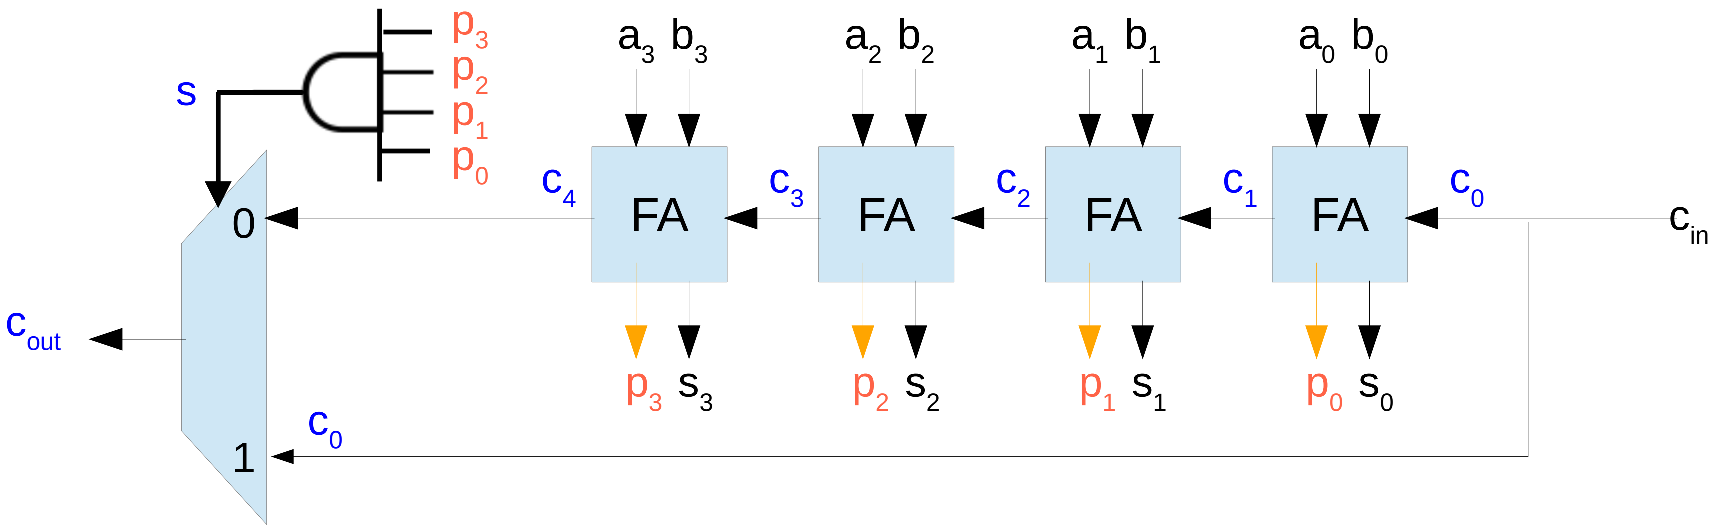
Carry Skip Adder



The n-bit Carry Skip Adder consists of

a n-bit **carry-ripple-chain**,
a n-input **AND-gate** and
one **multiplexer**.

