second—A legislative body who, working together in a representative capacity, have all power of appointment, all powers of legislation, to raise revenues and to spend them appropriately, and to create,

Third—A judiciary to pass upon the justice and legality of their governmental acts, and to recognize certain inherent individual rights was and should be again the supreme law of the land.

It is simple; its observance makes a republic. Any adding or taking away from the powers of any one of the tripartite changes the government to an autocracy or a democracy, the unfailing breeders of injustice, tyrannical destruction of individual rights and spoliation. Of the two, an unbridled democracy is the worst, for at all times men in crowds will do shameful acts that, as individuals, they would not dare, or doing, deplore. "The constitution provides a way for protecting individual liberty from the invasion of the powers of the government itself, as well as from the invasion by others, more powerful and less scrupulous than ourselves." Under the constitution the people are permitted to do but two things—once in four years to vote for a President and Vice-President, which has always produced a disturbance, social and commercial, and once in two years to vote for a member of Congress in their districts; and that is enough.

If that is done and done intelligently, the voter will have made the best provision possible for the safeguarding of his rights, and if it is done by all who have the right to vote, how can the elected representative gainsay the conscience and intelligence of his constituency?

From direct legislation is substituted, for the conclusions of deliberate judgment and debate, the organized propaganda of prejudice, or the unreasoning demands of the selfish but determined minority, swayed by the oratory of men who by noisy and impudent clamor seek to conceal their interest and full intent by posing as patriots guarding the public funds in the interest of the lowly and oppressed while fishing in the troubled waters for the power and its profits from which an orderly government excludes them.

In seeking a remedy for the evils arising in the selection of candidates for our elective offices, under a representative form of government as expressed in bossism and combinations of great industrial interests for the purpose of controlling legislation and directing it into improper channels, Theodore Roosevelt as leader, supported by men of honest purpose and sincerity, and filled with patriotism as they saw it, sought by girdling the tree to remove all nourishment from the branches which showed evidences of decay, and they opened the way for a slow and persistent attack upon our constitutional growth by the pestilent, destructive, radical insects of socialism, communism and sovietism, which threaten to destroy it. In steering away from Scylla, we scraped the ledge of Charybdis.

In place of the one recognized political boss, who was not always as nefarious as he has been painted, the cabal was substituted. In the place of the caucus, before which no unknown man could appear with any hope of success of obtaining a nomination for office, was substituted the direct primary into which candidates entered without the accredited and public sponsorship of party organization, which in case of misdeed, at least, possessed the power of the disciplinary punishment of ostracism. For the legislative enactment of statutory decrees was substituted the initiative and the referendum, which gave for the first time in history, in a great government, the opportunity for the unsettled, unprepared, and undisciplined voting populace to originate extra statutory measures of law and to enact them, usually to the detriment of the body politic, to the disturbance of order and to the enormous increase of debt burden to the state. At the same time these socialistic demands by bodies intent upon public recognition of their theories of reform have resulted under pressure, including the passage of Article XVIII of the amendments, of the enactment of so many laws in the city, county, state, and nation, that it is no longer possible for anyone to live consciously or unconsciously from sunrise to sunrise without being a breaker of law.

But this was not the only disruptive force at work in high places. In 1912 an educator was elected by the people to be the twenty-eighth President of the United States. This man was an historian and a lawyer, who must have been absolutely familiar with that constitution which he solemnly swore to preserve, protect and defend. Inaugurated in 1913, apparently sane; by education and surroundings presumably conservative, but he had the fatal gift of rhetoric and had acquired a command of our language not equalled by any other American of his time; a phrase-maker; as an educator, an autocrat; as President, a man who, while professing the greatest interest in the people, held himself aloof from them and closed the White House gates. A man who was self-sufficient, and often obstinately refused both before and during the war to give audience or counsel, or advise the highest officers in departmental or diplomatic life, whose duty it was to carry out his behests, and many of whom did not even know him in person. At the same time, the

doors of the President's house were open for the comings and goings of many strange and curious people — propagandists, whose political doctrines were widely at variance with those of a republic and who at times became his personal representatives abroad. A man who was in many ways a wonderful statesman, and yet the first President of the United States to abrogate the sovereign power entrusted to him by the people in the face of duress by menace, in time of public stress by leaders of a portion of the labor world, demanding class legislation. This man, "too proud to fight" when we were in the midst of war, wanted "peace without victory," to make the world "safe for democracy" when he had known, before his exaltation, that there is no safety in a world in which government is unrestrictedly democratic.

Now why does he bring all this to us, I read in some of your faces. This is politics; what have we to do with politics? We are doctors of medicine. We should worry about direct legislation and its results. Sufficient for each day is its own trouble.

I bring this to you, because it is the privilege of my age and position to advise you; because my daily life spent in many countries and in all social planes has taught me, by friendly concourse, the habits and the psychology of the farmer and stockraiser, the mine and the mill, the newspaper office, the police and the criminal they track, the leaders of labor and the transportation manager, the teacher and the mechanic, the banker and the day laborer, the bureaucrat and the legislator, the Church and the brothel, the Samaritan and the reformer, in hovel and in palace. It has taught me to be broad, to value men for what they are and not for what they seem to be. It has dissipated any prejudice I may have ever had and left me with the ability to see clearly, and I thank God that at least I was born in a republic, whatever may be the form of government I am destined to die under.

Government is the contract by which all agree to live together with as little friction and as much freedom as possible. There is no reason why one group should rule more than another. All are citizens, with the certain constitutional rights of all bound as fasces to give the added strength to union. One need not have any illusions about the character of the poor, or of the attitude of the rich. The composing of the differences existing in the ever-present struggle between the multifarious interests of the many callings is an occupation which is entitled to consideration, respect, and reverence. This is politics. It influences every act of our lives, grants or denies every wish, controls our birth and our burial, our movements from place to place by land, by water or air, the character of our residence, our food, the price of our labor, what we drink and when, how we drink it, our luxuries, our comforts, our possessions and what part of them we may keep for our own use. In fact, there is nothing in life, wherever and whoever we may be, that is not controlled by politics—the science of government, which, instead of being an object of derision and distrust to a free people, should be sacred.

I bring it to you because I am interested in you more than in those who follow any other calling, and because I want to awaken in you a sense of duty as citizens and arouse you to the fact that there is a definite, persistent and well-considered and thought-out plan to entirely change the republic of Benjamin Franklin, John Hancock, and George Washington to a socialistic democracy or worse, and that to stand idly by and not oppose it is a crime against ourselves and the calling which we represent.

To realize and understand the true gravity of the situation, we must visualize the unrest and bitterness of labor of all kinds that has obtained during this century; that powerful and often rival industrial organizations have arisen and been in almost constant warfare with the federal government and that of the states, and frequently with each other.

The labor unions of transport with those of the American Federation, always militant, have at times been obnoxiously so. A dictatorial spirit has evolved from these disturbances that a public opinion, adverse to them, has alone at times been able to curb. But in the main, they have been managed by intelligent men to whom the integrity of the constitution, as protector and guarantor of individual rights, means as much as it does to any other set of patriotic citizens. If at times they appear to be selfish, they are not supremely so. They are socialists only in the acquisition of power to control their wage, with no desire to divide it with anyone or submit to extortion on the part of their leaders. But while their aim to control the government has been continuously developed, it is their right to do so if it can be accomplished by legal means and lawful methods.

There are other groups, however, that have a hatred for all control by government and restraint even by their elected leaders, whose mission is to promote and originate factional industrial strife, creating and fomenting discord in the labor world, bringing it into disrepute so that the unions may be destroyed with the government when their masters determine the opportune moment.

During the fierce economic war of the Western Federation of Miners, in its struggle to control the mines of Western America in Colorado in 1903, one of these outlaw unions was created. A labor organization of revolutionary character, the Industrial Workers of the World, was born. I have already stated that my experience with human groups has been so varied that I usually have no difficulty in understanding their group psychology. It is generally easy for me to put myself in the other man's place. But I never have been able to disentangle the twisted political complex of an I. W. W. They are doctrinaires, inhuman and incendiary, who boldly proclaim their dogma—"that the working class and the employing class have nothing in common. Between these two classes a struggle must go on until the workers of the world are organized, as they believe, to do away with capitalization. They claim that there can be no arbitration or conciliation, and no contract is binding on employees. Life is a continual war against the capital class." They recognize any kind of direct action, by strife, fire, poison or bullet, either in mass or individual, against organ-

ized society as permissible and commendable if it is to assist in the winning of their objective.

To produce such a state of mind in a mass of men, who set themselves aside as a class and who go to jail by hundreds and inaugurate the hunger strike in order to impede and clog the courts so as to make more disorder to help the cause, indicates a sullen hatred engendered by a conscious or unconscious injury by someone representing the law, as described by Balzac in "The Country Doctor," published in 1832. "The men to whom power is momentarily conferred never think seriously of the effect in the long run of an injustice done to a man of the people. Such injustices keep up in the minds of the people a covert hatred against social superiority. The bourgeois becomes and remains an enemy to the poor man, who forthwith puts him outside the pale of law and deceives and robs him. To the poor, robbery is no longer a crime, but a vengeance. If when a question of justice to the poor man arises an administrator maltreats him and cheats him of his acquired right, how can we expect the unhappy, perhaps starving, creature to feel resignation at his wrongs or respect for property?"

The I. W. W. are never at peace. Always at war with their hands against all who are not affiliated with them. During the World War, they posed as pacifists and went to jail, sooner than fight for the country. With their purposes avowed, they still attract that foolish sympathy so usual in this country for the underdog, without inquiry as to why he is under. Because of their incessant clamor about injustice and martyrdom, active organizations of rich socialists like the Civil Liberties League defend them in the courts and assist them in every conceivable way in their struggle with the government.

But we have a greater and mightier force, for which the I. W. W. is as the prophet John, who went to prepare the way for him who was to follow. An organization not ephemeral, but rich and powerful, whose tenets and rules of conduct are widely different from the ethics which control daily life among governments. It was organized by Carl Marx in London, in 1864, and grew out of the association of English and continental workmen in the World Exposition two years before. It is the International Workmen's Association, known today as the Third Internationale. It had many vicissitudes, but ultimately became the breeding ground for anarchists of the Bakunin type, "propagandists by action," like Johann Most—the type that has destroyed so many European rulers and assassinated two of our Presidents and attempted the life of a third. But, after all, the revolutionary anarchist is dangerous only to those who are rulers. The Internationale has another lot of lawless children who are dangerous to the governments themselves—the syndicalists. Syndicalism is a political and industrial doctrine which demands "that the means of production be distributed to and the government turned over to those workers who are actually useful." Unrestricted force is its basis. It differs from the I. W. W., in that the latter looks forward to the eventual control being in the hands of one big union, while syndicalism uses the same weapon of pacifism to get rid of the army, inaugurating in a general strike a reign of terror, with violence and cunning obtaining political control by abolishing capital, destroying any police force that may attempt to restrain them, reaping the field that socialism has sown, which compels capitulation or, as in Italy, a dictatorship to escape it.

Long before the European war, the Internationale was strong in Russia. These followers of Marx divided themselves into the moderates, who were just ordinary advanced types of socialists; the Mensheviks, and the ultimates, or extremists; the syndicalists, the bolshevists. When German intrigue had broken down the Imperial Government of Russia, the mensheviks, the social democrats were, for a short time, in power, but under the rhetorician, Kerensky, who could talk but not act, it did not take very long until the intrepid, cunning, wise, powerful and unscrupulous doctrinnaires, the syndicalists of the Internationale, though in a minority, had seized the government and established the soviet—a word which, signifying council and concord, has become synonymous with absolutism and discord, chaos, and disaster. Their leader, Lenine, "offered to the oppressed toiling masses the opportunity to participate actively in the free construction of a new society, a higher form of democracy, the organized form of the dictatorship of the proletariat."

These men who had had their program long prepared were men of action and not of words. Many of them were not even Russians, but all were men admirably fitted for the task they had undertaken. They immediately proscribed the following classes, in that all those who employed others for profit, those living on incomes not derived from their own work, from interest or capital, industrial enterprises, or landed property, private business men of all kinds, including all of the learned professions, middlemen, priests of all denominations, those who had been connected with the police, lunatics and criminals, were not allowed to vote or have voice in governmental affairs. Then this band of criminals, commanded by, as events subsequently proved, a paretic, proceeded to put into effect a scheme of government which, for oppression and murderous malignancy, destroying untold millions of human lives and reducing to poverty and misery all of the creative and administrative intelligence of the land, has never been equaled in any other revolution since the world began. At first, and for a long time, their government was an interesting experiment for the philosophic looker-on and even now, if its results were confined to the country in which it was tried, the interest of other peoples might be only an academical one, for it is axiomatic that the people of a country ultimately obtain the government to which the degree of their intelligence and their virility entitles them. But guided by their idol with the luetic brain, a human Robot, without conscience, faithless, denying the sacredness of any pledge, and of all financial responsibility, they complacently left their subjects to starve while spending the money which they had acquired from the government preceding them, and all that they could extort and rob wherever it could be obtained from private purses, banks, industrial establishments and churches in all Russia so that they might, by bribery and corruption, through the agents of the Third Communist Inter-

nationale, undermine and overrun all the other governments of the world, spending only at home what was necessary to acquire and maintain a great Red army to suppress all freedom of speech and action at home and prevent any counter-revolution, and to be used, if necessary, like that of Mahomet to force the doctrines upon an unwilling world by conquest.

The Soviet Government at Moscow is now the absolute rulers of all Russia, and is synonymous with and controls the Third Communist Internationale. It is and has been for over four years the bitter and persistent enemy of this republic, seeking to destroy it by the silent process of attrition. Many of its leaders have lived in our country and speak our language, and know that two governments supposedly democratic in principle, but as widely different as the sun and darkness, cannot exist together on this earth, and that for the survival of their own chosen form ours must be destroyed. Controlling an imperial purse and indifferent to the economic condition of their subjects, they have much conscious aid among our own people who take, as Judas did, the pieces of silver. The proofs of this are and have been in the possession of our government at Washington, gathered at home and abroad by the agents of the State Department and the Department of Justice under both the Wilson and the Harding administrations, according to the public admissions of the Attorneys-General and the statement of Mr. Hughes, our Secretary of State, and recognition of their government has been steadfastly declined on the ground that it would be opening the door of our house to an enemy. Take heed from the Scriptures: "But know this that if the good man of the house had known in what watch the thief would come, he would have watched, and would not have suffered his house to be broken up."—Mathews xxiv, 43. But know this: A million thieves are boring from within; the shutters are loose and the threshold is worn.

The most of us have contributed to the delinquency of our government, state and national, by fervor or by lack of understanding. Intelligentsia have no place under a Soviet, except in jail or the grave. Before we face a civil war, let us go back to the republic which has its best protection against aggression from without and dissension from within, in its possession of an unceasing flow of unending millions of young voters with sound bodies and sane minds to obey its fiats and uphold its laws, and this may only be obtained by a common compulsory military training, which adds to the principle of universal suffrage the appreciation of its honor, and breeds a willingness to make any sacrifice to uphold the government, which assures its permanency.

I bow the knee to General George Washington, who, rising from the President's chair in the constitutional convention 137 years ago, when palliatives and half-measures were suggested in the debate, in the fear that the people might not approve it, and speaking with suppressed emotion, said:

"It is too probable that no plan we propose will be adopted. Perhaps another dreadful conflict is to be sustained. If, to please the people, we offer what we ourselves disapprove, how can we afterward defend our work. Let us raise a standard to which the wise and honest can repair. The event is in the hands of God."

RELATION OF SURGERY AND RADIOTHERAPY IN THE TREATMENT OF MALIGNANT DISEASES *

By REX DUNCAN, M. D., Los Angeles

The undiminished, if not increased, mortality rate from malignant diseases would seem to indicate that little has been accomplished in the prevention or treatment of cancer. As a matter of fact, however, considerable progress has been made. Our failure to reduce the mortality rate is due not so much to our lack of knowledge as to our failure to apply to the individual case that treatment, or combination of treatment, which experience has shown offers the greatest prospect of benefit or cure. Propaganda for the purpose of educating the public and the profession has undoubtedly led to the earlier recognition of malignant diseases and the treatment of early malignant conditions. While this is extremely important, we must demonstrate to the public and profession statistically our ability to cope with malignant diseases.

The treatment of malignant diseases necessarily depends upon the characteristics of the individual case. First, it is necessary to determine definitely the location and character of the disease and possible extension or metastasis, as well as to ascertain definitely the patient's general physical condition. Secondly, one must possess a thorough knowledge of the clinical course of the type of malignancy existing. Third, it is extremely important to know the histopathological characteristics of the particular neoplasm. Fourth, one must possess sufficient training and experience with the various methods of therapy to determine that type of treatment or combination of methods which offers the greatest possibility of cure.

Recent developments in the histopathological studies of neoplasms have added a new and ofttimes determining factor in our consideration of the treatment of malignant diseases. It is no longer sufficient for the pathologist to tell us that the neoplasm is simply benign or malignant, but he must tell us more definitely of the degree of malignancy. The most important factor with which we have to deal in carcinoma seems to be the degree of cellular activity. The more a carcinoma tends to differentiate, that is, resemble normal tissue, the lower is its degree of malignancy. Conversely, the more embryonal or more undifferentiated the cells the higher the degree of malignancy. Upon these facts Broders, in 1919, classified epithelioma of the lip into four grades. His plan of grading dependent upon the degree of cellular activity is briefly as follows: Grade 1 is an epithelioma, which shows about three-fourths of its structure differentiated and about one-fourth undifferentiated, with no mitotic figures and no "one-eyed" cells. Grade 2. If the percentage of differentiated or undifferentiated epithelium are about equal, with an occasional mitotic figure and "one-eyed" cells. Grade 3. If the undifferentiated epithelium forms about three-fourths and the differentiated about one-fourth of the growth, with

*Presented to the General Surgery Section at the Fifty-second Annual Session of the California Medical Association, San Francisco, June 22, 1923.

numerous mitotic figures. Grade 4. Where there is no tendency for the cells to differentiate, with numerous mitotic figures and "one-eyed" cells.

This work has been extended by Broders, ourselves and others to cover carcinomata in general. During the past year, in our laboratories we have demonstrated that carcinomata undergo progressive changes in their grades both in the primary lesion and in the metastasis which explains the sudden and rapid progress in certain cases of cancer. We have carried the work further to demonstrate the relative radio susceptibility of the different grades, which work is to be published in detail. Broder's studies cover a series of 537 cases of epitheliomata treated surgically at the Mayo Clinic. A division of the epitheliomata according to cellular activity on the basis of one to four, and the mortality according to grades is as follows: Grade 1 represents 15.82 per cent and a mortality of 11.12 per cent; Grade 2, 61.1 per cent and a mortality of 33.33 per cent; Grade 3, 21.4 per cent and a mortality of 75.38 per cent; and Grade 4, 1.11 per cent and a mortality of 100 per cent. Inasmuch as this relation in the grade and mortality applies to carcinoma in general it is quite obvious that operability is not dependent entirely upon the anatomical distribution of the disease, and that even in so-called operable cases surgery has its distinct limitations.

In more than one hundred cases of carcinomata treated in our institution during the past year, we have been able to make certain histological studies both before and at various intervals after these tumors have been exposed to irradiation. Microscopic sections were made before radiation in order to determine the degree of cellular activity and to ascertain the particular cell type. After radiation, sections were studied at fixed intervals in order to determine histological changes which had taken place. Histological changes produced in cancer, as a result of irradiation, were similar in all four grades. There is a marked difference in their degree of susceptibility. Grade 1, which more closely resembles a normal tissue, is more resistant, while grades 2, 3, and 4 are more sensitive, respectively, as they are more embryonal in type. We have demonstrated that the radio susceptibility in cancer depends in a marked degree upon the histopathological characteristics or grade of the neoplasm, the age of the host, and the quantitative relation of the pathological to normal tissues. These points are of particular importance from a surgical standpoint. Grade 2, which offers a poor surgical prognosis, and grade 3 and 4, which are practically hopeless from a surgical standpoint, are most susceptible to radiation therapy, and should always receive radiation either alone or in combination with surgery, dependent upon the characteristics of the individual case. The second or quantitative relation of pathological to normal tissues, particularly in Grade 1 and 2 carcinomata, explains the necessity for surgical combination, with radiation in certain cases that would offer a poor prognosis from either method alone. There are certain types of massive breast tumors with metastasis, generally considered inoperable, that do, with preliminary radiation, consisting of the burying of radium emanation tubes and high voltage x-ray, radical surgery and post-operative radiation, yield surprisingly good results. Large, malignant papillary and cystic tumors of the ovary yield remarkably well to combination treatment. The same principle applies to a large number of neoplasms. I would particularly stress, however, the extreme importance of adequate preliminary radiation in these cases.

Murphy and Wood have each demonstrated, experimentally, that cancer cells previously radiated do not transplant favorably, and also that normal tissues previously subjected to radiation are an unfavorable medium for the growth of transplanted cancer cells. These observations confirm our studies and explain the pre-operative value of radiation in neoplastic diseases, which produce not only inhibitory or destructive changes in the cancer cells, but render the normal tissues an unsatisfactory media for their development, and also explains why even certain cases of incomplete surgery with preliminary and post-operative radiation may yield surprising results. We should, however, bear in mind the old axiom that incomplete surgery alone in malignant diseases always hastens death.

Treatment, then, must depend upon the application to the individual case, all of the pertinent facts previously referred to, combined with a broad clinical knowledge and experience.

Unfortunately, our medical training has taught us to look upon malignant diseases from a purely surgical standpoint. If operable (the term operable has an extremely broad interpretation), such surgical procedure is undertaken as the training and ability of the individual surgeon permits; if inoperable, or recurrent, a hopeless prognosis is rendered, and the patient is either sent home to die or referred to someone, usually the radiologist for palliative treatment. This attitude may have been justifiable twenty years ago, but certainly the progress in other methods of therapy, together with the clinical value of the pathological study of the neoplasm, necessitates a complete readjustment of our ideas regarding the treatment of malignant diseases. An unprejudiced study of the abundant statistics, extending over a period of years, demonstrates quite conclusively the value and limitations of surgery alone. The past ten years have seen a marked development in radium therapy, and during the past two years tremendous progress has been made in x-ray therapy. The shorter time for observation is more than compensated for by thorough histological studies of the effect of radiation upon neoplastic and normal tissues.

Adequate facilities for the use of radium emanation permits of a much more elaborate technique and greatly increases the scope of radium therapy. In those cases in which it is possible to effect an equal and homogeneous radiation with radium—and for this purpose the burying of the emanation tubes is of extreme value—the effect upon the neoplastic tissues is in many instances more favorable than that obtainable by x-ray. However, recent developments in x-ray make it possible, with high voltage equipment, to effect a homogeneous radiation of the neoplasm in any part of the body without injury to the overlying or adjacent tissues and without serious

constitutional disturbances. We have had an opportunity to observe, during the past eight years, microscopically and clinically, the local and constitutional effects of radium therapy in nearly four thousand cases and more than five hundred cases treated with high voltage x-ray therapy during the past two years.

The time is not propitious for a detailed discussion of radio therapy, but suffice to say that we have, with proper equipment and technique, facilities permitting the employment of radium and x-ray, either alone or in combination, as a means of effecting or destroying malignant cells in practically any portion of the body. Neither is it within the province of this paper to attempt to outline in detail the precise method of treatment of any of the numerous types of malignant diseases; rather would I emphasize the basic principles underlying the intelligent treatment of neoplastic diseases, leaving their precise application to a more exhaustive discussion of certain types or individual cases.

While less study has been given to sarcoma and other types of neoplastic diseases, in a general way the same principles apply as in the treatment of carcinoma, although, on the whole, sarcoma is less favorable from a surgical standpoint.

There is sufficient statistical material available covering certain types of cases based largely upon their anatomical distribution to permit of a comparative value of various methods of treatment. As an example, we may cite cervical carcinoma, in which radium therapy alone yields clinical cures in 75 per cent of the earlier or operable cases as against approximately 20 per cent from the most radical surgical procedure. Willis, in a recent report, covering the operative end-results of more than two thousand cases of carcinoma of the breast treated by our most capable surgeons, shows clinical cures for a three-year period of approximately 35 per cent as compared with recent reports by Lee, Sittenfield, and others, showing clinical cures of approximately 85 per cent from combined radiation and surgery. Lymphosarcoma, on the other hand, is strictly a non-surgical condition yielding favorable results from combined radium and x-ray therapy. In superficial epitheliomata there are obtained not only a higher percentage of cures, but much more favorable cosmetic and functional results with radium than by x-ray or surgical methods. In malignant diseases involving the bone, surgical methods, preferably cautery, combined with radiation therapy is essential.

It is obvious, from a consideration of the above, that the treatment of malignant diseases is not a matter to be considered from the standpoint of any single method of therapy, but requires a thorough knowledge of the various therapeutic methods, as well as a thorough understanding of the pathological and clinical course of the disease.

A broader and more intelligent application of the above factors to the treatment of the individual case would relieve untold suffering and yield a higher percentage of cures, improve our mortality statistics, regain the confidence of the medical profession and the public, and prove a determining factor in solving the cancer problem.

1052 West Sixth Street.

DISCUSSION

John M. Rehfisch (391 Sutter Street, San Francisco)—A paper like this of Duncan's is a very welcome addition to the literature in these days, when the schoolmen of radiology both in this country and abroad are exercising their wits in the pursuit of the new philosopher's stone, the cancer dose. Duncan lays emphatic stress upon the complicated multiplicity which underlies the superficial, simple unity of malignant manifestations. He has chosen to lay special emphasis upon the morphological differences which influence the reaction of tumor cells, and has ignored other less well-known—perhaps hardly even guessed at—biological factors which, undoubtedly, play at least as important parts in tumor growth and control.

In the present state of our knowledge, and with the present necessity upon us of weaning the unwary radiotherapist from the dangerous doctrine of the cancer dose, it is probably wise to stick, as Duncan has done, to items of propaganda that are susceptible of physical demonstration. Let us hope that the biologists will shortly give us other biologic data even more important than the morphologic on which to base our theories and our practice of radiotherapeusis.

I wish most heartily to second Duncan's plea for more consistent combination of surgery and radiotherapy with the employment of pre and post-operative courses of radiation. Many surgeons are missing opportunities for improving their results in malignancy by adhering to their old and formerly quite justifiable custom of inviting the aid of the radiotherapist only in their hopelessly advanced, and sometimes their moribund cases. Little by little, by demonstration and by precept, we should seek to do away with the widespread surgical preconception and prejudice that radiotherapy is a placebo for the hopeless and a gentle and harmless diversion for the dying.

Edwin I. Bartlett (291 Geary Street, San Francisco) — Conflicting opinions between radiotherapy and surgery values in the treatment of cancer are naturally stronger among those whose training and experience has been more highly developed in a limited field. Then, too, evidence in both fields is frequently inconclusive because of competition or prejudice. Radiotherapy is a therapeutic agent of increasing value, but it will not now accomplish all that some of its enthusiastists claim for it. Conservatism is a necessity if radiotherapists are to give patients the greatest number of chances for a cure, and if they are to retain the confidence of the medical profession.

The use of radium against malignant disease is still in the stage of experimentation, and must necessarily remain in this state until more is known about its biological reaction and more definite rules for dosage are established. Statistics and discussions of the comparative value between surgery and radium in the treatment of malignancy are unfortunate, and do not add to progress in the prevention and cure of these diseases. Most experienced students believe that where surgery cannot accomplish a cure radium also fails, while, on the other hand, where radium fails, surgery may accomplish a cure. In other words, surgery fails only where the disease cannot be eradicated or reached. When there are metastases, radium is not effective and surgery seldom so.

This statement is supported by pathological examination, follow-up records over long terms of years, and frequently by autopsy reports. It is not dependent upon "surprising results" or "clinical cures" based upon a record over a term of a few years. It may be true that a totally undifferentiated epithelial cell is very susceptible to radium, but this does not prove that radium should be employed in place of surgery

in cancer of the lip; the cases cited by Duncan ultimately died of metastases over which radium had no control, regardless of the degree of differentiation. On the other hand, if the type of cancer which invariably metastasises is not curable by radium because of that fact, and the type which does not metastasise until very late is extremely resistant to radium, then why is it not better to use surgery first in all cancers of the lip? It is admitted by all that radium will frequently get rid of the local lesion, and when combined with proper gland dissection may yield as satisfactory a result as surgery. Furthermore, in many localities and in non-metastasising growths its use in the treatment of the primary lesion is decidedly preferable. If we cannot realize, however, its limitations, radium will prove a curse rather than a blessing, under the present knowledge as to its action. One cannot help being enthusiastic about anything which promises cures in cancer, but for the present we cannot afford to give precedence to any physical agent where proper surgery holds out proven opportunities for a cure. The locations where radium treatment is most promising are the same locations where surgery has already fully demonstrated its curative value.

Frank W. Lynch (University of California Hospital, San Francisco)—Doctor Duncan states that our present knowledge concerning cancer forces a revision of the idea that the treatment of malignant disease is purely surgical, to which all cancer students unhesitatingly agree. Of that there can be no possible doubt. As a reason for his belief, Duncan states that, working along histopathological lines, he has been able to classify his own cases so that he may select radium or radium and surgery as a proper method of treatment for an individual case.

His article presents chiefly propaganda, and from that standpoint merits no criticism, because there is no doubt that there are an enormous number of surgeons who are as yet unconscious of a fact that has been established for years; i. e., that surgery can cure only such cases as permit of the removal of the entire cancer-bearing area, except in a few types of a semi-malignant growth. Since early, or operable growths, are unfortunately extremely rare, radium or high voltage x-ray should be used for the very great majority of cancer cases now being presented for treatment.

From the standpoint of a scientific article, however, Duncan's paper is open to many criticisms. Thus, he presents no detail of his own investigations (although he promises it later) so that others may pass upon them. This would be unimportant were it not for the fact that Duncan urges a further restriction of surgical procedures and a corresponding increase in radium and x-ray therapy. Even at that, there could be no objection to this doctrine if cancer therapy is to remain in the hands of the general practitioner; but Duncan states, at the beginning of his paper, that one who undertakes the treatment of malignant disease must possess not only a comprehensive understanding of the structure of the neoplasms, but also of its individual methods of growth so that he may select the type of therapy which is best adapted to the individual case. This would remove the treatment from many practitioners. From the standpoint of the specialist, we must judge the paper.

Duncan, unfortunately, misquotes the literature—a most serious error, since many men who do not have a first-hand knowledge of the literature quote from this type of paper and develop their own method of therapy from them. The misquotation to which I refer is in reference to cervical cancer. He argues that "cervical carcinoma, in which radium therapy alone [is used] cures 75 per cent of the earlier or operable cases, as against 20 per cent from the most radical surgical procedures."

The facts are quite different since a radical operation in a properly selected case cures upward of 50 per cent. The most radical procedure for the treatment of cancer of the uterine cervix is that of Ries. This surgeon reports that, of thirteen cases surviving operation, seven were alive, one living twelve years, one eleven years, one ten years, two nine years, and one seven years. The seventh case was counted lost sight of, although she returned with a growth in the inguinal canal nine years after operation, was reoperated, and followed for one year later. The ordinary radical operation for cancer of the uterine cervix is that of Wertheim. These reports are in recent text-books. Wertheim's series comprises 863 cases, of which 36 refused operation, 447 were inoperable, and 380 were operated. There were 160 cases which were free from recurrence at the end of five years' observation, or 53 per cent of the cases surviving operation, or 43 per cent of the cases operated, or 19½ per cent of the entire number of cases of operable and inoperable cancer which were presented for treatment. Cobb, in Boston, reports that 83 per cent of his private cases ssurvived a five-year period of observation and reported without recurrence. In nearly all series, surgeons have excluded the cases which died following operation from the list from which they calculated their percentage of cures. Strictly speaking, therefore, these operative results should be reduced approimately 2 0per cent for operative mortality if you desire to contrast them with the results of radium. Duncan's statement, therefore, is a serious error. Had he said, however, that surgery did not cure 20 per cent of the women operated on throughout the country for cancer of the uterine cervix, we would be compelled to say his percentage of estimated cures were too high. He did not, however, so state.

If the surgeon is in error for various definitions of the term "operability"—and there is no doubt but that he is—the radiologist has to answer usually for a more serious fault. It has taken the surgical world a full generation to learn that no case can be counted a cure that has not stood for a minimum of five years. Many cancer students insist upon seven, since Weibel has shown that 6.6 per cent of Wertheim's 169 cases which had stood for at least six years developed carcinomatous recurrences in the pelvis six to eight years after operation. In spite of this, the radiologist has flooded the literature with reports of "clinical cures" that have stood for comparatively few months. It seems a pity to thus confuse the literature. While anyone can get nearly any type of statistics he desires from any literature, it is well worthwhile to turn to the reports of Bumm of the University of Berlin, considered by many one of the most brilliant of the European operators and one who has had an extremely large experience in radiotherapy. His report reviews his own series of early and operable cases, some of which were treated by operation alone, while others received only radium. Only 28½ per cent of fourteen operable cervical carcinoma which were radiated and not operated remained cured for a five-year period. Of 157 similar cases operated and not radiated, seventy-seven, or 49 per cent, were well after periods from six to eight years. Bumm emphasizes that the percentage of cures after radium in operable or border-line cases of carcinoma of the cervix was one-third less than that obtained by operation if the cases had stood for six years. When the cases are observed for a period of only three years, the results of radium far surpass those of operation. These figures, while in accord with the facts, confirm in another way that he who would treat cancer properly must be prepared to use surgery, radium, and high voltage x-ray.

R. E. Skeel (The Westlake Professional Building, Los Angeles)—Doctor Duncan's paper is of so general a character that its discussion is difficult, but two features perhaps may be specifically mentioned. Microscopic diagnosticians have known for years that certain cell characteristics indicated that some growths were possessed of a higher degree of malignancy than others, but I believe it will be a considerable time before a definite classification can be adopted on this basis, and it never will be possible to consider this alone to the exclusion of clinical

signs, duration of the growth, its location, etc. There is no doubt, however, that this attempt is a step in the right direction, and its continued study is judicious.

Speaking generally, the trend is away from the huge, high mortality, radical operation for advanced or moderately advanced cancer, since the ultimate outcome in the individual case is bad, and the effect on the public mind such as to discourage operative procedures upon patients in whom operation might prove curative.

Thus in cancer of the cervix, while I remain skeptical as to the permanent cure of even the moderately advanced case by any method of treatment, I am convinced that palliative methods prolong life and relieve suffering, and of these methods radiology is by all means the most promising. It is conservative to say that the high mortality extensive operation carries with it no better "clinical cure" outcome, while every operative death or early recurrence makes many potential enemies for all surgery in cancer.

"Early cancer extensive operation, late cancer little or no surgery," is the best surgical motto, and to this radiological treatment adds an element of hope not to be obtained in any other manner.

