## Overview

- 1 Correlation (Review)
- 2 Simple linear regression
- 3 Multiple linear regression

3

---

---

---

---

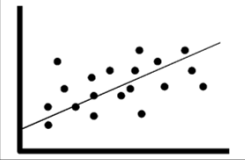

---

---

---

---

**Correlation (Review)** 

*Linear relation between two variables*

---

---

---

---

---

---

---

---

**Purposes of correlational statistics**

Purpose	Correlation	Factor analysis	Regression
Exploratory	✓	✓	
Descriptive	✓	✓	
Explanatory	✓		✓
Predictive			✓

Explanatory - Regression   Predictive - Regression  
 e.g., cross-sectional study   e.g., longitudinal study  
 (all data collected at same time)   (predictors collected prior to outcome measures)

---

---

---

---

---

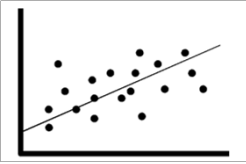

---

---

---

**Linear correlation**

- Linear relations between interval or ratio variables
- Best fitting straight-line on a scatterplot

---

---

---

---

---

---

---

---

### Correlation - Key points

- Covariance = sum of cross-products (unstandardised)
- Correlation = sum of cross-products (standardised), ranging from -1 to 1 (sign indicates direction, value indicates size)
- Coefficient of determination ( $r^2$ ) indicates % of shared variance
- Correlation does not necessarily equal causality

7

---

---

---

---

---

---

---

---

### Correlation is shared variance

Venn diagrams are helpful for depicting relations between variables.

---

---

---

---

---

---

---

---

### Simple linear regression

*Explains and predicts a Dependent Variable (DV) based on a linear relation with an Independent Variable (IV)*

---

---

---

---

---

---

---

---

### Linear regression

- Extension of correlation
- Best-fitting straight line for a scatterplot between two variables:
  - **predictor (X)** – or independent variable (IV)
  - **outcome (Y)** - or dependent variable (DV) or criterion variable
- IV is used to explain a DV
- Helps to understand relationships and possible causal effects of one variable on another.

10

---

---

---

---

---

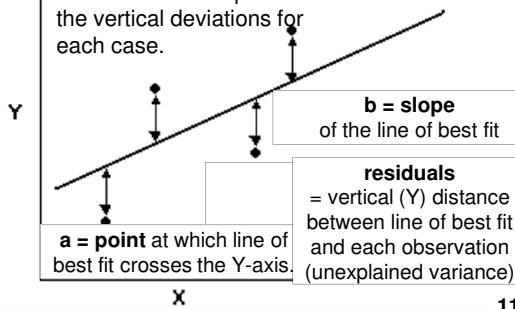

---

---

---

### Least squares criterion

The line of best fit minimises the total sum of squares of the vertical deviations for each case.

11

---

---

---

---

---

---

---

---

### Linear regression - Example: Cigarettes & coronary heart disease

Landwehr & Watkins (1987, cited in Howell, 2004, pp. 216-218)

IV = Cigarette consumption

DV = Coronary Heart Disease

12

---

---

---

---

---

---

---

---

**Linear regression - Example:  
Cigarettes & coronary heart disease  
(Howell, 2004)**

**Research question:**

How fast does CHD mortality rise with a one unit increase in smoking?

- **IV** = Av. # of cigs per adult per day
- **DV** = CHD mortality rate (deaths per 10,000 per year due to CHD)
- **Unit of analysis** = Country

13

---

---

---

---

---

---

---

---

**Linear regression - Example:  
Cigarettes & coronary heart disease  
(Howell, 2004)**

Cigarette Consumption and Coronary Heart Disease Mortality for 21 Countries

Cig. 11 9 9 9 8 8 8 6 6 5 5  
CHD 26 21 24 21 19 13 19 11 23 15 13

Cig. 5 5 5 5 4 4 4 3 3 3  
CHD 4 18 12 3 11 15 6 13 4 14

Cig. = Cigarettes per adult per day  
CHD = Coronary Heart Disease Mortality per 10,000 population

---

---

---

---

---

---

---

---

**Linear regression - Example:  
Scatterplot with Line of Best Fit**

---

---

---

---

---

---

---

---

**Linear regression - Equation**

(without error)

$$\hat{Y} = bX + a$$

predicted values of Y

b = slope = rate of predicted ↑/↓ for Y scores for each unit increase in X

Y-intercept = level of Y when X is 0

---

---

---

---

---

---

---

---

**Linear regression equation (with error)**

$$Y = bX + a + e$$

X = IV values

Y = DV values

a = Y-axis intercept

b = slope of line of best fit (regression coefficient)

e = error

17

---

---

---

---

---

---

---

---

**Linear regression - Example Equation**

Variables:

$$\hat{Y} = bX + a$$

- (DV) = predicted rate of CHD mortality
- X (IV) = mean # of cigarettes per adult per day per country

Regression co-efficients:

- b = rate of ↑/↓ of CHD mortality for each extra cigarette smoked per day
- a = baseline level of CHD (i.e., CHD when no cigarettes are smoked)

18

---

---

---

---

---

---

---

---

**Linear regression - Example  
Explained variance**

- $r = .71$
- $r^2 = .71^2 = .51$
- $p < .05$
- Approximately 50% in variability of incidence of CHD mortality is associated with variability in countries' smoking rates.