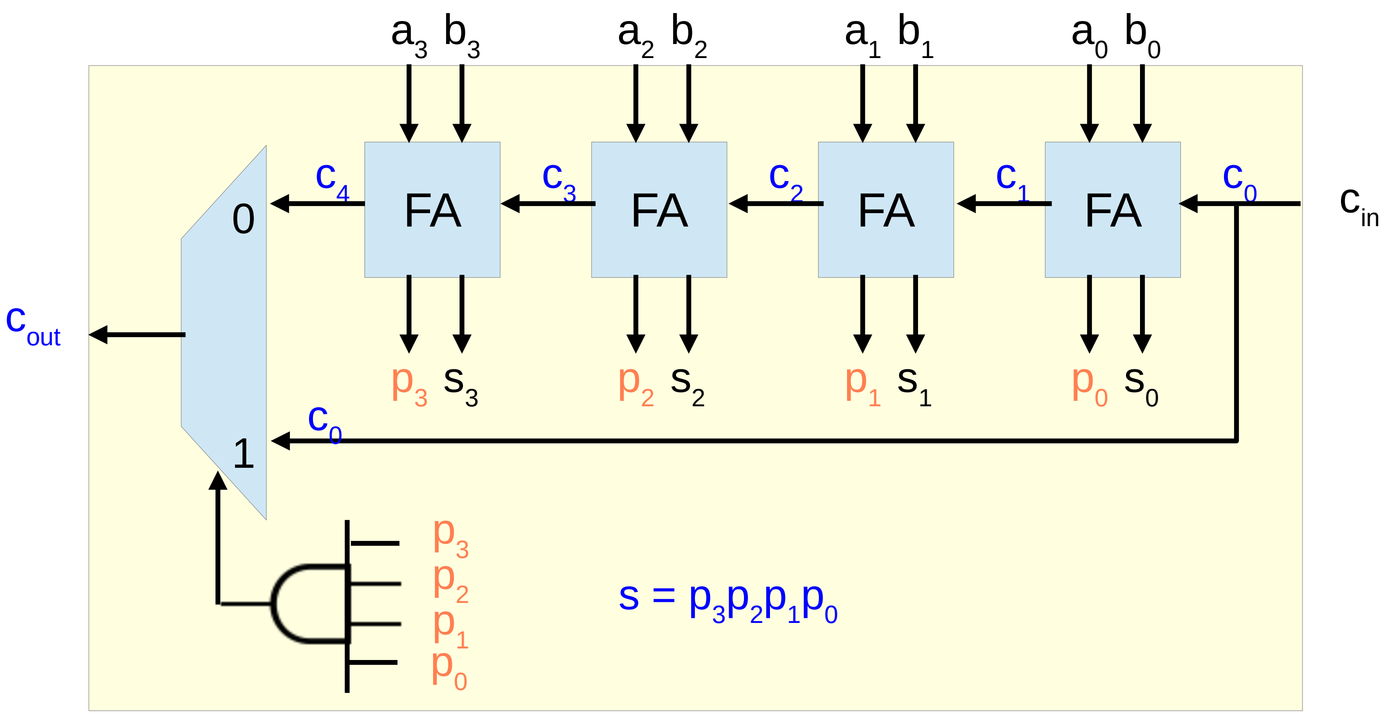
a multiplexer switches
either the last carry-bit c_n or the carry-in c_0
to the carry-out signal c_{out}

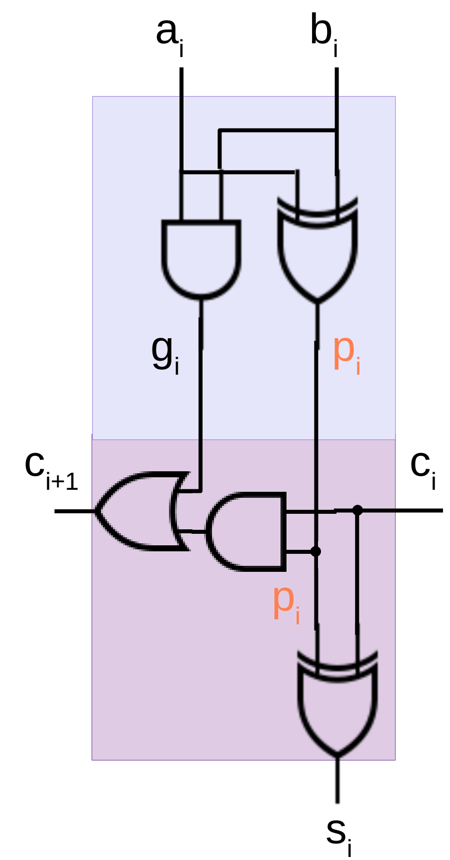
$s = p_3 \wedge p_2 \wedge p_1 \wedge p_0 = p_{[3:0]}$

when $s = 1$, $c_{out} \leftarrow c_0$
otherwise, internally generated carries
can be propagated to $c_{out} \leftarrow c_4$

https://en.wikipedia.org/wiki/Carry-skip_adder

Carry Skip Adder





https://en.wikipedia.org/wiki/Carry-skip_adder

Carry Skip Adder

The critical path of a Carry Skip Adder begins at the first full adder, passes through all adders and ends at the sum bit s_{n-1}

Since a single *n-bit* Carry Skip Adder has no real speed benefit compared to a *n-bit* Ripple Carry Adder

$$T_{CSA}(n) = T_{RCA}(n)$$

Carry Skip Adders are chained to reduce the overall critical path, (Block Carry Skip Adders)