Doctor Duncan (closing)—The purpose of presenting this paper was to urge more careful study and broader consideration in the treatment of malignant disease, particularly referring to certain scientific work that unquestionably demonstrates that radiation therapy is a very valuable adjunct. It is unfortunate that many men who consider themselves competent to discuss and treat malignant disease surgically and otherwise have little knowledge of the pathological aspects of malignancy, a very limited clinical experience, an incomplete knowledge of the literature and—as would naturally follow—decidedly prejudiced opinions.

Replying to Lynch's criticism of my statistical reports, I would suggest that he review Janeway's paper, which was the most comprehensive statistical report on uterine cancer covering approximately 6000 cases reported by various surgeons throughout the world. And I further repeat, that based upon this report of a large number of cases operated by numerous surgeons, that the ultimiate clinical cures resulting from surgery alone in early cervical carcinoma were less than 20 per cent. It is quite true that there have been reported small series of carefully selected cases operated that yielded a much higher percentage of cures; however, this would include such a small percentage of the actual cases of uterine cancer and of those actually operated on as to be of little real statistical value.

I agree with Lynch when he says that "He who would treat cancer properly must be prepared to use surgery, radium, and high voltage x-ray," but would add, with emphasis, that he must also have proper facilities and training, as well as a thorough understanding of malignancy to use them in their proper relation. Referring also to a more detailed report of our investigation, I would refer the doctor to the article entitled, "The Grading of Epitheliomata and Their Radiation Sensibility," published in the New York Medical Journal, page 681, under date of December 5, 1923.

An opportunity to observe thousands of cases of malignancy treated by various methods during the past ten years has convinced me that we all have much to learn regarding this disease. However, there is no question but that a thorough study of the individual case and a less prejudiced and broader use of various methods or combination of methods of therapy of proven value would yield more favorable results in the treatment of malignancy and as a consequence increase the confidence of the public and the profession in our ability to cope with malignant diseases.

THE SECOND GREAT TYPE OF CHRONIC ARTHRITIS IN ITS RELATION TO INDUSTRIAL ACCIDENT CASES *

By LEONARD W. ELY, M. D., San Francisco

The relationship of trauma to the second great type of chronic arthritis is a question of frequent recurrence in industrial accident cases, and seems as far from settlement as it was years ago. Opinions differ radically, and cases are argued again and again, coming up periodically for adjudication. Sooner or later the problem must be solved, and as a step to the solution I am bringing it up for discussion at this meeting. Let me state the problem as it usually presents itself. A man at work falls; or he twists, wrenches or strains his spine or one of the larger joints of an extremity. Immediately, or after a short interval of time, he complains of pain. If the injured joint is of an extremity the pain is felt in the affected joint; if the spine is injured, the pain is felt in the back or running around the trunk, or more frequently down the lower extremities. Less often the pain runs down the arms. X-ray films are taken, and show the spurring and lipping characteristic of the form of arthritis known by so many different names—hypertrophic arthritis, degenerative arthritis, osteoarthritis, arthritis deformans, etc., etc. What relation has the injury to the arthritis, or, more exactly expressed, what relation has the injury to the bone and cartilage changes plainly shown by the X-ray film?

In the past the opinion has been strongly held that the bone changes were the direct result of the trauma, but of recent years this view has been challenged on many grounds, viz.:

1. In almost every disease of bones and joints, trauma has been advanced as the cause. As our knowledge of the disease has increased, the impossibility of trauma causing it has been demonstrated. This is true of tuberculosis as well as of other infectious processes.

2. Bone can be injured in one way only, and that is by fracture. It cannot be strained, sprained, or suffer contusion. Trauma either fractures a bone or leaves it uninjured. In the absence of a fracture, bone can be attacked only by a disease of its contained marrow.

3. The gross bony changes existing in these cases must take a long time for their formation. It is impossible that they would appear on an X-ray film taken a day or two after an injury if they had not been there already. They must have been present before the injury. This view is substantiated by the presence of the same changes in other uninjured joints, radiographed at the same time. In the spine especially, when the pain is felt in the lumbar region and running down the legs, the X-rays may show more or less extensive involvement, perhaps of the entire spinal column.

4. This disease is seen almost invariably in persons of middle and later life. It is unknown in children. It occurs almost exclusively in persons

* Presented to the Section on Industrial Medicine and Surgery at the Fifty-second Annual Meeting of the California Medical Association, San Francisco, June, 1923.

whose alveolar processes have abscesses at the roots of their dead teeth. Young people injure their joints as much as older people, but, immune from these root abscesses, they are immune also to the disease under discussion. On the other hand, the disease occasionally is seen in persons with sound teeth.

5. Intestinal parasites have been found in the stools of a large proportion of the patients, and are suspected as the cause of the bone lesions. Their portal of entry is assumed to be in the great majority of cases the suppurative osteomyelitis at the roots of the teeth.

In a case like this, when opinion is so divided, the solution is often found by laboratory study. I might instance pulmonary tuberculosis and appendicitis. Clinical study was unable to find the cause of either disease.

The gross changes of this type of arthritis have been known for a long time. They have been recognized in Egyptian mummies, it is said, and since the introduction of the Roentgen rays, their frequency has been appreciated. On the other hand, the histological changes have received rather scant notice, though a few writers have given excellent descriptions of them, notably the late Dr. Nichols of Boston. They have always been rather mysterious. Their sequence was hard to figure out. Given the original tubercle in bone marrow, what followed then in the bone, cartilage and joint was quite comprehensible, but in the second type of arthritis we noted the remarkable changes in the bone and joint tissues, and could not detect what was behind them. No reliable evidence of any bacterial infection ever has been adduced.

Three years ago I called attention to the areas of aseptic necrosis in the marrow in the immediate vicinity of the joints in specimens of this type of arthritis, and ascribed to them the primary role in the pathology of this disease. Since then I have accumulated more material, and have confirmed the observation repeatedly. They constitute the fundamental change. What follows in the bone and cartilage is the result, and its sequence upon the primary necrosis in the marrow is comparatively easy to understand. The pathological changes in the tissues in and about the joint may be briefly enumerated, more or less in the order of their occurrence:

1. Bone production immediately under the articular cartilage, and especially at its circumference. This bone formation probably extends into the ligaments for a short distance, giving the appearance of the spikes and spurs seen in the X-ray films, but not extending from bone to bone to produce a bony ankylosis, except possibly in the spine. It forms a layer of greater or less thickness under the articular cartilage, causing it to degenerate. More or less of the cartilage is also transformed into bone. Bone formation also goes forward within the bone, but not to a marked degree. The necrosis in the marrow causes a preponderating bone absorption, and this bone absorption can usually be detected in the X-ray film, if it is looked for. All these changes take time to produce; hence, if they are present a few days after the occurrence of an injury, we know that the injury did not cause them, but that they were there before.

2. Part of the articular cartilage may be transformed into bone, as has already been said. As the result of the damage to its nutrition the rest of the cartilage becomes fibrillated, degenerates, and then, in whole or in part, wears away, leaving the subjacent bone bare. This thickened subjacent bone becomes polished like ivory (eburnated), and becomes grooved in the line of joint motion.

3. The synovial membrane becomes thickened, fatty, fibrous, and villous. In other words, as the result of the bone and cartilage changes, which have distorted the joint, and probably exclusively as the result of the trauma occasioned by the ordinary use of the joint, viewed as a damaged machine, a chronic synovitis or arthritis is added.

The changes enumerated above may occasion considerable pain, but more often do not. On the other hand, a badly affected joint may be comparatively painless for a long time, and then, without known cause may become very painful. The pain may become so severe that a resection of the joint offers the only relief. Sometimes the disease is painless, and then the characteristic changes appear as accidental findings in the X-ray films.

Let us now state the problem as it exists in industrial work: A man falls, or wrenches one of his larger joints, particularly one of the joints of his spine. He complains of pain and disability. The radiogram shows the characteristic changes of this form of arthritis. After a greater or less time the man complains that the pain and disability have continued, and puts in a claim for permanent disability. Just what relation does the injury bear to the case? I have maintained for some time that all results of the injury were only temporary, and I have reached this conclusion along two lines of reasoning:

1. We have been paying especial attention to this disease at the Stanford Medical School for a number of years, and I do not remember to have seen a case unconnected with accident work in which a simple trauma resulted in permanent disability. The disease is very frequent. We can usually count on about 100 cases a year out of about 1000 patients. Many of our patients give no history of trauma. Some date their symptoms from a trauma, but we expect the symptoms referable to the trauma to subside in a few weeks. Thereafter we look for the disease to take its natural course. If intestinal parasites be eradicated in either case, and if all dead teeth be removed, all symptoms may subside in the milder cases, but we always remember that the pathological changes are permanent, and look on the joint as we would upon any other damaged machine. If it be required to perform the work of a normal joint, or if it undergo a slight strain or sprain that in a normal joint would pass unnoticed, pain, stiffness, and limitation of motion may recur. No operation can restore the normal contour of the articular surfaces, nor make normal cartilage grow over the roughened end of the bones.

2. The second objection to the traumatic theory is the loose and vague employment of the word "trauma," a looseness and vagueness unknown in the discussion of organs other than bones and joints. Just what is this trauma? One does not speak of

a trauma of the appendix or muscle. The appendix may be ruptured, the muscle may be contused, severed or lacerated. Leaving out the results of penetrating wounds, we can conceive of two things only which trauma can do to the joint tissues. It can cause an intra-articular fracture or a sprain.

The presence or absence of a fracture can be demonstrated by the Roentgen rays.

The symptoms of a sprain subside in a few weeks.

There is one important aspect of the great second type of arthritis in its relation to industrial accident work, as well as to other surgical work, that has not received the attention it deserves. I allude to its relation to intra-articular fractures. To it are probably due the stiffness, pain, and restriction of motion following intra-articular fractures in elderly persons, and the only rational explanation we can make for this fact is that the fracture set free into the joint the infectious material previously locked up within the bone.

I wonder that we have been able for so long to plead this connection between the great second type of arthritis and trauma. Some day, I feel sure, the thought will occur to some examining attorney of penetrating acumen to ask the medical expert the simple question, just what is this trauma and how does it act?

California Northern District Medical Society (reported by C. J. Durand, secretary)—At the thirty-fifth semi-annual meeting of the California Northern District Medical Society, held in Sacramento on January 22, C. E. Schoff of Sacramento was elected president and C. J. Durand of Colfax was elected secretary.

The thirty-sixth semi-annual meeting of the society was held in Colfax on April 22, thirty-eight members being present. The morning session, held at the Colfax School for the Tuberculous was in the form of a clinic on artificial pneumothorax in the treatment of pulmonary tuberculosis. Robert A. Peers and his staff did some fluoroscopic work, demonstrated x-ray plates of compressed lungs and made two actual lung compressions. Luncheon was served at the Standard Oil Sanatorium, through the courtesy of Louis P. Howe, chief surgeon of the Standard Oil Company of California. The afternoon session, held at the Colfax Theater, comprised four papers. F. F. Gundrum of Sacramento spoke on "Spirillosis" and gave a clear outline of Vincent's angina, its diagnosis, divers manifestations, complications and treatment. He was followed by F. J. Conzelmann of Stockton State Hospital, whose subject was "Mental Sickness." This paper covered the subject very thoroughly, discussing diagnosis, emphasizing the need of more study in examination of the patient and taking up in detail the different phases of insanity and the psychoses. Another paper on "Psychotherapy in General Medicine" was given by V. H. Podstata of Livermore. This paper was of great interest and contained many practical details for all present. Leo P. Bell of Woodland treated the subject of "Supra-pubic Prostatectomy Under Regional Anaesthesia," illustrated with lantern slides. Each one of these papers proved of general interest to all present and provoked much timely and valuable discussion.

You who dream of the great things to come, why don't you commence? Why do you wait for the campaign, the posters, the meetings, the influential names, the backing? Why must you float on rivers of ink? Why must you start where the toilers left off? Begin!

ERRORS IN DIAGNOSIS OF ABDOMINAL CONDITIONS *

By WALTER WESSELS, M. D., Los Angeles,
(From the Department of Clinical Medicine, College Medical Evangelists.)

Progress is made in all lines, including medicine, by profiting from experience, especially from mistakes. In an active practice it is fitting to occasionally pause and survey our own work, take stock as it were; thereby anticipating future repetitions of the same mistakes. Each of us can recall many blunders, but unless these mistakes help us they are in vain.

In such a survey recently made, the disclosures have been of so much interest to me that I thought it might be of sufficient import to share a part of this experience with you.

The cases about to be reviewed are from the records of the Los Angeles General Hospital, and from my own files. Needless to say, they represent only a *few* of our mistakes.

The Stomach—Davidson says, "With the possible exception of carcinoma, there are no primary diseases of the stomach." When we think of the stomach as one of the earliest embryonic structures, and that the organ may be removed with impunity, one may indeed pause. While the above statement is too broad, still there is an element of truth in it. If we look up primary chronic gastritis in any textbook on internal medicine, we find many pages devoted to this subject; yet, excluding alcoholic gastritis, toxic gastritis, and achylia gastrica, we have rarely seen any cases of primary chronic gastritis in a practice extending over twenty years, although many cases have been referred with this diagnosis. When a study of the case is made, we usually find either ulcer, carcinoma or secondary gastritis due to anemia, cardiac, hepatic or renal diseases. In our experience, nephritis is the most frequent condition sent in with the diagnosis of chronic gastritis.

Example — A woman of 45 years, after being treated for persistent vomiting of mucus, which occurred several hours after eating, and with diaphragmatic pain (from retching), was sent in with a diagnosis of gastritis. The stomach symptoms had overshadowed everything else, as a urinalysis cleared up the true condition, and a study of the blood chemistry corroborated the diagnosis of nephritis.

Exanthemata — The exanthemata are often mistaken for acute gastritis on account of the vomiting, but as this occurs mostly in children who are under observation in the home until the true nature of the condition is disclosed, I rarely see them.

Not infrequently children have had appendecectomies performed on account of the reflex abdominal symptoms due to pneumonia or pleurisy, but occasionally the exanthemata with enanthem may present baffling symptoms.

In April, 1922, a young man of 18 years was sent to the General Hospital. He had been ailing for a few days. On the day of admission he had a slight temperature, a slight cough, abdominal pain, vomiting; diffuse abdominal tenderness, especially

* Read before the Nevada State Medical Association annual session, Reno, September, 1923.

at McBurney's, with slight rigidity; W. B. C. 14,000; urine negative. An appendecectomy was performed the same day. The pathology found was insufficient to account for all the symptoms. On the next day he developed the typical rash of measles, and the diagnosis was disclosed. The abdominal symptoms were probably due to the severe enanthem, which was aggravated by taking castor oil. Osler describes the enanthem (or rash of the mucous membrane), which appears before the external rash.

Fantus advises against the administration of castor oil in these cases because it acts as an irritant; however, had we looked for Koplik spots in this case, the operation probably would have been avoided.

Ulcer, Cholecystitis, Appendicitis — The three conditions which are most difficult in abdominal diagnosis are ulcer, cholecystitis, and appendicitis.

Even after the closest observation, I am sure that we have all made errors. Present refinements in diagnosis have not cleared up the question; experience alone will not suffice. Probably? No. Surely! Future medicine must find a way to differentiate these conditions. Personally, if I make a diagnosis of ulcer, and put the patient on frequent feedings and alkalinization, and it does not clear up, I look for some other conditions as the cause of the symptoms.

Examples — 1. A woman came in with all the symptoms of ulcer—pain, recurring at definite times after meals, with food ease, vomiting of blood, occult blood in the feces, deformed duodenal cap, and hyperperistalsis. Particularly on account of the hematemesis, a diagnosis of an ulcer was made. At the Mayo Clinic three months later gall-stones were removed. No ulcer was found.

2. Another patient had all the typical symptoms just enumerated, except hematemesis. Several gastro-intestinal studies had been made previously, and there was a diagnosis of ulcer. A gall-bladder plate, which had not been taken before, fortunately revealed shadows of calculi. Stones were removed, and the patient recovered.

3. Another patient with the typical symptoms of peptic ulcer, including duodenal cap deformity, hyperperistalsis, hyperacidity, and definitely recurring pain, we diagnosed as ulcer. He was treated for a few weeks with proper ulcer treatment, with no change in symptoms. Another x-ray study was made after giving belladonna. The appendix was found to remain filled for over eight days. An appendecectomy cleared up the symptoms.

Gastric Crises—There was quite a group of cases which had had various diagnoses. Some of them had been operated upon for gastric ulcer before we saw them, but without relief. These proved to be gastric crises of locomotor ataxia. In a few, the only other sign, except the positive spinal fluid, was the Argyl-Robertson pupil. This mistake is a rather common one and should be guarded against.

While I could continue citing other errors in which angio-neurotic edema, renal calculi, and ovarian cysts were found to be present, it would take more time than I have at my disposal.

Spider-bite—There is a group of cases, however, that might be of interest. There were four in the series during the past two years. Let me give you the history of one in detail.

A man, 42 years of age was sent to the Receiving Hospital after being sick for twelve hours. He had eaten fish for dinner the evening before, and later went to an out-of-door toilet. After straining without effect, he went back to the house and to bed. Almost immediately he noticed pain in the left groin, which became more severe, going over to the right side. In fifteen minutes the pain became intense. A doctor was called. Hypodermics which were administered did not relieve him, so he was sent to the Receiving Hospital. On admission his temperature was 101.2°, his abdomen was board-like; he was in agony, and drenched with perspiration. A diagnosis of either food-poisoning from the fish, or a possible peritonitis was made, and he was transferred to our service. When admitted, his blood count was 21,000, with a normal differential count. His breathing was rapid and forced, his face reddened; his eyelids swollen; his abdomen tense, but not tender. The admitting interne made a diagnosis of acute appendicitis. Our chest man saw him and found a few rales. This, together with the rapid, forced breathing and flushed face, convinced him that we were dealing with a beginning pneumonia. The resident physician called it ruptured gastric ulcer.

On the following morning the resident physician and I went over the case together. He found the signs enumerated, and also what looked like a small insect-bite on the glans penis. He had in mind the three other cases, so questioned the patient further, and found that he had been stung by a spider while in the out-of-door toilet.

This group of cases of spider-bite is interesting because of the severity of the symptoms produced from such slight cause, and its possibility must be in our mind, especially in the countryside, where out-of-door latrines are used.

In all of these cases the bite was on the glans penis. Whether toxic or anaphylactic, we do not know, but the vascularity of the parts is responsible for the rapid absorption and severity of the symptoms.

Recovery took place in a few days with symptomatic treatment. The spider which causes these symptoms is the Latrodectus mactans. It has a large black body, with a red spot on its belly. Its habitat is chiefly California and Texas, but it is also found in other parts of the United States. Strangely, its common name is the "black widow."

In this study, which could be extended ad infinitum, certain facts stand out.

1. The cases all had abdominal symptoms.
2. They all had wrong diagnoses.
3. The correct diagnosis was arrived at by various means—in one the x-ray was the criterion, in another the laboratory findings, in another a careful history, and again, clinical experience. X-ray in abdominal conditions has become indispensable, but we must be warned from time to time not to be too dependent on this aid. The modern tendency is to attach too much importance to laboratory results.

These findings are important. Indeed, I believe future medicine will be advanced more by laboratory research in physiology and chemistry than by any other means; still, at the present time, we must restrain ourselves from allowing the laboratory to usurp the place of clinical experience. The human body is not a living test tube.

If I were to evaluate the most important elements that these errors have taught me I would say:

1. We should be most careful in the taking of histories (everyone of us can do that), for I believe many mistakes can be avoided thereby.

2. The most important lesson is that, after all, it is the clinician, who in an unbiased way evaluates the important points wherever they appear, whether in the history, the physical examination, the laboratory findings, or in the x-ray studies, who is of the most value to his patient and to his profession.

In the words of Connor, read before the annual meeting of the Yale graduates last June: "My plea then is, for an effort on the part of all of us to resist and counteract the growing inclination to regard the use of the laboratory and instrumental aids as the chief means of diagnosis, and to give too little weight to the more laborious but more important measures of painstaking clinical observation and careful deductive reasoning."

1501 South Grand Avenue.

A SYSTEMATIC USE OF OPIUM FOLLOWING CERTAIN LAPAROTOMIES

By ASA W. COLLINS, M. D., San Francisco

Although in principle the use of opium and its derivatives after abdominal operations has been all but discarded by most modern operators, I have found it so useful as a routine measure in my own practice that I take this occasion to report my results during the past year.

The chief reason why the routine use of morphine after laparotomy has been abandoned seems to be a general agitation against its use dating from the time since the use of narcotics was restricted by the Harrison law, but the fear of its dangers is decidedly unjustified, considering my own experience. One should not forget that there are sometimes contra-indications. In very serious and critical cases, especially in patients who seem close to the lethal exitus, most physicians have a dread of a possible unfavorable result and hesitate assuming responsibility. Of course, there may be some danger of its abuse when permitted to be used on slight provocations or, which is worse, the administration of this powerful drug only when the patient is completely exhausted and fairly screaming with pain, then, and only then, does she learn for the first time its marvelous action and demand a repetition of the dose when first symptoms of the previous attack are manifest.

My method is the regular administration every four hours of a tablet, per hypodermic, containing all the alkaloids of opium, or the alkaloid in ¼ grain doses, beginning four hours after the preoperative dose has been given and repeating every four hours day and night for from three to five days after operation, whether awake or asleep.

The results of this method of treatment I will refer to later.

When we review the best text-books and the literature of recent years on this subject, we find more authors opposed to the use of opiates in the after treatment of abdominal operations than are in favor of it.

For this reason, it may be interesting first to examine the antagonistic opinions which some of them advance.

Clinton Cushing says: "The less opium a patient gets after an abdominal section the better, and much the larger proportion of my patients get no anodynes whatever. The pain from the operation gradually subsides; the patient is turned on either side from time to time to rest him; no food is allowed until peristalsis has commenced sufficiently to expel flatus from the anus, etc."

After describing their routine, Deaver and Muller maintain a very decidedly declining attitude: "If the operation is performed rapidly and if the patient is not saturated with ether, the element of shock plays but a small part as a sequela to operation. By the prompt use of such stimulants as strychnine, atropine, whisky, and camphorated oil, hypodermically, with hot water bags and the use of hot saline solution by the bowel, the patient will rapidly react. Routine use of oxygen has lessened the number of cases suffering from ether sickness (nausea)—paresis due to mild peritonitis, simple atony of the bowel or to the use of morphine which should not be given for post-operative pain." Again: "That the giving of morphine after abdominal operations is responsible for a mortality, we have no doubt."

A non-committal attitude is shown by Skene Keith: Some surgeons have been in the habit of giving a dose of opium, in some form or other, at stated times and in every case; others have limited its use to cases of distension, or so-called peritonitis. Naturally, a routine practice of this kind has not proved suitable in every case; and now the tendency is to use this drug rather too little than too much. This is perhaps as great a mistake to use too little as it is to give too often, and especially in too large doses. There is no one drug which is of greater service when given in suitable cases and with a distinct object in view; and none is capable of doing greater harm when used in a haphazard way."

H. A. Haubold says: "The administration of opiates may be stated as objectionable in principle, but necessary in a certain number of cases. The objections are that they paralyze peristalsis, which favors the formation of adhesions, they lessen secretions and excretions, of which the latter is the most important factor, and that they mask symptoms which are indicative of complications. On the other hand, arrest of peristalsis is not objectionable for twenty-four hours after invasion of the lumen of the digestive tract. Again, pain which is sufficiently severe to cause restlessness is best controlled, even if the objectionable features of the opiates have to be taken into account."

One generally recognized authority expresses his

opinion particularly with clearness. Moynihan says: "The administration of morphine after an operation is rarely necessary nowadays. More especially since the introduction of Crile's method (anoci-association). In some cases, however, especially, for example, in secondary gall-bladder cases, some relief from post-operative pain may be urgently requested. I never withhold morphine if the patient is suffering. In the old days we were all afraid of morphine, and surgery was often cruel. An injection of 1/6 or 1/4 grain of morphine on the night after the operation will give a peaceful night and the patient wakes refreshed and cheered by the repose he has had. I do not think that this amount of the drug causes any flatulent distension of the intestines; indeed, I think by relaxing a spasm of the bowel, it may aid in the expulsion of gas. It was the repeated administration of opium and morphine in the olden days that led to these drugs being discredited. Today we use them sparingly; but to the great advantage of our patients."

We have yet to hear the opinion of another generally recognized authority, Howard A. Kelly: "If the patient is tired and restless, a tepid sponge bath followed by gentle rubbing and a cup of hot chicken broth or beef tea will often take the place of a narcotic. If there is much pain after the operation, a hypodermic injection of 1/8 or 1/4 grain of morphine may be given when consciousness has fully returned, and the dose should be repeated if sleep during the first night cannot be secured without it. Milder sedatives are useless, but the morphine must not be continued longer than thirty-six to forty-eight hours. Morphine must be used with greater caution when the woman is hysterical. Indeed, it is often better to allow a hysterical woman to suffer than to use it at all. I know that the medical profession is divided on the question of using morphine after abdominal operations, some able physicians objecting strongly to its use, while not a few surgeons still venture to assert its necessity. I have no hesitation in declaring myself emphatically in favor of hypodermics of morphine during the first twenty-four hours in all cases of severe suffering, under the limitation I have just indicated."

In Kelly and Noble's Gynecology and Abdominal Surgery we read under the treatment of shock, chapter by Brown Miller: "Morphine in repeated small hypodermic injections (grain 1/8 to 1/6) is one of the best remedies we have, especially where restlessness is present."

We have seen that, although most authorities mention that morphine is at present not in such general use as was customary years ago, they are not entirely opposed to it in principle and appreciate the usefulness of it when needed.

H. J. Boldt is of the opinion: "In many instances one dose of morphine is administered soon after the operation, because it is but seldom that a patient does not complain of sufficient pain to make such treatment not only humane, but beneficial to the patient, acting far better on the heart than, under some circumstances, strychnine. I believe that strychnine is used far too extensively and indiscriminately, whereas the administration of a dose of morphine after an operation is too much dreaded by many."

Von Mikulicz says: "In case of vomiting, one had better give nothing at all; eventually hypodermically morphine 0.01-0.02 g; sometimes swallowing of pellets of ice giving relief, etc." . . . "If a remedy for pains is indicated, morphine should be given subcutaneously. Morphine given in reasonable doses does surely not harm the laparotomy patient; we are even, compared with our experience of former times, when less strict asepsis was practiced, under the impression that morphine supports the organism in overcoming a septic infection." There is much to be said in favor of morphine after any kind of and particularly an abdominal operation. "No remedy is more apt than morphine to support the organism in its final, most vehement struggle for restitution of the disturbed equilibrium" is the gist of what Prof. O. Rosenbach of Berlin says. "In small doses it can—at least as efficiently as atropine—excite peristalsis, which must be taken as a sign of recuperation of tissue tone. With correct indications and precise dosage, it is the best tonic, the most excellent means for 'reestablishment of essention work to energize the inner tone of the tissues.'"

Rosenbach says again: "We recommend morphine in the therapy of heart disease because of its effect being in many respects similar to that of digitalis; both remedies act, properly used, as tonics. Narcotics, the importance of which in cardiotherapy we estimate very highly, decrease excitability of the nervous system, without diminishing the local parenchymatous metabolism."

The value of morphine for the promotion of a patient's recovery after operation is at once evident when we consider how promptly it removes causes of sleeplessness: in the first place, pain; then excitement, worry, and all kinds of torturing sensations. It is also important to remember that sleep is essential not only as a saving factor, preserving energy, but chiefly as a producer of a period of rebuilding energy. While ordinary somnifera or sedatives merely decrease the excitability of the cerebral cortex, narcotics have the additional advantage of energizing the tissue cells for the purpose of carrying on protoplasmic reconstruction. Thus morphine is of direct assistance in the healing processes after abdominal operations, as a dynamic builder of internal energy which increases tissue tonus.

Morphine has the same properties as opium, but with less tendency to constipation. It is known as the remedy of greatest value in the treatment of peritonitis and other abdominal inflammation. To relieve the patient of pain and afford sleep after an operation, to support the organism in overcoming shock—those are the well-known qualities which have established morphine in its time-honored office which hardly any other remedy will dispute to it.

The time of absorption from an empty stomach is fifteen to twenty minutes, while its full effect is reached not before an hour. By rectum, one must allow from one and one-half to twice as long, and it requires about one-third larger doses for the same results. By hypodermic injection, the first effects are felt in from three to five minutes, the full effect

in from fifteen to thirty minutes. Morphine is eliminated in the urine. As it is excreted into the stomach, it may be reabsorbed from the lymph ducts, whereby its cumulative action is explained. Some is excreted by the liver and appears in the bile, a small portion in the perspiration.

Henry Smith of Armritsar, India, who has carefully watched the post-operative care of his cases, is an enthusiastic believer in the efficiency of opium; so much so that it is a routine treatment in his practice. He gives the tincture of opium hypodermically in comparatively large doses, preferring it to the alkaloids.

Being impressed with the great number of cases covering many years of practice during which opium had been used, I decided to try his method of treatment. My practice in the past was to give heroin or morphine when necessary to control pain; this meant when everything else had been tried first, and then only as a last resort, feeling that we were licked when we did prescribe it; that pain so severe as to demand the use of morphine should mark the uneventful recovery of the patient. This hypothesis was all wrong.

Before operation, the standing order in all hospitals is to give morphine; upon this we are agreed. During operation the patient is completely under the anesthetic, and we can assure him that he will not suffer. But what can we offer him for the next three or four days. Will surgery be robbed of its terrors while patients continue to suffer the distressing symptoms following operation? Can this be overcome? Is there any objection to the use of opium? How shall it be used?

In practically every laparotomy peristalsis is suspended for several hours, and sometimes many days, dependent upon the magnitude of the operation, time consumed, manipulation of the viscera, particularly in operations for fecal fistula, ruptured appendix, pelvic peritonitis, ruptured viscus, operations for traumatic injury of the intestine, anastomosis, etc.

We must expect a considerable amount of pain before the resumption of peristalsis. When peristalsis begins it starts locally and is signaled by pain. This collicy pain is the contraction of the circular muscular fibers of the intestine at one or more points, and produces at the particular point a temporary partial obstruction of the canal. There is no uniform peristaltic wave downward, but the wave is obstructed and we have reverse peristalsis, which means vomiting. This must be prevented and can be prevented by the use of opiates. One dose will relieve the spasm, but another dose must be given in four hours to prevent its return.

Following the severer types of laparotomies I have mentioned, I begin four hours after operation with a hypodermic of pantopon, tincture of opium, or morphine, and repeat the dose every four hours as a standing order. This is kept up from twenty-four hours to four days. A peculiar thing about the regular use of opium is that invariabily the patient begs to have it discontinued, usually objecting to the prick of the needle, and once discontinued never asks for it again; in fact, I do not advise allowing the patients to know what they are taking. The mention of opium subconsciously brings to mind the dread of habit-formation. If there is any possibility of acquiring the habit, it will be by giving the patient a demonstration of the properties of the drug. This can best be illustrated by giving a general anesthetic to a woman in labor. At first she objects to the administration of ether, even after suffering great pain; but one demonstration of the happy relief of suffering and you have a woman whose whole mind for the time is concentrated upon the ether-cone. Her cry is, "Give me some more." So with morphine.

Peristalsis will come when it will come, and purgatives given too early will not start it, but only cause more vomiting, pain, and suffering.

My personal experience of fifty cases of the severer types of laparotomies, consisting of operation for fecal fistulae, ruptured appendix, pelvic abscess, anastomosis of intestine, resection of cecum, large ventral hernia, pyloric resection, hysterectomy, etc., may be summed up briefly: In 30 per cent of the cases the bowels moved with expulsion of gas, without a physic on or before the third day; 22 per cent had some nausea after the first day. All patients had little difficulty lying on the side.

None of the cases had pain or hiccough. Not one case asked for an injection after the injections were ordered stopped. Fifty-four per cent requested that the injections be discontinued, objecting to the injection. Nearly all the cases did not know what they were getting and, feeling fairly comfortable, did not see why they should be disturbed by being pricked with a needle. Unfortunately, I did not keep a record of the percentage of cases that had to be catheterized, but feel sure that they were less than when an opiate is not given regularly. All the patients enjoyed more sleep.

The two essential requisites for a surgeon are reverence for human life and sympathy for human suffering. To say intuitively that every doctor is conscientiously striving day and night to give unselfishly the best there is in him to prolong the life of his fellow-man is obvious. But a sympathy for human suffering must be expressed, as far as the patient is concerned, in a material way when it comes to pain. Obstetricians have robbed nature of the pangs of pain. Will the surgeon, after the peaceful sleep of the operation, try to alleviate the agony of pain and train of depressing symptoms of a post-operative period? When this has been accomplished, surgery will have attained a plane far beyond the reach of its critics.

126 Post Street.

DISCUSSION

Burt S. Stevens, (909 Hyde Street, San Francisco) —I have employed morphine more or less routinely in such a large number of post-operative cases and over a period of so many years that I feel no hesitancy in agreeing with what Collins has to say. My practice, while differing slightly in minor details, practically corresponds to that of Collins, and my reasons for using it are also essentially the same.

When not contra-indicated—and I believe that it rarely is—I modify the dose according to the age and weight of the patient, but in the average adult I give morphine ¼ grain hypodermically, and my routine instruction to the nurse is "keep the patient comfortable." This ordinarily means to give the narcotic

every four hours until the acute pain and restlessness have disappeared, and seldom is it necessary to continue with the drug for more than twenty-four to thirty-six hours. It is a decided advantage to give a large enough dose to accomplish the desired effect early and to continue until such time as the patient is practically free from pain, at which time it may be abruptly withdrawn. If a patient is placed at rest mentally and pain abolished, a speedy convalescence is much more likely. Small nagging doses of the drug frequently stimulate rather than quiet and do not accomplish the desired result; consequently, one should use sufficiently large doses for the required time and then stop.

I am convinced that the intelligent use of morphine does not provoke complications; that the patient makes a much more comfortable and satisfactory convalescence; that when used as Collins has suggested there is no danger of the habit being formed, and that its use is a sensible and humane procedure.

W. Harriman Jones (131 Pine Avenue, Long Beach)—"Systematic Use of Opium Following Laparotomies" seems to imply a routine being carried out in every case, which to me seems unwise. No matter if an opiate is used following every laparotomy it should be specifically prescribed as to quantity, form, and time in each individual case after a careful consideration of the needs of that case. In my own practice I practically always give an opiate preceding operation, which in many instances is all that is required if the operation is short and the temperament of the patient permits, and rarely are more than one or two hypos necessary after operation. If pain is great enough to produce restlessness and insomnia, particularly the first post-operative night, I believe less damage is done and convalescence hastened by a reasonable use of opiates. Collins' observations on the humanity of surgery deserve consideration, and the observant, conscientious surgeon will not need to fear the reasonable use of opiates post-operatively.