19

---

---

---

---

---

---

---

---

**Linear regression - Example:  
Test for overall significance**

$r = .71, r^2 = .51, p < .05$

ANOVA<sup>b</sup>

	Sum of Squares	df	Mean Square	F	Sig.
Regression	454.482	1	454.48	19.59	.00 <sup>a</sup>
Residual	440.757	19	23.198		
Total	895.238	20			

a. Predictors: (Constant), Cigarette Consumption per Adult per Day

b. Dependent Variable: CHD Mortality per 10,000

---

---

---

---

---

---

---

---

**Linear regression - Example:  
Regression coefficients - SPSS**

Coefficients<sup>a</sup>

	Unstandardized Coefficients	Std. Error	Standardized Coefficients	t	Sig.
(Constant) <i>a</i>	2.37	2.941		.80	.43
Cigarette Consumption per Adult per Day <i>b</i>	2.04	.461	.713	4.4	.00

a. Dependent Variable: CHD Mortality per 10,000

---

---

---

---

---

---

---

---

**Linear regression - Example:**  
**Making a prediction**

- What if we want to predict CHD mortality when cigarette consumption is 6?

$$\hat{Y} = bX + a = 2.04X + 2.37$$

$$\hat{Y} = 2.04 * 6 + 2.37 = 14.61$$

- We predict that 14.61 / 10,000 people in a country with an average cigarette consumption of 6 per person will die of CHD per annum.

---

---

---

---

---

---

---

---

**Linear regression - Example**  
**Accuracy of prediction - Residual**

- Finnish smokers smoke 6 cigarettes per adult per day
- We predict 14.61 deaths / 10,000
- But Finland actually has 23 deaths / 10,000
- Therefore, the error ("residual") for this case is  $23 - 14.61 = 8.39$

23

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

### Hypothesis testing

Null hypotheses ( $H_0$ ):

- $a$  (Y-intercept) = 0  
Unless the DV is ratio (meaningful 0), we are not usually very interested in the  $a$  value (starting value of Y when X is 0).
- $b$  (slope of line of best fit) = 0

25

---

---

---

---

---

---

---

---

### Linear regression - Example: Testing slope and intercept

		Coefficients <sup>a</sup>				
		Unstandardized		Standardized		
		Coefficients		Coefficients		
		B	Std. Error	Beta	t	Sig.
<i>a</i>	(Constant)	2.37	2.941		.80	.43
<i>b</i>	Cigarette Consumption per Adult per Day	2.04	.461	.713	4.4	.00

a. Dependent Variable: CHD Mortality per 10,000

---

---

---

---

---

---

---

---

### Linear regression - Example

Does a tendency to “ignore problems” (IV) predict “psychological distress” (DV)?

27

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

### Linear regression - Example: Model summary

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.325 <sup>a</sup>	.106	.102	19.4851

a. Predictors: (Constant), IGNO2 ACS Time 2 - 11. Ignore

$R = .32$ ,  $R^2 = .11$ , Adjusted  $R^2 = .10$

The predictor (Ignore the Problem) explains approximately 10% of the variance in the dependent variable (Psychological Distress).

---

---

---

---

---

---

---

---

### Linear regression - Example: Overall significance

ANOVA<sup>a</sup>

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	9789.888	1	9789.888	25.785	.000 <sup>b</sup>
	Residual	82767.884	218	379.669		
	Total	92557.772	219			

a. Predictors: (Constant), IGNO2 ACS Time 2 - 11. Ignore

b. Dependent Variable: GWB2NEG

The population relationship between Ignoring Problems and Psychological Distress is unlikely to be 0% because  $p = .000$  (i.e., reject the null hypothesis that there is no relationship)

---

---

---

---

---

---

---

---

### Linear regression - Example: Coefficients

Model	Unstandardized Coefficients		Standardized Coefficients		Sig.
	B	Std. Error	Beta	t	
1 (Constant)	118.897	4.351		27.327	.000
IGNO2 ACS Time 2 - 11 Ignore	-9.505	1.872	-.325	-5.078	.000