The skip logic consists of a m-input AND gate and one MUX

$$T_{SK} = T_{AND}(m) + T_{MUX}$$

https://en.wikipedia.org/wiki/Carry-skip_adder

Carry Skip Adder

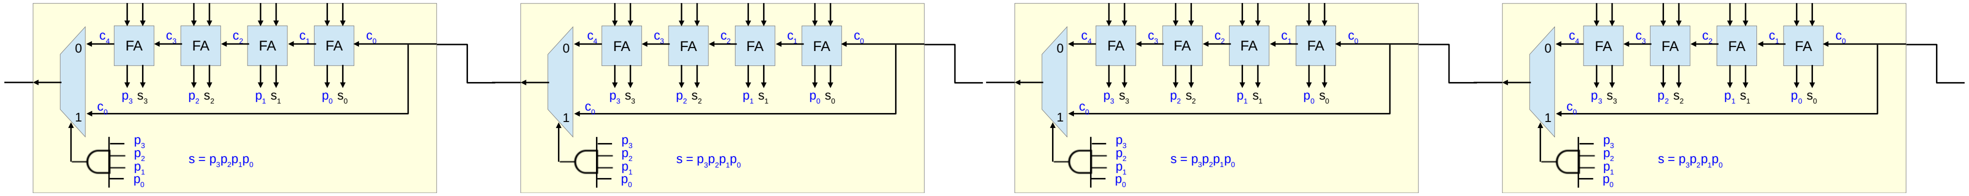
As the propagate signals
are computed <u>in parallel</u> and
are early available,

the critical path for the skip logic in a Carry Skip Adder
consists of the delay imposed by the multiplexer (conditional skip)

$$T_{CSK} = T_{MUX} = 2D$$

https://en.wikipedia.org/wiki/Carry-skip_adder

Carry Skip Adder



Www.cs.tufts.edu

https://en.wikipedia.org/wiki/Carry-skip_adder

Carry Skip Adder

Fixed size block carry skip adders split the n bits of the input bits
Into blocks of m bits each, resulting in k = n / m blocks.

The critical path consists of the ripple path and the skip element of the first block,
The skip apths that are enclosed between the first and the last block,
And finally the ripple path of the last block

$T_{FCSA}(n) = T_{CRA[0:cout]}(m) + T_{CSK} + (k-2)T_{CSK} + T_{CRA}(m)$
$= 3D + m\ 2D + (k-1)2D + (m+2)2D = (2m+k)2D + 5d$

The optimal block size for a given adder width n is derived by equating to 0

$dT_{FCSA}(n) / dm = 0$

$2D(2-n(1/m^2)) = 0$

$M1,2 = +\text{-}sqrt(n/2)$ $\quad$ $m = sqrt(m/2)$

https://en.wikipedia.org/wiki/Carry-skip_adder

Carry Skip Adder

Block carry skip adders are composed of a number of carry skip adders

There are two types of block carry skip adders

The two operands A = (a_{n-1}, a_{n-2}, … a_1, a_0) and B = (b_{n-1}, b_{n-2}, … b_1, b_0)
Are split in k blocks of (m_k, m_{k-1}, … m_2, m_1) bits

Why are block carry skip adders used
Should the block size be constant or variable?
Fixed block width vs. variable block width