H. A. L. Ryfkogel (516 Sutter Street, San Francisco)—The paper of Collins discusses a subject that greatly interests surgeons. Morphine after operations not only relieves pain, but gives the tissues the physiological rest that is so necessary to proper healing.

Patients following operations, even though in no great pain, often become very restless and any threshing about is very apt to put an undue burden on a heart already affected by disease and the strain of an anesthetic. It also tends to place undue friction and stress on recently sutured parts. Morphine, by quieting the patient, minimizes these dangers. The nervous exhaustion that follows operative procedures is largely due to the great pain suffered during and after operations. Crile has shown that pain is really felt by the cerebrum even though consciousness is abolished by a general anesthetic and degenerative changes take place in the central nervous cells as a result. Morphine should be given before an operation to lessen the amount of the general anesthetic, which also produces degeneration of the tissues, particularly those of the liver and brain.

During operations all tissues should be thoroughly blocked off from the cerebrum by an injection of local anesthetic. After the operation pain should be lessened as much as possible by safe doses of morphine. The question to be debated is "What is a safe dose of morphine?" The answer depends on the nature of the operation, the age of the patient, and his idiosyncrasy to this drug. It must be remembered that in those with the tendency to bronchitis that morphine lessens the desire to expectorate, and there is danger of the retained infected mucus producing a bronchial pneumonia. This should be controlled by deep breathing, by urging the patient to cough, by liquifying the sputum with stimulating expectorants, of which the best is probably camphorated oil in 2 cc. doses every two or three hours intramuscularly.

Doctor Collins—In closing the discussion I wish to emphasize a few facts. The action of morphine is well understood by all surgeons, possibly the best known of all drugs used in the last half-century.

It is just as important to relieve pain after an operation as during an operation. Ether, during an operation, should be used continuously and with the greatest care. Likewise I recommend the regular, continuous, or systematic use of opium (every four hours) from two to four days following certain laparotomies, with all the confidence of experience in this method of treatment, and have found no drug or method of treatment to take its place, and lastly, there is practically no contra-indication to its use.

THE CARE OF THE NEW-BORN BY THE OBSTETRICIAN *

A QUERY BY THE PEDIATRICIAN

By A. J. SCOTT, JR., M. D., Los Angeles

To ascertain the routine care of the newly born infant by the obstetrician and the hospitals in our community, a questionnaire was sent to forty-nine members of the Los Angeles Obstetrical Society and to eleven hospitals and maternity cottages of the city. Among the doctors thirty-three answered, and of the hospitals nine answered, no replies being received from the maternity cottages. The questionnaires to the doctors and the replies were as follows:

No. 1—What feeding hours do you prefer for the new-born, three or four hours?

Two hours (1); 3 hours (27); 4 hours (3).

Comment—The first 24 hours by most was given over to a 4 or 6-hour period. After the first 24 hours there was a preference for the 3-hour period, days, and 4 hours at night. Only 3 chose 4 hours all through the 24-hour period. This seems to show that most obstetricians feel that the 3-hour period, days, and 4 hours at night is productive of the best results, not only for the mother, but the child.

No. 2—Do you give a feeding between 10 p. m. and 6 a. m.?

Answers—Twenty-one feed about 2 a. m., 6 "if it is necessary," and 5 "not at all."

Comment—Is this merely a routine, or is it absolutely necessary for the welfare of the infant and mother? Does that disturbed 2 a. m. period interfere enough with the mother's rest to have any inhibitory effect on the milk production, or is it an aid? Does the infant need the extra food, especially if on the 3-hour day schedule? I think a great deal depends upon the individual infant as to whether it is gaining or not, and the general reaction on the mother's nervous system. If the infant is getting a 4-hour schedule day and night it might need the extra food, but I cannot see why it would otherwise.

No. 3—Do you give a laxative to new-borns routinely? If so, what kind? Why?

There were 27 who gave nothing, while 4 gave something, and the choice of laxatives ran as follows: A much-advertised patent medicine, castor oil and olive oil equal parts, milk of magnesia, enemas, and plain castor oil. As to why, the only answer

* Read before the Los Angeles Obstetrical Society, October 9, 1923.

given was by one who thinks "meconium causes colic." I would like to state that, from the number answering against the use, it would seem that there is no necessity, and as to meconium causing colic, this seems hardly logical, as most of the colic as such does not appear until the milk supply has come in the mother's breasts sufficiently to show up in the stools.

No. 4—What is your preference in the maternal diet until the milk comes in and while still in bed?

A variety of answers were given. The average replies were: Occasionally malted milk, but generally nothing for 12 hours, then liquids and semi-liquids.

Liquids exclusively (10); regular diet with plenty of liquids (6); no special diet (5); soft (6); very light (3). "Liquids predominate—no objection that I can see, but is it necessary to hasten milk secretion?" "After the milk comes in." Select diet (6); soft diet (6); regular diet (12). "Avoid corned beef and cabbage." "Not convinced milk is any more of a milk producer than an equal amount of other fluids." "No special diet except as indicated." "Watch for gas-producing foods like starches." This last seems to be in contra-distinction to what will be noted later on.

One man puts on a constipating diet for 5 to 6 days while there are stitches. Apparently, liberal feedings are most satisfactory.

No. 5—Do you put any restrictions on the kind of food mothers eat while nursing, viz.: avoidance of acid fruits or vegetables, etc.?

Yes (6), No (24), and the replies ran as follows: "Eliminate all heavy articles of food, highly seasoned, acid and gas-producing, as grapes, peaches, tomatoes, etc." "Certain vegetables, as cabbage; no restrictions on fruits." "Avoid certain vegetables and acid fruits." "If baby is cross and has colic, have them restrict acids." "Balanced ration. Avoid acids and highly flavored foods." "Not unless child becomes colicy." "Varies with mother and child." "Beans and onions are to be avoided." "Avoid strawberries and spices only."

This would seem to show there is no uniformity in the opinions of the different men. It would seem more logical to advise a regular diet such as the mother has been accustomed to prior to the birth of the infant. The numerous things advised against would leave a very limited supply to draw upon, and, in fact, do the opposite of what we are trying to prevent; namely, having a colicy baby. Too many of these mothers crave the very things they have been accustomed to and really need, particularly in the fruits and vegetables, and what agreed with them prior to the birth certainly ought to agree with them afterwards. Again, there is need of the coarse foods to aid in bowel evacuation, for there is the constipating effect of a too completely digested diet, with no residue. Again, acid foods are usually eliminated in entirely different forms than when ingested, and the acids are not passed through the milk. Of course, while still in bed a mother naturally does not need as much food for the first few days as when the infant is older, and when she begins to move around in bed more she requires more food.

No. 6—Do you advocate formula feedings for infants while the mother is still in bed? If so, what kind and how often?

There were, No. (21). "Yes, if necessary" (6), and "as complemental when needed" (6). The kind was either a milk and water modification or a dried milk preparation. To be commented on later.

No. 7—Do you find that formulae tend to get mothers away from breast-feedings inside of the first six weeks of the infant's life?

Yes (25). No (6). Never used (1).

This shows the opinion of the majority as to the pernicious effect of the easily flowing bottle, as compared to the harder work of suckling the maternal breast. It also shows that most of the men prefer to help the mother and keep the baby on the breast rather than to not bother and let the mother follow the advice of anyone and substitute some kind of an artificial feeding.

No. 8—Do you give the mothers a formula to take home from the hospital?

Yes (1). No (22). Only as aid (9).

Not advisable in the opinion of most.

No. 9—What is your favorite laxative for nursing mothers and why?

There were quite a number of ideas and drugs used. For example: Licorice powder (3); saline (1); agar agar (1); phenolphthalein (2); A. B. & P. pills (1); what accustomed to (1); liquid petroleum (5); milk magnesia (6); enemas routinely (1); cascara preparations (14); A. B. S. C. pills (1); castor oil if indicated (1); a patent medicine (1); a proprietary medicine (8).

All stated they wished to use something that would not affect the infant, and, as seen from the above, the mineral oil and agar preparations, as well as the cascara preparations, seem to be the most popular.

No. 10—When do you leave the baby's abdominal binder off?

Soon as possible after stump healed (10); end of first month (3); 6 to 8 weeks (9); 3 to 4 months (1); 6 months (4); 1 year (2); 2 years (2).

The majority favor early removal because there is no need for keeping the binder on after the cord has dropped off and the wound is dry. The binder will not prevent hernia of the umbilicus, and if it is on tightly enough to do any good it crowds the small abdominal contents and causes distress, not allowing expansion, and if loose enough it slides out of position and has no effect on the prevention of hernia. A good light-weight woolen knit band, which goes over the shoulders and has a tab fore and aft for the attachment of the diapers is sufficient to keep the little abdominal contents fully protected from chilling. This causes no pressure over the soft muscles, and allows of the free movement of the abdominal contents.

No. 11—Do you give any special treatment for icterus neonatorum? If so, what?

Yes (6). No (18). The treatments were: Calomel (9); castor oil (5); laxative if necessary (1); gray powder ¼ gr. twice daily (1); push fluids (6).

Icterus neonatorum is a physiological process and

needs no treatment, other than possibly giving water freely, but that is no more than what should be done in any case. True icterus is not a septic process, and if there is a septic temperature, it must be from some other cause. If there is a septic hepatitis it is not true icterus neonatorum, and calomel and castor oil are not indicated, as they may do more harm than good.

No. 12—What directions do you give mothers as to diet while nursing the infant, especially if the milk supply is scant?

This corresponds to what was answered in No. 4, and the replies were as follows: Good food (13); additional milk between meals (13); pump breasts after nursing (1); force liquids (12); force liquids with galactagogues (1); increase the starches and sugars (cereals, etc.) (15); placento-mammary extract (2); cod liver oil (1); remove cause, as worry, etc. (1); complemental feedings (1); fresh air and exercise (3).

It seems that some of the most important points have been overlooked, namely: the avoidance of worry, the need of plenty of fresh air and out-of-door exercise, and the emptying of the breasts completely at the end of the nursing period. All the complemental methods for producing increased milk supply fail if they are not attended to. The excess fluid is eliminated through the kidneys and bowels, the galactagogues are undoubtedly psychic, and as to the increase of the starches, the corn meal gruel, etc., it seems to me this fact is overlooked: breast milk is undoubtedly a secretion. It is made from the elements in the blood carried to the mammary glands, where it is manufactured. How, by increasing any one group or groups of foods, or the restricting of the use of certain foods or elements, are we going to affect the manufactured product? Toxic substances are, of course, not included. If the mother has a calm mind, avoiding worries and anxieties, good hours of rest, plenty of fresh air, sufficient exercise—but not to the point of exhaustion—plenty of cool, fresh water, good, wholesome food which she is accustomed to, and eats everything she ate prior to the birth of the child, plenty of fresh fruits and vegetables of all kinds for their essential elements—vitamins—and nurses regularly, there ought to be sufficient milk. The first 6 weeks of the infant's life is the hardest period for the mother. Then is when, if ever, she is likely to have the baby off the breast and on the bottle, and then is when she needs the wise counsel of her obstetrician as to what to eat and how to live. Too often the mothers get advice from the hospitals and nurses on leaving, and sometimes this is good and sometimes not so good, and for that reason the following questionnaire was sent to the hospitals:

HOSPITAL QUESTIONNAIRE

No. 1—What feeding schedule do you use for new-born infants, three or four hours?

Two and one-half hours (1); 3 hours (7); 4 hours (1).

The night feedings were every 4 hours. This corresponds to the doctors' replies.

No. 2—Do you use any laxative for the new-born routinely; if so, what and why?

No (9). Yes (2). On doctor's orders.

No. 3—What diet do you recommend mothers before the milk comes in, after the milk comes in, and while still in the hospital?

"Forty-eight hours liquid, next 24 hours soft, next 48 hours light, and then regular tray after fifth day." "General diet after 48 hours." "Soft, increase to regular" given by four with these modifications: "Avoid what does not agree with mothers." "Avoid meat." "Avoid rich or fried foods."

This shows some general trend in answers as the doctors' replies.

No. 4—Do you use bottle feedings as additional feeding routinely; if so, why?

No (6). Only as doctor orders (3). (Yes (1). "Only prematures receive breast milk formula, and all other infants under six pounds standard cows milk formula routinely. The gain is more uniform this way," reports one large institution.

No. 5—What kind of formula do you use as "stock formula" for new-born?

Cream and water mixtures (1); milk, water, and sugar (3); dried milk (2); doctor's orders (2).

"Usually enough pumped breast milk to supply all our needs," says one of the institutions. Why, in all of our hospitals which have large maternity services should it not be possible to have a supply of breast milk on hand? If our nurses were only trained to get all the excess milk, by stripping the breasts after baby has finished, by pumping where there is an excess amount, or by manual expression in place of pumping, a more rational and less painful measure in most instances, this would take care of those infants whose mothers have a scant supply, would care for prematures, and if there was sufficient, might even be supplied to outside cases who would pay the cost.

No. 6—Do you give mothers a formula to take home?

Answers were all against this practice unless the infant was on an exclusive formula feeding while in the hospital, excepting one charity institution, where feeding was under supervision of the district nurses.

No. 7—What kind?

All answered, "On doctor's orders."

No. 8—What directions as to future diet do you give mothers?

The general tone corresponds to the answers of the doctors' questionnaire. "Full diet." "General diet, large service cereal, one quart of milk daily." "Regular diet, avoid foods found to disagree." "Avoid acid foods. Drink plenty milk and cocoa." "Follow hospital diet." "Doctor's orders—usually liberal and full plus 2000 cc. milk daily." "No particular diet."

SUMMARY

1. Three-hour days and four-hour nights is average rule for feedings while in hospital.

2. A 2 a. m. feeding seems to be advisable in first few weeks of the infant's life.

3. Laxatives are not needed in the new-born.

4. Maternal diet until milk supply is established seems to be: soft with liquids and after milk established and while in bed, more liberal, varying with

the different men. All, however, warn against indigestible foods.

5. Most men put no restrictions on the nursing mother's diet, and this is only rational.

6. Formula feedings while in the hospital are not in favor with the majority.

7. Formulae tend to wean the baby from the mother's breast.

8. Taking formulae home from the hospital is not in favor.

9. Many different laxatives are used for mothers; all, however, with the idea of not upsetting the infant.

10. Most men leave the abdominal binder off before the end of two months; a few leave on unnecessarily long.

11. Icterus neonatorum is left alone by most all physicians.

12. For aid in stimulating scanty milk supply, there are many methods, showing that most obstetricians have their own viewpoints, and these are based more on dietetic than physiological grounds.

CONCLUSION

A little closer co-operation between obstetricians and pediatricians would work to the advantage of both for the best interest of mother and child. There are still a few old theories held which could be abandoned to the advantage of the infant. Dietetics should play a more important part in the curriculum of our medical schools, as well as schools of nursing, and more time should be spent on physiology of the mother and new-born, which would result in a better start in life for the infant.

1501 South Grand Avenue.

DISCUSSION

Frederic M. Loomis (350 Twenty-ninth Street, Oakland)—The "pernicious effect of the easily flowing bottle" does not compare, in my opinion, with the pernicious effect of a hungry baby honestly howling for food which he can't get from a mother's breast when the food isn't there. No young mother, especially with the first baby, can have a "calm mind, avoiding worries and anxieties" when her child is raising its voice to high Heaven. The sudden responsibility of finding herself in full charge of her baby very frequently disturbs the milk supply, which then "upsets" the baby, and in turn is doubly disturbing to the mother, with augmented protests from the child; and I think we should foresee this vicious circle before it occurs, and prepare our patients for it by teaching them while still in the hospital the principles of complemental feeding whenever there is any probability of the breast supply being inadequate; and we should understand that the inadequacy lies in the mother's nervous system rather than in her breasts very frequently.

The best antidote for an anxious and worried mother is a satisfied and sleeping child, and the best way to get it that I know is by the temporary use of complemental feeding, invariably using the breast, or both breasts, each time first with a definite time limit of twenty to twenty-five minutes for each nursing. I have been puzzled at the number of my babies, exclusively breast-fed, who failed to gain in the hospital, though apparently satisfied and quiet. Careful weighing, as a routine, of every baby before and after each nursing soon showed that most of these children, though apparently content, were getting a totally inadequate supply of food. Temporary complemental feeding, tiding them by their first few days at home, has solved their problem, and many have again become exclusively breast-fed, with proper gain in weight as the mother's life became more normal.

I believe, with Scott, in a four-hour schedule when the baby is above seven pounds and when that schedule is successful, but change back to three hours when necessary; in a general, complete diet for mothers without restrictions except as to foods which the mother knows from experience "disagree" with her; in the avoidance of the 2 a. m. nursing when possible—and it frequently is possible—even with the four-hour schedule; and in discarding the binder within a few days after birth. Scott's paper is useful and interesting, and should help to overcome the present wide divergence in our orders.

Langley Porter (380 Post Street, San Francisco)—Doctor Scott's interesting paper is a very definite contribution to pediatric knowledge. It emphasizes the entire lack of accepted principles, in dealing with the mothers of new-born babies.

The attitude of the obstetricians toward the diet for the nursing mother shows that many of the superstitions about foods current among the laity influence the medical profession, with a result that is certainly of no advantage to the nursing mother or to the baby.

The replies to questions about laxatives for nursing mothers, laxatives for infants, the use of the abdominal binder for the infant, and the matter of treating jaundice in the new-born, all show the same lack of uniform reasoning on the part of those replying to the questionnaire.

Scott's comments of these questions are shrewd, and should be very helpful in establishing a modern point of view and in bringing to obstetrical practice a greater rationality.

Especially interesting is his insistence that galactagogs are of very little value in the development of the milk flow, and that the most important influences are to be found in the proper management of the mother's environment, especially in the avoidance of worry, the provision of fresh air, outdoor exercise, and in the complete emptying of the breasts at regular intervals. (It may be that quite as important as any of these is the insistence that the baby shall not be allowed to nurse for a long time on breasts that are empty.)

One of Scott's most trenchant criticisms is directed against the failure on the part of the obstetrician to advise and direct the mother about the future care of the child, once the puerperium has passed.

In San Francisco, many of the obstetricians cooperate closely with pediatric specialists, several of whom have organized a service for following the infant's feeding from week to week throughout the first year. This sort of service is especially valuable to the young woman, a mother for the first time who, unfortunately, has never been taught anything about infants or about infant care. Under such a plan, skilled and friendly teachers are provided to lift the heavy burden and the terrible anxiety from the young girl who struggles ignorantly to do her best for her new-born child.

This paper of Scott's is as valuable a contribution as could possibly be made. I wish to congratulate him because he has recognized the necessity for gathering this data and because he has worked out the information in a simple and illuminating way.

G. C. H. McPheeters (Fresno)—Doctor Scott's paper upon "The Care of the New-born by the Obstetrician" is interesting to me especially, because in my particular local field I am called upon to practice both obstetrics and pediatrics.

The lack of uniform methods used by pediatricians and obstetricians in the care of the mother and her baby is well brought out by the answers which Scott received to his execllent questionnaire. This is not surprising, since obstetrics still is not considered seriously by a number of doctors, many of whom allow the nurse or attending relative to direct the care of the baby after its arrival, even to hours of nursing, bottle formulae whether needed or not, etc., etc. There are all gradations of services rendered by phy-

sicians attending obstetrical cases, from the meticulous care of the obstetrician who turns the baby over to the pediatrician at birth down to the doctor who makes none, one, or two perfunctory calls only upon the parturient mother and never looks at the baby at all. Scott has done us all a service by directing our thought along these lines.

In my practice I still adhere most commonly to the three-hour feeding schedule for breast babies during the day, and the 2 a. m. nursing until the baby is two or three months of age.

It is well for us to remember that the breast produces for the next feeding just the amount which was taken out at the last nursing. Therefore, emptying the breast after baby nurses, preferably by manual expression, is valuable in obtaining and keeping a uniform production adequate to the increasing demands of the infant. We try to have each mother do this as a routine procedure after each nursing.

Formulae should not be given for complemental feedings before the lying-in period is over, as many patients immediately improve in breast function after being up and about again. Formulae are certainly advisable in preference to undernourished babies, but the physician should be the only one permitted to advise the formulae.

Prenatal care will pay large dividends in better mothers and babies; especially will it increase the number of mothers that can nurse their babies. With this and other objects in view, we place in the hands of every mother carefully selected books on "Prenatal Care," "Infant Care," and "Child Care," together with other reliable information. This is much appreciated by every patient, particularly the young woman who expects her first baby. Even experienced mothers appreciate instructions as to the care of themselves and the baby. All physicians should teach their patients these better things, not merely limiting their obstetrical care to the narrow field of attendance at labor.

Doctor Scott (closing) — Discussions always bring up important features and emphasize them.

Loomis' comments are timely, but do not leave the complemental feedings to a nurse, unsupervised.

If necessary to give additional feedings, work out a satisfactory schedule, and when it is not needed discontinue it. Don't prescribe it and forget all about it.

Syphilitic Bursitis — John E. Lane, New Haven, Conn. (Journal A. M. A.), reports two cases. In one patient both knees were affected. The pertinent points in her history were: Her husband had syphilis seven years before. Five years before that she had an ulcerated throat, ulcerations on the arms, and headaches; two years later, she had ulcerations on the legs. The diagnosis was bilateral syphilitic prepatellar bursitis. Arsphenamin was given with some improvement at first, but later the slow healing justified the surgical advice of excision of the bursae. In the second case the right elbow was affected. The only thing in the patient's history or that of his family suggesting syphilis was the story of ulcerations. He had received a blow on the right elbow two years before. Within two or three days, a swelling began to appear on the elbow. In the course of the next few weeks it gradually grew larger until it was about half the size of an egg, when it broke through the skin and began to discharge. A diagnosis of bursitis had been made before it broke down. From that time on, other ulcerations appeared in the vicinity, some persisting for a long time, new ones appearing as some of the older ones slowly and spontaneously healed. The diagnosis was: gummatous syphilitic olecranon bursitis; multiple syphilitic gummas and fibroid subcutaneous syphilomas. The patient was placed on anti-syphilitic treatment, with immediate improvement, and the lesions were completely healed in about eight weeks.

NARCISSE JOSEPH MARTINACHE, A REMARKABLE OPHTHALMOLOGIST *

By DOUGLASS W. MONTGOMERY, M. D.,
San Francisco

Narcisse Joseph Martinache came to San Francisco, like many another, in hopes of acquiring a rapid fortune. Instead of this he lived a quiet, orderly life full of good works and kindnesses to those around him, and died leaving a good name and a modest competence.

It happened that I saw a good deal of him when I came to San Francisco in 1886. He was then over fifty years of age, and enjoyed a small but sufficient practice. He was not the kind of man to have a large one. In the first place, he was not a good propagandist; he was not at all showy and he loved to converse. It has been said that no man should be so addicted to work as to have no time to be polite, but it is remarkable how time flies during a friendly conversation. And in conversing with Marinache one picked up many things, for he was an excellent clinician, with the capacity both for seeing facts in their just proportion, and for applying the appropriate remedy. As far as seeing things was concerned, he had been trained in an excellent school, for the Parisian clinicians have always been noted for clarity of thought, the Latin lucidity joined with the tenacity of the Northern races. And as a school it is also noted for adhering to the definite study of the patient.

Before coming to San Francisco he had been chief of clinic for five years under De Wecker, probably the most famous oculist of his day, and collaborated with him on the Encyclopedia of Ophthalmology.

Martinache, however, was no mere hand workman striving to make his specialty a closed field. To illustrate: One day when coming down Mason street, between Post and Geary, I met Martinache. It is strange how an unimportant scene will fix itself in one's memory. I can recall his lineaments and figure distinctly as he came toward me. He was stockily built and rather slow and awkward-gaited; he could never have been a deft operator, although he was a careful one. He had a full beard and moustache, and he was dressed in black throughout—in a long black coat and a tall hat tipped a little back. He had a perfectly serene temper and a pleasant address devoid of self-consciousness or embarrassment, and he was very friendly. He gave the impression of solidity of character, worth and ability, but he was no Jupiter in the sense of being a cloud compeller.

He, of course, stopped to talk. I was then about twenty-eight years of age and he was over fifty. He spoke of the hypersensitiveness some people showed to the ingestion of certain foods, and more particularly of the case of a young girl who developed a pustular eruption from certain articles of diet. It was an instance of what we now recognize as anaphylaxis. I had recently returned from Europe, thoroughly imbued with the study of structural anatomy, and the then developing bacteriology, with

* Read before the Medical Society of the City and County of San Francisco, on the presentation by Dr. C. S. G. Nagel of a portrait of Dr. Martinache.

the attendant scholastic intolerance of any other branches of pathology.

As we parted my unexpressed opinion was that his observation had been incorrect, and that the patient's symptoms were due to some other cause, and not at all attributable to food. With this was probably associated the condescension of a young man towards any ideas of the elderly.

THE ACTUAL CAUTERY IN ULCER OF THE CORNEA

Martinache was the original discoverer of the use of the actual cautery in ulcer of the cornea. During his life his priority in this was disputed, in some instances acrimoniously, and very especially in medical literature by an oculist in Lyons, France. After three years this man acknowledged the priority of Martinache. Martinache would take any wire and heat it to a dull cherry-red in a spirit-lamp flame, and then draw it over the ulcer. Adolf Barkan tells me that for this purpose a strabismus hook is excellent, and, if heated to a cherry-red, the time consumed in carrying it from the flame to the patient's eye is just sufficient to allow the instrument to cool to the proper heat.

I have no doubt this discovery did Martinache a great deal of harm. Full use, to his detriment, was made by at least one of his confreres of this startling and apparently destructive procedure, and this unexpected result of a fine discovery is not without precedent in the history of medicine. It has its counterpart in the effect produced on the practice of Harvey on the announcement of the discovery of the circulation of the blood. Instead of increasing Harvey's reputation it caused a decided decrease in his practice, of which he bitterly complained.

Martinache was especially expert with the ophthalmoscope, and he had a notable case in the person of Hall McAllister. The great jurist had but one eye, which was beginning to give him trouble, presumably from its blemished brother. The findings of Martinache in this case secured a well-merited compliment from Knapp of New York, whom McAllister subsequently consulted.

In many ways Martinache had the art reduced almost to a science of impeding his material advantage. For instance, his office, 5 Kearny street, was reached by climbing two long flights of stairs, and the ceilings were high and the flights were long in those days, and there were no elevators. Mrs. Abbie Parrott, one of his most loyal patients, used to arrive panting, and would complain of his inaccessibility. "Why don't you get a more accessible office, doctor?" "Why should I, madam? You see, you come," was the Gallic response.

In the practice of his profession every medical man does his share toward helping his fellow-man as a matter of the day's work, never thinking of reward, and a strong, naturally benevolent nature with a well-trained mind, as in the case of Martinache, does more than his share. Some were grateful, others were thoughtless and a few were actively vindictive, as fearing a bill for the work done. The writer of one of the Gospels relates that Jesus cured ten lepers and one returned to thank him. In California 10 per cent is a rather high average of gratitude, even to the Deity, but it may have been different in Palestine.

But Martinache's beneficences did not end with his professional work. Louis Bazet relates that when he came to San Francisco he was urged to remain because it was a location particularly favorable for him, as knowing three languages—English, Spanish, and French. He sought Martinache's advice, who told him frankly that he would have a

NARCISSE JOSEPH MARTINACHE

"Fortunatumque laborum egregiusque animi" (Both fortunate in labors and noble of soul). Virgil, Aen. XI, 416.

long pull for it. When the resolution was taken, however, Martinache wrote out a check at the end of each month covering the deficit. This help endured for one year, at the end of which time Bazet was on his feet. It is needless to relate that Bazet has always cherished the deepest gratitude for his benefactor and friend.

Martinache was born in 1833 in the town of Hornaig (Departement du Nord), France, in what was formerly the Province of Picardie. He died December 23, 1892, in San Francisco, Calif.

The circumstances of his death are interesting to medical men. For some time before his death he had premonitory twitchings of the muscles of the left side of his face, and he resigned his position as oculist and aurist to the French Hospital in favor of Kaspar Pischel. He had been twenty years connected with this institution.

On the date above mentioned, on coming out of

his room, he suddenly pitched forward and all was over.

The autopsy showed sclerosis of the basilar artery, with a large spindle-shaped aneurism below it. The sclerosed artery was perfectly white, very thick and fibrous, and the lumen most minute. Arteriosclerosis was one of the subjects in which he was most deeply interested.

So passed away one of the most gentle of men, to enter the vast bosom of Nature, whose moods and ways it had been his greatest pleasure to study and observe.

323 Geary Street.

CARBON DIOXIDE COMBINING POWER OF BLOOD PLASMA IN PULMONARY TUBERCULOSIS *

By FRANK PORTER MILLER, M. D., Los Angeles

We are somewhat indebted to the work of McCann and Barr for their recent investigations upon respiratory metabolism, but this study does not parallel, as their carbon dioxide estimations were made entirely in terms of expired air. It might be well to reiterate a few salient facts relative to respiratory metabolism, and thereby make the scheme of reasoning a little more comprehensive. We know that in cases of advanced pulmonary tuberculosis the total pulmonary ventilation is approximately twice that of normal controls. We also know that the percentage of carbon dioxide produced and oxygen absorbed, in terms of expired air, is much reduced as compared with the normal.

It has been suggested that the increase in pulmonary ventilation was due to a reduction in the vital capacity of the tuberculous individual, but I feel that this reasoning is partially faulty, as they have not taken into consideration the para-sympathetic reflex (vagus), and also the fact that carbon dioxide in solution acts as an acid, and its effect upon the respiratory center must be accounted for. Assuming that the decrease in vital capacity is productive of increased pulmonary ventilation, we should then recall the disparities existing in vital capacities, depending upon the age period, height, and weight. Vital capacity markedly decreases after the thirty-fifth year, but there is an increase of eight cubic inches of air for each additional inch between five and six feet in height.

The increase of pulmonary ventilation will lower the percentage of carbon dioxide eliminated per unit time, but the total amount is found to be higher in the tuberculous than in the non-tuberculous controls. The amount of carbon dioxide eliminated in cc. per minute time is approximately 14 per cent greater in advanced tuberculosis than in the non-tuberculous.

Basal metabolism in tuberculosis has also been studied by Barbour, as well as McCann and Barr. Their determinations were made when the diurnal range of temperature was at its lowest, and only those cases which were extremely quiet during the test were considered basal. Basal metabolism implies minimal metabolism, and this is what is sought. For each individual case the normal metabolism is the metabolism maintained during health, and the surface area in each case was determined from the height and weight, by the "height-weight" chart of Dubois & Dubois, or, in other words, the normal heat production per square meter of body surface was taken from these tables, and this takes into account the age. As the result of their work, they concluded that the basal metabolism in tuberculous patients may be normal or very slightly above that of normal men of the same size. Thus, in thirteen cases the variation was from a minus 3 to a plus 15 per cent.

Whitney has called attention to the very severe degrees of acidosis which may occur in the terminal stages of disease of whatever sort, often sufficient, apparently, to account for the death or to add seriously to the existing intoxication. Unfortunately, in the cases examined by him there were no typical cases of advanced pulmonary tuberculosis, but since anemia, terminal infections, and cardiac decompensation commonly exhibit marked terminal acidosis, it was to be expected that a final acidosis would exist in phthisis. The numerous studies on the subject of acidosis in various diseases also omit consideration of tuberculosis, except the inclusion of isolated cases which are of no significance.

Here it might be thought that, since carbon dioxide is a waste product of the oxidation process, the best possible condition would be its complete removal; but it has been clearly shown by Haldane that a definite minimal percentage of carbon dioxide is required for the regulation of the respiratory exchange; and that when the percentage is reduced by artificial ventilation, the subject passes into apnoea, or suspension of breathing, until the amount is brought back toward normal in the lungs and tissues. The normal amount of carbon dioxide in the alveolar spaces lies between 4 and 5 per cent, and, if it rises or falls but slightly from the normal, corresponding changes take place in the respiratory rhythm and depth, which tend to restore the balance once more. It has further been shown by Henderson that excessive and prolonged ventilation of the lungs by artificial means leads by lowering of the carbon dioxide concentration to irregularity of the heart beat, and finally, if pushed, to delirium cordis and death of the animal. Short of this limit, stoppage of the positive ventilation has the effect of restoring the heart to regular rhythm. Passing in the opposite direction, and observing the effects of increasing amounts of carbon dioxide, administered in artificial mixtures containing as high, or higher, amounts of oxygen as are present in atmospheric air so as to avoid asphyxiation from deficiency of oxygen, it is found that carbon dioxide has directly poisonous effects upon the bioplasm. Thus with 12 to 15 per cent of carbon dioxide and 20 to 25 per cent of oxygen, it is found that animals become somnolent, the urine will contain glucose, while with 20 to 25 per cent of carbon dioxide, even in presence of excess of oxygen, death rapidly occurs. The same effects are seen upon isolated tissues. Thus Waller has shown that the first effect of minimal traces of carbon dioxide is to increase the excitability of

* Read before the Sixty-ninth Regular Semi-annual Convention of the Southern California Medical Society, held in Los Angeles, Calif., November 3, 1923.

nerves, while larger doses diminish excitability, and finally all excitability disappears. Similar results have also been found in unicellular organisms.

Our interest was first aroused in the carbon dioxide determinations, because of the paucity of the literature and also the diversity of opinion as regards acidosis in this particular disease. In discussing this phase of tuberculosis, a number of us have been offenders, and have discussed this from the positive phase alone, making our deductions largely from clinical observation and have not sought confirmation through the most approved laboratory methods.

In this series of cases which we examined, we grouped them into five classes, all being placed upon a fifteen-hour fast.

1. Far advanced fibro-ulcerative-caseous type of tuberculosis with excavation. A number of this class were of the acute pneumonic type with a diurnal variation of temperature from 97.6 degrees to 103 degrees. All of this first group were confined strictly to bed, and the only exercise permissible was toilet exercise. By minimizing all forms of physical exertion, we lessen the carbonic and lactic acids; also the metabolites which escape into the blood stream during exercise.

2. Moderately advanced type. A few in this group were up as much as three hours per day, but the remaining portion of the time was spent strictly in bed. Many of these had temperature.

3. Early cases. This group was also confined to bed.

4. Ambulatory type. In this group we included one of each of the above types. At this time we became curious to ascertain the carbon dioxide findings under working conditions, so the ambulant cases were allowed their regular breakfast, and the blood withdrawn three and one-half hours after ingestion of food. We might add that these cases were ambulatory through sheer lack of finance and this was not the treatment of predilection, but was their only alternative. Seven days following the test they were placed upon the usual fifteen-hour fast and a recheck made.