<sup>a</sup>. Dependent Variable: GWB2NEG

There is a sig. *a* or constant (Y-intercept) - this is the baseline level of Psychological Distress. In addition, Ignore Problems (IP) is a significant predictor of Psychological Distress (PD).

$$PD = 119 - 9.5 * IP$$

---

---

---

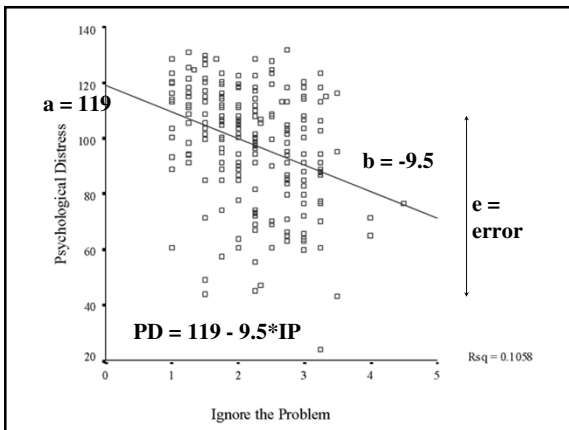

---

---

---

---

---

---

---

---

---

---

---

---

---

### Linear regression - Summary

- Linear regression is for *explaining or predicting* the linear relationship between two variables
- $Y = bx + a + e$
- $= bx + a$   
(*b* is the slope; *a* is the Y-intercept)

---

---

---

---

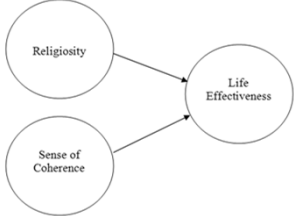

---

---

---

---

**Multiple linear regression** 

*Linear relations between two or more IVs and a single DV*

---

---

---

---

---

---

---

---

**Multiple linear regression**  
**Visual model**

Linear Regression

Single predictor X → Y

Multiple Linear Regression

Multiple predictors  $X_1, X_2, X_3, X_4, X_5$  → Y

35

---

---

---

---

---

---

---

---

**What is MLR?**

- Use of several IVs to predict a DV
- Weights each predictor (IV) according to the strength of its linear relationship with the DV
- Makes adjustments for inter-relationships among predictors
- Provides a measure of overall fit ( $R$ )

36

---

---

---

---

---

---

---

---

### What is MLR?

Correlation  
Regression

Correlation  
Partial correlation  
Multiple linear regression

---

---

---

---

---

---

---

---

### Multiple linear regression

A 3-way scatterplot can depict the correlational relationship between 3 variables.

However, it is difficult to graph/visualise 4+-way relationships via scatterplot.

---

---

---

---

---

---

---

---

### MLR - General steps

- 1 Develop a visual model (path or Venn diagram) and state a research question and/or hypotheses
- 2 Check assumptions
- 3 Choose type of MLR
- 4 Interpret output
- 5 Develop a regression equation (if needed)

39

---

---

---

---

---

---

---

---

**LR → MLR example:  
Cigarettes & coronary heart disease**

- Using linear regression, ~50% of the variance in CHD mortality could be explained by cigarette smoking
- Strong effect - but what about the other 50% (unexplained variance)?
- What about other predictors?  
–e.g., exercise and cholesterol?

40

---

---

---

---

---

---

---

---

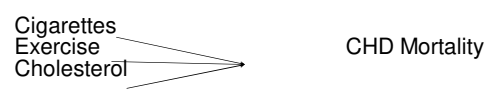

**MLR example:  
Research question 1**

How well do these three IVs:

- # of cigarettes / day ( $IV_1$ )
- exercise ( $IV_2$ ) and
- cholesterol ( $IV_3$ )

predict

- CHD mortality (DV)?

41

---

---

---

---

---

---

---

---

**MLR example:  
Research question 2**

To what extent do personality factors (IVs) predict annual income (DV)?

42

---

---

---

---

---

---

---

---

**MLR example:  
Research question 3**

Does the # of years of formal study of psychology (IV1) and the no. of years of experience as a psychologist (IV2) predict clinical psychologists' effectiveness in treating mental illness (DV)?

