# Existence of the z-Transform

$$X(z) = \sum_{n=0}^{\infty} x[n]z^{-n} = \sum_{n=0}^{\infty} \frac{x[n]}{z^n}$$

the existence of the z-transform is guaranteed if

$$|X(z)| \leq \sum_{n=0}^{\infty} \frac{|x[n]|}{|z|^n} < \infty \quad \text{for some } |z|$$

any signal  $x[n]$  that grows no faster than an exponential signal  $r_0^n$ , for some  $r_0$  satisfies the above condition

if  $|x[n]| \leq r_0^n$  for some  $r_0$

$$\text{then } |X(z)| \leq \sum_{n=0}^{\infty} \left(\frac{r_0}{|z|}\right)^n = \frac{1}{1 - \frac{r_0}{|z|}} \quad |z| > r_0$$

therefore  $X(z)$  exists for  $|z| > r_0$

Almost all practical signals satisfy this condition

$$|x[n]| \leq r_0^n \quad \text{for some } r_0$$

and z-transformable

Some signal models (e.g.  $r^{n^2}$ ) grows faster than

the exponential signal  $r_0^n$  (for any  $r_0$ )

and do not satisfy this condition

and are not z-transformable

Such signals are of little practical or theoretical interest

Even such signals over a finite interval are z-transformable

But even though the DTFT does not exist, the  $z$ -transform does exist.