5. This included a series of three normals (nurses) all upon exercise, with the usual fast.

The method of Van Slyke was used in our determinations, and we followed the precautions outlined by him. Ten cc. of blood was withdrawn from the median vein at the elbow, placed in a centrifuge tube containing potassium oxalate and covered with liquid petrolatum. The blood was then centrifuged, and the carbon dioxide combining power of blood plasma was estimated in from three to six hours. Before each individual determination was made, the apparatus was washed with a solution of ammonium hydroxide which contained barium hydroxide, as this will absorb any excess of carbon dioxide. Furthermore, a few drops of a solution of phenothalein was added so as to prove our alkalinity. We attempted to be very meticulous in the whole procedure, and attention to detail made it a time-consuming process.

Forty-one determinations were made upon thirty-six different individuals. Thirty-three of these were patients and three were nurses, which were used as controls.

In the far advanced cases, eighteen determinations were made, with an average carbon dioxide range of 61.3. Moderately advanced group with thirteen cases showed a general average of 64.4. Early cases, of which there were four, produced an average of 57.6. Ambulatory cases, of which there were four, showed 63.4 as an average. Our average for controls was 66.3 or very slightly above the determinations made for patients. The carbon dioxide findings and their relation to temperature of 100 degrees Fahrenheit, or above, for six cases produced an average of 63.5. In twenty-six cases below 100 degrees Fahrenheit, the average was 61.7. In the ambulatory cases, no appreciable difference was noted in the finding, with the usual breakfast or upon the fast.

From the foregoing results of our study, no depletion of the blood alkali was evident, and we failed to find any evidence of acidosis, even in those cases fast approaching exitus. Two of our cases were examined fourteen to eighteen days prior to death, and in each case the determinations did not even approach the lower limits of normal. In all these cases the urine was examined for total acidity, and there was usually an increase of 50 to 100 per cent above normal. Of course, an acid urine does not imply an acidosis. We also examined for urochromogen and diazo substances, and the continued presence of these usually bespoke a bad prognosis. When an acute infection of any nature is superimposed upon these cases, the urochromogen and diazo substances would appear, but only during the course of infection.

Even though we failed to find an increase of acid radicles in the blood stream, the increased acidity of the urine, plus a 14 per cent increase of carbon dioxide in expired air, makes us again plead for use of alkalies in the treatment. The introduction of alkali facilitates the interchange of gases, by giving to the blood an excess of buffer substances, and our clinical experience certainly justifies its continuance.

A study of the gaseous exchange, which is of such vital importance to cellular life, will illustrate this point. We find the blood corpuscles contain carbon dioxide and carbonic acid in solution, as phosphates, carbonates, or bicarbonates of sodium or potassium, or as methemoglobin, and convey these substances to the excretory organs of the body. Remembering the diffusibility of gases, and since the tension of oxygen in air is greater than that of blood, and the tension of the carbon dioxide in blood is higher than the outside air, the exchange can readily take place. Naturally, the oxygen of the air passes through the lungs into the hemoglobin, in exchange for carbon dioxide and carbonic acid. When this occurs, the alkalies are liberated into the blood and again assume the function of combining with carbonic acid affinities. By the introduction of "buffer substances," through the means of alkalies, we prevent even a moderate depletion.

Shortly after we began this study, Hachen published his results upon alkali reserve, and I am happy to state that our results coincide, especially upon the essentials, though differing somewhat in detail. His cases were selected from a series of 213 patients, showing every type of lesion, with the far-advanced type predominating. He found a moderate depletion in the blood alkali in advanced cases, if there was an accentuation of the process. He also thought

there was a drop in alkali reserve a few days preceding death, and also those cases with a temperature above 100 degrees Fahrenheit showed a slight decrease. He concluded that there was a moderate depletion of alkali in the blood, but at no time approaching an acidosis. In our own determinations we failed to note a diminution in alkali reserve in cases with temperature; those approaching death; or in advanced cases with increased activity. The discrepancy in results may have been due to the fact that he failed to "fast" his patients, or if they were placed upon the fast, no mention was made of same.

One of the outstanding features of this study is the ability of the body to maintain its equilibrium, even though the mechanism is impaired through the dissolution which is in progress. It is well to recall the delicate and lightly balanced labile equilibrium existing between the colloids of the cell protoplasm and the osmotic pressures of the inorganic ions and other crystalloid constituents. Because of the loose union which binds the various constituents of the bioplasm, a change in the osmotic pressure will cause a dropping of one of the components, and it is this component which is most needed to aid in the compensation process. The process of compensation is also aided by the longevity of the disease, which allows the adjustment. I wish to state, in closing, that this work was made possible through the splendid co-operation and many helpful suggestions of M. C. Terry.

CHART I

Carbon Dioxide Determinations in Forty-one Cases

Clinical condition	1	2	3	4	5
Number of determinations	18	13	4	4	3
Carbon dioxide range	49.6-68.1	57.8-73.8	53.3-63.6	59.7-69	61.6-69
Average	61.3	64.4	57.6	63.4	66.3

Normal findings, 53-78 mg. per 100 cc. of blood plasma.

CHART II

Carbon Dioxide Findings and Its Relation to Temperature

	100° F. or more	Below 100° F.
Number of determinations	6	26
Carbon dioxide range	57.9-67.3	49.6-73.8
Carbon dioxide average	63.5	61.7

CHART III

DISCUSSION

P. J. Hanzlik and F. De Eds (Stanford Medical School, San Francisco) — The discussion of Miller's paper requested of us by the editor, we desire to limit to the feature of alkali therapy. After making determinations of the carbon dioxide combining power of blood plasma in cases of pulmonary tuberculosis, Miller concludes that no depletion of the blood alkali was evident and that there was failure to find any evidence of acidosis. However, inspection of his data on the carbon dioxide combining power of the plasma indicates a deviation from the normal values in the direction of acidity. It is our opinion that these deviations are of sufficient magnitude to indicate a definite tendency to acidosis, and if electrometric or colorimetric measurement of the pH of the blood had been made at the same time, a shift toward acidity might have confirmed this tendency.

The paper points out further that an increase in acidity of 50 to 100 per cent occurred in the urine, but fails to attach importance to this observation. Contrary to the author's conclusion, the urinary changes, we believe, harmonize with the data on blood, and indicate a depletion of alkali in the body and a tendency toward acidosis.

The statement is made that no increase of acid radicles was found in the blood stream, but it is not clear whether or not this refers to an absence of lactic acid and acid phosphate. These acids may be increased when the CO_2 is decreased. It cannot be said definitely whether the tendency to acidosis indicated by the blood data is of sufficient magnitude to be of pathological importance, since the problem of small deviations from normal is just being investigated and their significance is not fully understood, but it is likely that they have a greater meaning than has been heretofore attached to them, especially when it is borne in mind that small differences in the negative exponential values used for expressing pH really mean large differences in hydrogen ion concentration.

With respect to the information concerning the manner in which the blood corpuscles carry carbon dioxide, we disagree with the author's statement that blood corpuscles carry the carbon dioxide as phosphates or as methemoglobin. This is not in accordance with the teachings of physiology. We also disagree with the author's opinion regarding the ability of the body to maintain its neutrality equilibrium. In our opinion, the limits within which equilibrium is maintained are not so narrow as has been believed to be the case. This opinion is sustained by results that have been obtained in our laboratory in experiments on the effects of intravenous injections of various agents on the composition of blood of dogs, by the results of Barr of New York on patients, and of Miss Denis of New Orleans on animals.

In conclusion, we would say that Miller's work points to a moderate though definite tendency toward acidosis in the blood stream, and that there is, therefore, a rational basis for the administration of alkali; but the ultimate beneficial effects, if any, of such therapy in the treatment of a condition like tuberculosis may only be conjectured. Presumably, the treatment is intended to give temporary and symptomatic relief.

F. M. Pottenger (Monrovia) — I have been using alkalies in the treatment of active advanced tuberculosis for several years. Miller has also been carrying out the same principle in his own practice. It was the favorable clinical effects which we had noticed in active tuberculosis that suggested the laboratory research here reported, so the conclusions which Miller drew from his laboratory investigation came as a great surprise to us.

For several years we have been using bicarbonate of soda for the relief of such symptoms as nervousness, insomnia, digestive disturbance, loss of appetite, malaise and general weakness, as found in a large proportion of cases of advanced active tuberculosis. A certain amount of relief, varying in different patients, has almost invariably occurred. If there is no acidosis, as is suggested by the interpretation of the laboratory experiments conducted by Miller, it certainly is due to the marked compensatory powers possessed by the physiologic mechanism of the body. The fact that there was no increase in the CO_2 of the blood, as shown by the experiments, was very much opposed to what was anticipated when the experiments were started. The increase in the output of acids in the urine was the same as we had observed previously. Even though no acidosis is shown by Miller's experiments, this increase in the urinary acid output of itself is evidence that there is an enormous increase in the production of acids in the body. From this it seems rational to conclude that there must be a marked drawing upon the alkali reserve of the body.

This paper supports a rule which should always be found in medicine, and that is, where laboratory opinion differs from clinical experience it is better to follow clinical experience.

Doctor Miller (closing) — Considering the present state of our knowledge in regard to blood chemistry, I made the only plausible deduction that I thought the findings would justify. I must admit that the absence of acidosis in far-advanced tuberculosis came as a distinct surprise. I am in hopes, as we delve further into this subject, that a deviation toward the side of acidity may later be interpreted as an acidosis, and confirm the suspicions of Hanzlik.

BONE TUMORS

By HENRY SNURE, M. D., Los Angeles

From time to time we have cases of bone tumor referred to us with a diagnosis of rheumatism or neuritis. As this seems to be a common error, it might be well to briefly consider the x-ray diagnosis of these tumors.

The best method of study, and the one most widely adopted, seems to be that of Baetger and Waters. They classify tumors according to four cardinal points and several laws of probabilities. The four cardinal points are: Origin of tumor; the presence or absence of bone production; the condition of the cortex of the bone; invasion. The law of probabilities relates to sex, age, and the particular bone involved. It is not necessary to answer all these points. To make a diagnosis only two points are often sufficient.

In regard to the first point, that of origin: By origin is meant whether the tumor arises in the medullary canal or in the cortex. All tumors of bone are either primary or metastatic; therefore, if we can prove that a tumor arises in the cortex we can rule out carcinoma, as there are no epithelial cells normally in bone tissue, and such cells must gain admission through the nutrient artery or the accompanying lymph vessels. Sarcoma being of connective tissue, origin can be either primary or metastatic. Enchondroma and cysts are medullary in origin, but have other diagnostic points. We now consider the second cardinal point, that of bone formation. If we can prove that bone is being produced, we can immediately rule out carcinoma, round cell, spindle cell, and giant cell sarcoma, as these tumors are not bone producers, and this in turn limits us to the bone producers, namely, osteoma, osteochondroma, periosteal sarcoma, osteosarcoma, and ossifying hematoma. Traumatic and progressive myositis ossificans can also be mentioned here. Next we consider the third point concerning the condition of the cortex. We determine whether the cortex is present or absent, and if present if it is expanded in a spherical or longitudinal manner.

Malignant tumors grow in a spherical shape and sweep through the cortex so rapidly that it is destroyed, or if a small bit remains it is not expanded. There is one exception to this rule and that is, the giant cell sarcoma, which grows in a spherical manner, but does not destroy the cortex, only thinning it out, and is definitely limited to the medullary canal. The cells are so large it cannot metastasize. The benign tumors follow the path of least resistance and extend up and down the medullary canal and slowly expand it in a spindle-shaped manner, the cortex being pushed out and thinned. We must also determine whether the tumor springs from the cortex or the periosteum; from either the character of the bone production must be noted. As a general rule, in benign conditions, the bone is laid down parallel to the shaft and in malignant conditions perpendicular to the shaft. The fourth cardinal point is that of invasion; if this can be demonstrated, it means malignancy and is usually all the clinician or surgeon wants to know.

If there has been surgical intervention before making the x-ray film, it is often impossible to make a diagnosis. By the law of probabilities is meant what is most frequently found when the age and sex of the patient are taken into consideration with the particular bone involved. Statistics show us that carcinoma of the breast and pelvic organs are most common in the female and those of breast origin metastasize in the following order of frequency: First the ribs, then dorsal spine, lumbar spine, ilia, femur, especially the greater trochanter, skull and humerus. Rarely does it metastasize below the knee or elbow. Tumors of the pelvic organs usually metastasize to the lumbar spine. In the male the most common tumors are those of the tongue and lip and of the genito-urinary organs. Those arising in the tongue and lip extend directly to the mandible, if at all. Those of the genito-urinary tract, particularly of prostatic origin, cause metastasis in the lumbar spine and the pelvic bones. In regard to age, under thirty years most likely to be sarcoma; above thirty, either sarcoma or carcinoma. The particular bone involved does not help much in sarcoma, as it may be either primary or metastatic. However, sarcomas are commonly found at the end of the bones and carcinomas in the middle of the shaft.

The chief point to bear in mind is, not to make a diagnosis because the film resembles one you have seen before, but to work it out along the definite lines of known x-ray pathology.

1501 South Figueroa Street.

DISCUSSION

James B. Bullitt (San Jose)—The statement by Snure that "if we can prove that bone is being produced we can immediately rule out carcinoma, round cell, spindle cell and giant cell sarcoma, as these tumors are not bone producers," is correct insofar as round cell tumors are concerned, as all round cell growths of bone have origin from bone-marrow cells, and should be sharply separated from tumors arising from bone cells. On the other hand, spindle cell tumors are the usual form of periosteal growths, which, as the author states, are typical bone producers.

In regard to bone production, as the author states, in benign conditions the new bone is laid parallel to the shaft, and in malignant conditions (notably periosteal sarcoma) perpendicular to the shaft. To this statement should be added the single exception that in syphilitic periostitis the new bone is frequently laid down at right angles to the cortex, the strands interlacing at their extremities to form a lacework pattern, this interlacing giving the clue to the differentiation from periosteal sarcoma.

In regard to osteosarcoma being a bone producer: In the more malignant rapidly growing type there may be little new bone formation, but rapid destruction of shaft, while in the slow-growing types there may be massive production of bone and much less destruction of shaft (ossifying sarcoma).

The discussion of bone tumors should embrace a few emphatic words as to the importance of differentiating the benign bone cysts from the malignant growths. There is good reason to believe that many limbs have been needlessly sacrificed because of failure to make this differentiation. In this connection it is interesting to note that review of cases of cure of sarcoma by amputation by Bloodgood has brought forth the conclusion that some of these cases, probably many, were not sarcoma at all, but unhealed bone cysts mistakenly diagnosed sarcoma.

The great majority of bone cysts, or osteitis fibrosa, give evidence of their presence before eigh-

teen years of age, usually earlier, by localized swelling, pain or limp, sometimes by pathological fracture as the first symptom. Bone cysts untreated may reach huge dimensions.

Bloodgood is of the opinion that in central lesions of the bone in which the bony shell is intact and in which there may or may not be recent fracture, the differential diagnosis between the various possible central pathological lesions cannot be made by the x-ray alone. Several points, however, will help in making the differentiation. If the expanded cortex has been broken through, central sarcoma is to be considered. If the epiphysis is involved, giant cell sarcoma is probable, pathological fracture being rare; or epiphysial involvement may mean sarcoma. New periosteal bone would indicate osteomyelitis or periosteal sarcoma. In central giant cell tumor, sarcoma, chondroma, myxoma, and in the bone cyst, there is never evidence in the x-ray of new periosteal bone.

Chondroma and myxoma cannot be recognized by the x-ray alone, and from these the greatest difficulty will be had in differentiating bone cyst.

W. Edward Chamberlain (Stanford University Hospital, San Francisco)—Doctor Snure states that if we can prove that bone is being produced we can immediately rule out carcinoma. It is necessary to bear in mind a very striking exception to this rule. In addition to the more common variety of metastatic carcinoma in bone, in which the neoplasm produces characteristic destructive changes (osteoclastic type), there is a group of cases in which the neoplasm produces a remarkable laying down of dense bone salts (the osteoplastic type of metastatic carcinoma). It is our present understanding that the difference between the two types is entirely explained by a difference in rate of growth. In other words, the bone reacts differently to the very slow-growing neoplasm from what it does to the more rapid types.

The accompanying plate shows another essential feature of these osteoplastic cases. There may be increase in dimensions as well as in density of the affected bones. The radiographic appearance frequently resembles that of Paget's disease of the bone.

In our experience the most frequent site of the primary cancer in these osteoplastic types has been in the prostate.

Doctor Snure (closing)—I wish to add that the rules given in this paper are not 100 per cent positive, but are true in at least 90 per cent of the cases. As Bullitt states, the spindle cell tumor of the periosteal sarcoma usually produces bone and for this reason is classified as a bone producer. The spindle cell tumors referred to in the classification are those in which there is no bone production. Mallory lists the following tumors as those having spindle cells: Fibrosarcoma, chondrosarcoma, osteosarcoma, melanoma, leiomyoma, glioma, rhabdomyoma, hemangioendothelioma and neuroblastoma. I am glad that Bloodgood's opinion of benign tumors was mentioned. He feels that rarely do we have malignant tumors of central origin in the upper third of the femur under fourteen years of age. He advises the following treatment: Crush benign cysts, curette giant cell tumors, and use the cautery for the myeloma and chondroma.

Chamberlain's remarks are important. The metastasis from prostatic malignancy is the most common in the male and often gives the clinical symptoms of arthritis and osteomyelitis. I have a case in which the ilium was incised and drained; staphylococci were found in cultures from this area. The x-ray findings and microscopic tissue sections showed the condition to be metastasis from a malignant prostatic tumor.

A Caution to Members — Some of our members have called our attention to an advertisement from one I. W. Long of Columbus, Ohio, offering certain courses to doctors under certain conditions, by "D. V. Ireland, M. D." of Columbus, Ohio. Ireland proposes to be in California in December. Before subscribing the $100 fee for this course, we suggest that you read page 1951, Journal of the American Medical Association of December 2, 1922. Among other things, this article says: "I. W. Long seems to make a business of promoting the activities of those members of the medical profession who have sensational or bizarre theories to exploit and who wish to commercialize these theories. Long also seems to act as an agent for the sale of such devices and publications as may be necessary to the proper practice of the particular brand of therapy that is being exploited. Long has acted as publicity agent for courses in 'Electrotherapy' by C. L. Ireland, in 'Diseases of the Rectum' by D. V. Ireland, in 'Zone Therapy' by W. H. Fitzgerald, in 'Bio-Dynamo-Chromatic Diagnosis' by George Starr White, in 'Spondylotherapy' by Albert Abrams, etc. He has also sold 'abdominal supporters,' books on osteopathy, devices for performing stunts in 'Zone Therapy,' a chart advertised as 'A Key to the Practice of Osteopathy, Chiropractic, Massage and all Drugless Methods," and many other things. According to our records, D. V. Ireland was born in 1855 and was graduated by a homeopathic school in 1881—forty-one years ago. He seems to have practiced exclusively in Ohio and to have stayed but a few years in each town. The medical directories' record: 1886, Mansfield, Ohio; 1890, Xenia, Ohio; 1893, Fredericktown, Ohio; 1896, Mt. Sterling, Ohio; 1900, London, Ohio; 1902, Dayton, Ohio; 1906, London, Ohio; 1908, Columbus, Ohio; 1910, London, Ohio; 1914 Chillicothe, Ohio; 1916, Wilmington, Ohio; 1918, Columbus, Ohio. A study of the medical literature of importance for many years past fails to show that D. V. Ireland has published anything. He is not, and never has been, so far as our records show, a member of his local society." If more of our members would take the trouble to refer all their mail about which there may be any question to the Secretary of the California Medical Association, they might help the cause of better medicine, and even sometimes save money.

Our present social order, with all its defects, represents the best that human beings have been able to work out for themselves. "Before any man sets himself up as a professional critic of it," says Bruce Barton in a well-named "Common-sense" editorial (Red Book Magazine), "I want to ask him four simple questions:

1. Have you a family and are you supporting it? If not, don't pick on me. I have, and am.

2. Have you engaged in some gainful occupation and shared the problems and worries of the employers you are so ready to condemn.

3. Are you tolerant and fair-minded toward those who disagree with you?

4. Do you pay your bills?"

EDITORIALS

THE CALIFORNIA MEDICAL ASSOCIATION

Editorial Notes About the Fifty-third Annual Session, Held in Los Angeles, May 11 to 15, 1924

LOS ANGELES

For the first time in a number of years the annual session of the California Medical Association was held in Los Angeles, the metropolis of Western America. The session was by all odds and in every important sense the largest and most successful in the history of the association. Much of the success and very much of the fine, happy, fraternal spirit that pervaded the gathering was due to the attractive setting, and many comforts and pleasures showered upon us by a great city acting as hostess. We doubt very much if there is anywhere another city of a million inhabitants where so much is done for invited guests. Surely, there is no other where the climate in May is so perfect that one is as unconscious of it as he is of a well-fitting and much-worn suit of clothes; where "taps" sung by mocking birds and perfume from tropical flowers and filtered moonlight soothes us to peaceful sleep; and where "reveille" is sounded by meadow larks calling us to another day's work.

The Honorable George E. Cryer, mayor of the city, welcomed our association as guests of the city in a public address; friendly newspapers carried the mayor's message to all the citizens, and thereafter we were made to feel the welcome wherever we were and whomsoever we came in contact with.

The Biltmore Hotel not only placed at our disposal their unusual facilities for housing a convention, but their officials and employes were courteous and tireless in efforts to please.

THE PRESS AND PUBLICITY

Many favorable comments were heard on every hand commending the generous quantity and the fine, constructive, informative quality of publicity about the doings of the convention. This was brought about by the co-operation of the great news distributing services; by the generous attitude of the editors of the metropolitan press, not only in providing space and editorials, but by assigning experienced staff writers to cover the convention.

The tireless and effective work of Mr. Celestine J. Sullivan as chairman of the publicity of the session was of the greatest value in collecting, assembling and interpreting the news and in assisting the staff writers in its distribution. The chairman, with his office assistants, had been very busy for more than two months collecting advanced copies of papers and abstracts and getting them into shape for the press. Two editors and several reporters told this writer that the material was presented to them in better and in a more attractive manner than at any previous convention, medical or otherwise.

OUR HOSTS

The Los Angeles County Medical Association, through its committee of arrangements and various special committees, provided a remarkable number of unusually attractive social features, and successfully co-ordinated the many scientific sections.

The *Central Committee of Arrangements* was made up of William H. Kiger, chairman; Harlan Shoemaker, W. T. McArthur, George H. Kress, Donald Frick, William Duffield, Wayland Morrison.

Other committees were:

Golf—Donald Frick, chairman; Guy Cochran, Stanley Granger, Lewis B. Morton, Roy Thomas, W. H. Kiger.

Finance — Wayland Morrison, chairman; C. G. Toland, Lyle G. McNeile.

Entertainment — George H. Kress, chairman; John V. Barrow, W. W. Beckett, G. Bjorkman, William B. Bowman, J. M. Brown, F. K. Collins, William Duffield, F. C. Ferry, Trusten M. Hart, Maurice Kahn, Carl Kurtz, Percy T. Magan, Harry W. Martin, F. C. E. Mattison, H. G. McNeil, E. C. Moore, P. Newmark, E. A. Newton, H. E. Southworth, F. A. Speik, C. P. Thomas, H. M. Voorhees, N. N. Wood.

Hostesses — Eleanor Seymour, chairman; Addie B. Allen, Helen O. Anderson, Venturia C. Armstrong, Hannah Beatty, Laura B. Bennett, Mona E. Bettin, Marietta Bewley, Margaret Bigby, Lorena M. Breed, Blanche C. Brown, Charlotte M. Brown, Mary Hess Brown, Annie S. Bullock, Grace W. Cahoon, Katherine M. Close, Belle Wood Comstock, Elmina F. Cook, Mary E. Dennis, Nannie C. Dunsmoor, Lula T. Ellis, Alice Barker Ellsworth, Margaret Wilson Fate, Kate Wild Glass, Etta Gray, Mary E. Hagadorn, Nattie H. Thurston, Margaret Farr-Hara, Helena A. Hunt, Josephine Jackson, Etta C. Jeancon, Cora W. Jones, Florence Keller, Mila J. Kinney, Anna B. Lefler, Evalyn F. McNealy, Olga McNeile, Caroline McQ. Leete, Julia T. Metcalf, Lillian Mitchell, Margaret M. Morris, Marcis A. Patrick, Josephine Platt, Harriet G. Probasco, Ruth Purcell, Cecelia Reiche, Louise M. Richter, Julia Riddle, J. Margaret Roberts, Elizabeth Saphro, Gertrude C. Seabolt, Gladys P. Shadovitch, Charline Smith, Lillian Ray-Titcomb, Elsa H. Van Soest, Louise Wagner, Gertrude Wolferman, Anna Hohanshelt.

Section Committees—There was a special committee to look after the general sessions and each of the fourteen sections of the association. These committees were:

General Sessions—W. H. Gilbert, W. L. Huggins.

General Surgery — A. B. Cooke, Elliot Alden, C. T. Sturgeon.

Radiology — O. R. Stafford, H. H. Heylmun, William Costolow.

Obstetrics—Willard Fox, H. M. Rooney, John Vruwink.

Dermatology, Syphilology — Kendall P. Frost, Samuel Ayers, H. P. Jacobson.

Eye, Ear, Nose, and Throat — Simon Jesberg, R. W. Reynolds, H. S. Muckelston.

Pediatrics—A. J. Scott, Montague Cleeves, William Happ.

Urology—A. R. Rogers, Anders Peterson, W. B. Parker.

Orthopedics—John Dunlop, Alfred E. Gallant, William Arthur Clark.

Pathology — F. M. Pottenger, Guy Cochran, R. B. Hill.

Internal Medicine—Stanley Boller, H. O. Bames, Arnold Scholz.

Industrial Medicine—Philip Stephens, Louis Josephs.

Neuropsychiatry — George G. Hunter, Martin G. Carter.

Anesthesiology — Eleanor Seymour, W. W. Hutchinson, Edwin F. Boyd, Donald E. Baxter.

Public Health League — W. H. Kiger, E. C. Moore, Harlan Shoemaker.

SOCIAL FUNCTIONS

These functions were of such great variety and so successfully conducted that the convention had hardly gotten well started before they seemed to blend into a charming social atmosphere, rarely, if ever, equaled at previous sessions.

The outstanding social gathering was the reception and dinner dance held in the beautiful ballroom of the Biltmore, in honor of President T. C. Edwards and President-Elect Granville MacGowan. More than one thousand members and their families and guests attended this charming function, which did much to cement the bonds of brotherly love that sometimes grow strained in the storm and stress of every-day life.

THE GENERAL SESSIONS

If further proof of the value of devoting the mornings of our annual meetings to general sessions and the afternoons to section meetings, started three years ago, were needed, surely that proof was supplied in the remarkable success of the recent program.

At the first of these general sessions, and after an invocation by Bishop John J. Cantwell, the Honorable George E. Cryer, mayor of Los Angeles, delivered a stirring address of welcome. The annual addresses of the president and president-elect of the association were presented, as were also the reports of the council, general counsel, secretary and editor.

The second general session, as is customary, was a public meeting under the auspices of the League for the Conservation of Public Health, with the president of the League, Dudley Smith, presiding. In addition to the League president's address, the program included addresses by Hon. C. C. Young, Lieutenant-Governor of California; Ray Lyman Wilbur, president of the American Medical Association; Mariana Bertola, chairman of Child Welfare of California Federation of Women's Clubs, and W. E. Musgrave.

The third general session was addressed by Judge Paul D. Burke of Los Angeles, Paul G. Woolley of Detroit, and Alfred Decastello, Vienna.

All of these meetings drew unusually large audiences and many critical observers studying effects from the side lines considered the general sessions the most valuable feature of the altogether important meetings.

SECTION MEETINGS

All of the fifteen sections of the association held interesting and largely attended meetings. The attendance at the sections was so unusually large that more spacious quarters had to be found for some of them. The story of the section meetings will be told as the officers' reports come in.

EXHIBITS

Both the commercial and scientific exhibits were constantly crowded with visitors. Both exhibitors and visitors expressed themselves as well pleased with the results of the meetings.

OTHER ACTIVITIES

The story of the work of the Council; House of Delegates; the meeting of officers of county medical societies, and other special features will be told in the columns of CALIFORNIA AND WESTERN MEDICINE in this and subsequent numbers.

THAT MUCK-RAKING "SURVEY" OF THE HEALTH AGENCIES OF SAN FRANCISCO

The hypercritical, muck-raking, incomplete, inaccurate, in part untruthful, "Survey" report of some 150 printed pages, made by Haven Emerson and Anna C. Phillips, ostensibly for the Council of Social and Health Agencies and Community Chest authorities, is out.

It appears to be typically Emersonian, in that it has already and justly invoked the same sort of resentment from the same groups of service-loving and service-giving citizens and organizations that some of his other "surveys" have called forth.

A reply to this "survey" is already in course of preparation. It will be published in installments in both CALIFORNIA AND WESTERN MEDICINE and in Better Health, and when complete, will be issued in permanent form. This reply will analyze the vicious, exaggerated and, in part, untruthful attack upon the medical profession of California as a whole; our two medical schools; the health authorities; the hospitals; the French and the German communities; the Sisters of the Catholic Church, and all others.

The "surveyors'" invidious comparisons with other cities will be accurately analyzed, and the motives behind the survey will receive adequate attention.

The alleged constructive part of the report will be explained, with particular attention to that part of it whereby the Community Chest is urged to become a superdictator in the *administration* of all health functions of the community, instead of a legitimate collecting and allocating body handling public trust funds as there should be. There appears good reason to believe that the Community Chest will refuse its indorsement of many of the statements and recommendations of these imported surveyors, and will rely more upon the opinions of our own physicians and hospital authorities. The attempts to force the hospitals of the city to become contributing tails to certain so-called national associations as a constructive (?) movement, and the drastic criticism of the Council on Medical Education and Hospitals of the A. M. A., will be explained. The reasons why the "surveyors" ignored the medical and hospital organizations of the state

after their many years of constructive work ought to be interesting reading.

The definite injury that even the preliminary report of this "survey" caused was reflected in the difficulties connected with raising the budget of the last Community Chest drive. The complete report will further injure the development of an otherwise praiseworthy institution calculated to serve well, provided it stays out of the field of the *administration* of its funds, either by conducting services itself or utilizing arbitrary and dictatorial policies over the hospitals, organizations, and persons whose function is to serve.

The thousand copies of this "survey" would serve best by being collected and burned.

THE PHYSICIAN'S SOCIAL CONFERENCES

Some mighty interesting and important things about which the world so far has heard little are being done by a growing number of California physicians. The movement has not been named, but may be appropriately designated physicians' social conferences. They are being held by both general practitioners or family physicians and by those who limit their work to children.

The principle is the same in all, but varies in details as between individual physicians. One day or part of a day in each month, more or less, is set aside for a certain group of the physician's patients—those under one year of age, those between one and three, four or five years of age, for example. Whatever the grouping, the group is invited to visit the office for a conference. These conferences are kept largely upon a social plane, but naturally the physician sees and records much of the effectiveness of his health advice and treatment. Naturally younger children are accompanied by older members of the family. No fees are charged for these conferences, and those who wish further specific medical service are given appointments which they keep upon the basis of professional service.

There are opportunities for splendid work by this custom, provided that the invitations are strictly limited to the physician's legitimate clientele. This movement after all is only a development of a commendable practice widely current in many places whereby the physician caring for young children has them report to his office at stated intervals for observation and treatment when necessary. Both movements are calculated to increase the value of medical service and insure sound health service. Both are praiseworthy, provided only that the physician limits his service to his own clients.

A PATHETIC SPECTACLE

At the recent local election, the people of Whittier, California, repudiated the terms of an agreement by which Colonel Simon J. Murphy built and gave to the community the Murphy Memorial Hospital, a well-built, well-equipped 100-bed hospital costing nearly $400,000.

During election day, Colonel Murphy, who is in exceedingly poor health, drove through the city with banners on his car, asking the people to vote "No" on the local initiative, which was designed to make a "scrap of paper" out of a written agreement and to flaunt the wishes of a public benefactor. The osteopaths, chiropractors, eddyites, and other groups one would expect to see co-operating in any attack upon scientific medicine and adequate education as a qualification of its practitioners, succeeded in carrying their initiative.

The issue was clear-cut. The people were informed that, if such action was taken and sustained, the Murphy Memorial Hospital would lose all standing as a hospital by the American Medical Association, the American College of Surgeons, and the American Hospital Association. Both medical and nursing organizations must then refuse to serve in it, and it becomes what the majority of voters of Whittier evidently want it to be—a place for cultists to treat their patients. There may be a few physicians, not members of this organization, who will connubiate with the cultists in their fine new hospital. They apparently are of the kind the majority of the voters want, but they are not the kind that can get into any really worthwhile hospital. It will be equally difficult to secure a staff of nurses who so far forget their moral code as to serve in such a discredited place. They will not, of course, be permitted to operate an accredited school of nursing. This means, in addition to other failures, that students who might be induced to train in the hospital could not secure their properly much-coveted R. N. from the State Board of Health.

The only thing left for the educated physicians, nurses, and that element of the public who still believe in scientific medicine, and medical agencies, to do is, to build their own hospital, or go to the nearby city of Los Angeles for hospital service.

If the action of the Whittier electorate is sustained, it might be well for people who hold any municipal bonds, or who are contemplating the purchase of municipal bonds, to consider the possibility carefully. Because if Whittier, or any other municipality, can by a local initiative repudiate one financial agreement, it can repudiate another.

The most important lesson of all is the one that private benefactors will, no doubt, get from the Whittier debacle. It is safe to predict that within a short time the Murphy Memorial Hospital will remind one of the buildings sometimes seen in the outskirts of a deflated boom town. Its service to the sick will be in harmony with the appearance.

Poor Whittier!

"PHYSICAL EDUCATION" AND "SCHOOL HYGIENE"

A great deal of space is being taken in various school magazines published by official school bodies and supported by the tax money as to whether the "physical education" department or the "school hygiene" department or the "school health" department or all three should have charge of the practice of medicine among school children. It is rare in official school publications to see even a mention of the physician as a health worker and it is equally rare

to see mention of the necessity of a medical education as a prerequisite for teachers or practitioners of medicine and health among school children.

A few brief abstracts from *"School Life,"* an official organ of the bureau of education may prove interesting:

"Emphasize health always as a positive rather than as a negative thing. Present health to children in terms of beauty, strength, and joy. **Never mention illness or disease to children if it is possible to avoid it.**

"Teachers should make simple physical tests. Not adequate substitute for inspection by physicians, but a step in that direction. Relatively little training required.

"Any person capable of holding a teacher's license can be taught in a short time to test vision and hearing, to know of the presence of decayed teeth, to judge whether the tonsils are normal or diseased, and to recognize the general indications of malnutrition.