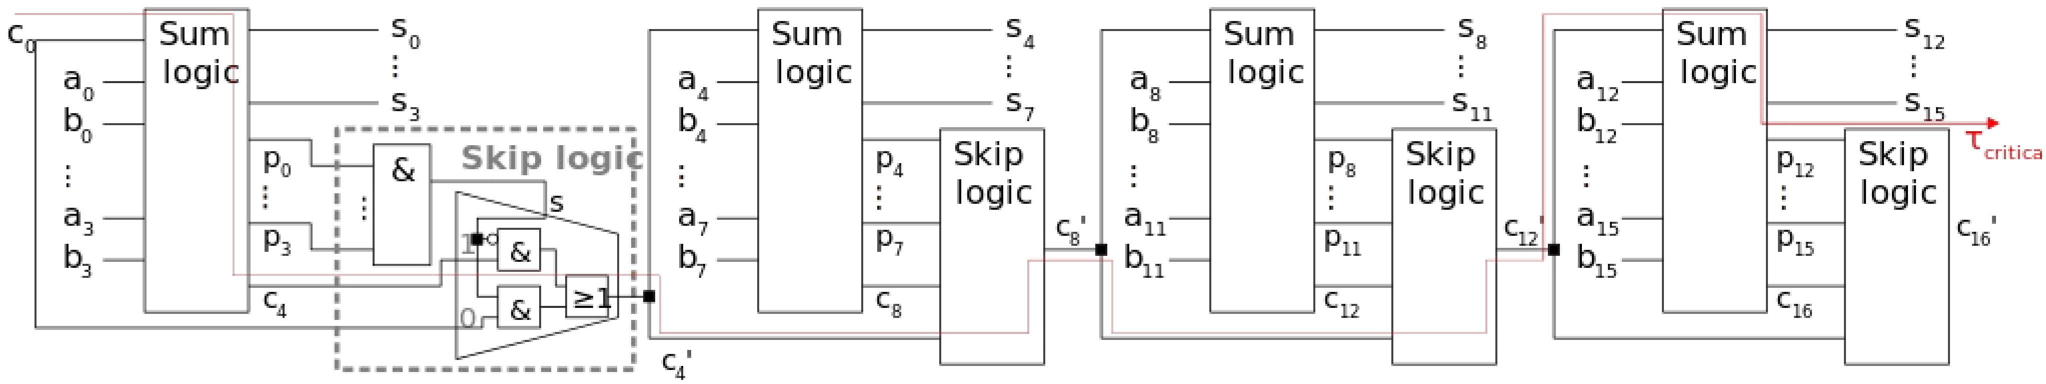
Block Carry Skip Adder



https://en.wikipedia.org/wiki/Carry-skip_adder

Carry Skip Adder

Since the Cin-to-Cout represents the longest path
in the ripple-carry-adder, an obvious attempt is
to accelerate carry propagation through the adder.

This is accomplished by using Carry-Propagate
p_i signals within a group of bits.

If all the p_i signals within the group are $p_i = 1$,
the condition exist for the carry to bypass the entire group:

$$P = p_i \bullet p_{i+1} \bullet p_{i+2} \bullet \ldots\ldots \bullet p_{i+k-1}$$

Www.cs.tufts.edu/103/notes/Lecture14(Adders-2).pdf

Carry Skip Adder

The Carry Skip Adder (CSKA) divides the words
to be added into groups of equal size of **k-bits**.

The basic structure of an **N-bit Carry Skip Adder**

Within the group, carry propagates in a ripple-carry fashion.