43

---

---

---

---

---

---

---

---

**MLR example:**

**Choose your own research question**

Generate your own MLR research question

(e.g., based on some of the following variables):

- Gender & Age
- Enrolment Type
- Hours
- Stress
- Time management
  - Planning
  - Procrastination
  - Effective actions
- Time perspective
  - Past-Negative
  - Past-Positive
  - Present-Hedonistic
  - Present-Fatalistic
  - Future-Positive
  - Future-Negative

44

---

---

---

---

---

---

---

---

**MLR - Assumptions**

- Level of measurement
- Sample size
- Normality (univariate, bivariate, and multivariate)
- Linearity: Linear relations between IVs & DVs
- Homoscedasticity
- Multicollinearity
  - IVs are not overly correlated with one another (e.g., not over .7)
- Residuals are normally distributed

45

---

---

---

---

---

---

---

---

### MLR - Level of measurement

- **DV = Continuous**  
(Interval or Ratio)
- **IV = Continuous or Dichotomous**  
(if neither, may need to recode into a dichotomous variable or create dummy variables)

46

---

---

---

---

---

---

---

---

### Dummy coding

- Dummy coding converts a complex variable into a series of dichotomous variables (i.e., 0 or 1)
- i.e., several dummy variables are created to represent a variable with a higher level of measurement.

47

---

---

---

---

---

---

---

---

### Dummy coding - Example

- Religion  
(1 = Christian; 2 = Muslim; 3 = Atheist)  
in this format, can't be an IV in regression  
(a linear correlation with a categorical variable doesn't make sense)
- However, it can be dummy coded into dichotomous variables:
  - **Christian** (0 = no; 1 = yes)
  - **Muslim** (0 = no; 1 = yes)
  - ~~**Atheist**~~ (0 = no; 1 = yes) (redundant)
- These variables can then be used as IVs.
- More information (Dummy variable (statistics), Wikiversity)

48

---

---

---

---

---

---

---

---

### Sample size - Rule of thumb

- Enough data is needed to provide reliable estimates of the correlations.
- $N \geq 50$  cases +  $N \geq 10$  to 20 cases x no. of IVs, otherwise the estimates of the regression line are probably unstable and are unlikely to replicate if the study is repeated.
- Green (1991) and Tabachnick & Fidell (2013) suggest:
  - $50 + 8(k)$  for testing an overall regression model and
  - $104 + k$  when testing individual predictors (where  $k$  is the number of IVs)
  - Based on detecting a medium effect size ( $\beta \geq .20$ ), with critical  $\alpha \leq .05$ , with power of 80%.

49

---

---

---

---

---

---

---

---

---

---

### Sample size - Rule of thumb

Q: Does a researcher have enough data to conduct an MLR with 4 predictors and 200 cases?

A: Yes; satisfies all rules of thumb:

- $N > 50$  cases +  $4 \times 20 = 130$  cases
- $N > 50 + 8 \times 4 = 82$  cases
- $N > 104 + 4 = 108$  cases

50

---

---

---

---

---

---

---

---

---

---

### Dealing with outliers

Extreme cases should be deleted or modified if they are overly influential.

- Univariate outliers - detect via initial data screening (e.g., min. and max.)
- Bivariate outliers - detect via scatterplots
- Multivariate outliers - unusual combination of predictors – detect via Mahalanobis' distance

51

---

---

---

---

---

---

---

---

---

---

### Multivariate outliers

- A case may be within normal range for each variable individually, but be a multivariate outlier because of an unusual combination of responses which unduly influences multivariate test results.
- e.g., a person who:
  - Is 18 years old
  - Has 3 children
  - Has a post-graduate degree

52

---

---

---

---

---

---

---

---

### Multivariate outliers

- Identify & check for unusual cases using Mahalanobis' distance or Cook's *D*

53

---

---

---

---

---

---

---

---

### Multivariate outliers

- Mahalanobis' distance (MD)
  - Distributed as  $\chi^2$  with *df* equal to the number of predictors (with critical  $\alpha = .001$ )
  - Cases with a MD greater than the critical value could be influential multivariate outliers.
- Cook's *D*
  - Cases with CD values  $> 1$  could be influential multivariate outliers.
- Use either MD or CD
- Examine cases with extreme MD or CD scores - if in doubt, remove & re-run.

54

---

---

---

---

---

---

---

---

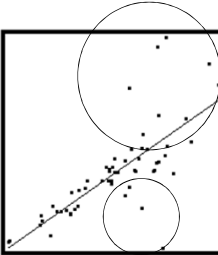

### Homoscedasticity & normality

**Homoscedasticity**

- Variance around the regression line should be the same throughout the distribution
- Even spread in residual plots

**Normality**

- If variables are non-normal, this will create heteroscedasticity

55

---

---

---

---

---

---

---

---

### Multicollinearity

- IVs shouldn't be overly correlated (e.g., over .7) - leads to unstable regression
- If IVs are overly correlated, consider combining them into a single variable or removing one
- Singularity - perfect correlations among IVs
- Leads to unstable regression coefficients

56

---

---

---

---

---

---

---

---

### Multicollinearity

Detect via:

- **Correlation matrix** - are there large correlations among IVs?
- **Tolerance statistics** - if  $< .3$  then exclude that variable.
- **Variance Inflation Factor (VIF)** - if  $> 3$ , then exclude that variable.
- VIF is the reciprocal of Tolerance (so use TOL or VIF - not both)

57

---

---

---

---

---

---

---

---

### Causality

- Like correlation, regression does not tell us about the causal relationship between variables.
- In many analyses, the IVs and DVs could be swapped around – therefore, it is important to:
  - Adopt a theoretical position
  - Acknowledge alternative explanations

58

---

---

---

---

---

---

---

---

### Multiple correlation coefficient

- “Big R” (capitalised)
- Equivalent of  $r$ , but takes into account that there are multiple predictors (IVs)
- Always positive, between 0 and 1
- Interpretation is similar to that for  $r$  (correlation coefficient)

59

---

---

---

---

---

---

---

---

### Coefficient of determination

- “Big R squared”
- Squared multiple correlation coefficient
- Always report  $R^2$
- Indicates the % of variance in DV explained by combined effects of the IVs
- Analogous to  $r^2$

60

---

---

---

---

---

---

---

---

**CoD - Rule of thumb**

0.00 = no linear relationship  
0.10 = small ( $R \sim .3$ )  
0.25 = moderate ( $R \sim .5$ )  
0.50 = strong ( $R \sim .7$ )  
1.00 = perfect linear relationship  
 $R^2 > .30$   
is "good" in social sciences

61

---

---

---

---

---

---

---

---

**Adjusted  $R^2$**

- $R^2$  = explained variance in a sample.
- Adjusted  $R^2$  = explained variance in a population.
- Report both  $R^2$  and adjusted  $R^2$ .
- Take more note of adjusted  $R^2$ , particularly for small  $N$  and where results are to be generalised.

62

---

---

---

---

---

---

---

---

**MLR - Overall significance**

- Tests whether there is a significant linear relationship between the X variables (taken together) and Y
- Indicated by  $F$  and  $p$  in the ANOVA table.
- $p$  is the likelihood that the explained variance in Y could have occurred by chance.

63

---

---

---

---

---

---

---

---

### MLR - Equation

- $Y = b_1x_1 + b_2x_2 + \dots + b_ix_i + a + e$
- $Y$  = observed DV scores
  - $b_i$  = unstandardised regression coefficients (the  $B$ s in SPSS) - slopes
  - $x_1$  to  $x_i$  = IV scores
  - $a$  =  $Y$  axis intercept
  - $e$  = error (residual)

64

---

---

---

---

---

---

---

---

### MLR - Coefficients

- $Y$ -intercept ( $a$ )
- Slopes ( $b$ ):
  - Unstandardised
- Slopes are the weighted loading of each IV on the DV, adjusted for the other IVs in the model.

65

---

---

---

---

---

---

---

---

### Unstandardised regression coefficients

- $B$  = unstandardised regression coefficient
- Used for regression equations
- Used for predicting  $Y$  scores
- But can't be compared with other  $B$ s unless all IVs are measured on the same scale

66

---

---

---

---

---

---

---

---

**Standardised regression coefficients**

- Beta ( $\beta$ ) = standardised regression coefficient
- Useful for comparing the relative strength of predictors
- $\beta = r$  in LR but this is only true in MLR when the IVs are uncorrelated.

67

---

---

---

---

---

---

---

---

**MLR - IV significance**

Indicates the likelihood of a linear relationship between each IV ( $X_i$ ) and  $Y$  occurring by chance.

Hypotheses:

$H_0: \beta_i = 0$  (No linear relationship)

$H_1: \beta_i \neq 0$  (Linear relationship between  $X_i$  and  $Y$ )

68

---

---

---

---

---

---

---

---

**Relative importance of IVs**

- Which IVs are the most important?
- To answer this, compare the standardised regression coefficients ( $\beta$ s)

69

---

---

---

---

---

---

---

---

**Multiple linear regression - Example**

Does 'ignoring problems' (IV<sub>1</sub>) and 'worrying' (IV<sub>2</sub>) predict 'psychological distress' (DV)?

70

---

---

---

---

---

---

---

---

Correlations			
	Psychological Distress	Worry	Ignore the Problem
Psychological Distress	1.000	.521	-.325
Worry	-.521	1.000	.352
Ignore the Problem	-.325	.352	1.000
Psychological Distress	.	.000	.000
Worry	.000	.	.000
Ignore the Problem	.000	.000	.
Psychological Distress	220	220	220
Worry	220	220	220
Ignore the Problem	220	220	220

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

### MLR - Example: Model summary

Model Summary<sup>b</sup>

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.543 <sup>a</sup>	.295	.288	17.34399

a. Predictors: (Constant), Ignore the Problem, Worry

b. Dependent Variable: Psychological Distress

Together, Ignoring Problems and Worrying explain 30% of the variance in Psychological Distress in the Australian adolescent population ( $F^2 = .30$ , Adjusted  $F^2 = .29$ ).