"It is no more difficult to rate children on their physical condition than on their knowledge of arithmetic and geography.

"Many teachers have stated emphatically that never again would they admit a child to their classes without first examining him physically.

"At first glance it might appear that physical inspection places upon the teacher an added burden, but the reverse is true.

"Inspection by a teacher is not an adequate substitute for inspection by a doctor, but it is a step toward attaining regular medical inspection.

"Physical examinations of school children indicate that 70 per cent have actual or potential physical defects.

"In at least one state there is a state director of physical education and a state director of school health. The objectives found are named as follows: Obedience, subordination, self-sacrifice, co-operation, friendliness, loyalty, capacity for leadership, fair play, sportsmanship, self-confidence, self-control, mental and moral poise good spirits, alertness, resourcefulness, decision, perseverance, courage, aggressiveness, initiative.

"Many teachers, parents, and, we fear, more children, have been much perplexed, because the children, after following faithfully all the laws prescribed for the "nutrition game,' have failed to measure or weigh up to the standard laid down in the tables and charts.

"Malnutrition is the most serious and most expensive condition with which we have to deal. It is the cause of the two most common of our diseases—rickets and carious teeth, and there is good evidence that it has very much to do with the production of adenoids and abnormal tonsils.

"You cannot by any means make a Poland China pig out of a razorback, nor change a thoroughbred colt into a Percheron horse."

And so on as far as you are interested to go. Most, if not all the volumes of propaganda published in the form of regular magazines, bulletins and what not by the educational authorities and paid for out of public funds indicates a well-laid and persistent plan for the complete control of the health of children *by the school boards,* instead of by physicians and legitimate medical agencies.

No such powerful, well co-ordinated and well financed (by public funds) movement for placing the control of the practice of medicine, including public health, in the hands of those incompetent by education and training to handle the subject, has ever before confronted any civilized people. In no other state has it made greater or more rapid progress than it has in California.

The practice of medicine under the guise of "physical education," "school hygiene" and what not has become so extensive by teachers, nurses, and other inadequately educated technicians that even the chiropractors and other cultists are protesting. Official medically educated health officers and physicians for the most part have been protesting for a long time. A small number of health officers, and an even smaller number of other physicians, endorse the movement, we hope, for other reasons than the apparent ones.

Nor is this opposition on the part of physicians a selfish one. The more active these school authorities are in the incompetent practice of medicine and in the equally incompetent and often dangerous health advice they are purveying, the more physicians will have to do. As a specially qualified citizen, however, interested in promoting the welfare of his fellow man, the intelligent physician gets nausea and indigestion from much of the foolish and often dangerous health advice that is put out almost daily by these "near doctors" as health information.

It would be hard to describe his feelings over the little patients he sees with malaria, kidney, heart, lung and scores of other troubles who come to him for assistance much later than they otherwise might, because these patients held school board diagnoses of "undernutrition," "malnutrition" or some other *symptom* and who have been officially treated by diet and otherwise by the agents of the board of education.

A prominent public health officer reports that the feelings of a school nurse were much hurt because he criticized her for both diagnosing and treating an epidemic skin disease among the pupils. A threat of arrest for practicing medicine without a license corrected the situation temporarily. These school children were suffering from impetigo contagiosa—fortunately.

Another school child, diagnosed "malnutrition" by the board of education and being treated by "scientific diet," finally consulted a physician who found her spleen enlarged and her blood swarming with malarial parasites.

Still another school child, diagnosed by the board of education as suffering from "undernutrition" and being treated by a "nutrition specialist," finally consulted a physician who found a disqualifying disease of the heart.

Still another school child with the same formularized diagnosis and line of treatment finally fell into the hands of a physician. The child's blood showed a pronounced anemia; there was a slight elevation of temperature and the chest contained suspicious signs. X-ray examination confirmed the diagnosis of early tuberculosis.

In the face of these things and the more and more yet to be discussed, why bother about the incompetent health work of a few hundred chiropractors and other recognized cultists?

The editors of California and Western Medicine appreciate the co-operation of physicians reporting to us instances like the above, and we want many more—enough so that we can quote from a few hundred of them in an article in the course of preparation.

IODIDE IN PLUMBISM

Perhaps the most commonly used therapeutic measure in the treatment of chronic lead poisoning is the oral administration of iodide, either sodium or potassium. Clinical opinion, however, is at variance as to its beneficial effects, some claiming positive, other, negative results. The question resolves itself into two propositions: first, the mechanism of the action of iodide in lead poisoning, and second, the nature of chronic lead poisoning. The latter proposition will be considered first, since this logically precedes consideration of the former. That is, a therapeutic measure cannot be applied rationally until the cause or nature of the disease condition is understood.

Experimental studies on animals (cats, mice, rats, and birds) made by a number of investigators yield two explanations. One explanation is that lead accumulates in the form of deposits in various organs, and then is gradually released and acts upon various structures, giving rise to the well-known symptoms of the poisoning. This notion rests on good evidences, namely, accumulated deposits of lead, especially in bones, as claimed by Aub and Minot of the Harvard Laboratories of Applied Physiology; and the continuation of the poisoning after stoppage of lead administration. The other notion is based on equally good evidences, namely, absence of lead deposits in certain species exhibiting characteristic symptoms and immediate signs of recovery upon withdrawal of the lead, as observed by Straub of the Freiburg Pharmacological Institute, and Hanzlik of the Stanford Pharmacological Laboratory. Accordingly, the storage theory is not held to be valid, and the poisoning is explained by accumulation of injuries due to the continued passage of adequate concentrations of lead through the body, recovery taking place when the concentration and passage are inadequate as upon withdrawal of the lead. These two notions, apparently equally well sustained by evidences, leave the nature of the poisoning unsettled, and, therefore, the study of therapeutic measures difficult. Nevertheless, attempts to ascertain the mechanism of iodide action in experimental lead poisoning have been made and interesting results obtained.

Scremin of the Pharmacological Institute, in Padua, has made several ingenious experiments. Using chemosis in rabbits and guinea pigs as a test of tissue action from increased lead solubility, this investigator administered sodium iodide gastrically, and then dusted the eyes with different insoluble salts of lead. No yellow iodide of lead was found, and also no chemosis or other effects. This indicated that the lead salts on the tissues were not acted upon by the iodide in the body fluids. Yellow lead iodide introduced subcutaneously in small amounts in iodized animals disappeared as such, but the lead ion remained at the place of application, as indicated by a black discoloration of the tissue when exposed to hydrogen sulphide. When sodium iodide was injected together with lead iodide subcutaneously, the lead iodide remained in the tissue uninfluenced, though in the absence of sodium iodide only the lead ion remained. In other words, the presence of the iodide ion in the tissues, as from administration of sodium iodide, caused retention of the lead as lead iodide locally and not removal, as is supposed to be the case in iodide therapy. Scremin concluded, therefore, that iodide did not react chemically with lead compounds (chloride, carbonate, phosphate, and sulphate) which occur in the tissues of lead poisoning. He suggests, therefore, that the clinical beneficial effects of iodide depend on some increase in metabolism, or, in other words, on a general iodide action, and not upon the removal of the cause; that is, the lead.

Sodium iodide given by mouth to pigeons poisoned with metallic lead (administered gastrically) was found by Hanzlik and Presho to be beneficial, as to relief of symptoms and reduction of the fatal dose. The results were explained on the basis of insolubility of the lead, this having occurred also *in vitro*. These results, therefore, agreed with those of Scremin as to the chemical influence of iodide on lead, namely, that the iodide tended to render lead insoluble, if anything, and, therefore, more localized. Accordingly, it would be expected that iodide would tend to form deposits of lead iodide, or, in other words, produce accumulation of lead as in one of the theories of the nature of lead poisoning. From this it follows that the less soluble the deposit the lesser the poisoning and the greater the benefit. This line of thought, however, is confronted with the difficulty that recovery from the poisoning occurs clinically, which should not occur as long as the lead is retained according to the same theory. The insoluble lead (rendered so by iodide) might be removed by some other mechanism. This comes almost to the same thing as saying that iodide per se does not remove the lead. The negative results with iodide as to solubility of the lead indicate indirectly that the nature of chronic lead poisoning is not due to an accumulation of lead, but that it is concerned with injuries accumulated from the continuous passage of lead in adequate concentration, the higher the concentration the shorter the time necessary for the result.

Other treatments besides iodide are used and claimed to be beneficial. Their bases appear to be different from that for iodide. Experimental lead poisoning (not the acute) in animals may not be the same as chronic lead poisoning in man. This appears to be an important difficulty in the study of the problem. Meantime the use of iodide in plumbism is still to be regarded as an empirical remedy. However, in view of the extent and seriousness of plumbism throughout the civilized world, the problem merits attention from all sides, and it is hoped that new methods of attack, especially from the clinical side, may be devised.

Medicine in the Public Press

"Synthetic Psychology" — Physicians have noticed the news value attached to the puerile and disgusting statements of Mrs. Edith Rockefeller McCormick about her "new" philosophy of life and treatment of disease. The best reply that we have seen is contained in an editorial with the title of "Old Brains for New" in the San Francisco Daily News, which says:

"First thing Mrs. Edith Rockefeller McCormick, of the Chicago McCormicks, knows, she will be infringing on the Coué patent. She has a cure which she calls 'synthetic psychology,' and which she explains to be renovation of the brains. The human mind is a house, with old, worn furniture in the shape of old, worn thoughts. 'Synthetic psychology' simply throws out the old and puts in new furniture. Mrs. McCormick admits that it is much easier to throw out old than to get in new furniture, wherein the lady certainly indicates that she knows furniture.

"We wish her well. Anybody devoting time, money and argument to renovating the average human mind of these times needs encouragement."

Are There Any Limits? — Recently, front-page "news" stories announced the discovery of still another discovery of a still further improved x-ray tube. The story quoted J. C. Bloodgood as endorsing the new tube. This was promptly repudiated in a telegram to the New York Times, in which he said: "Your special from Baltimore, published on your front page this morning, quoting me on new x-ray tube, is an error and a dangerous error. I know of no such discovery or new tube, and did not give out the interview. I am sorry, because I would welcome such a great discovery."

Comedy in Health Reform — Most of our health reform movements, particularly the popular ones, are so steeped in melodrama and even tragedy, or at best a grim sort of humor, that a touch of light comedy now and then encountered is refreshing.

The best recent example is being interpreted by the courts of New York. It seems that a motion picture corporation prepared a film illustrating the everyday problems and practices in childbirth. The film was to be shown only to physicians and nurses. A temporary injunction prohibiting the showing of the picture was secured by the public health, licensing and film censorship people on the ground that its exhibition was derogatory to the morals of physicians and nurses. Funny, isn't it? Both physicians and nurses encounter so much of the real problems that it is difficult to understand how or why they would be interested in having their work portrayed on the "silver sheet." It would be more important to analyze the motives of the kid-gloved, swivel-chair guardians of our health by those sanctimonious supermoral persons who have never worked all night with the hard problems of life-saving that is part of the day's work of the worthwhile physician and nurse. They encounter nothing immoral in naked nature in travail.

Statistics Always Supply What You Look for— Geniuses, as a rule, are not the offspring of young parents, says a report of the Society of Bavarian School Teachers. After investigating into seventy-four cases of prominent personalities of the artistic and literary world, this organization found that among them were only ten first-born children. The report points out that Fenimore Cooper was the eleventh of twelve children; Honore Balzac, the youngest son of his parents; Napoleon Bonaparte, the eighth child; Benjamin Franklin, the youngest of seventeen; Rembrandt, the fifth of six children; Richard Wagner and Wolfgang Amadeus Mozart were the last of seven; Robert Schumann, the fifth, and Franz Schubert, the thirteenth of fourteen children. The investigations thus convince these teachers that a rather advanced age of the parents seems to be more favorable to the production of great personalities.

Again, we see that statistics supply what one looks for.

Cornelia and Dionysus — Large numbers of our people still look upon the physician as something more than a giver of pills. Every true physician recognizes that his most important and useful work is outside the field of stethoscopes and materia medica. The proudest day in a doctor's life is the day a dignitary confers upon him his degree of Doctor of Medicine. The day when he feels most humble is when some young girl he has assisted into the world comes to him to explain the new threshold of life she is about to cross. He knows that it is not so much his skill as his soul that the young, the old and the dying love him for. This always has been so, and it will continue so long as the art of medicine lasts.

To meet his broader responsibilities with tact and wisdom, it is necessary, however difficult the problem, for the modern physician to read much and broadly. He will find much of the knowledge required to meet effectively this ever greater field of his usefulness, not in medical journals, but in the better class of literature, art and other tangible expression of life and ideas available to all. The power not only to assimilate the good from these lessons, to adopt them to special needs and pass them on in understandable language to those looking to him for guidance is the highest art of medicine.

One of our members has called our attention to the article under the above title in the May Atlantic which suggests the above introduction to the editor. We pass it on to you.

Biased Evolution—Doctor, if you are interested in what many of your patients are reading about evolution, may we suggest that you read the article under the above title (Harper's) by Alfred J. Lotka? It is well written and it is stimulating whether you agree with the author or not. Certainly, you will find there the source of some of your patients' questions to you.

The Renewal of Youth by Surgery—If you are interested in "educating" everyone in medicine and are curious as to the quality of the educational matter, how it is put and why, it might be well to scan an interview with Voronoff by Armstrong Perry, in the May issue of The Forum. Your patients are reading this sort of "educational" material, and they are likely to base their questions to you accordingly. And what is more important, some of them are quite likely to estimate your ability in proportion as you agree with the claims made by this and similar writers. The "atmosphere" of the article and its purposes is indicated in a short paragraph:

"A ring at the gate of Dr. Voronoff's garden brought a competent valet de chambre, who said that the doctor was attending the celebration of the one hundredth anniversary of the birth of Pasteur. After my mission was explained, the man left me in a drawing room full of old masters, wonderful rugs, and exquisite furniture, returning with the welcome announcement that the doctor would receive me between 6 and 7 in the evening."

Lopsided Farmers — An official bulletin of the Bureau of Education at Washington says: "Farm life, instead of promoting all-round physical development, tends in many cases to overdevelop certain muscles while completely ignoring others."

This will be "news" to farmers and physicians; at least, all of those who have actually worked on a farm will be delighted to know that some of their muscles get a rest now and then.

STATE SOCIETY

MINUTES OF THE HOUSE OF DELEGATES, FIFTY-THIRD ANNUAL SESSION OF THE CALIFORNIA MEDICAL ASSOCIATION.

FIRST SESSION

Held in the Ballroom of the Los Angeles Biltmore, Los Angeles, California, Monday evening, May 12, 1924, at 8 p. m.

Calling to Order—The meeting was called to order by the president, T. C. Edwards of Salinas.

Roll-Call—The secretary called the roll; sixty-eight (68) delegates were seated, and the president, T. C. Edwards, declared a quorum present.

Report of President—The president, T. C. Edwards, presented the following report:

As the various reports to be submitted at this session cover the work of the association during the past year, there is little for me to say except what I have personally done. There were eleven meetings of the Executive Committee during the year, and I have attended ten of them besides attending all meetings of the Council. Doctor Parkinson, chairman of the Council, and I visited various county societies at Sacramento, Woodland, and Chico, at which meetings members and representatives of over ten counties were present. I also visited in Marin County. I have found, in making these visits, that the country men like their councilors and officers to meet with them, and at the last Council meeting councilors reported great interest in their work and their visits to the various county societies in their districts, and I believe that if this is followed up great good will come of it.

Appointment of Reference Committee—The president appointed the following Reference Committee: Harlan Shoemaker of Los Angeles, Robert Pollock of San Diego, and Clarence G. Toland of Los Angeles.

Report of the Council

James H. Parkinson of Sacramento, chairman of the Council, submitted the following report:

Doctor William Stover—The Council again regrets to record the loss of a member during the current year, William Stover having passed away on April 4, 1924. Doctor Stover, who represented the Third District, has been a member of the association for many years and was elected to the Council at the last annual meeting.

Doctor B. F. Keene—The committee appointed in the matter of the restoration of the grave of Doctor B. F. Keene, the first president of the society, has submitted a final report embodying details as to specifications and costs. The Council recommends that the report be adopted and instructions issued to give it effect.

Meetings—The Council has held, in all, three regular meetings during the year. One open meeting was held in Los Angeles, January, 1924, at which all interested in Industrial Medicine and Surgery were invited to discuss the problems of this particular branch of our activities. The results of this meeting were issued in the form of a questionnaire, 200 of which were sent out. These were sent to men known to be doing industrial work, including those indicated by the secretary of the Section on Industrial Medicine and Surgery, and to secretaries of all county societies. Copies were also mailed to members requesting them. To date fifteen have been returned, and these have been submitted to the Industrial Medicine Section.

The Executive Committee has held eleven meetings during the year. It was thought best to notify all members of the Council of these meetings so that whenever convenient they could attend. This new departure has worked well and we have had a larger attendance.

Five questions were submitted to the Council by mail ballot.

Office of the Society—The work of the office has been most successfully and satisfactorily conducted by the present staff. Constant attention by the secretary to many little details has resulted in greater efficiency than we have ever known. The report of the Council, covering as it does all phases of the society's activity, must necessarily deal in a general way with the duties of its staff.

The following table shows the growth of the society from the year 1912 and gives our active membership at the close of 1923 as 3809.

Membership—1912, 2300; 1913, 2396; 1914, 2503; 1915, 2557; 1916, 2602; 1917, 2699; 1918, 2534; 1919, 2496; 1920, 3136; 1921, 3484; 1922, 3666; 1923, 3809.

The Journal—Upon recommendation of the editor the California State Journal of Medicine is now entitled California and Western Medicine. During the year it has become the official organ of the Utah Medical Association, as it had been of the Nevada Medical Association. It has recently had a new cover and has added sixteen pages to its regular form. The editorial pages under Doctor Musgrave's able direction have given earnest attention to the many problems with which medicine is constantly confronted. With quite remarkable perspicacity the editor seems to discern the needs and aspirations of the rank and file of the profession, and topics directly affecting the welfare of the great mass of physicians are dealt with in a singularly clear and forceful way. At Doctor Musgrave's request all editorials on general questions are submitted to the Executive Committee in advance of publication. Doctor Musgrave continues to serve at a salary of $1 per annum.

THOMAS CLAY EDWARDS
President 1923-1924

Medical Defense—In accordance with the decision of the House of Delegates at the meeting in 1923, medical defense by the society will cease as of June 30, 1924. Our general counsel has made every effort during the year to clear the calendar. Most of the cases and threats of cases for the defense of which the society is obligated will be known by July 1, 1925. Until that date is reached the Council feels it would be imprudent to reduce the annual assessment.

Optional Medical Defense—In accordance with authority granted by the House of Delegates, the Council proceeded to put in operation a plan for optional medical defense in conjunction with commercial carriers retaining the present statewide legal staff that has been built up in the past eight years. After several conferences and much correspondence it was found impossible to effect a policy contract that would be satisfactory to the society as a whole. It was recommended that the membership seek coverage as individuals and that the retention of the present legal staff be accomplished on the basis of an annual assessment payable by all who had expressed the desire to do so over their own signatures. These facts with illustrative details were submitted to the membership in Letter No. 4, issued on February 6.

GRANVILLE MacGOWAN
President 1924-1925

Optional medical defense by the society's legal staff, in conjunction with commercial carriers, will automatically go into effect July 1, 1924, for 168 members of the society and will continue on that basis to June 30, 1925. While the future of this feature must be governed entirely by the response of the membership, the Council wishes again to emphasize the desirability of keeping in close contact with the insurance situation and urges a substantial representation in the new optional medical defense plan.

Uniform Constitution and By-Laws for County Societies—It would seem desirable, as far as purposes of organization are concerned, to have a uniform constitution and by-laws for all county societies. That recently adopted by the San Francisco County Medical Society is, at the suggestion of our general counsel, tentatively submitted for that purpose.

Financial Impositions Upon the Profession—Chief of these may be cited:

1. The $2 annual tax by the Board of Medical Examiners, which now automatically becomes part of the contingent fund of the board and cannot be used for board purposes unless budgeted out by the governor.

2. The federal income tax, which makes no distinction between earned and unearned income and which, by bureau interpretation, denies to the medical profession the convention expenses allowed commercial organizations.

3. The federal license under the Harrison Narcotic law, through which the government last year collected from the medical profession funds far in excess of anything needed by licensure, under an enactment wholly unnecessary as far as we are concerned.

4. The local licenses as imposed in various municipalities in which we are included with other professions.

The subject seemed of such importance that the Council appointed a committee, consisting of Rene Bine, chairman of the Executive Committee; Granville MacGowan, president-elect, and William E. Musgrave, editor of the Journal, to take such steps as it deemed proper in co-operation with similar professional organizations. This committee has made a progress report and has been continued.

The books of the society show: Cash on hand January 1, 1923, $4,219.01; receipts during the year 1923 from all sources, $59,949.09; total disbursements, $49,578.28; cash on hand, January 1, 1924, $14,589.82. They are always open for the personal inspection of members, as are all our records. No money is used for other than strictly society purposes. This definite statement is made because there seems to be a suspicion more or less prevalent that the society in some way contributes to the funds of the League for the Conservation of Public Health. This suspicion has absolutely no foundation in fact. The league is a distinct organization with its own officers and its own set of books, which similarly are open at all times to investigation by its members. It has always, when requested, co-operated with the society in any matter, and this co-operation has been absolutely gratuitous. It would seem obvious that its finances and its affairs, with which this society has nothing whatever to do, are only open to criticism or investigation by its members. The league's funds are derived from the contributions of citizens of the great republic of medicine, made voluntarily as their means and their judgment dictates. To such citizens the league only is responsible.

In considering these receipts and disbursements particularly in relation to the amount of cash on hand January 1, 1924 ($14,589.82), certain facts must be taken into consideration. The actual surplus for the year 1923 was $10,370.81, $4219.01 having been carried over from the year 1922. This surplus with our present assessment has only been possible because the society is not paying for some services it now receives and is paying a modest compensation for others. Since May, 1922, Doctor Musgrave has edited the Journal at a remuneration of $1 per annum. No salary was paid to anyone as secretary during the months of February, March and April, 1923. Since then Doctor Emma W. Pope has been drawing $200 per month. Doctor Phillip Mills Jones, as secretary and editor, received $6000 a year. Should the society at any time find a man able and willing to act in this dual

capacity it will no doubt be necessary to increase that figure.

It is a fact that the amounts charged the society for legal services, by which is meant professional work, exclusive of court costs and other expenses, is much below that generally obtaining in commercial law practice, and really quite out of proportion to the services rendered.

When a reduction in the annual assessment from the present figure of $10 is discussed, these facts and figures must be borne in mind. It should also be remembered by those who advocate a "society at cost" that a comparatively small excess fund each year would make possible many desiderata of which the publication of a medical directory by, for and of the society, original investigation, research work and

EDWARD N. EWER
President-Elect

worthwhile prizes for subjects of general advancement in medicine may be mentioned.

Annual Assessment—The Council recommends that the annual assessment for 1925 be fixed at $10.

Report of Committee on Scientific Program—The secretary, Emma W. Pope of San Francisco, as chairman of the Committee on Scientific Program, submitted the following report:

The program for the present session is in your hands and I think shows the good work done by the Program Committee, the section officers and the men who present papers. Special thanks are due the section officers, who willingly responded to all requests made by the state office. With few exceptions programs in full were submitted by February 15 in ample time for the necessary checking of their speakers.

Any one member may present but one paper at an annual session, and only members in good standing in the association, invited guests from other states and countries, or internes not yet licensed, and hence ineligible to membership, are privileged to present papers. All these facts must be verified by the office before the program can be printed. Licensed physicians resident in California who are not members may not be included. A few papers of unquestioned merit were offered section officers, but are not on the program, as the men who desired to present them were unwilling to apply for membership in the California Medical Association. In each case this ruling has been clearly put by the section officer and an invitation to join the society extended. We feel strongly that physicians who are unwilling to ally themselves with the society should not receive privileges that rightfully belong to the membership.

We regret that Doctor Alfred Decastello and H. Finkelstein are unable to be with us. Doctor Ray Lyman Wilbur will speak before the League for the Conservation of Public Health on Wednesday morning, as he is compelled to return to the university before the Thursday session. We especially regret that he could not present his paper before the California Medical Association meeting, where he, as president of the American Medical Association, properly belongs. At that meeting Judge Paul D. Burks of Los Angeles will present a paper on "Relation of the Doctor to Expert Medical Testimony." Doctor P. G. Woolley, Assistant Professor of Pathology, Detroit College of Medicine and Surgery, will speak on "The Relation of Laboratory to Clinical Medicine," and Doctor U. G. Houck of the U. S. Bureau of Animal Industry, and inspector in charge of hoof and mouth disease eradication, will give a timely address on the medical question that is of paramount interest to California at the present time, "Hoof and Mouth Disease."

Report of Auditing Committee—Rene Bine of San Francisco, chairman of the Auditing Committee, stated that the books of the association were audited each year by a firm of certified public accountants; that Lester Herrick and Herrick of San Francisco had audited the books for the year 1923, and certified that all accounts were in due form and had been verified. He also stated that the reports of the auditors would be passed around for those to see who so desired.

Report of Committee on Bunnell Memorial—Emmet Rixford of San Francisco, chairman of the Committee on Bunnell Memorial, not being present, Saxton T. Pope of San Francisco presented the report of this committee:

The committee wishes to report that it has reviewed the literature sent to the association by Doctor Howard A. Kelly of Baltimore, and find it very explicitly demonstrated that Doctor Lafayette Houghton Bunnell was among the first to enter Yosemite Valley. He was a member of an exploratory party which visited the valley in 1851. He was the first man to propose the name of Yosemite to the valley and, through his writings, he first made it known to the world. The claims of discovery are, therefore, properly awarded to him and the matter of priority has been carefully worked upon by Doctor Kelly. We, therefore, feel that dedication may be made with propriety and justification.

Your committee addressed a communication to the superintendent of the Yosemite National Park, which was later forwarded to the Director of National Parks, Mr. Stephen T. Mather. In this communication we asked permission to place a tablet in Yosemite Valley at the base of El Capitan, the spot where these first explorers camped in the month of March, 1851. We are now in receipt of permission from Mr. Mather to erect a suitable plaque conditioned on his approval of the design.

The tablet itself has been placed in the hands of Mr. Paul J. Fair, an animal sculptor, and a photograph of it will be passed around for all to see. The subject, as you will see, is a large figure of a grizzly bear, which represents the translation of the name Yosemite from the Indian, and the medical caduceus, which is the emblem of medicine since the time of Hippocrates. The inscription on the tablet is as follows:

"To commemorate Dr. Lafayette Houghton Bun-

nell—one of the first party of white men to enter the Yosemite Valley in March, 1851. He proposed the name Yosemite and was the first to proclaim its beauty and wonders to the world. Dedicated by the California Medical Association, 1925 A. D."

Photographs of the plaque will be sent to Mr. D. R. Hull, landscape engineer of the National Park Service, and to Mr. W. B. Lewis, superintendent of the Yosemite National Park, and will thereafter be forwarded with their recommendations to Mr. Mather.

The expenses of the tablet have been assumed, so far, by your committee, and will probably not amount to more than $200, including the sculptor's fee, the casting in bronze, and the placement upon a boulder at the foot of El Capitan.

Doctor Kelly stated that he had collected $14, which he has since raised to $50. A check for this $50 has been received by your committee from Doctor Kelly for the proposed memorial to Doctor Bunnell in Yosemite.

Your committee feels that, if the 1925 convention is held in Yosemite National Park, the proposed memorial to Doctor Lafayette Houghton Bunnell should be dedicated at that time, and recommends that an invitation be extended to Doctor Kelly to be present at the dedication and to address the association on that occasion.

Report of Secretary—The secretary, Emma W. Pope of San Francisco, presented the following report:

After hearing the reports of the chairman of the Council, the editor of the Journal, the legal counsel, and the chairman of the Auditing Committee, the secretary feels that the activities and the reports of the state office have been rather fully covered. It is pleasant, however, to report a few statistics and facts.

During 1923 we received eighteen resignations, owing mainly to removal from California, and there were forty deaths of members of the society. In spite of this we had eighty-five more members at the close of 1923 than at the end of 1922. There was also an increase in the cash on hand of $10,370.81, due to an unexpected halt in the legal output and a decrease in office expense.

We cannot be sure that the peak of legal expense has been reached. We hope that it has, and that the society may report a similar saving to the membership during 1924. On the other hand, it may become our unpleasant duty to report an inroad upon the association's reserve, rather than an addition to it.

Two activities of the state office deserve repeated mention until fully understood by our members. I refer to your placement bureau and the extension service. The placement bureau has meant more than any comfortably settled physician can realize to our young men and women starting their life work, to men coming in from outside states, and to country physicians who need assistance during illness or enforced absence. More than fifty such positions have been filled this year, which, being understood, means that 100 requests were complied with, for the request of the man seeking work necessarily dovetails into that of the man needing assistance; five technicians, one dietitian, and twelve nurses and stenographers for doctors' offices were also located. Wherever possible, physicians should use this bureau and maintain its efficiency. In no other service of this office are so many stanch friends made for the society. The placement bureau is a very tangible and material evidence of the association's good-will and personal interest in its membership.

In line with this work, we co-operate with The Californians, Incorporated, in answering questions from physicians who desire to settle in California. As a direct result men who have received courteous answers and helpful suggestions have in many instances become members and active friends of the society.

The extension list of speakers for county society meetings has not been enlarged this year, awaiting the report of the committee appointed to look into the work. Now that it has been definitely decided that county societies desire set papers rather than clinics, as was suggested by the committee, an effort will be made to enlarge the present panel of available papers and speakers.

Four assistants carry on the work of the office and Journal at an aggregate salary of $640 a month. Few offices handling the volume of work that passes through the state office employs so small a force. The compilation of a monthly journal of 112 pages, the reports of the legal department that successfully defends its 4000 members, a placement bureau and general information desk, a clipping and statistical file in reference to our membership, the work of arranging for the annual meeting, for three Councils and many executive meetings, the recording of members in good standing and delinquent, the bookkeeping incident to the handling of funds amounting to $50,000, is all done by your four capable and efficient assistants.

In closing, let me emphasize that misunderstandings and suspicion vanish before open question. When in doubt concerning the policy of your state organization, ask questions. To the best of our ability they will be answered. I am glad to report that from county secretaries all over California have come questions during the year relating to the termination of indemnity and legal defense, the reduction of dues, and to the expenditures of the society. The San Francisco County Medical Society at its last board of directors' meeting requested the office to have a representative present at that meeting to explain our financial condition. All such requests are cheerfully acceded to and make for mutual understanding.

Report of Editor—In the absence of William E. Musgrave of San Francisco, Rene Bine of San Francisco read the report of the editor, which will be published in the July issue.

Unfinished Business—There was no unfinished business to come before the House of Delegates.

New Business—In accordance with the rules of the association, the following resolutions were presented and referred to the Reference Committee. For text of these resolutions and final action by the House of Delegates, see minutes of the second session.

Resolution No. 1. **Farming Out of Medical Service to Laymen.** Presented formally by Morton R. Gibbons of San Francisco for and at the request of the Section on Industrial Medicine of the San Francisco County Medical Society.

Resolution No. 2. **Physicians' and Surgeons' Panel for Industrial Accident Work.** Presented by Morton R. Gibbons of San Francisco.

Resolution No. 3. **Dealers in Cut-Rate Industrial Contract Practice.** Presented formally by Saxton T. Pope of San Francisco for and at the request of Carl Hoag of San Francisco, who was unable to be present.

Resolution No. 4. **Ethical Standing of Physicians Employed by Lay Organizations Practicing Medicine for Profit.** Presented by Walter V. Brem of Los Angeles.

Adoption of Minutes—The minutes of this session were read and approved.

Adjournment—There being no further business the house adjourned to meet at 8 p. m. Wednesday, May 14, 1924, in the Music Room.

SECOND SESSION

Held in the Music Room of the Los Angeles Biltmore, Los Angeles California, Wednesday evening, May 14, 1924, at 8 p. m.

Calling to Order—The meeting was called to order by the president, T. C. Edwards of Salinas.

Roll-Call—The president announced that the president of the Tulare County Medical Society, A. W. Preston of Visalia, was present and, if there was no objection, would act as delegate from his county society. There being no objection, the president declared A. W. Preston of Visalia delegate from the Tulare County Medical Society.

The secretary, Emma W. Pope of San Francisco, called the roll; fifty-two (52) delegates were seated, and the president declared a quorum present.

Place of Meeting for 1925—The chairman of the Council, James H. Parkinson of Sacramento, announced that, by unanimous action of the Council, the invitation of the Yosemite National Park Company to hold the 1925 meeting in Yosemite National Park had been accepted, and that the date would be fixed later by the Council in accordance with correspondence with the Yosemite National Park Company and so as not to conflict with the 1925 meeting of the American Medical Association.

Election of Officers

President-Elect—Edward N. Ewer of Oakland was nominated for president-elect by Pauline S. Nusbaumer, Oakland. On motion of Paul M. Carrington, San Diego, seconded by James H. Parkinson, Sacramento, the nominations were closed. The secretary cast the ballot, and Edward N. Ewer was declared elected president-elect of the association for the year 1924-1925.

Vice-President—Harry E. Alderson of San Francisco was nominated for vice-president by Joseph Catton, San Francisco. The nomination was seconded by A. S. Musante, San Francisco. On motion of A. J. Scott, Jr., Los Angeles, seconded by William E. Stevens, San Francisco, the nominations were closed. The secretary cast the ballot, and Harry E. Alderson was declared elected vice-president for the ensuing year.

Councilors

First District—Lyell C. Kinney of San Diego was nominated for councilor for the First District by Paul M. Carrington, San Diego. On motion of P. T. Phillips, Santa Cruz, seconded by Victor G. Vecki, San Francisco, the nominations were closed. The secretary cast the ballot, and Lyell C. Kinney was declared elected councilor for the First District for the ensuing three years.

Third District—A. H. Wilmar of Paso Robles stated that the Third District had been unable to find a man to fill the vacancy caused by the death of the councilor from their district, William M. Stover of San Luis Obispo, and requested that the matter of filling the unexpired term of Doctor Stover be left to the Council. There being no objection, the president declared that there would be no election at this time to fill the vacancy caused by the death of the councilor from the Third District, and that the matter would be referred to the Council for action.

Councilor-at-Large—Morton R. Gibbons of San Francisco was nominated by W. Edward Chamberlain, San Francisco, for councilor-at-large. The nomination was seconded by Joseph Catton, San Francisco. On motion of William E. Stevens, San Francisco, seconded by James H. Parkinson, Sacramento, the nominations were closed. The secretary cast the ballot, and Morton R. Gibbons was declared elected councilor-at-large for the ensuing three years.