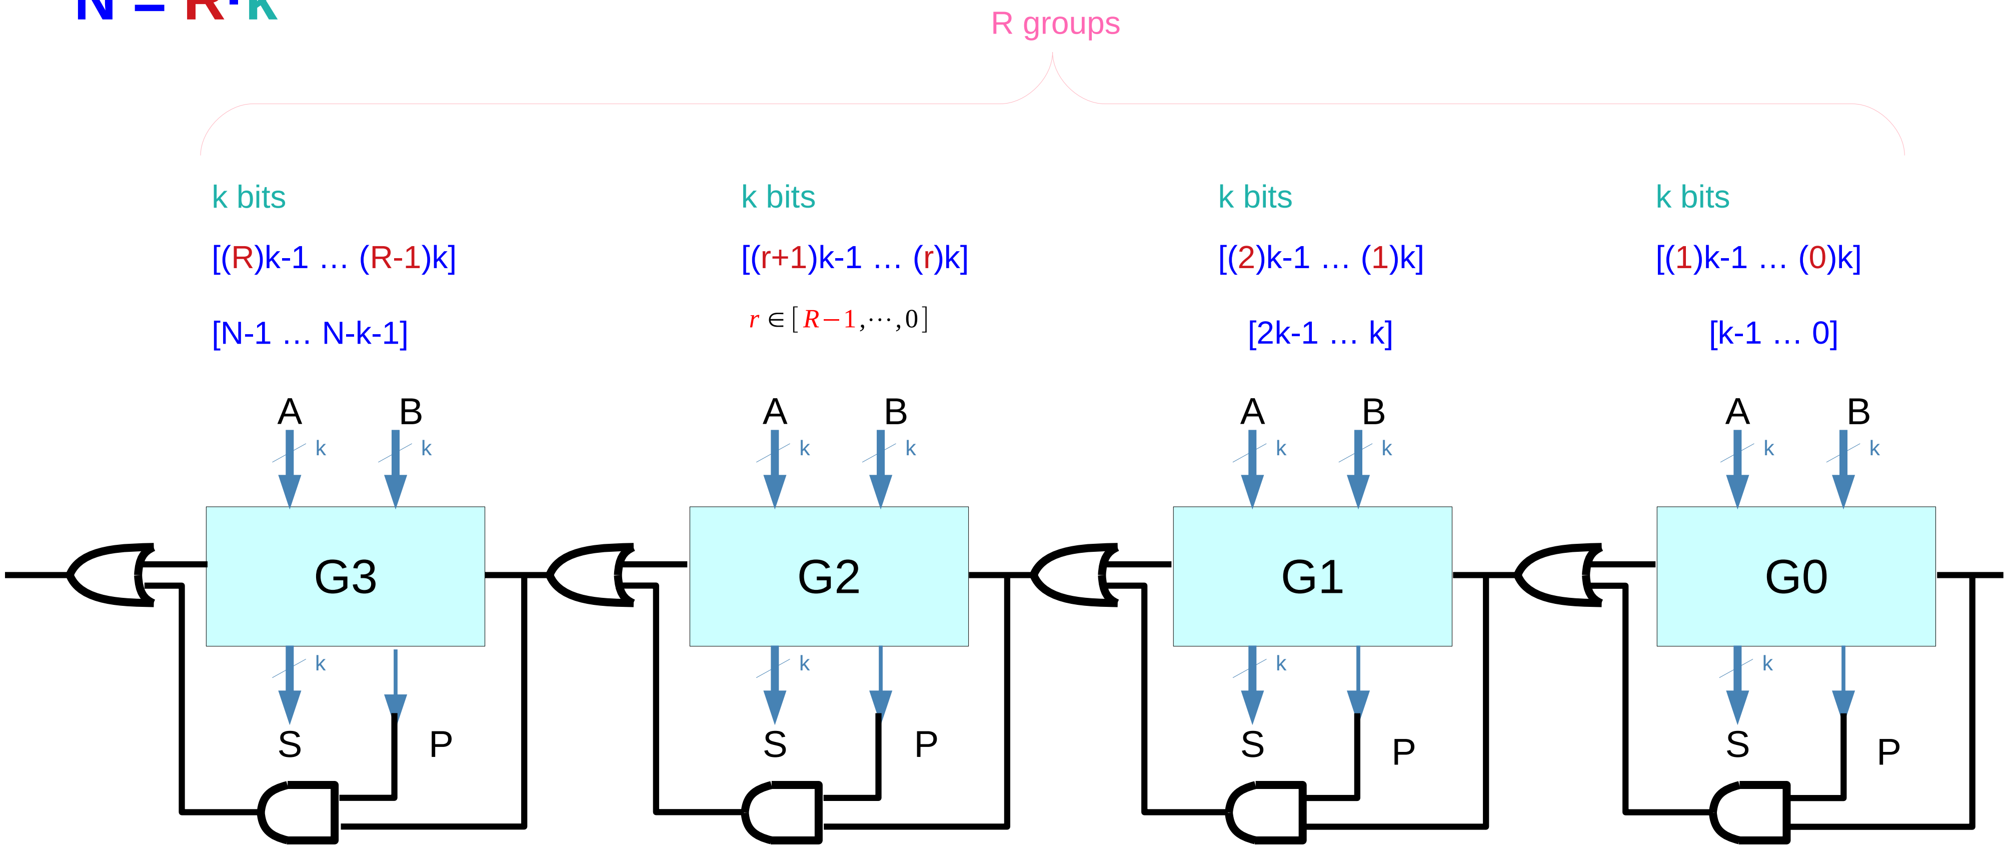
In addition, an AND gate is used
to form the group propagate signal P.