---

---

---

---

---

---

---

---

---

---

### MLR - Example: Overall significance

ANOVA<sup>b</sup>

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	27281.12	2	13640.558	45.345	.000 <sup>a</sup>
	Residual	65276.66	217	300.814		
	Total	92557.77	219			

a. Predictors: (Constant), Ignore the Problem, Worry

b. Dependent Variable: Psychological Distress

The explained variance in the population is unlikely to be 0 ( $p = .00$ ).

---

---

---

---

---

---

---

---

---

---

### MLR - Example: Coefficients

Coefficients<sup>a</sup>

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	138.932	4.680		29.687	.000
	Worry	-11.511	1.510	-.464	-7.625	.000
	Ignore the Problem	-4.735	1.780	-.162	-2.660	.008

a. Dependent Variable: Psychological Distress

Worry predicts about three times more variance in Psychological Distress than Ignoring the Problem, although both are significant, negative predictors of mental health.

---

---

---

---

---

---

---

---

---

---

### MLR example - Equations

#### Linear Regression

$$PD(\hat{)} = 119 - 9.50 * Ignore$$

$$R^2 = .11$$

#### Multiple Linear Regression

$$PD(\hat{)} = 139 - 4.7 * Ignore - 11.5 * Worry$$

$$R^2 = .30$$

	B
(Constant)	138.932
Worry	-11.511
Ignore the Problem	-4.735

---

---

---

---

---

---

---

---

### MLR - Example: Confidence interval for the slope

Coefficients <sup>a</sup>					
Model		Standardized	95% Confidence Interval for B		
		Coefficients	Beta	Lower Bound	Upper Bound
1	(Constant)			129.708	148.156
	Worry	-.464	-14.486	-8.536	
	Ignore the Problem	-.162	-8.242	-1.227	

a. Dependent Variable: Psychological Distress

Mental Health (PD) is reduced by between 8.5 and 14.5 units per increase of Worry units.  
 Mental Health (PD) is reduced by between 1.2 and 8.2 units per increase in Ignore the Problem units.

---

---

---

---

---

---

---

---

### Multiple linear regression - Example

#### Effect of violence, stress, social support on internalising behaviour problems

Kliewer, Lepore, Oskin, & Johnson, (1998)

Image source: <http://cloudking.com/artists/roa-terluuc/family-violence.php>

---

---

---

---

---

---

---

---

**MLR example - Violence study - Design**

- Participants were children:
  - 8 - 12 years
  - Living in high-violence areas, USA
- **Hypotheses:**
  - Stress behaviour → ↑ internalising
  - Violence behaviour → ↑ internalising
  - Social support → ↓ internalising behaviour

79

---

---

---

---

---

---

---

---

**MLR example - Violence study - Variables**

- **Predictors**
  - Witnessing violence
  - Life stress
  - Social support
- **Outcome**
  - Internalising behaviour (e.g., depression, anxiety, withdrawal symptoms) – measured using the Child Behavior Checklist (CBCL)

80

---

---

---

---

---

---

---

---

Correlations

Pearson Correlation

Correlations amongst the IVs	Amount witnessed	Current stress	Social support	Internalizing symptoms on CBCL
Amount witnessed				
Current stress	.050			
Social support	.080	-.080		
Internalizing symptoms on CBCL	.200*	.270*	-.170	

\*. Correlation is significant at the 0.05 level (2-tailed).  
 \*\*. Correlation is significant at the 0.01 level (2-tailed).

---

---

---

---

---

---

---

---

$R^2$

13.5% of the variance in children's internalising symptoms can be explained by the 3 predictors.

**Model Summary**

R	R Square	Adjusted R Square	Std. Error of the Estimate
.37 <sup>a</sup>	.135	.108	2.2198

a. Predictors: (Constant), Social support, Current stress, Amount violence witnessed

---

---

---

---

---

---

---

---

**Coefficients**

	Unstandardized Coefficients	Standardized Coefficients	2 predictors have $p < .05$	
	B	Std. Error	Beta	t
(Constant)	.477	1.289		.37
Amount violence witnessed	.038	.018	.201	2.1
Current stress	.273	.106	.247	2.6
Social support	-.074	.043	-.166	-2

a. Dependent Variable: Internalizing symptoms on CB

---

---

---

---

---

---

---

---

**MLR example - Violence study - Equation**

$$\hat{Y} = b_1X_1 + b_2X_2 + b_3X_3 + b_0$$

$$= 0.038Wit + 0.273Stress - 0.074SocSupp + 0.477$$

- A separate coefficient or slope for each variable
- An intercept (here called  $b_0$ )