Member of Committee on Scientific Program—Joseph Catton of San Francisco was nominated by William E. Stevens, San Francisco, a member of the Committee on Scientific Program. The nomination was seconded by W. Edward Chamberlain, San Francisco. On motion of A. S. Musante, San Francisco, seconded by Harry E. Alderson, San Francisco, the nominations were closed. The secretary cast the ballot, and Joseph Catton was declared elected a member of the Committee on Scientific Program for the ensuing four years.

Delegates to the American Medical Association (two to be elected for a two-year term)—C. Van Zwalenburg of Riverside was nominated by Clarence G. Toland, Los Angeles; said nomination being seconded by Charles D. Lockwood, Pasadena.

Victor G. Vecki of San Francisco was nominated by William Duffield, Los Angeles; said nomination being seconded by A. S. Musante, San Francisco.

Albert Soiland of Los Angeles was nominated by Robert V. Day, Los Angeles.

T. C. Edwards of Salinas was nominated by Paul M. Carrington, San Diego; said nomination being seconded by Thomas O. Burger, San Diego.

Robert V. Day of Los Angeles then requested permission to withdraw the name of Albert Soiland of Los Angeles as delegate to the A. M. A. for a two-year term, as he had desired to nominate Doctor Soiland for the one-year term. There being no objection, the president declared the name of Albert Soiland withdrawn.

There being no further nominations, the president declared that, as only two delegates were to be elected for the two-year term, the House would proceed to ballot, and appointed William E. Stevens of San Francisco and W. A. Clark of Oakland as tellers. The president declared that fifty-six ballots were cast and, as only fifty-two delegates were seated when the roll was called, the secretary would again call the roll. The secretary then called the roll and fifty-nine delegates were seated, and the president announced that the former ballot would be thrown out and a new ballot taken. Fifty-eight ballots were cast as follows: T. C. Edwards of Salinas, 47; Victor G. Vecki of San Francisco, 34; C. Van Zwalenburg of Riverside, 31. The president then declared T. C. Edwards and Victor G. Vecki elected delegates to the A. M. A. for the two-year term.

(Two to be elected for a one-year term)—Albert Soiland of Los Angeles was nominated by Robert V. Day, Los Angeles.

John C. Yates of San Diego was nominated by Paul M. Carrington, San Diego.

On motion of P. T. Phillips, Santa Cruz, duly seconded, the nominations were closed. The secretary cast the ballot, and the president declared Albert Soiland of Los Angeles and John C. Yates of San Diego elected delegates to the A. M. A. for the one-year term.

Alternates to the American Medical Association (two to be elected for a two-year term)—William E. Stevens of San Francisco was nominated by Harry E. Alderson, San Francisco; said nomination being seconded by Joseph Catton, San Francisco.

C. Van Zwalenburg of Riverside was nominated by Harlan Shoemaker, Los Angeles.

On motion of George H. Kress, Los Angeles, seconded by Clarence G. Toland, Los Angeles, the nominations were closed. The secretary cast the ballot, and the president declared William E. Stevens of San Francisco and C. Van Zwalenburg of Riverside elected alternates to the A. M. A. for the two-year term.

(Two to be elected for a one-year term)—Robert V. Day of Los Angeles was nominated by William Duffield, Los Angeles; said nomination being seconded by William T. McArthur, Los Angeles.

Charles D. Lockwood of Pasadena was nominated by T. C. Myers, Los Angeles.

On motion of George H. Kress, Los Angeles, seconded by Victor G. Vecki, San Francisco, the nominations were closed. The secretary cast the ballot, and the president declared Robert V. Day of Los Angeles and Charles D. Lockwood of Pasadena elected alternates to the A. M. A. for the one-year term.

Delegates to the A. M. A. with their corresponding alternates are as follows:

T. C. Edwards, Salinas, 1924 and 1925; alternate, William E. Stevens, San Francisco, 1924 and 1925.

Victor G. Vecki, San Francisco, 1924 and 1925; alternate, C. Van Zwalenburg, Riverside, 1924 and 1925.

Albert Soiland, Los Angeles, 1924; alternate, Robert V. Day, Los Angeles, 1924.

John C. Yates, San Diego, 1924; alternate, Charles D. Lockwood, Pasadena, 1924.

Report of the Reference Committee

Harlan Shoemaker, chairman of the Reference Committee, read the following report:

1. **President's Address**—The committee commends this scholarly and timely address and recommends, if possible, that it be given wide publicity.

Action by the House of Delegates: On motion, duly made and seconded, it was unanimously resolved that the recommendation of the Reference Committee be approved.

2. **Address of President-Elect** — The committee commends the address of the president-elect for its literary excellence and its erudition, its sound Americanism and its timeliness in a day when standards in the community, state and nation seem uncertain and when in our own profession we find our ideals less clearly perceived and less earnestly sought.

Action by the House of Delegates: On motion, duly made and seconded, the recommendation of the Reference Committee was approved.

3. **Report of the Council—Doctor B. F. Keene**—The committee recommends that the report of the committee of the Council in the matter of the grave of our first president be adopted and that the Council be instructed to put it into effect.

The Journal—Recommends that the society express its gratification in the constant improvement of the Journal and, while congratulating the editor upon the success already attained, records its approval of his policy in its editorial conduct.

Optional Medical Defense—Recommends that members seriously consider the proposed Optional Medical Defense, so that by promptly applying for membership it can be placed upon a satisfactory basis at the earliest opportunity.

Uniform Constitution and By-Laws—Recommends that the Council take steps to ascertain the views of county societies on adoption of the proposed model constitution and by-laws.

Financial Impositions Upon the Profession—Recommends that the society approve the steps taken by the Council to lessen the financial burdens upon its members and to remedy injustices inflicted upon the profession.

Annual Assessment—Recommends that the annual assessment for 1925 be fixed at $10.

Action by the House of Delegates: On motion, duly made and seconded, it was unanimously resolved that the recommendations of the Reference Committee be approved.

4. **Report of Bunnell Memorial**—Recommends that the committee, if possible, arrange so that the memorial tablet can be dedicated in May, 1925.

Action by the House of Delegates: On motion, duly made and seconded, it was unanimously resolved that the recommendation of the Reference Committee be approved.

5. **Report of the Secretary**—(a) **Placement Bureau**—Recommends that physicians generally bear in mind this service so that it can be made available when occasion arises.

(b) **Finances of the Society**—Urges members when in doubt as to any matter of expenditure to visit or to correspond with the office and thus obtain direct information.

Action by the House of Delegates: On motion, duly made and seconded, it was unanimously resolved that the recommendations of the Reference Committee be approved.

6. **Report of the Editor**—Congratulates the editor, William E. Musgrave, upon the great improvement in the Journal. Recommends that members of the society more generally adopt the suggestion that the professional card service be fully availed of. Commends the plan of obtaining a wider discussion of all papers and urges members of the society to co-operate therewith.

Action by the House of Delegates: On motion, duly made and seconded, it was unanimously resolved that the recommendations of the Reference Committee be approved.

7. **Resolutions on Insurance**—Resolution No. 1. **Farming Out of Medical Service to Laymen.** The text of the resolution is as follows:

Whereas, Persistent reports are current that the State Compensation Insurance Fund has contracted for the medical care of injured workmen with an organization promoted and controlled by a layman and operated by him at a profit to himself, secured by a reduction of the fees regularly allowed for medical services; and

Whereas, These reports, if true, indicate a situation and a procedure which will lead to a dangerous subversion of the intent and purpose of the Workmen's Compensation Act; now, therefore be it

Resolved, That the Council of the California Medical Association be requested to investigate these reports, and that it invite the attention of the State Industrial Accident Commission and the management of the State Compensation Insurance Fund to the fact that the said State Compensation Insurance Fund, by virtue of its prestige as a state institution and the vast business which it controls, does, in effect, set the standard of industrial medical service in California, and that such a degradation of standards as is implied in any farming out to lay contractors, for profit, of the medical care of the industrially injured, can not result otherwise than in wrong and hardship to injured workingmen.

Resolution No. 2. **Physicians' and Surgeons' Panel for Industrial Accident Work.** The text of the resolution is as follows:

Whereas, An effort has already been made by the California Medical Association to devise a panel of physicians and surgeons to do industrial accident work; and

Whereas, The effort has not been successful, partly because of the difficulties of selecting the members to compose such panel; therefore be it

Resolved, That the Council of the California Medical Association renew its effort to devise such a panel by means of a questionnaire which shall require physicians and surgeons desiring to engage in industrial accident work to state their own qualifications, and to pledge themselves to abide by the standards set by the California Medical Association; and further be it

Resolved, That the Council of the California Medical Association appoint a suitable committee whose duties shall embrace, one, the devising of such a panel; two, the management of such machinery as may be required to administer such rules as are provided to govern industrial accident work; and three, the affixing of penalties for violation of such rules; and further be it

Resolved, That all regularly licensed physicians and surgeons in California be given opportunity to file answers to the questionnaire.

Copy of a suggested questionnaire is herewith submitted.

1. Name. Address. Age.
2. Graduate of what medical school? Year.
3. Specialty?
4. Experience in Industrial Surgery and Medicine. Where?
5. Associations in Industrial Accident Medicine and Surgery?
6. Contact with what Hospitals?
7. If accepted on the panel of the Industrial Accident Surgeons, do you pledge yourself to abide by the code of ethics of the American Medical Association, as published in Journal (date)?
8. Do you pledge yourself to abide by the fee schedule of the Industrial Accident Commission, and California Medical Association?
9. Do you pledge yourself to refrain from over-

charge, and over treatment for purposes of augmenting your bills?

10. Will you abide by the intent of the Resolutions (before the House of Delegates 1924) relating to Industrial Accident Medical and Surgery?
11. Do you agree to submit to adjustment of misunderstandings between yourself and Insurance Company, employer, or other physicians in matters not within the jurisdiction of the Industrial Accident Commission, by the Committee provided by the California Medical Association for such purpose?
12. Do you agree to abide by decisions of such Committee?
13. For recent graduates—
    (a) What clinical experience?
    (b) What hospital experience?
    (c) What affiliation with Industrial Accident surgeons? Give names.
    (d) Do you intend to pay considerable attention to industrial medicine and surgery?

Note—Penalties for violation shall be provided by the authorities of the California Medical Association.

Weight of each answer?

Society membership not recorded, nor required.

Resolution No. 3. **Dealers in Cut-Rate Industrial Contract Practice.** The text of the resolution is as follows:

Whereas, Certain dealers in cut-rate contract practice, in the field of industrial medicine, have been able to build up their business and to enjoy a considerable prestige, by reason of the fact that they openly boast that they retain the services of certain well-known specialists to care for cases of serious injury; and

Whereas, The activities of such dealers in contract practice are inimical to proper standards of all medical practice and, particularly, a menace to the general practitioner, taking away large numbers of his patients and substituting for the services of such general practitioner an impersonal, perfunctory, routine service, to the detriment of both the patient so taken and the general practitioner; and

Whereas, It is largely by reference of cases from general practitioners that the clientele of every specialist is built up; now, therefore be it

Resolved, That the (society or section) go on record condemning the acts of specialists who accept cases upon any terms, basis of compensation, salary or fee, from dealers in contract practice, be such dealers doctors or laymen, who take their profit by retaining a portion of the established fee of the doctor who actually renders service, or from moneys ostensibly collected for the specific purpose of paying for medical service; be it further

Resolved, That acceptance of cases from such dealers is, in effect, a most pernicious form of fee splitting and should be held good and sufficient cause for dropping the name of the specialist who continues to serve patients, referred by such dealers from the membership roll of any reputable medical organization; be it further

Resolved, (1) That the necessary steps be taken by the officers of (section or society) to give to each and every member of (section or society) the opportunity to endorse with his signature a copy of the above resolutions; (2) that a copy of the above resolutions, with signatures of all who have endorsed them appended, be published in California and Western Medicine as soon as a reasonable opportunity has been given for the specialists concerned to sign such resolutions.

Resolution No. 4. **Ethical Standing of Physicians Employed by Lay Organizations Practicing Medicine for Profit.** The text of the resolution is as follows:

The following resolution was passed by the Council of the Los Angeles County Medical Association on December 17, 1923:

"Lay organizations practicing medicine are not insurance companies. The Council considers that any member of the Los Angeles County Medical Association who works for such an organization, practicing medicine for profit, is guilty of unethical conduct. Railroads are not exploiting the medical profession; they are not soliciting and are not holding out that they have a better service than can be gotten elsewhere, and are not practicing medicine for profit."

Resolved, That the House of Delegates of the California Medical Association endorse the above resolution of the Los Angeles County Medical Association, and that it is also understood that lay organizations that attempt to conduct clinical laboratories, radiological laboratories, and services to the sick which require experienced medical direction, are hereby included within the terms of the resolution.

Action by the Reference Committee: The committee having gone over the various resolutions and matter in connection therewith, upon which some of these are based, and having attended the open meeting of the Section on Industrial Medicine and Surgery, and subsequently further discussed these questions with members interested therein, has decided that all this material had best be referred to the Council for consideration and action, and so recommends.

Action by the House of Delegates: On motion, duly made and seconded, it was unanimously resolved that the recommendation of the Reference Committee be approved.

8. **Resolution of Appreciation to the Press.**

Action by the Reference Committee: The committee recommends the adoption of the following resolution:

Resolved, That the California Medical Association hereby expresses its thanks to the press of Los Angeles for the splendid publicity given to the important work of the convention and to Mr. Celestine J. Sullivan for his services as director of publicity.

Action by the House of Delegates: On motion, duly made and seconded, it was unanimously resolved that the resolution submitted by the Reference Committee be adopted.

9. **Resolution of Appreciation to the Los Angeles Biltmore.**

Action by the Reference Committee: The committee recommends the adoption of the following resolution:

Resolved, That the California Medical Association hereby records its appreciation of the facilities afforded us at this meeting and the courtesies extended our membership.

Action by the House of Delegates: On motion, duly made and seconded, it was unanimously resolved that the resolution submitted by the Reference Committee be adopted.

On motion of Harlan Shoemaker, Los Angeles, seconded by James H. Parkinson, Sacramento, the report of the Reference Committee as a whole was unanimously adopted.

Resolution of Appreciation to the Profession of Los Angeles—James H. Parkinson, Sacramento, submitted the following resolution:

Resolved, That the visiting members desire to express their sincere appreciation of the magnificent hospitality and many courtesies extended them by the profession of Los Angeles.

Action by the House of Delegates: On motion of Parkinson, Sacramento, seconded by Victor G. Vecki, San Francisco, the resolution of appreciation to the profession of Los Angeles was unanimously adopted.

Presentation of the President—The president appointed James H. Parkinson, Sacramento, and George H. Kress, Los Angeles, to escort the incoming president, Granville MacGowan of Los Angeles, to the chair. Doctor Kress announced that Doctor MacGowan was not present, and requested that he be formally presented at the General Session tomorrow morning.

Presentation of the President-Elect—Edward N. Ewer of Oakland, president-elect, was escorted to the platform by Doctors Parkinson and Kress, and expressed his appreciation of the honor conferred upon him.

Adoption of Minutes—The minutes of this session were read and, on motion of James H. Parkinson, Sacramento, seconded by George H. Kress, Los Angeles, were unanimously approved.

Adjournment—There being no further business before the House, the meeting adjourned to meet in Yosemite at a time to be fixed by the Council.

BOARD OF MEDICAL EXAMINERS

Interesting Data Supplied by C. B. Pinkham, Secretary Board of Medical Examiners—Abstracts from their correspondence that are in each instance self-explanatory.

Communication from Special Agent Carter to Board of Medical Examiners relating to itinerant optometrists traveling about the country and swindling the unsophisticated:

"We enclose herewith a copy of a report made to us by Mr. A. M. Storch, showing the method by which two clever swindlers have reaped a harvest in California for the past two or three years.

"It is practically impossible to apprehend these two men, as they travel by automobile, pull off a job in one section, and the next day are in some other county, hundreds of miles away. We never hear of them until after they have performed some fake eye operation (usually upon some farmer in the country districts), and have moved on.

"Recently, they obtained $300 from Maxim Smith, an elderly farmer of Richfield, Orange County, Calif., who obtained a warrant for their arrest. Sheriff Sam Jernigan of Orange County holds the warrant, but is unable to locate them.

"They have various schemes for locating their victims. The one used in most cases is to call at some farm house in the country, and one of them who poses as an optician or oculist makes inquiry regarding the address of Mr. or Mrs. ——, an elderly man or woman who has some kind of eye trouble, usually stating that he has a pair of glasses to deliver to this person and has just lost the slip bearing patient's name and address. In this manner he usually obtains the names of anyone suffering from eye trouble. He then visits the one who appears to be the most prosperous, and usually makes some inquiry, casually noticing that he or she has eye trouble, and mentioning that he has with him 'Dr. Pierce,' or some other famous eye specialist, usually of St. Francis Institute, San Francisco, and that Dr. Pierce just happens to be making the trip with him for the ride, etc., and is not practicing, that he has no license to practice in this county, but that if patient wishes him to do so perhaps 'Dr. Pierce' will make an examination. 'Dr. Pierce' is then called in, bringing with him an imposing array of instruments, examines the patient's eyes, and solemnly tells him that he will be stone blind within six months. By this time the patient is usually in the mood to beg the great 'specialist' to do something for him, and finally the 'specialist' is persuaded to perform an operation—just for humanity's sake—provided, of course, that patient will say absolutely nothing about it to anyone, as he has no license and doesn't want to get into trouble. He will, of course, not charge anything, except for the "radium" or medicines used. He then puts something in the patient's eye, shows him a white foam, or something that he claims has been removed from the eye, and tells him the operation has been a great success. Then 'Dr. Pierce' figures up so much for radium, so much for medicine, etc., and the amount is usually several hundred dollars, which the poor dupe, in his gratitude to the great 'specialist' for saving him from total blindness, pays at once.

"Various names are used by these two swindlers, but in almost every case one of them poses as an oculist or optometrist and the other as an eye, ear, nose and throat specialist, sometimes from St. Francis Institute, San Francisco, and at other times from hospitals in Chicago and various other places.

"During the past three years we have made many attempts to apprehend these clever swindlers, and in one instance we reached the bank a few minutes after they had appeared to cash a check secured from an old farmer at Calabasas for a 'radium' operation.

"Perhaps if this were given publicity through the medical and other journals, it might eventually lead to the capture of these two men."

Statement of Mr. Storch regarding his parents' experience with the itinerant optometrists:

"On April 18, 1924, Mr. A. M. Storch of 1406 La Prada Park, Los Angeles, Calif., called at our office and gave the following report regarding the experiences of his father and mother with fake eye doctors who travel about the country in a blue Buick automobile.

" 'In the early part of February, three men in an automobile came to the home of my father and mother, Mr. P. H. Storch and Mrs. Eliza A. Storch, who live at Oceanside, Calif. (on Washington street just east of the ball grounds). Two of the men came into the house, while the other waited in the machine. They said that they were doctors and had charge of a hospital in St. Louis; that they were here just for the winter, that they didn't have any license to practice and weren't doing any regular practice, but just running around and doing what little good they could. They said they had heard that mother's eyes were diseased, and said they could cure her for the price of the medicine only.

" 'They took a syringe of some description and made two injections of some kind of fluid into the eye, and then removed from the eye something resembling the pulp of a grape. Then this alleged doctor said, "There it is! That is it! Now you are fixed." He then sat down and began to figure, and when he got through figuring he said the bill was just the cost of the medicine, which was $837; that the medicine had radium in it. He refused to take payment in the form of a check, and my father got cash and paid him the money. They said that on account of their not being licensed to practice here, for father and mother not to mention this to anyone at any time. The folks promised they wouldn't.

" 'About ten days or two weeks later, two other men came to the home there at Oceanside, one of them coming into the house and the other waiting in the machine. The one who came into the house inquired as to father's name and the fact of my mother's having had a treatment given her eye, and when my father said the facts were true, this man said he had something very serious to tell him; that the doctor who had performed that operation had been killed in an automobile accident, and that on his dying bed, being worried by the fact that he didn't know whether this operation had been successful or not, he had charged this fellow particularly to go and see my mother, and if the operation had not been successful the money would be returned to her. He then looked at my mother's eye and said that the operation had not been successful, that my mother would get the money, $800, returned to her; that he would cure her for $500. By my father wouldn't have anything to do with it, and that being more money than my mother had, the man agreed to perform the operation for $250. He went through some alleged operation similar to the former one, said it was all right now, and took the check for $250, which was later cashed at the bank.'

"Mr. Storch told of a similar case, which occurred last April, 1922, when these men came to a woman who had been doctoring at Oceanside without obtaining relief, and performed an operation on her eyes. Mr. Storch said:

" 'I think it was $1400 she paid them the first time. They came back in November, 1922, and had the same story regarding the man killed in an auto accident and money waiting in escrow, waiting for his affidavit if she had not been cured. He charged her $900 for the second operation. She went to the bank at Oceanside for the money, and information can probably be obtained from the bank at Oceanside as to the woman's name, etc.' "

Letter to Journal of National Association of Chiropodists relating to two recent deaths in California alleged to have resulted from improper treatment by unlicensed chiropodists:

"We are wondering whether or not you would be

interested in learning that recently there have been two deaths in California, which have been attributed to careless treatment by unlicensed chiropodists.

"Roy Finney, operating 'a flashily advertised chiropody parlor at 421-A South Main street, Los Angeles,' was alleged in January to have treated a Mr. W. C. Bowman, who wandered into Finney's place. Finney was alleged to have put Bowman's feet into an electric baking apparatus, thereafter rubbing on a salve, and the patient is reported never to have walked again, gangrene having developed and the foot amputated; later the other foot was amputated, and the patient died.

"Finney was found guilty of violation of the Medical Practice Act on the seventeenth day of April, 1924, and sentenced to pay a fine of $200 or in lieu thereof serve 180 days in the city jail of Los Angeles, from which judgment defendant gave notice of appeal.

"The other case just reported is that of Ed E. Collins, an unlicensed itinerant chiropodist, who recently removed a corn from the foot of Frank C. Counlon. 'A short time after the operation, blood poisoning set in, Dr. P. F. Page was called, and took charge of the case, but the patient got worse and died April 9. Dr. Page says he died as the result of the operation performed by Collins.' Collins has disappeared, and cannot be located.

"The above is a strong argument in favor of employing only licensed chiropodists, and is submitted to you for whatever interest may be attached thereto."

Notes on the question of repealing the provision for the annual tax, by C. B. Pinkham, secretary Board of Medical Examiners:

Our attention has been called to the editorial on page 114 of the March, 1924, issue of California and Western Medicine, wherein suggestion is made that the League for the Conservation of Public Health introduce legislation to repeal the annual tax.

It is our impression that such an action would be shortsighted policy for the following reasons:

We believe that the $2 annual tax paid by those who are licensed to practice in the State of California is not particularly burdensome financially and it does afford a means whereby an absolutely accurate check is kept on those who are legally entitled to practice medicine, being of vast assistance to the federal authorities in the enforcement of the Harrison Narcotic Act, as well as other agencies both of the federal and state government.

Harking back to the time when the undersigned was appointed secretary of the Board of Medical Examiners in February, 1913, we recall the chaotic state which presented itself, for there was no available record to determine who of the many thousand licentiates of the State of California were dead, nor to accurately determine who were legally practicing. The Board of Medical Examiners did not publish a directory; however, such a volume was distributed by the medical society to its members and the volume contained names of individuals who were not licensed to practice medicine in the State of California. The volume had no particular standing legally in that it was not an official state publication.

Since the "diploma mill" scandal was presented to the public in October, 1923, many states have determined the value of an annual registration and legislation to that effect has been agitated.

The State of New York and the State of Illinois are fair samples of the chaotic condition incident to having no accurate check on licentiates.

There is now pending before the legislature of the State of New York legislation tending to correct this evil. U. S. Senator Copeland, former health commissioner of New York, is one of the strong proponents of the annual tax or annual registration feature, claiming that it is the only method whereby accurate check can be kept on those who are legally entitled to practice and those who are practicing without authority.

The provisions of Section 3 read in part as follows:

> "The receipts of the said annual tax referred to herein shall be paid into the Contingent Fund of the Board of Medical Examiners of California and after the expenses of issuing said directory have been paid, in the event that there shall be a surplus of such funds, the board may from time to time in its discretion apply said surplus for **any other expenses** incurred by the board under the provisions of this act."

Referring to page 231 of the Directory of 1923 you will note the income from the annual tax was $17,071.02 and on page 232 you will note that the directory expenditures amounted to $6,356.60, leaving a balance of $10,714.42, which heretofore has been expended for investigation and enforcement.

Our investigation departments, both north and south, are functioning very satisfactorily and we are receiving cordial support from the district attorneys in the various counties; hence we believe that our report for the year 1924 will show commendable activities.

If a tax of $2 proves financially burdensome, may we suggest that a reduction be made, rather than that the statute be repealed?

Letter to P. D. Doucett, Aberdeen, Wash., regarding the "Therapeutic Sunbeam—Kendall System":

"We have your written statement that you are qualified as a therapist, using the 'Therapeutic Sunbeam—Kendall System,' and we must confess this is a new one to add to our list of over thirty-seven varieties of drugless practice.

"It is with interest that we read your pronunciamento of this 'therapeutic sunbeam' system, which reads as follows:

" 'Therapeutic Sunbeam, with a shot from the tips of the fingers into the pulse—Opens the main artery. Gives a free circulation of the blood. A test and a perfect setting of the sexual organs. Leads to the main simple of the head that lies in Pearly with the brains. A medical treatment as well with personnel right. Capacity at 13,000. Direct therapeutic massage in a manipulation of the joints. The movement includes punching, rubbing or friction. Children a specialty. Experience since 1903 under this one theory.' (Signed) P. D. Doucett, Specialist.

"If we have not correctly quoted your letter, please advise us at once and also inform us whether you are licensed to practice in the State of Washington; if so, the kind of license you hold and whether you have had any institutional training or have you yourself developed this system as outlined above."

Communication to Special Agent Carter from C. B. Pinkham, secretary Board of Medical Examiners, regarding case of Arthur R. Timme, M. D.:

"We are quite interested in your report that Arthur R. Timme, recently arrested in Los Angeles charged with violation of the State Poison Act, is said to have prescribed more than 10,000 grains of morphine per month for the last two years.

In view of your statement that Arthur R. Timme would fill out narcotic prescriptions for patients or addicts and leave them with the office girl, Miss O'Brien, and that when a patient came in for a prescription and wanted a 'hypo' needle, Miss O'Brien would add 'one' hypo needle to the prescription, it is our impression that this procedure on the part of Miss O'Brien lays her liable to prosecution for violation of the Medical Practice Act, and we wish you would suggest the matter to Dr. Campbell, legal committeeman in Los Angeles, with the idea of filing a complaint charging Miss O'Brien with violation of Section 17, provided, of course, you have sufficient evidence.

"We hold that Miss O'Brien would have no more authority to add a hypodermic needle to the doctor's prescription than she would to add some drug to a prescription already written by Dr. Timme. However, the courts may not agree with this interpretation, but it would be well to take some action to discourage any such procedure on the part of office nurses."

COUNTY NEWS

Two Counties 100 Per Cent in Paid-up Dues—It is with pleasure we announce that San Mateo County Medical Society and Sonoma County Medical Society have no delinquent members, but every member is fully paid up for this year, a record to be proud of.

ALAMEDA COUNTY

Alameda County Medical Association (reported by Pauline Nusbaumer, secretary)—The Alameda County Hospital staff presented the program as arranged by L. P. Adams at the regular monthly meeting of the Alameda County Medical Association.

"The Bond Issue for the Completion of the Highland Hospital," by R. G. Broderick.

Case Reports—Diffuse carcinoma of the liver, by Q. O. Gilbert. Epilepsy due to pollen allergy, by A. H. Rowe. Peculiar cartilage lesion in the heel analogous to Perthe's disease in the hip, by F. J. Carlson.

Papers—"The Sliding Hernia—Report of Cases," by F. H. Bowles. "Methods and Results in Partial Gastrectomies," by Dexter N. Richards. "Observations on the Effect of Posture in Some Types of Low Back Pain," by Harold H. Hitchcock. "The Use of Mercurochrome and Gentian Violet in the Treatment of Infections," by Gertrude Moore.

These subjects provoked a general discussion, M. L. Emerson, S. H. Buteau. Q. O. Gilbert, N. A. Cary, R. G. Van Nuys, taking part. The attendance was good, and the refreshments aided the enjoyment of good fellowship.

Rat-bite fever by William Mills, and the use of radium in uterine fibroid by William H. Sargent, were the subjects discussed at the monthly meeting of the Merritt Hospital staff, held May 5 at 8:15 p. m.

Since the beginning of 1924 a program of mental hygiene for children has been undertaken in the Oakland-Berkeley district. Three clinics are now under way—at the Oakland Health Center, the Oakland Baby Hospital, and at the Berkeley Dispensary. The clinic at the Baby Hospital is a "Habit Clinic" fashioned on the lines of the Thom clinics in Massachusetts, while the other two clinics are child guidance clinics, dealing with juvenile court cases, school cases, conduct problems, mental deficiency, etc.

The work at the Oakland Health Center is carried on under V. H. Podstata and Sydney Smith, while the work of the other two clinics is directed by Smith. Uniform records are kept in the three clinics. A medical psychologist and a social service worker are included in each clinic.

In addition to the actual clinic work, a fairly comprehensive program of education is being outlined and carried out, including talks on mental hygiene to visiting nurses, teacher-parent associations, and club groups.

The regular monthly meeting of the general staff of Fabiola Hospital was held at the hospital April 29. The attendance was large.

The bond issue for the new Highland Hospital was discussed and a liberal donation was made by the staff to defray the campaign expenses.

Mrs. J. P. H. Dunn, president of the Fabiola Hospital Association, requested the staff to lend their moral as well as financial support to the new Peralta Hospital Association, or any other hospital enterprise of like merit.

The program for the evening was as follows:

"Physical Signs Produced by Foreign Bodies in the Bronchial Tubes," by Clifford D. Sweet; discussed by F. M. Shook, E. A. Majors, George McClure and O. R. Etter. "An Unusual Infection in Mastoiditis," by F. M. Shook; discussed by George McClure and Roderick O'Connor. "Oral Sepsis," by W. E. Rideout; discussed by C. D. Sweet and W. R. Bell. "Lethargic Encephalitis," by H. D. Bell; discussed by A. H. Rowe, E. W. Goodman, R. L. Richards, and Daniel Crosby.

At the monthly meeting of the Alameda County Hospital staff, the evening was devoted to the discussion of house cases and proved very instructive.

Providence Hospital staff omitted its meeting, on account of date conflicting with meeting of the state association.

Bonds for completion of Highland Hospital carried, making it possible to complete the hospital within two years.

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary)—The regular monthly meeting of the society was held at the residence of the superintendent of the County Hospital at Martinez on Saturday, April 26.

The lecture by Albert H. Rowe of Oakland was confined to asthma and hay fever and the causes and cure. A free discussion followed by many of the members. It was demonstrated that many of the common skin diseases, such as eczema, were caused by certain foods acting as poisons on this particular individual; when that particular food was withdrawn from the diet the disease immediately disappeared. In nearly all these cases individuals can be immunized and return to this food element. Tests are made to find which food or vegetable pollen is causing an asthma, then they are vaccinated (so-called) against this poison, thus removing the effect of the particular poison. The lecture was very exhaustive and enjoyed by the members. A dainty lunch was served by the hostess. The following members were present: George W. Sweetser, E. Merrithew, Hall Vestal, C. R. Leech, Denninger-Keser, J. Emmett Clark, E. B. Fitzpatrick, John Beard, F. Lisle Horne, H. L. Carpenter, L. St. John Hely, S. H. Marks, Wise, L. A. Clary, Clara Spalding, J. B. Spalding.

FRESNO COUNTY

Fresno County Medical Society (reported by T. Floyd Bell, secretary)—The regular meeting of the Fresno County Medical Society was held at the Hotel Fresno on May 6. A banquet preceded the meeting. Members present were as follows: Aller, Anderson, Barrett, Bell, Binkley, Broemser, Collins, Couey, Cross, Craycroft, Drake, Dearborn, Ehlers, Ellsworth, Hare, Jamgotchian, Kjaerbye, Konigmacher, Lamkin, Larson, G. L. Long, Luckie, Madden, Manson, Maupin, Miller, Montgomery, Mordoff, Morgan, Milholland, McConnell, McPheeters, Newton, Nedry, Peterson, Pettis, Pomeroy, Rosson, Schottstaedt, Sheldon, Staniford, Stein, Scorboro, Thompson, Tillman, Tobin, Vanderburgh, J. R. Walker, G. W. Walker, Wiese, and Willson.

Visitors—Brunn, Kruse, Seligman, H. O. Collins, Betts, Preston, and Calahan.

Fred H. Kruse, of the University of California Medical School, presented a very interesting paper on "Peptic Ulcer from the Medical Standpoint." He gathered together in his paper the essential points in regard to the disease and gave an excellent summary of the subject. He considered etiology from the standpoint of the two great schools of thought. He enumerated the conditions which required surgical intervention. The treatment he took up also according to the two schools of thought, Sippy and Smithies, the former using alkaline treatment, and the latter rest and cutting down of the secretions of the stomach. He discussed alkalosis in relation to the alkaline treatment.

Harold Brunn, also of the University of California Medical School, spoke on the surgical aspect of peptic ulcer. As to etiology, he said that there is much that is not known about peptic ulcers. Focal infection is a very important part and must be removed to get a permanent cure. Each case must be considered individually, either medically or surgically. The type of operation done should be determined at the operating table. In speaking of the surgical indications, he said that gastroenterostomy was taking a second place in the surgical care of peptic ulcer. Cauterization is better than excision in small ulcers. Large ones should

be excised with resection of the stomach. Duodenal ulcers are best treated by the Finney or Horseley operation, the latter being very good. The cases of perforating ulcers seen at the San Francisco Hospital can be divided into two classes: (1) those with an old history, and (2) those coming on suddenly with great pain and shock without any previous digestive disturbances. The latter are probably embolic and the perforation leaves a clean hole in the wall of the gut.

Brunn also presented the subject of diverticulitis before the staff of the General Hospital at noon on May 6. He had pathological specimens and x-rays to illustrate his paper, besides having several histories of such cases. This was a very instructive talk, as few of the staff had ever seen many cases.

KERN COUNTY

Kern County Medical Society (reported by H. W. Moore, secretary)—The regular meeting was held at the Kern County Hospital the evening of April 17, President P. J. Cuneo presiding. Thirteen members present.

Ellis Jones and Ross Sutherland, of Los Angeles, visitors.

Moore, Rogers, and Veon were instructed to formulate an obituary to the memory of S. F. Smith, who died at Bakersfield April 13, 1924.

Ellis Jones gave a talk on "Practical Problems of Orthopedic Surgery," supplemented by lantern slides. He brought out and discussed clubfoot, congenital dislocation of the hip, arthoplastics, bone inlays, Perthes' disease, arthritis, and many other orthopedic problems.