$P = p_i \bullet p_{i+1} \bullet p_{i+2} \bullet \ldots\ldots \bullet p_{i+k-1}$

If P = 1 the condition exists for carry to bypass (skip) over the group

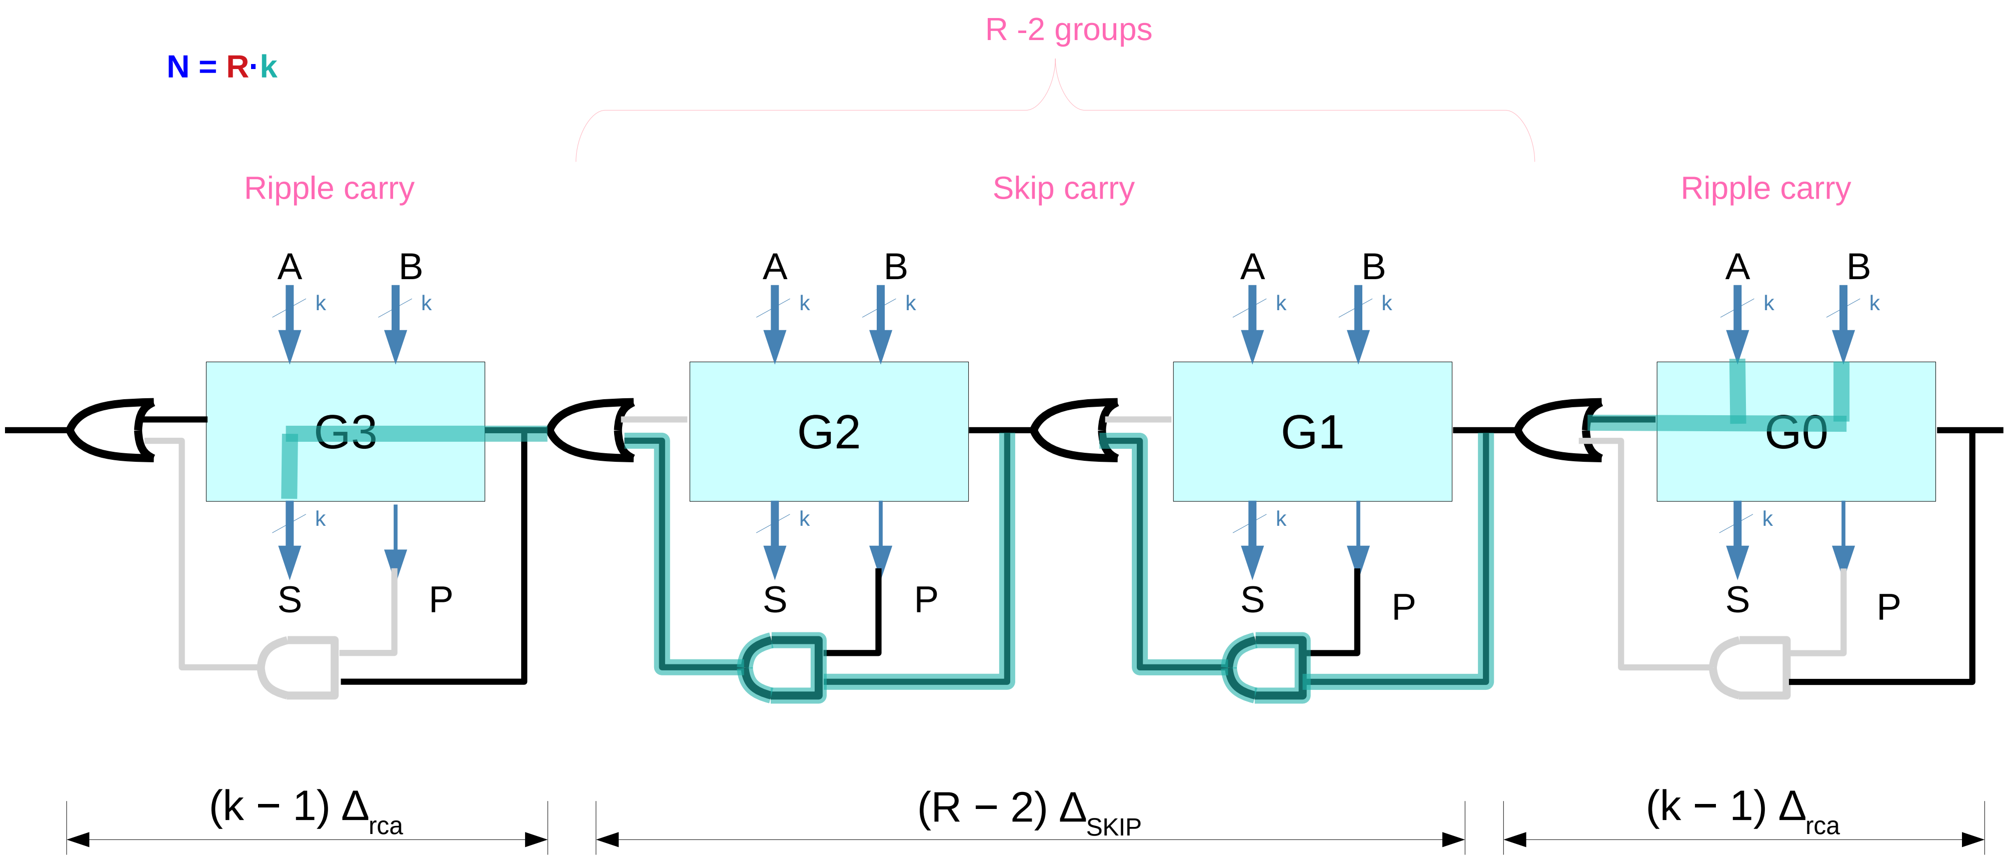
Oklobdzija: High-Speed VLSI arithmetic units : adders and multipliers