84

---

---

---

---

---

---

---

---

**MLR example - Violence study - Equation**

$$\hat{Y} = b_1X_1 + b_2X_2 + b_3X_3 + b_0$$

$$= 0.038Wit + 0.273Stress - 0.074SocSupp + 0.477$$

- Slopes for Witness and Stress are +ve; slope for Social Support is -ve.
- Ignoring Stress and Social Support, a one unit increase in Witness would produce .038 unit increase in Internalising symptoms.

85

---

---

---

---

---

---

---

---

**MLR example - Violence study - Prediction**

Q: If Witness = 20, Stress = 5, and SocSupp = 35, what we would predict internalising symptoms to be?

A: .012

$$\hat{Y} = .038 * Wit + .273 * Stress - .074 * SocSupp + 0.477$$

$$= .038(20) + .273(5) - .074(35) + 0.477$$

$$= .012$$

86

---

---

---

---

---

---

---

---

**MLR - Example:**

The role of human, social, built, and natural capital in explaining life satisfaction at the country level:

Towards a National Well-Being Index (NWI)

Vemuri & Costanza (2006)

---

---

---

---

---

---

---

---

### MLR example - Life satisfaction - Design

- IVs:
  - Human & Built Capital (Human Development Index)
  - Natural Capital (Ecosystem services per km<sup>2</sup>)
  - Social Capital (Press Freedom)
- DV = Life satisfaction
- Units of analysis: Countries (N = 57; mostly developed countries, e.g., in Europe and America)

88

---

---

---

---

---

---

---

---

Table 1  
Bivariate correlations between variables

		Average life satisfaction	HDI	Log ESP/km <sup>2</sup> index
Average life satisfaction	Pearson cor.	1		
	Significance			
HDI	Pearson cor.	.463	1	
	Significance	.000		
Log ESP/km <sup>2</sup> index	Pearson cor.	.358	.071	1
	Significance	.007	.353	
Press freedom	Pearson cor.	-.502	-.502	.295
	Significance	.000	.000	.000

- There are moderately strong positive and statistically significant linear relations between the IVs and the DV
- The IVs have small to moderate positive inter-correlations.

---

---

---

---

---

---

---

---

Table 2  
Basic regression model coefficients for national-level analysis

	Unstandardized coefficients		Standardized coefficients	t-value	Significance
	B	Std. error	Beta		
Constant	1.857	.900		2.063	.044
HDI	3.524	.832	.470	4.234	.000
Log ESP/km <sup>2</sup> Index	3.498	1.021	.380	3.427	.001

Sample size of the regression model was 56.

- $R^2 = .35$
- Two sig. IVs (not Social Capital - dropped)

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

Table 4  
Revised regression model coefficients for national-level analysis

	Unstandardized coefficients		Standardized coefficients	t-value	Significance
	B	Std. error	Beta		
Constant	-2.220	.799		-2.781	.008
HDI	8.875	.884	.777	10.038	.000
Log ESP/km <sup>2</sup> index	2.453	.739	.257	3.319	.002

Sample size of the regression model was 50.  
•  $R^2 = .72$   
(after dropping 6 outliers)

---

---

---

---

---

---

---

---

### Types of MLR

- Standard or direct (simultaneous)
- Hierarchical or sequential
- Stepwise (forward & backward)

Image source: <https://commons.wikimedia.org/wiki/File:Stumble.png>

93

---

---

---

---

---

---

---

---

**Direct (Standard)**

- All predictor variables are entered together, at the same time.
- Assesses relationship between all predictor variables and the outcome (Y) variable simultaneously.
- Manual technique & commonly used.
- If you're not sure what type of MLR to use, start with this approach.

94

---

---

---

---

---

---

---

---

**Hierarchical (Sequential)**

- IVs are entered in blocks or stages.
  - Researcher defines order of entry for the variables, based on theory.
  - e.g., enter “nuisance” variables first to “control” for them, then test “purer” effect of next block of important variables.
- $F^2$  change - change in variance of Y explained at each stage of the regression.
  - F test of  $F^2$  change.

95

---

---

---

---

---

---

---

---

**Hierarchical (Sequential)**

Example: Research question: To what extent does Drug B reduce AIDS symptoms *above and beyond* the effect of Drug A?