MARIN COUNTY

Marin County Medical Society (reported by J. H. Kuser, secretary)—The society met on April 24 at the office of W. Jones in San Rafael, with the following members present: Clark, Dufficy, Furlong, Hund, Jones, Landrock, Kuser, Mays, Larson. The guest of the evening was Ellen Stadtmuller, who requested the interest of the members in the examination of children in the pre-school age.

SAN BERNARDINO COUNTY

San Bernardino County Medical Society (reported by E. J. Eytinge, secretary)—This society met May 6 at San Bernardino County Hospital, with twenty-three present, fifty-three absent, and ten guests. The program was as follows:

"Indications and Contra-indications for Caesarean Section," by Titian Coffey of Los Angeles. "Classical Caesarean Section; Technique and After Care," by Peter O. Sundin of Los Angeles. "Low Cervical Caesarean Section; Technique and After Care" (with Lantern Slides), by John Vruwink of Los Angeles; discussion will take place after all three papers have been read and will be opened by W. A. George.

Luncheon at 10:30.

This program was given at a joint meeting of the Los Angeles County Medical Society with the Obstetrical Section in Los Angeles at their last meeting, and we are indebted to that society for its repetition.

The appeals of the secretary for assistance in enrolling new members have at last reached one man. J. B. Craig of Ontario forwarded the names of seven possible applicants. Perhaps you cannot send as many, but you can try and your efforts would be appreciated.

Loma Linda Sanitarium and Hospital Accredited—Under date of May 13 the Council on Medical Education and Hospitals of the American Medical Association advise that they have placed the Loma Linda Sanitarium and Hospital, Loma Linda, California, on the list of accredited hospitals of California. It is always a pleasure to physicians, and would be to the general public had they full appreciation of what it all means, to see one hospital after another advance its work to a plane where it is carried throughout the world as an accredited agency of scientific medicine.

SAN DIEGO COUNTY

San Diego County Notes (reported by Robert Pollock)—A liberal delegation of San Diego County Society members attended the state meeting in Los Angeles, several of whom were represented on the scientific programs.

A scientific program of high order was expressed before the monthly meeting of the Naval Hospital staff April 26, when Ellis Jones of Los Angeles read an excellent paper on orthopedics, and Arthur E. Smith, also of Los Angeles, read a comprehensive and thoughtful paper on "Diagnosis and Treatment of Oral Pathologic Conditions." These monthly gatherings at the Naval Hospital in Balboa Park are greatly appreciated by the members of the County Medical Society, who are always extended the courtesy of an invitation by Captain Wieber. Not only are the papers presented of a high order by men of authority from outside cities, but the sociability, coupled with the serving of light refreshments, tend to add materially to the enjoyment of the evening.

At the regular meeting of the county society of April 22 C. E. Howard presented an excellent paper on the differential diagnosis between biliary tract infections and peptic ulcer. This very important diagnostic field was carefully mapped out and classified into its various phases. The discussion taken up from the x-ray standpoint, that of the medical and the surgical diagnosis, respectively, was entered into by Kinney, Pollock, and Burger.

The bulletin of the San Diego County Medical Society, in its May 9 number, presented a survey of the available hospital beds in and about San Diego, tending to show the city's present inadequacy in this matter. It behooves all cities to take an occasional inventory of their ability to take care of their citizens needing hospitalization, and to consider their fullest capacity if suddenly confronted by serious epidemic.

SAN FRANCISCO COUNTY

Proceedings of the San Francisco County Medical Society (reported by J. H. Woolsey, secretary)—During the month of April, 1924, the following meetings were held:

Tuesday, April 1—Section on Medicine—Some phases of the work of the Council of Pharmacy and Chemistry, by Felix Lengfeld. The rationale of hexamethyleneamine therapy, by P. J. Hanzlik.

Tuesday, April 8—General Meeting—The present status of hoof and mouth disease as it affects San Francisco, by William C. Hassler. The importance of biochemical research to clinical medicine, by Carl L. A. Schmidt.

Tuesday, April 15—Section on Industrial Medicine—The doctor under the compensation law, by Mr. D. W. Burbank. Some problems in compensation practice, by M. R. Gibbons. The doctor in industrial medicine, by E. F. Glaser.

Tuesday, April 22—Section on Eye, Ear, Nose, and Throat—Clinical meeting at the University of California Hospital.

Tuesday, April 29—Section on Urology—Gonorrhea and responsibility, by Melville Silverberg. Experimental hydronephrosis, by Frank Hinman and A. B. Hepler.

Franklin Hospital (reported by Ewald H. Angerman, secretary)—The regular monthly meeting of the Franklin Hospital Clinical Society was held Monday, April 28, at the hospital, J. Wilson Shiels presiding. An interesting and varied program was presented by the following:

Demonstration of an unusual case of septicemia and pyemia, following a slight trauma in an apparently robust adult, by Alfred Roncovieri. An atypical case of syphilis, chiefly involving the mediastinal contents, by J. Wilson Shiels. Two unusual cases of fracture of the femur, by Conrad Weil. A Case of recurrent formation of ureteral calculi, by George W. Hartman. Selected pathological specimens, both

gross and microscopic, of the skin, intestine, and uterus, by Carl Werner.

The numerous discussions that followed this program gave evidence that the evening spent was decidedly educational.

St. Luke's Hospital Clinical Club (reported by H. H. Johnson)—At the meeting held on May 6 Z. E. Bolin spoke on "What We Know of Blood Chemistry," stating that chemistry in medicine does not deal with what was formerly called physiologic chemistry, but takes in with it at the present day every branch of chemistry and with it more or less of physics. It would be hard, if not impossible, to think of an organ or system the diagnoses of the disorders of which are not aided by blood chemistry. It is used in diseases of the lungs, the stomach, the liver, the thyroid, the kidneys; in organic neurological conditions; in tests to determine the operability of patients from the standpoint of kidney function; in acidosis; in the estimation of coagulation time of blood, and determination of the onset of uremia. It is used by internists, obstetricians, and dermatologists. Many and varied tests have been evolved by the laboratory man; however, it is the interpretation that counts. There is absolute need for co-operation between the pathologist and clinician, and in this interpretation and its practical application the greatest progress in the next few years will be made.

Many tests and their practical application were given in detail, and the use of the resources of blood chemistry in its methods of diagnosis and prognosis was strongly urged.

St. Joseph's Hospital Staff Active (reported by Sister M. Sylvia, superior)—Hartley F. Peart, general counsel for the California Medical Association, spoke on "Specific Obligations of Physicians Under the Law" before St. Joseph's Hospital staff, of San Francisco, on May 21. He prophesied an increase of laws and regulations. Under licensure, proper conduct is demanded and derelicts, such as those guilty of criminal abortions, improper return of reportable matters and unethical behavior, are subject to revocation. Federal obligations deal with alcoholic and narcotic prescriptions, the former being limited as a remedy, except under "grave emergency." Orders for either are not refillable. The state poison law restricts the use of narcotics also, except for incurables, if the pharmacy board is notified. The Sheppard-Towner act makes it a duty to report all pregnancies, but the consent of patients should be obtained, so that there will be no liability for divulging confidential information. The general requirement is that a practitioner should use the skill and care exercised by the average of the same school in the locality. No guarantee of cure or prevention of suffering is contemplated by law. Consent for an operation is required.

Captain Duncan Matheson talked on "Local Regulations Affecting Doctors." He also regretted the increasing of legal enactments. An appeal for the co-operation of physicians in all lesions which are self-inflicted or caused by others was made. Dying statements should be made early, as also identification of accused by victim. In poisonings, preserve all evidence. Report lost certificates of practice.

G. W. Pierce illustrated "Plastic Surgery" with lantern slides and patients. Tubular grafts and epithelial inlays are used. Operations for keloids, scars, saddle nose, hare lip, and rhinophyma were shown, as well as transplantation of rib cartilage. Andrew Nagy reported a case of intussusception.

The program for June 11 follows: "Modern Management of Labor Cases," by A. B. Spalding, and "Operations in Obstetrics," by Reginald Knight Smith.

YUBA-SUTTER COUNTIES

Yuba-Sutter Counties Medical Society (reported by A. L. Miller, secretary)—Election of officers of the Yuba-Sutter Counties Medical Society for the coming year resulted as follows: John Duncan, Marysville, president; R. G. Scribner, Hammonton, secretary.

Utah State Medical Association

PROGRAM THIRTIETH ANNUAL MEETING OF THE UTAH STATE MEDICAL ASSOCIATION, LOGAN, JUNE 19-20-21, 1924.

One can ill afford to miss a single paper on this most excellent program, as they are all written by men who come from the largest clinics in the United States and rank among the most eminent men in their fields in America.

In order that we may get their best thoughts and that no time may be wasted, the Program Committee has decided to eliminate discussions, except at the request of the president. However, the free asking of questions, if they come within the time allotted to the paper, is encouraged.

Meetings will be held in the Agricultural Engineering Building at the Agricultural College, where members will register.

The Council will meet at 9:30 a. m., Thursday, and daily thereafter. The House of Delegates at 10 a. m., Thursday, June 19, and at 8 a. m., Friday, June 20, at the Agricultural College.

Cafeteria luncheon will be served daily at the Agricultural College during the session.

Papers and addresses delivered at this meeting shall be the property of the association, and shall be handed to the secretary as soon as read.

The visiting ladies will be entertained by the ladies of Logan, as follows:

Luncheon at the Blue Bird followed by cards at 7:30 p. m., Thursday.

Mrs. Joseph R. Morrell's reception, 3 to 6 p. m., Friday.

Valley drive and basket lunch at Agricultural College campus Saturday noon.

The Committee on Post-graduate Work are now active and are preparing a course in post-graduate work for this fall, and the present plan contemplates courses in both surgery and medicine.

Officers

President, Joseph R. Morrell, Ogden; president-elect, Sol G. Kahn, Salt Lake City; first vice-president, L. B. Laker (deceased), Eureka; second vice-president, Homer E. Rich, Vernal; secretary, William L. Rich, Salt Lake City; treasurer, F. L. Peterson, Salt Lake City; councilors, R. R. Hampton (1924) Second District, Salt Lake City; E. G. Hughes (1925), Third District, Provo; W. L. Smith (1924), First District, Brigham City; delegate to A. M. A., E. M. Neher, Salt Lake City, 1924; alternate delegate to A. M. A., A. C. Behle, Salt Lake City, 1924.

Standing Committees

Scientific Work—Clarence Snow, chairman; M. M. Critchlow, vice-chairman; Ernest Van Cott, William L. Rich (secretary).

Public Policy and Legislation—John Z. Brown, chairman; D. C. Budge, F. A. Goeltz, J. R. Morrell (president); William L. Rich (secretary).

Arrangements—D. C. Budge, chairman; T. B. Budge, P. W. Eliason.

Special Committees

Education and Post-graduate Work—R. O. Porter, chairman; Hyrum L. Marshall, W. R. Calderwood.

Health and Public Instruction—Eugene H. Smith 1924, chairman; Fred Dunn (1925), C. E. McDermid (1926), Willard C. Christopherson (1927), E. M. Neher (1928).

Advisory on Hospitals—Ezra C. Rich (1924), chairman; E. F. Root (1925), J. W. Aird (1926), J. W. Hayward (1927), A. C. Behle (1928).

Industrial Medicine—R. S. Allison, chairman; J. C.

Landenberger, chairman; T. F. H. Morton, L. F. Hummer, C. L. Sandberg.

Necrology—D. L. Barnard, chairman; J. A. Phipps.

Professional Welfare and Ethics—J. C. Landenberger, chairman; H. P. Kirtley, F. K. Bartlett, H. J. Merrill.

Medical Department University of Utah Advisory —R. R. Hampton, chairman; F. A. Goeltz, Clarence Snow, D. C. Budge, E. G. Hughes, J. W. Aird, J. C. Landenberger, E. H. Smith, E. F. Root, H. P. Kirtley, C. E. McDermid, Homer Rich, Joseph R. Morrell, Sol G. Kahn, president-elect; William L. Rich, secretary.

House of Delegates

President, Joseph R. Morrell; president-elect, Sol G. Kahn; secretary, William L. Rich; councilors, R. R. Hampton, E. G. Hughes, W. L. Smith.

Boxelder County—Odeem Luke; alternate, R. A. Pearse.

Cache Valley—D. C. Budge, W. O. Christiansen; alternates, Eugene Worley, H. R. McGee.

Carbon County — William T. Elliott; alternate, Charles Ruggeri.

Salt Lake County—(Holdovers: E. F. Root, chairman; John Z. Brown, T. A. Flood, F. A. Goeltz, F. F. Hatch, E. D. Hammond, J. P. Kerby, W. G. Schulte, J. E. Tyree.) D. L. Barnard, A. C. Behle, W. R. Calderwood, V. J. Clark, M. M. Critchlow, A. A. Kerr, H. P. Kirtley, J. C. Landenberger, E. M. Neher, C. L. Shields, F. B. Steele, W. R. Tyndale, Ernest Van Cott; alternates, T. B. Beatty, William F. Beer, Clifford J. Pearsall, David E. Smith, F. E. Straup.

Utah County—J. R. Anderson, Fred Dunn, G. E. Christensen, J. W. Hagan; alternates, J. W. Aird, J. Karl Beck, O. H. Maybe, Arnold Robinson.

Uinta County—Homer E. Rich.

Weber County—E. R. Dumke, W. J. Wright, E. I. Rich, A. Z. Tanner; alternates, H. W. Nelson, E. P. Mills, W. A. Whitlock, E. M. Conroy.

Program

Thursday, June 19

9:30 a. m.—Meeting of the Council.

10 a. m.—Meeting of the House of Delegates.

12 noon.—Lunch at Agricultural College Cafeteria.

2 p. m. — "Five-Minute Address of Welcome"— President Elmer G. Peterson, Utah Agricultural College.

2:05 p. m.—"General Infections and Their Surgical Significance" — Dean Lewis, Rush Medical College, Chicago.

3 p. m.—"Non-purulent Nephritis" (illustrated)— A. S. Warthin, University of Michigan, Ann Arbor.

4 p. m. — "Studies in Cardio-renal Vascular Diseases"—L. G. Rowntree, Mayo Clinic, Rochester, Minn.

4:45 p. m.—"The Present Status of Our Knowledge of Vitamins"—E. V. McCollum, Johns Hopkins University, Baltimore, Md.

7 p. m.—Annual banquet, Hotel Eccles. Tickets $3, stag. The president's address will be delivered, as well as toasts, and there will be a general relaxation from the more serious aspects of medicine.

Friday, June 20

8 a. m.—Meeting of the House of Delegates.

9 a. m.—"Localization of Spirocheta Pallida in Human Tissues" — A. S. Warthin, University of Michigan, Ann Arbor.

10 a. m.—"Clinical and Functional Diagnosis of Liver Diseases"—L. G. Rowntree, Mayo Clinic, Rochester, Minn.

11 a. m.—"Goiter Survey in Utah"—James Wallace, Rockfeller Foundation, New York.

11:30 a. m.—"Present Status of Our Knowledge of the Etiology of Rickets"—E. V. McCollum, Johns Hopkins University, Baltimore, Md.

12:15 noon—Lunch at Agricultural College Cafeteria.

1 p. m.—Meeting of the House of Delegates.

2 p. m.—"Constitutional Entity of Grave's Disease, Toxic Adenoma and Toxic Goiter"—A. S. Warthin, University of Michigan, Ann Arbor.

3 p. m.—"Clinical Manifestations and Treatment of Encephalitis Epidemica" — John B. Doyle, Mayo Clinic, Rochester, Minn.

4 p. m.—"Reconstructive Surgery" — Dean Lewis, Rush Medical College, Chicago.

5 p. m.—Meeting of the Council.

Basket lunch, Logan Canyon, 5 to 7:30 p. m. Guests of the Cache Valley Medical Society.

8 p. m.—Public meeting at the Tabernacle, under the auspices of the Utah State Medical Association, speakers to be announced during the session.

Saturday, June 21

9 a. m.—"Intestinal Obstruction" — Dean Lewis, Rush Medical College, Chicago.

10 a. m.—"Nutritional Aspect of Preventive Dentistry"—E. V. McCollum, Johns Hopkins University, Baltimore, Md.

10.45 a. m.—"Recognition of the Psychoneuroses" —John B. Doyle, Mayo Clinic, Rochester, Minn.

11:30 a. m.—Subject to be announced—Thomas D. Wood, Columbia University, New York.

"Causes and Treatment of Hay Fever"—George M. Fister, Henry Ford Hospital, Detroit.

Report of the House of Delegates.

Installation of officers.

The Council will meet immediately following adjournment.

Proposed Change in Amendment to the Constitution and By-Laws of the Utah State Medical Association

It is proposed to amend the constitution and by-laws of the Utah State Medical Association, so that the calendar year shall be the fiscal year. As the amendments now read, the fiscal year ends March 31, and it is proposed to have it end December 31. This will mean that all dues for the calendar year must be paid January 1 for that calendar year, and all dues not paid by that time will constitute a suspension of the members on the rolls of the Association. The members may be reinstated by payment of dues at any time during the calendar year.

The present by-laws provide that a member shall not be suspended before March 31, so that members are carried on a three months' period of grace. The American Medical Association has adopted the calendar year for its fiscal year, and has advised the various state associations to do the same. This matter was referred by the last meeting of the House of Delegates to the Council for consideration and recommendation. The Council has considered and now recommend to the association that such action be taken.

If the proposed amendment is adopted, it will change the words in Chapter 9, Section 11, from "March 31" to "January 1," and in the same paragraph, Section 13, the words "on or before March" to "on or before January 1" in two places, namely: line 7 and line 13.

The above has been published in our official journal California and Western Medicine, and is brought to the attention of the members for the last time, and will now be considered by the House of Delegates.

Exhibits

There will be commercial exhibits by the various manufacturers of surgical supplies, including new features in X-ray and Helio-Therapy. These exhibits will be shown in rooms adjoining the lecture room at the Agricultural College.

Announcements will be made at the meeting regarding sight-seeing trips.

Cache County Medical Society (reported by W. H. Budge, secretary)—The regular monthly meeting of the Cache Valley Medical Society was held at Logan at the Chamber of Commerce, May 5, at 7:30 p. m.

M. C. Lindem of Salt Lake City read a paper on "Ethylene Gas." H. R. McGee of Logan read a paper on "Pyelitis in Infants and Children." James Wallace of Salt Lake City, who is representing the State

Board of Health, gave a talk on goiter among school children in Utah.

Minutes of the Salt Lake County Medical Society (reported by M. M. Critchlow, secretary)—The regular meeting of the Salt Lake County Medical Society was held at the Commercial Club, Salt Lake City, Utah, Monday, April 28. Sixty-three members and three visitors were present. Meeting was called to order at 8:05 p. m. by President A. A. Kerr. Minutes of the previous meeting were read and accepted without correction.

No clinical cases were presented.

V. J. Clark gave a paper on "Dysmenorrhea," giving the causes and treatment, both medical and surgical. The paper was discussed by W. R. Maddison, A. N. Minear, George W. Middleton, and Sol G. Kahn.

B. E. Bonar presented a paper on "Water Requirements in Infancy." He described the symptoms of water retention, and dehydration with its end-result acidosis, and described the treatment. This paper was discussed by Helmina Jeidell.

James Wallace, state epidemiologist for the State Board of Health, formerly with the Rockefeller Health Foundation, discussed "Goitre as a Public Health Problem," and gave some interesting facts as to the goitre survey now in progress in Utah. This paper was discussed by T. B. Beatty, George W. Middleton, A. N. Minear, and John Z. Brown, who commended Beatty for his untiring efforts in getting the goitre survey started for this state. J. F. Critchlow also discussed the paper, and moved that the society endorse the efforts and the objects of the State Board of Health and stand back of the present plans in regard to the prevention of goitre; that it deny the propaganda that seems to be opposed to it; and that it deplore any obstruction placed in the way of the survey. Seconded and carried.

J. J. Galligan suggested that the president cause to be published articles to combat the false ideas that seem to be prevalent in regard to the survey. F. E. Straup moved that a committee of three, consisting of the president, secretary, and J. F. Critchlow, be appointed to carry out Galligan's suggestion. Seconded and carried. Discussion of the survey was continued by J. R. Llewellyn, S. C. Baldwin, C. J. Albaugh, and T. B. Beatty.

A letter was read from Gaylen S. Young, chairman of the Fourth Annual National Convention of the Disabled American Veterans of the World War, in which he asked for the appointment of a committee of five to attend meetings with the Fraternal Liaison Committee, to assist in providing welcome and entertainment for the disabled veterans in their coming convention next June. W. R. Calderwood moved a committee of five be appointed, as suggested in the letter. Seconded and carried.

A letter from F. M. Whitney, assistant secretary, Heber J. Grant Company, general agents for the Hartford Accident and Indemnity Company, was read in which it was stated that the Hartford Company would issue the identical policy which had been approved at the last meeting, with the special privileges, for $20 per physician. J. F. Critchlow discussed the letter and moved that the secretary be instructed to communicate with Heber J. Grant Company that the society has adopted the policy of the Aetna Company. Motion was seconded. It was discussed by J. C. Landenberger, who suggested that all the companies be given a chance to bid for the policy. J. F. Critchlow stated that he was willing to withdraw his motion if a substitute motion was made to reconsider the action taken by the society at its last meeting, and an invitation was accorded the Aetna Company for a hearing, if it were agreeable to the seconds. Sol G. Kahn also discussed the proposition. Motion was put to a vote. Motion lost. J. C. Landenberger moved that the society reconsider the insurance question. Seconded and carried.

J. F. Critchlow moved that the same Insurance Committee be appointed. Seconded and carried.

W. R. Calderwood reported on the Emergency Hospital for the Committee to Investigate Charity Institutions. The committee recommended that the Committee on Public Health and Legislation cooperate with the city physician to instruct the public as to the purposes of the emergency hospital. J. J. Galligan said he would welcome any suggestion that would make for a greater degree of efficiency in conducting the City Emergency Hospital. J. Z. Brown moved that the report of the committee be adopted. Seconded and carried. M. M. Nielson suggested that physicians individually give their suggestions and recommendations to the committee.

Minutes of Meeting of May 12—The meeting was held at the Commercial Club, Salt Lake City, May 12, 104 members and five visitors being present. Meeting was called to order by President A. A. Kerr. Minutes of the previous meeting were read and accepted without correction.

B. F. Robbins presented a clinical case, seventy-three years old, with cancer of the right orbit, twenty years' duration, on which some excellent surgical work had been done. Discussed by J. F. Critchlow.

George F. Roberts read a paper on the "Use of Sodium Thiosulphate in Metallic Poisoning." The therapeutic effects in cases of arsenic, lead and mercury poisoning were described, with excellent results in the lead and arsenic cases, but not so good in the mercury cases. This most interesting paper was discussed by T. C. Gibbson, J. S. Alley, and H. S. Scott.

Fuller B. Bailey read a paper on "Ulcerative Colitis," giving the etiology symptoms, x-ray and laboratory findings, and the treatment. This very interesting paper was discussed by W. L. Lindsay and G. G. Richards.

Ernest Van Cott reported progress for the Committee on Public Health and Legislation.

Sol G. Kahn reported for the Committee on Liability and Insurance, in which it was requested that the society decide at this meeting whether they would accept the Aetna policy at $25 per physician or the Hartford policy at $20. L. W. Snow moved that the society accept the Hartford policy, if the provisions as suggested by the committee were incorporated in the policy. Seconded. Discussed by H. S. Scott, J. F. Critchlow, Ralph Richards, E. M. McHugh, and Sol G. Kahn. G. G. Richards offered a substitute motion that the society vote at this meeting, and the company being chosen that received the nighest number of votes. Accepted and seconded. Discussed by F. F. Hatch, J. Z. Brown, and Byron Reese. Motion carried. The Aetna company was chosen by the society, forty-nine members wishing the Aetna, and eleven members, the Hartford. S. C. Baldwin moved that the committee be authorized to make a contract with the Aetna company at once. Seconded and carried.

L. J. Paul reported for the committee to act with the Fraternal Liaison Committee of the Disabled American Veterans of the World War. He stated that a promenade would be held at the Hotel Utah, May 22, tickets to be $1.

W. R. Tyndale reported for the Library Committee, stating that the Loan Library shelves were up and the committee was anxious to accept books loaned by the members of the society.

President A. A. Kerr reported for the committee appointed at the last meeting to publish articles to combat the false ideas that seemed to be prevalent in regard to the goitre survey now being conducted by the State Board of Health in Utah. He read the article published in the local press, May 3 and 4, regarding this matter.

There followed a friendly discussion of the goitre survey in Utah, in which the views of the University and the State Board of Health were aired, the discussion being entered into by H. J. Sears, J. F. Critchlow, E. G. Gowans, T. B. Beatty, G. G. Richards, Clarence Snow, Sol G. Kahn, Byron Reese, Joseph R. Morrell, R. W. Fisher, and Ralph Richards, the result of which was that the survey now

being conducted by the Utah State Board of Health was endorsed.

G. G. Richards read a communication to him from Libman of New York, which stated that Aschof, the eminent pathologist, would be in Salt Lake City on June 25 and again on July 5, and if the society desired to have him lecture it could do so. His fee would be $100, and Libman suggested that his talk be either on the "Pathogenisis of Tuberculosis" or "Atherosclerosis."

George F. Roberts moved that Aschof be requested to lecture for the society; that those who heard the lecture pay $2, the balance to be paid by the society. Seconded and carried.

Kahn offered to amend that a committee of two be appointed, one of whom should be G. G. Richards and the other to be appointed by Richards, to handle first, the finance, and second, the meeting. Seconded and carried.

Nevada State Medical Association

HORACE J. BROWN, M. D., Reno.....President
CLAUDE E. PIERSALL, M. D., Reno.....
Secretary-Treasurer and Associate Editor for Nevada

NEVADA MEDICAL BULLETIN

For two reasons the Bulletin need not be issued often or regularly. One reason is because the A. M. A. bulletin, which you should all be receiving, covers better and more fully part of the subject matter of the Nevada Medical Bulletin. The other is that of our official organ, California and Western Medicine, contains our state news. Any news you want printed in our organ should be sent to your secretary, so it can be incorporated in time for publication.

It is vitally important that your patients read Hygeia, which is the layman's magazine of health published by the A. M. A. It presents the merits of scientific medicine to the American public.

The secretary of each of our county societies will hereby be notified that he is delegated to help increase the circulation of Hygeia through individuals, institutions, and agencies. It is $3 per year for less than five subscriptions. For group subscriptions there is a sliding scale of prices. Put Hygeia in your city library.

Out of 40,000 samples of liquor seized by the government in all parts of the country, only 2 per cent were genuine. The majority were poisonous. All of the stuff smuggled in by rum runners is raw alcohol, made in Cuba from blackstrap molasses and bottled under counterfeit labels.

Do not forget our state meeting at Bower's Mansion September 12, 13 and 14, and your 1924 receipt.

Tax Reduction and Tax Exemption—The successful physician's daily work teaches him the necessity of securing all available evidence before making up his own mind and pronouncing judgment. As a good citizen, he ought to apply the same principles to any subject before deciding for himself what he will do and what he will advise his friends to do. This applies to the question of taxation, and regardless of what one's opinion may be before or afterward, he certainly will have been entertained and probably instructed by a careful reading of an article under the above title (The April North American Review) by Edwin R. A. Seligman.

A Case of Malta Fever in Man—W. R. Tyndale and L. E. Viko, Salt Lake City, Utah (Journal A. M. A., December 8, 1923), report a case occurring in a man who died three months after handling the placental tissue from an infected animal. Aside from old cardiac findings not significant to the illness, the necropsy showed only chronic passive congestion of the lungs and liver (enlarged, firm "nutmeg" liver) and a firm, fibrous spleen. From the spleen cultures of Micrococcus melitensis were obtained.

Medical Economics and Public Health

Los Angeles County Medical Association's Permanent Quarters—In the spring of 1922, the Board of Trustees of the Los Angeles County Medical Association purchased a lot at the corner of Westlake and Orange for $24,500 upon which to build the permanent home of this association. This purchase was approved almost unanimously by the membership. Subsequent increase in value has demonstrated the wisdom of this purchase. The lot was paid for long since, and an income has been derived from it much of the time of our ownership.

Some months ago some of our officers and many of our members felt that this property gave promise of such an increase in value as to render it too valuable for our purpose and possibly too small in size. After consulting many of the best authorities on real estate values, bankers, lawyers, and the best business authorities not only at home, but abroad, your board decided to safeguard the association's interest by a further purchase not as a speculation, but as an investment of a potential reserve. Accordingly the Forve home at 427 South Westlake on a lot 200 feet by 165 feet was purchased for $80,000. Of course, no decision has been made by the board as to which will be the site of our proposed assembly, library and museum building.

To some of our members this step may seem too ambitious, especially to those who see in the so-called "peak" the end of the marvelous growth of our great Southern California. To these the board can say that when such disinterested journals as The Nation's Business, Washington, D. C., Business Conditions Weekly, and the London Economist place our Southern California business and growth on the permanent and not the boom basis; when the experience of the past shows that so long as there are people east of the Rockies who can acquire a competency and retire, and that our geographic, climatic and social conditions will draw them with an absolute certainty; when the great commercial and manufacturing interests are a unit as they are for employment and market expansion: when every indication shows that the higher class business, artistic and cultural trend is in the direction of our properties, your board feels that time—and a comparatively short time, too—will show the wisdom of this second step as it has shown the soundness of the first.

I think I am safe in saying that two-thirds of our membership has subscribed to the building fund. If every member who has not subscribed or who is objecting to the plan adopted by the trustees could see these values as they are, could see this future as it is, and could realize that no organization as such can function powerfully without hearty co-operation—then we would soon see right here a splendid medical center, the equal of the best in Eastern cities ten times our age.

And remember it is less than a cigar a day, less than a package of Camels, less than the price of a Sunday paper, less than a shoe shine. This is very small individually, but very great in the aggregate. Why not co-operate?—William Duffield, M. D. (Los Angeles County Medical Association Bulletin.

A Compliment to California Physicians — Some months ago, quite a little local excitement was created in Sonoma County over the news that "Doctor" Tilden of the "Tilden Health School" of Denver had taken an option on the Burke's Sanitarium property, with the intention of opening a branch of the Denver plant here. It is now announced that the option has been allowed to lapse for the interesting reason that Tilden was unable to "secure a proper physician to handle the proposed enterprise."

What is a Health Center?—That the definition of a

"health center," or "health unit" as some of them are now called, is whatever the particular group who are operating one cares to include in the definition, has long been known. Charles Wilinsky, in giving a brief and incomplete history of the movement (Boston Medical and Surgical Journal, April 3), adds his own definition to the variety already existing.

One important feature of his definition that ought to be interesting to California physicians says:

"In order to properly promote the principles of preventive medicine, it is important that only such services that are truly prophylactic in their nature and type be a part of the health center, leaving the curative field to the practitioner, hospital and existing dispensaries. Only in that way can we make the health center emphasize prevention of disease, and we should render only such treatment which may be classified as truly preventive."

Something of how extensively medicine may be socialized without holding treatment clinics is further illustrated by what the author considers the legitimate program of a health center when he says:

"We must begin by giving the expectant mother proper prenatal instruction. Upon the birth of a child, infant welfare guidance, and after two years of age the youngster must be carefully carried through the preschool-age period, receiving correct physical supervision through the most important age, so that we may be able to turn over to the school nurse and school physician, for their watchful care, a child physically able to cope with the classroom problems. In adolescence and adult life we must impress upon the individual the value and virtue of routine medical examinations, which may be properly defined as physical stock-taking. Emphasis must then be laid on careful living, proper hygiene, etc. In the creation and rounding-out of the above service, a health center becomes a powerful potent factor in the life of the individual, and become a community house where one will come for health and welfare relief."

In commenting upon this report editorially, the Boston Medical and Surgical Journal says:

"The expense of maintenance (of health centers) is relatively small as compared with that of a well-equipped dispensary so long as the medical work of the unit is kept within the limits of that which is essentially preventive in purpose. Undoubtedly, however, demands will arise from time to time for the inclusion in these units of treatment-clinics of various kinds. It seems to us that to do so, unless with prophylaxis as the aim, would be to depart from sound policy. It is arguable that medical advice for local cases of tuberculosis or of venereal disease might be included among proper functions of a health unit on the ground that a certain amount of such work is now being done at municipal expense as a means of eradicating these diseases, but there would seem to be no reasonable ground for providing accommodation in a health unit for treatment not essentially prophylactic in purpose, even if not conducted at the expense of the health department. Treatment clinics require more space and more apparatus than is needed for preventive work. Inclusion of treatment clinics in a health unit would tend to overshadow the preventive aspects of the work and would require larger buildings than have been planned for the accommodation of future health centers in Boston."

The real working motto of most of the health centers and similar organizations is to get all the "business" you can drum up from all the classes of people you can interest, and charge them less than they can get the service for from some other clinic or from their former physician.

Medical Insurance Examination Fees—The Canadian Medical Association, after due deliberation, resolved that $5 would be the minimum flat fee for a life insurance examination. They took the matter up with the various life insurance companies. Some of the companies did not pay them the courtesy of a hearing. Others told them their profits were so small they could not afford to pay a $5 fee for a medical examination. A few of the better companies in whom more people have confidence are already paying $5 fees. Most of the companies told the doctors in polite language where they could go to. They said they could hire all the doctors they wanted upon their own terms and that, therefore, they were not interested in what the Canadian Medical Association might resolve.

Physiotherapy Making Progress in Canada—Physiotherapy technicians in Canada have placed themselves under the protecting wing of the medical profession somewhat along the same lines, but less definitely, than have those of California.

Sir William Milligan chose "Physiotherapy" as his "founder's lecture" and complimented the physicians, physiotherapists, and the public upon the fine ethical manner in which the technical specialty was being practiced.

"The lecturer laid stress upon the importance of the thorough grounding in anatomy and physiology for its members which the society had instituted," says the Canadian Medical Journal. So long as an excellent training is insisted upon, no extravagant claims made, and no suspicion of charlatanism tolerated, the profession will have the support of the medical profession, and the gratitude of the public. Neither the physiotherapist, the masseur or masseuse was intended to be a mere mechanic or mere manipulator, but one who appreciates with the physician or surgeon under whom he or she may be working the reason and object of the special manipulations to be carried out. This intelligent appreciation will never be secured unless a high educational standard was maintained by the association.