N = R·k



Oklobdzija: High Speed VLSI arithmetic units : adders and multipliers

Carry Skip Adder



Any kill or generate condition results in divided (broken) critical paths

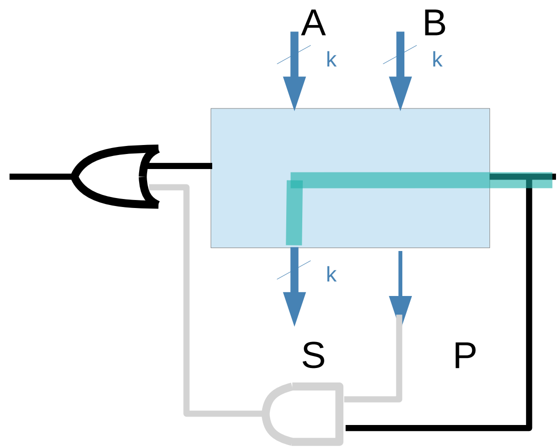
All FA's in R-2 groups must have the propagate condition

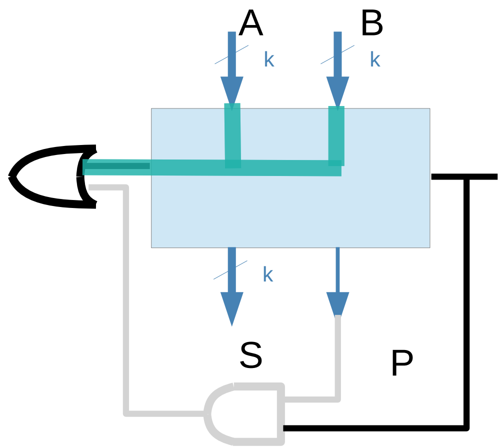
Oklobdzija: High-Speed VLSI arithmetic units : adders and multipliers

Carry Skip Adder

Ripple through k-1 bits

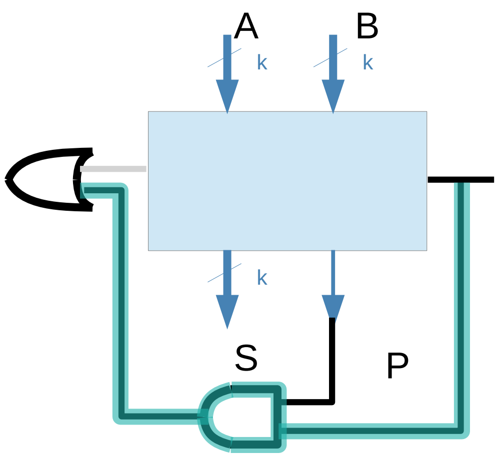
$(k-1)\,\Delta_{rca}$





Skip carry

Δ_{SKIP}



Oklobdzija: High-Speed VLSI arithmetic units : adders and multipliers

Carry Skip Adder

The maximal delay Δ of a Carry Skip Adder is encountered when carry is generated in the least-significant bit position,

- rippling through *k-1* bit positions,
- skipping over *R-2 = N/k-2* groups in the middle,
- rippling to the *k-1* bits of most significant group and
- being assimilated in the *N-th* bit position to produce the sum S_N :

$$\Delta_{CSA} = (k - 1)\,\Delta_{rca} + (R - 2)\,\Delta_{SKIP} + (k - 1)\,\Delta_{rca}$$
$$= 2\,(k - 1)\,\Delta_{rca} + (R - 2)\,\Delta_{SKIP}$$
$$= 2\,(k - 1)\,\Delta_{rca} + (N/k - 2)\,\Delta_{SKIP}$$

Oklobdzija: High-Speed VLSI arithmetic units : adders and multipliers

Carry Skip Adder

$$\Delta_{CSA} = (k-1)\,\Delta_{rca} + (R-2)\,\Delta_{SKIP} + (k-1)\,\Delta_{rca}$$
$$= 2\,(k-1)\,\Delta_{rca} + (R-2)\,\Delta_{SKIP}$$
$$= 2\,(k-1)\,\Delta_{rca} + (N/k-2)\,\Delta_{SKIP}$$

Carry Skip Adder is faster than RCA at the expense of a few relatively simple modifications.