- **Drug A** is a cheap, well-proven drug which reduces AIDS symptoms
- **Drug B** is an expensive, experimental drug which could help to cure AIDS
- Hierarchical linear regression:
  - **Step 1: Drug A (IV1)**
  - **Step 2: Drug B (IV2)**
  - DV = AIDS symptoms
  - Examine change in  $F^2$  between Step 1 & Step 2

96

---

---

---

---

---

---

---

---

### Forward selection

- Computer-driven – controversial.
- Starts with 0 predictors, then the strongest predictor is entered into the model, then the next strongest etc. if they reach a criteria (e.g.,  $p < .05$ )

97

---

---

---

---

---

---

---

---

### Backward elimination

- Computer-driven – controversial.
- All predictor variables are entered, then the weakest predictors are removed, one by one, if they meet a criteria (e.g.,  $p > .05$ )

98

---

---

---

---

---

---

---

---

### Stepwise

- Computer-driven – controversial.
- Combines forward & backward.
- At each step, variables may be entered or removed if they meet certain criteria.
- **Useful for developing the best prediction equation** from a large number of variables.
- Redundant predictors are removed.

99

---

---

---

---

---

---

---

---

**Types of MLR - Summary**

- Standard: To assess impact of all IVs simultaneously
- Hierarchical: To test IVs in a specific order (based on hypotheses derived from theory)
- Stepwise: If the goal is accurate statistical prediction from a large # of variables - computer driven

100

---

---

---

---

---

---

---

---

**Summary**

101

---

---

---

---

---

---

---

---

**Summary: General steps**

- 1 Develop model and hypotheses
- 2 Check assumptions
- 3 Choose type
- 4 Interpret output
- 5 Develop a regression equation (if needed)

102

---

---

---

---

---

---

---

---

**Summary: Linear regression**

1 Best-fitting straight line for a scatterplot of two variables

2  $Y = bX + a + e$

1 Predictor (X; IV)

2 Outcome (Y; DV)

3 Least squares criterion

4 Residuals are the vertical distance between actual and predicted values

103

---

---

---

---

---

---

---

---

**Summary: Assumptions**

1. Level of measurement
2. Sample size
3. Normality
4. Linearity
5. Homoscedasticity
6. Collinearity
7. Multivariate outliers
8. Residuals should be normally distributed

104

---

---

---

---

---

---

---

---

**Summary: LoM & dummy coding**

1 Level of measurement

1 DV = Interval or ratio

2 IV = Interval or ratio or dichotomous

2 Dummy coding

1 Convert complex variables into series of dichotomous IVs

105

---

---

---

---

---

---

---

---

**Summary: MLR output**

- 1 Overall fit
  - 1.  $R$ ,  $R^2$ , Adjusted  $R^2$
  - 2.  $F$ ,  $p$
- 2 Coefficients
  - 1. Relation between each IV and the DV, adjusted for the other IVs
  - 2.  $B$ ,  $\beta$ ,  $t$ ,  $p$ , and  $r_p$
- 3 Regression equation (if useful)  
$$Y = b_1x_1 + b_2x_2 + \dots + b_kx_k + a + e$$

106

---

---

---

---

---

---

---

---

**Summary: MLR types**

- 1. Standard
- 2. Hierarchical
- 3. Stepwise / Forward / Backward

107

---

---

---

---

---

---

---

---

**Practice quiz**

108

---

---

---

---

---

---

---

---

**Practice quiz question:  
MLR type of analysis**

Multiple linear regression is a \_\_\_\_\_ type of statistical analysis.

- a) univariate
- b) bivariate
- c) multivariate

109

---

---

---

---

---

---

---

---

**Practice quiz question:  
MLR LoM**

The following types of data can be used in MLR (choose all that apply):

- a) Interval or higher DV
- b) Interval or higher IVs
- c) Dichotomous Ivs
- d) All of the above
- e) None of the above

110

---

---

---

---

---

---

---

---

**Practice quiz question:  
 $R^2$**

In MLR, the square of the multiple correlation coefficient,  $R^2$ , is called the:

- a) Coefficient of determination
- b) Variance
- c) Covariance
- d) Cross-product
- e) Big  $R$

111

---

---

---

---

---

---

---

---

**Practice quiz question:  
MLR equation**

A linear regression analysis produces the equation  $Y = 0.4X + 3$ . This indicates that:

- a) When  $Y = 0.4$ ,  $X = 3$
- b) When  $Y = 0$ ,  $X = 3$
- c) When  $X = 3$ ,  $Y = 0.4$
- d) When  $X = 0$ ,  $Y = 3$
- e) None of the above

112

---

---

---

---

---

---

---

---

**Practice quiz question:  
MLR residuals**

In MLR, a residual is the difference between the predicted  $Y$  and actual  $Y$  values.

- a) True
- b) False

113

---

---

---

---

---

---

---

---