A Professor in a Class A Medical School Thus Characterizes His Colleagues and His Students—"From different parts of the world we hear of friction between the health officer and the practitioner," says Harry T. Marshall (Virginia Medical Monthly). "The doctor may set himself in stiff opposition to 'socialism in medicine.' He may resent the infringements of his freedom due to the activities of the health officer. He may growl because his young patients are examined by the school physician, or in the baby clinic. He may be shocked and demur when advised that he should call up his families every half year or so and arrange to give each one a health examination. At the same time, he will be very savage if someone else steps in and gives periodic health examinations to his patients, and will cry out about unethical conduct, contract practice or state medicine. He may feel that his means of earning a living is itself being snatched from him through the various health clinics and even more through the reduction in the diseases which bring him the bulk of his income."

Chiropractic from the Inside—A physician took the course in "chiropractic" at the Palmer School in Davenport, Iowa, and some of his findings published in the New York Medical Journal are:

"The absurdity of the pretentions of learning of the chiropractic can be appreciated only by one who has taken the course, lived under the same roof with them, breathed the stench of commercialism that reeks the halls of their so-called institutions of learning, and heard the blatant mouthings of their ignorant and egotistical leader, whom they all adore. You think that you know them, but you do not; nor can you know them without being there for four months."

"I was prepared to produce my credentials, but all I had to do was to say that I was a physician, and he fell on my neck and lifted up his voice and wept. I came across with a check, and was dismissed as a full-fledged student of that institution of learning. I never shall forget how fresh and pure the air seemed, even on that sultry day, after getting out of that man's office."

"For, be it known unto you, educational require-

ments for matriculation are conspicuous by their absence. None is needed to get in, and but few to get out. They insist that you must be able to write. If not, it would lead to all kinds of trouble to cash your check. Now, as to getting out after you are in: I asked some of the boys there about how many men failed to pass the examination, and no one had ever heard of a single one being plucked."

"I betook myself to the hall of learning that was set aside for the post-graduate students, and here I found about ten students, some chiropractors, some osteopaths, but no disciple of Hippocrates but myself; and I felt like a lone wolf. We were but a small body compared to the rest of the school, as there were some 1500 students among them, so it was claimed; but we made up in enthusiasm for that which we lacked in numbers. We ran along the trail of knowledge, like half-spent hounds after the wily fox, and we all ultimately received the coveted diploma."

"The faculty was made up of a bunch of good fellows, with no education except an ex-minister of the gospel, who was rather effeminate. He told me once 'I just love Doctor Palmer.' One medical man—and he seemed to be a good one too—and one high school graduate. The rest were just ignorant, ordinary men who seemed to think that they were doing some good, but not much more than the medical men. You know, the chiropractors—the more intelligent of them—know they are fakirs, but they know that we are, too. The only difference, as they see it, is that we have been working the graft longer than they, and so have developed a finer technique."

"There is the clinic where you learn to give the adjustments after you have developed your punch on an inanimate bench. I suppose that there are, each day, several hundred patients in that place. It is pathetic, too. People that anyone knows can receive no benefit come there with faces lit up by hope. The lame, the halt, and the blind, all are there. Hope springs eternal in the human breast, nor quits us when we die. The medical man has told you the truth. You are blind, have a cancer, pernicious anemia, T. B., or anything else, especially epilepsy—I don't want to forget that; and blindness—it seems to me that was the commonest thing that I saw. Oh, yes, infantile paralysis was raging then. Parents brought their little ones there by the cartload. None was cured. I think that I felt the most sorry for the blind and for the little kids' parents. The study of the faces of the blind from the standpoint of contrast was particularly sad. The new ones were uplifted with the faith. The ones that had been there were beginning to show doubt. You heard the priest of the cult come out and say that little Johnnie Jones, who came there three weeks ago suffering from infantile paralysis, after being given up by fourteen of the best doctors in Davenport, is now healed. (Just what there is to that number, fourteen, that appeals to them there, I don't know. But it is always fourteen of the best doctors in Davenport—never any more, never any less.) I investigated four or five of them, and I found not one who was any better than they would have been in the ordinary course of the disease; and one who was nearly dead—an acute case, that needed rest."

Abstracts from County Nurse's Report—Medical inspection, 540; number with enlarged tonsils, 147; number with defective teeth, 162; number with defective vision, 15; number with symptoms of impetigo, 18; ringworm, 28; conjunctivitis, 2; pediculosis, 3; scabies, 3; mumps excluded, 6; T. B. suspect, 1.

Percy T. Phillips, president of the Board of Medical Examiners, informs us that some of these nurses are not only violating the Medical Practice Act by making diagnosis of diseases, but are actually treating patients. The board takes a definite and positive stand on law enforcement and will prosecute persons practicing medicine without a license, even though they may be employees of the government itself.

The Physician of the Future—Under this title, Eugene R. Kelley, State Commissioner of Public Health, Massachusetts, in the "Commonwealth," says many things of great importance to physicians. For the convenience of our readers, a few brief abstracts are given:

"The Training of the Physician of the Future—Without going into any detailed corroborative evidence, it is probably fair to say that for the past twenty-five years medical schools have shaped their curricula more and more in the direction of emphasizing the specialties. More and more the attempt has been made to have the student master the principles of all of the ever-multiplying specialties and to establish at least a bowing acquaintance with each new 'instrument of precision' and each new laboratory procedure developed in connection with each such specialty. This process has reached and gone beyond the saturation point. One of the great schools of medicine has recently come out boldly with the statement that their policy for the immediate future will be a return to the Hippocratic ideal of training the student's native powers of observation of weighing of the facts elicited, and endeavoring to develop his judgment as to whether it is necessary or advisable to seek the advice of the specialist, with no attempt to turn out embryonic specialists in every aspect of medicine. I believe we will witness in a sense a reversion to the ideals of a generation or two ago—less attempt to turn out encyclopedic authorities on all the nooks and corners of medicine's vast domain, more attempt to turn out sympathetic students of humanity."

"The Recovery of the Lost Provinces of Medicine—This seems to be one of the definite jobs of the coming era in medicine if medicine is to maintain its grip upon the respect, regard and affection of the world at large. 'The obligations of the physician to his fellows, what are they? To cure sometimes, to relieve often, to console always!' says a great French physician. The fundamental mistake of the profession today has been its absorption in the pursuit of the first of these three fundamental duties as defined by the old French physician to the neglect or utter exclusion of the other two. This goes right at the bottom of much that is now admittedly out of joint in the relation of the physician to the rest of the community, and it indicates the line of campaign that medicine must wage to recover its 'lost provinces.' I predict that medicine of the future will come back and claim for its own the fields of alleviation and spiritual consolation just as the old family doctor of the past always did. But in his case he did this instinctively, unobtrusively, utilizing all the great potentialities for good in the way of palliative, psychic and spiritual measures that were at hand without dreaming of starting a new healing cult or a new religion in order to call dramatically to the world's attention the possibilities of such procedures."

"The Physician of the Future a Practitioner of Preventive Medicine—One other thing in reference to the medicine of the future that seems more certain to come to pass than any other probable or likely development is the shift of emphasis to preventive in contrast to curative principles not merely in public or community health matters, but in private practice as well."

"Clinical Medicine Already Entering the Preventive Medicine Phase—The medical profession today is giving more treatment for diseases that are in the early stage, and to patients who are predisposed than ever before. There is a strong irresistible, unceasing current in medicine to move from the obviously pathological toward the more physiological conditions of life. This tendency of medicine to find its patient before irreparable damage has been done and to treat disease in its more curable stages has been made possible (1) by a larger appreciation on the part of both physician and patient of the value of early treatment as contrasted with late treatment, this larger appreciation of early treatment having resulted

from the greater emphasis that has been placed upon disease prevention as compared with the treatment of disease during the last thirty or forty years; and (2) by easier means for reaching the patient because of (a) improved communication, telephones and roads, (b) improved transportation, automobile and electric car lines, (c) enlarged hospital facilities with segregation of the sick. Prevention is much newer as a practice than as an ideal in medicine. Medical ideals, the larger objectives of the profession, have always been the prevention of disease. The pride of the profession, the respect in which the public holds it, the distinction which it has over the cults, is that, through its discoveries and their application, smallpox and typhus and yellow fever have been banished and diseases in general have been greatly reduced; the efficiency and happiness of life and longevity have been defined and measurably advanced. The 'Principles of Medical Ethics,' embodying a statement of principles and ideals of the organized medical profession of the United States, in Chapter 3, relating to 'The Duties of the Profession of the Public' specifically and urgently advised the members of the profession to take an active and advanced position in their communities, their states and their nation in proposing legislation for disease prevention, in supporting officers for the enforcement of such legislation, and in every possible way preventing disease in the interest of the public welfare."

To summarize, the field of medicine, in both its practice and its claims, insists and rightly insists on including within its activities both the cure and the prevention of disease, and the unmistakable tendency in medicine is to increase its work in the prevention of disease as compared with its work in the treatment of disease.

Notice of Examination for Entrance into the Regular Corps of the United States Public Health Service—Examinations of candidates for entrance into the Regular Corps of the United States Public Health Service will be held at San Francisco, Calif., July 7, 1924.

Candidates must be not less than twenty-three nor more than thirty-two years of age, and they must have been graduated in medicine at some reputable medical college, and have had one year's hospital experience or two years' professional practice. They must pass satisfactorily, oral, written and clinical tests before a board of medical officers and undergo a physical examination.

Successful candidates will be recommended for appointment by the President, with the advice and consent of the Senate.

Requests for information or permission to take this examination should be addressed to the Surgeon-General, United States Public Health Service, Washington, D. C.

Mediaeval Medicine—"The profession of medicine, with all the chivalry and much of the despotism of the Middle Ages, has deliberately set itself to the pauperism of two classes of society," says the Boston Medical and Surgical Journal editorially. "The wage-earners with less, and the young physicians with more pride than financial resources. The free or low-priced hospital clinic is not an unmixed blessing as it is at present generally conducted. Designed to give service to the needy poor, and experience to the inexperienced graduate in medicine, it has abandoned its ideals and abused its privileges, misled by the ambition to increase its attendance, and the desire to gather half-dollar fees from many of its patients who should be paying regular fees to the same physicians, in their offices, now treating them free in the clinics."

Interesting Health Development Project for Kings County—The report of Mr. E. C. Bond, health officer, contains this illuminating statement: "On account of the large number of cases of measles, chickenpox and other diseases reported, this has been a very busy month for the health department, and has strongly reminded us of the need of an inspector to relieve the health officer and county nurse of a large amount of driving that could as well be done by an inspector as by the nurse."

The Beginner in Medicine—Every young physician of less than fifty years' experience can find much that is worthwhile thinking over in Henry Jones Mulford's article on the above subject.—New York Medical Journal, April 18, 1924, p. 605.

The Dermatological Research Laboratories Issue New Publication—We are in receipt of the "Progress of Chemotherapy and the Treatment of Syphilis," edited by George W. Raiziss.

With this initial copy of the Dermatological Research Laboratories (Branch of The Abbott Laboratories) establish a "house organ" devoted to the subject of treatment. The publication abstracts and reviews literature, and in the first number this work is creditably done.

Making Private Physicians' Services Unnecessary at Lodi—If newspaper publicity and personal reports from our correspondents are approximately correct, the public health department of San Joaquin County proposes to make the personal services of private physicians unnecessary at Lodi, through the bi-weekly clinic conducted by the department.

They propose to accomplish this, it is said, by keeping such close watch over children under school age that "it may be possible to eliminate all health examination work in the schools."

"The examinations in the five public grammar schools and the two private schools keep the children under the supervision of the health district until they enter high school," says Miss Edna Porter, in charge of the local health office.

All this work is "free," and it is said that the physicians of the community have offered to assist when the work became more than the salaried health staff could handle. This has not happened yet. San Joaquin County has a physician for about each 600 people, and one for each fourteen square miles of territory.

Doctor of Psychological Medicine—Outlines of courses of graduate medical instruction leading to a variety of special medical degrees is developing rapidly abroad and in this country. Some universities in England are now prepared to award diplomas in what is termed psychological medicine. The requirements for the degree are outlined in the curriculum, the important features of which are:

Model Scheme for a Diploma in Psychological Medicine

1. The candidate must be already a registered medical practitioner.

2. The candidate may present himself for examination on the subjects detailed under Part I of the curriculum (see paragraph 4) immediately he has concluded the prescribed course of instruction or can produce such other evidence of diligent study of the subjects to be examined upon as may be demanded. Part I must be passed save by special permission at least three months prior to entering for examination on Part II of the curriculum.

3. The candidate may not present himself for examination on the subjects detailed under Part II of the curriculum (see 4) until he has been a registered medical practitioner for not less than two years. He must, subsequently to qualification, have been in the practice of an approved mental hospital for not less than two years, or have attended for six months at a hospital, mental or general, for clinical instruction in psychological medicine, and subsequently held a resident appointment at an approved mental institution or mental wards of a general hospital for not less than six months. In both cases he must produce a certificate from a recognized source that he can apply his theoretical knowledge and has practical

acquaintance with, and is well and adequately versed in, the current clinical methods of examination and treatment of nervous and mental disorders. In the case of mental deficiency the certificate should include a practical knowledge of the various intelligence tests and other methods of ascertaining the degree of mental defect. He must also produce evidence of having attended, subsequently to qualification, courses of lectures, demonstrations or other evidence of diligent study of the subjects upon which he presents himself for Part II of the examination, as may be demanded.

4. Curriculum—

Part I—(a) Anatomy, histology, and physiology of the nervous system, including the autonomic system. Anatomy and physiology of the endocrine glands. Chemistry and cytology of the cerebro-spinal fluid. (b) Psychology, systematic and experimental.

Part II—(a) Morbid anatomy, histology, and pathology of the systems mentioned under Part I (a). Post-mortem and laboratory technique. (b) Neurology and clinical neurology. (c) Psychiatry (including the psycho-neuroses), clinical psychiatry, and the medico-legal relationships of mental disorders and mental deficiency.

In addition, the candidate for Part II will need to show special knowledge of any one subject, to be selected by him from the subjects comprising Part I or Part II; or may choose to be examined in any one of the following subjects: (d) Mental deficiency and the mental disorders of childhood and adolescence, and the duties of school medical officers in relation thereto. (e) Bacteriology as applied to mental and nervous disease. (f) Psycho-pathology and psychotherapy. (g) The principles of diet, vitamins, and basal metabolism, and their application. (h) Eugenics, and vital statistics. (i) Criminology and the jurisprudence of criminal responsibility.

5. The diploma, by request, may be endorsed that special knowledge has been shown in the subject selected.

6. It is suggested that any compulsory attendance at lectures and demonstrations and clinical courses should be limited to the subjects detailed for Part II, and that the course for Part I or Part II should not exceed eight weeks.—British Medical Journal, April 5, 1924.

Medico-Dental Building — This $1,200,000 doctors' and dentists' office building for San Francisco has reached a stage in its promotion where the Anglo London Paris Company are offering 6 per cent first (closed) Mortgage Sinking Fund Gold Bonds to the public. These bonds are exempt from personal property tax in California, and we are informed by reliable judges of investments that they are a perfectly good bond to buy. Applications have already been approved for over 70 per cent of the occupancy of the building. Excavation will begin June 15, and will be completed by the first of September, by which time the foundation will be all in. Steel work will be completed November 1, and the building itself will be ready for occupancy July 1, 1925.

The announcement of these bonds by the Anglo London Paris Company is found in the advertising pages of this issue of California and Western Medicine, and this company has entered into a contract to use a quarter-page of our advertising space for a year, for various announcements they will have to make that will be of interest to our members.

Offices for Doctors—We are glad to call the attention of our readers to the advertisements of the Butler building, Geary and Stockton streets; the Elkan Gunst building, Powell and Geary streets; the Physicians' building, Sutter at Powell, and the Union Square building, 350 Post street, carried in this and subsequent issues of California and Western Medicine. All of these buildings offer their space exclusively to educated, ethical physicians, dentists and other approved agencies of scientific medicine. All of them are well-known physicians' office buildings, and it may be confidently predicted that available space will not long remain idle in any of them. Certainly physicians who are now occupying space in these buildings will appreciate the spirit of cooperation shown by their owners.

Grinding and Repairing of Surgical Instruments—We feel quite sure that many physicians and hospitals will find exactly what they want in the advertisement in this and subsequent issues of California and Western Medicine of the Exclusive Cutlery Shop, 113-115 Stockton street, San Francisco, whose repair department is comprised of skilled surgical instrument-makers of the old school, trained to do scientific work in repairing, sharpening, and conditioning expensive surgical instruments.

Hospitals in Charge of Sisters of Charity—We welcome the advertisements contained in this and subsequent issues of California and Western Medicine, of the O'Connor Sanitarium, San Jose, and Mary's Help Hospital, San Francisco. Both of these hospitals are rendering high-grade service to the sick along ethical lines, endorsed by our medical organizations. What a pleasure it is to welcome more and more of the hospitals of the state who are constantly improving their service and who intend to continue to improve it, so as to merit the endorsement of physicians today and in the future.

Cloverdale Hospital—We are glad to add to our advertisers the Cloverdale Hospital, located at Cloverdale, Sonoma County, Calif. This hospital is under the medical direction of W. C. Shipley, a member of the California Medical Association. It is unusual for good hospitals located in smaller communities to have the vision and see the advantages of carrying announcements in accredited medical literature. Many hospitals of this kind fail to appreciate the fact that city physicians and city hospitals are constantly giving advice to sick people as to where to go for convalescence, care of chronic diseases, etc., in more rural communities, under more favorable climatic conditions. California and Western Medicine is particularly fortunate in carrying the announcement of several—The Alexander Sanitarium at Belmont; The Anderson Sanitarium, Oakland; Banksia Place Sanitarium, Pasadena; Gottbrath's Sanitarium, Belmont; Grande Vista Sanitarium, Richmond; Las Encinas Sanitarium, Pasadena; Livermore Sanitarium, Livermore; Tamalvista at Mill Valley; The Terrace, Saratoga; and Lomita Vista at Los Gatos. And in San Francisco, the Alice Lampson Thompson Rest Home, and Miss J. Price's Convalescent Home. All of these will be found listed on page 62 of each issue, together with general hospitals, tuberculosis hospitals and other special hospitals, whose advertisements are found in our pages monthly, and about which more will be written in this department from month to month.

Preparation of Manuscripts Made Easier—The advertising of the Corona Typewriter Company, which we have been carrying during the past year, has been very satisfactory, because they are making available an easy and attractive method by which doctors may put their thoughts into good shape for publication or other use. The Corona people are now prepared to offer what is called the "four-bank keyboard," with a special medical keyboard, which doctors have been asking for. Their advertisement in this issue contains a coupon. Why not fill it out and mail it to the Corona people and learn more about this new development? The Corona people will, of course, check up the interest of the physicians of California, Utah, and Nevada, by the extent to which they use this coupon. Or ring up your nearest agency and ask them for information. Los Angeles has an agency at 533 South Spring street; San Francisco, 546 Market street; Fresno, 1209 Broadway; Oakland, 1526 Franklin street; Salt Lake City, Utah, 131 South Main street; and Reno, Nev., 224 North Center street.

BOOKS RECEIVED

Abt's Pediatrics. By 150 specialists. Edited by Isaac A. Abt, M. D., Professor of Diseases of Children, Northwestern University Medical School, Chicago. Set complete in eight octavo volumes, totaling 8000 pages, with 1500 illustrations, and separate Index volume free. Now ready—Volume III, containing 1051 pages, with 223 illustrations. Philadelphia and London: W. B. Saunders Company, 1924. Cloth. $10 per volume. Sold by subscription.

The Circulatory Disturbances of the Extremities, Including Gangrene, Vasomotor and Trophic Disorders. By Leo Buerger, M. A., M. D., New York City. Octavo volume of 628 pages, with 188 illustrations. Philadelphia and London: W. B. Saunders Company, 1924. Cloth, $8.50 net.

Differential Diagnosis. Presented through an analysis of 317 cases. By Richard C. Cabot, M. D., Professor of Medicine and Professor of Social Ethics at Harvard University. Volume 2. Third edition, revised. Octavo of 709 pages, 254 illustrations. Philadelphia and London: W. B. Saunders Company, 1924. Cloth, $9 net.

The Operating Room—Instructions for Nurses and Assistants. By the Staff of St. Mary's Hospital, Rochester, Minn. (The Mayo Clinic.) 12mo of 165 pages, with 144 illustrations. Philadelphia and London: W. B. Saunders Company, 1924. Cloth, $1.75 net.

National Health Series. Edited by the National Health Council, written by leading health authorities of the country, and published by the Funk & Wagnalls Co. Price per volume, 30 cents. Complete set of twenty volumes, $6. The second five volumes have been received, and are as follows:

The Quest of Health—Where It is and Who Can Help Secure It. By James A. Tobey, Administrative Secretary, National Health Council.

The Human Machine—How Your Body Functions. By William H. Howell, M. D., School of Hygiene and Public Health, Johns Hopkins University.

Food for Health's Sake—What to Eat. By Lucy H. Gillett, A. M., Superintendent of Nutrition, Bureau of the New York Association for Improving the Condition of the Poor.

The Young Child's Health. By Henry L. K. Shaw, M. D., Clinical Professor of Diseases of Children, Albany Medical College, New York.

Taking Care of Your Heart. By Stuart Hart, M.D., President of the Association for Prevention and Relief of Heart Disease.

Modern Urology: In original contributions by American authors. Edited by Hugh Cabot, M. D., Dean and Professor of Surgery in the Medical School of the University of Michigan. Volume I, general considerations—discases of penis and urethra; diseases of scrotum and testicle; diseases of prostate and seminal vesicles. Volume II, diseases of the bladder; diseases of the ureter; diseases of the kidney. Second edition, thoroughly revised. 288 engravings and 8 plates. Lea & Febiger, Philadelphia and New York, 1924.

Medical and Sanitary Inspection of Schools: For the health officer, the physician, the nurse, and the teacher. By S. W. Newmayer, M. D., formerly Chief of Division of Child Hygiene; Supervisor of School Medical Inspection, Philadelphia. Illustrated with 79 engravings and 6 full-color plates. Lea & Febiger, Philadelphia and New York, 1924.

Local Anesthesia: Its Scientific Basis and Practical Use. By Prof. Dr. Heinrich Braun, Director of the KGL. Hospital at Zwickau, Germany. Translated and edited by Malcolm L. Harris, M. D., Professor of Surgery, Chicago Polyclinic; Chief Surgeon Alexian Brothers Hospital, Chicago, etc. Second American from the sixth revised German Edition. With 231 illustrations in black and colors. Lea & Febiger, Philadelphia and New York, 1924.

A Woman's Quest, The Life of Marie E. Zakrzewska, M. D. Edited by Agnes C. Vietor, M. D., Formerly Instructor in Physical Diagnosis and Surgery, Woman's Medical College of the New York Infirmary; later Assistant Surgeon, New England Hospital for Women and Children, Boston. D. Appleton & Company, New York: London, 1924.

A Manual of Gynecology and Pelvic Surgery: For Students and Practitioners. By Roland E. Skeel, M. D., formerly Associate Clinical Professor of Gynecology, Medical School of Western Reserve University. Second Edition, with 281 illustrations. Philadelphia: P. Blakiston's Son & Co., 1012 Walnut Street.

Fifty Years of Medical Progress, 1873-1922. By H. Drinkwater, M. D. With 37 illustrations. The Macmillan Company, New York, 1924.

Maternity Nursing in a Nutshell. By Elizabeth H. Wickham, R. N., Former Supervisor of the Maternity Department, Lebanon Hospital, New York City. With 28 illustrations. Philadelphia: F. A. Davis Company, Publishers, 1924.

A Study of Masturbation and Its Reputed Sequelae. By John F. W. Meagher, M. D., Neurologist of St. Mary's Hospital, Brooklyn; Consulting Neurologist to the Kings Park State Hospital, etc. New York: William Wood & Company, 1924.

The Relative Position of Rest of the Eyes and the Prolonged Occlusion Test. By F. W. Marlow, M. D., Professor of Ophthalmology in the College of Medicine, Syracuse University. Illustrated with original diagrams and charts. Philadelphia: F. A. Davis Company, Publishers, 1924.

The Treatment of the Common Disorders of Digestion: A Handbook for Physicians and Students. By John L. Kantor, M. D., Chief in Gastro-intestinal Diseases, Vanderbilt Clinic, Columbia University. Illustrated. St. Louis: The C. V. Mosby Company, 1924.

The Science and Art of Anesthesia. By Colonel William Webster, M. D., Professor of Anesthesiology, University of Manitoba Medical School; Chief Anesthetist, Winnipeg General Hospital, etc. Illustrated. St. Louis: The C. V. Mosby Company, 1924.

A Textbook of Pharmacology and Therapeutics, or the Action of Drugs in Health and Disease. By Arthur R. Cushny, M. D., Professor of Materia Medica and Pharmacology in the University of Edinburgh; formerly Professor of Materia Medica and Therapeutics in the University of Michigan, and later in the University of London. Eighth Edition, thoroughly revised. Illustrated with 73 engravings. Lea & Febiger, Philadelphia and New York, 1924.

Diseases of Middle Life: The Prevention, Recognition and Treatment of the Morbid Processes of Special Significance in this Critical Life Period. Comprising twenty-two original articles by various eminent authorities. Edited by Frank A. Craig, M. D., Associate Director of the Clinical and Sociological Department of the Henry Phipps Institute of the University of Pennsylvania. In two columns. Illus-

trated. Philadelphia: F. A. Davis Company, Publishers, 1924.

Management of Diabetes: Treatment by Dietary Regulation and the Use of Insulin. A manual for physicians and nurses based on the course of instruction given at the Presbyterian Hospital, New York. By George A. Harrop, Jr., M. D., Associate in Medicine College of Physicians and Surgeons, Columbia University. Introduction by Walter W. Palmer, M. D., Bard Professor of Medicine College of Physicians and Surgeons, Columbia University; Medical Director Presbyterian Hospital, N. Y. Paul B. Hoeber, Inc., New York, 1924.

Cosmetic Surgery: The Correction of Featural Imperfections. By Charles Conrad Miller, M. D. With 140 illustrations. Philadelphia: F. A. Davis Company, Publishers, 1924.

Cancer of the Breast, with study of 250 cases in private practice. By L. Duncan Bulkley, M. D., Senior Physician to the New York Skin and Cancer Hospital, etc. With 40 illustrations. Philadelphia: F. A. Davis Company, Publishers, 1924.

Handbook of Modern Treatment and Medical Formulary. A condensed and comprehensive manual of practical formulas and general remedial measures. Compiled by W. B. Campbell, M. D., formerly Resident Physician at Methodist Episcopal Hospital of Philadelhpia. Seventh Edition revised and enlarged, by John C. Rommel, M. D., and C. E. Hoffman, Ph. D. Philadelphia: F. A. Davis Company, 1924.

BOOK REVIEWS

Practice of Preventive Medicine. By J. C. Fitzgerald. St. Louis: C. V. Mosby Company. 1922.

The author states in his preface that the object of the volume is to outline some of the work of the physician who is to function on the preventive, as well as the curative side of medicine, and that the volume may be found useful by medical practitioners, students of medicine or public health nurses.

The volume will probably find a wider use. It should find a place in the libraries of those interested in construction problems, where matters of public health are likely to be considered.

The first chapter, "Aims and Problems of Preventive Medicine," is of interest to physicians whether for or against state medicine. Following the introduction, each communicable disease or group of related diseases are taken up under a separate chapter. At the end of each chapter there are references to standard texts or the principle articles on the subject. The chapters are clearly subdivided under a number of headings such as Etiology, Incidence, Modes of Transmission and Control. The book covers the subject in about 800 pages, including charts and illustrations, and the character of the language and comparative brevity make the subject readable to those not specially trained in medicine.

E. V. K.

Rhus Dermatitis. From rhus toxicodendron, radicans and diversiloba: its pathology and chemotherapy. By James B. McNair. 298 pp. Chicago: University of Chicago Press. 1923.

The author in his preface states that his object is to try to "isolate the principal skin irritant" of the rhus plant in the hope that a knowledge of its characteristic properties might serve as a basis for such treatment. He gives an interesting account from an historical, botanical and chemical standpoint which is well worth reviewing. He describes his researches which resulted in the isolation of what he considers the principal skin irritant principle of rhus diversiloba. This he calls lobinol. On the basis of studies of the pathological reactions of the skin and the chemical properties of lobinol, the author has suggested rational external treatment of rhus dermatitis. Natural and acquired immunity to poison oak and the pioneer work of Strickler and Schamberg, in attempts to artificially stimulate this process, are discussed briefly. The work represents a valuable contribution to the subject, and should find a place in the library of every progressive specialist in cutaneous medicine.

ALDERSON.

Text-book of Human Physiology. By Albert P. Brubaker. 7th ed. 835 pp. Philadelphia: P. Blakiston's Son & Co. 1922.

A book which has gone through seven editions must have many points in its favor, and must have reached a certain degree of excellence, if only through the process of attrition or of trial and error. About the only chapter in the book which the reviewer feels like criticizing is the one on physiologic apparatus which, on account of the retention of many old drawings, is far from up to date. In order to be of real use, it should picture the type of apparatus which is being used now.

W. C. A.

Manual of Diseases of the Nose and Throat. By Cornelius G. Coakley. 664 pages. Illustrated. 6th edition. New York and Philadelphia: Lea & Febiger. 1922.

In this book, the author has compiled an excellent, compact manual dealing with the diseases and treatment of nose and throat conditions.

It is particularly adapted to the needs of the student because it treats the subject in simple, readable language and is not crammed full of superfluous anatomy, physiology and theory.

Great stress is laid on the proper method of examination, technic being given in every detail.

Each disease is described and treatment given in a very brief and concise manner, thus making the work valuable to the rhinolaryngologist as well as to the medical student and general practitioner.

R. E. A.

Hygiene and Public Health. By Louis C. Parkes and Henry R. Kenwood. 7th edition. 783 pages. Illustrated. Philadelphia: P. Blakiston's Son & Co. 1923.

This book on hygiene and public health presents the subjects in a most full and comprehensive manner. It is a most valuable book and should occupy a place in every medical man's library, especially health officers' and others interested in this subject.

It would be an excellent book for the library of every high school, for it contains a world of sound information especially on sanitation and communicable diseases, their epidemiology, causes and prevention, and many other kindred subjects.

H. R. O.

What Re-write Editors Sometimes Produce — We wonder if the New York Medical Association members would recognize their reports about underwear after they have been man-handled a number of times and have traveled some 3000 miles. They are quoted here as saying:

"The doctors do not suggest long, angle-length undies, nor do they necessarily mean "heavies"; they insist that the way to acquire and keep slender ankles is to give the body itself plenty of protection so that the blood that goes through the legs will be warm and flow freely. They declare that thick ankles are due to swelling caused by pumping thick, congested blood through veins that have been contracted by cold."

Medical School News

University of California Medical School (reported by L. S. Schmitt, acting dean)—The Surgeon-General of the army has authorized the organization of a general hospital and a surgical hospital as University of California Medical School units. The General Hospital will be known as General Hospital No. 30, and the Surgical Hospital as Surgical Hospital No. 65. The General Hospital has been given the same number as the Base Hospital, which was organized by the University of California Medical School and sent overseas during the World War. Howard C. Naffziger has been designated as commanding officer of the General Hospital, and J. Homer Woolsey as commanding officer of the Surgical Hospital.

In order to meet a widespread demand, plans are now being made to offer post-graduate instruction in medicine during the summer of 1925. It is contemplated that the course will cover a period of six weeks, probably from May 19 to June 28, inclusive. As now outlined, the courses will include General Medicine, Laboratory Diagnosis, Borderline Medicine and Surgery, Gastro-Intestinal Diseases, Metabolic Diseases, Neuro-Psychiatry and Neurological Surgery, Dermatology, Syphilology and Radium Therapy, Technique of Intestinal Surgery, Surgical Pathology, Otorhinolaryngology, Ophthalmology, Pediatrics, Roentgenology, and Pathology. Further details concerning these courses will be announced next autumn.

Edible Gelatine—Edible gelatine is a pure protein readily assimilated. It is not only of distinct value in breaking up excessive casein curds into small particles, but also of potency in infantilism, infantile diarrhea and gastric hemorrhage, as well as stubborn intestinal infections. The action of edible gelatine as a protective colloid is also interesting because of the small amount required to produce results. The percentage of gelatine used in the infant food, as indicated by the various authorities, would average one-half of 1 per cent or even less.

California in Bad Company — The annual state board number of the Journal of the American Medical Association contains much important data. Editorially, the Journal says:

> "Special attention is called to Table J, which shows the classification of the medical colleges from which the physicians graduated who were licensed in each state during the last six years. In each of eight states, over 100 Class C graduates were licensed; the largest number, 324, in California, followed by 199 in Massachusetts; 171 in Connecticut; 162 in Illinois; 160 in Arkansas; 150 in Colorado; 125 in Texas, and 118 in Missouri."

It will take a lot of expensive advertising to overcome such a handicap.

Martha Berry started her school for the neglected children of the Georgia mountains in a wrecked log cabin, with two scared children. Lillian Wald began her Henry Street Settlement in a tiny flat in the tenement-house district, scrubbing the floors and tending the sick with her own hands. Dr. Grenfell went to the suffering people in Labrador without money or influence—just his wonderful ministering hands and an idea. They commenced.

"Good-will is developed by service, but the knowledge of good service must be continually advertised and the memory of service must be regularly stimulated,' says the "house organ" of the American Laundry Co.

CORRESPONDENCE

San Francisco, May 22, 1924.

Editor California and Western Medicine:

Will you please publish the following communication?

To the Medical Profession of California:

Newspaper publicity of some actions on Industrial Accident matters, at the recent convention of the California Medical Association, make necessary an explanation to the medical profession.

Some newspapers reported that certain actions of the Industrial Accident Section, and the House of Delegates, were acts hostile to the state administration and to the Industrial Accident Commission.

The acts and purposes of the acts were in no way hostile. The State Medical Association must depend for success in ridding the profession of the abuse which now exists, in large measure upon the co-operation of the Industrial Accident Commission. It will have co-operation if misguided antagonism does not make co-operation impossible.

The minutes of the sessions of the House of Delegates show that authority has been given the Council to provide panels of physicians to do industrial accident work. This was the result of co-operation and agreement between the Industrial Accident Section of the San Francisco County Medical Society, the San Francisco County Medical Society, the Alameda County Medical Society, and the Industrial Accident Section of the Los Angeles County Medical Association.

These organizations have also provided the council with material for guidance in formulating standards and rules of conduct for industrial accident practice.

Every action was designed to correct abuses within and without the medical profession.

MORTON R. GIBBONS.

Charles E. Stolz, Los Angeles—In reply to a few of your editorials in the May, 1924, issue.

Pay Clinics: The medical profession ought to withdraw their support and turn them over to the chiropractors and osteopaths so that the medical profession would be adequately paid for their services and leave sufficient worldly wealth to their families upon their death. The medical examiner tax of $2 should have been abolished a long time ago; likewise the narcotic tax we are also paying for the enforcement of the law and enabling a bunch of friends and relatives to get nice fat jobs at our expense.