$N = R \cdot k$

The delay is still linearly dependent on the size of the adder N, however this linear dependence is reduced by a factor of *1/k*

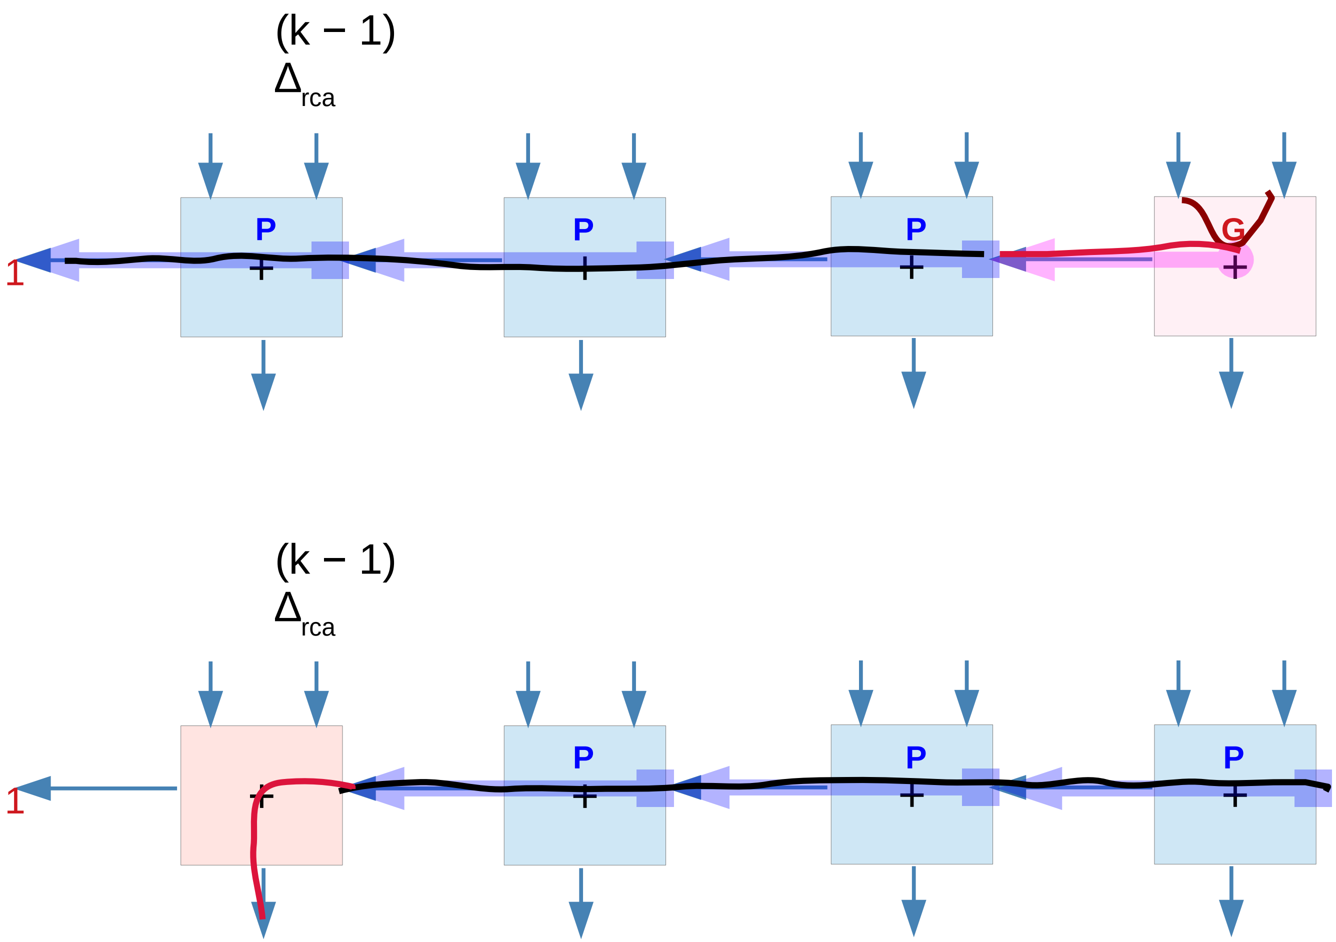
Design C (9) – When Cout1 = 1



High Performance Carry Chains for FPGAs, S. Hauck, M. M. Hosler, T. W. Fry

Carry Skip Adder

If an arbitrary block generated a carry by itself,
The carry will always propagate to the next block
However, if the second block generates a carry itself,
Or kill the carry, then that is the end of the critical path

If the second block propagates the carry, then we see
The advantage of the CSA architecture
