## Outline

#### Pardoxes and Haskell type system

- Using STAL.hs
- Paradox
- Types and Type Classes

#### 3 Lists

- Lists
- Database Applications

### Sets

- Sets
- Sets using Lists
- Show class methods
- Data Types for Sets

#### "The Haskell Road to Logic, Maths, and Programming", K. Doets and J. V. Eijck

```

- no general test for checking whether a given procedure terminates for a particular input
- the halting problem is undecidable
- the existence of an algorithm for the halting problem would lead to a paradox like the Russell paradox

# Halting problem Examples (1)

• an example for which no proof of termination exists

#### run 5

run 5 | odd 5 = 5 : run (3\*5+1) run 16 | even 16 = 16 : run (div 16 2) run 8 | even 8 = 8 : run (div 8 2) run 4 | even 4 = 4 : run (div 4 2) run 2 | even 2 = 2 : run (div 2 2) run 1 | n == 1 = [1] [5, 16, 8, 4, 2, 1]

A⊒ ▶ < ∃

## Halting problem Examples (2)

an example for which no proof of termination exists

run 6

```
run 6 | even 6 = 6 : run (div 6 2)
run 3 | odd 3 = 3 : run (3*3+1)
run 10 | even 10 = 9 : run (div 10 2)
run 5 | odd 5 = 5 : run (3*5+1)
run 16 | even 16 = 16 : run (div 16 2)
run 8 | even 8 = 8 : run (div 8 2)
run 4 | even 4 = 4 : run (div 4 2)
run 2 | even 2 = 2 : run (div 2 2)
run 1 | n == 1 = [1]
[5, 3, 10, 5, 16, 8, 4, 2, 1]
```

< A > < > > <

### Halting problem Examples (3)

#### • an example for which no proof of termination exists

run 7

run 7 | odd 7 = 7 : run (3\*7+1)
run 22 | even 22 = 22 : run (div 22 2)
run 11 | odd 11 = 11 : run (3\*11+1)
run 34 | even 34 = 34 : run (div 34 2)

run 13 | odd 13 = 13 : run (3\*13+1)
run 40 | even 40 = 40 : run (div 40 2)
run 20 | even 20 = 20 : run (div 20 2)
run 10 | even 10 = 10 : run (div 10 2)
...
[7, 22, 11, 34, 17, 52, 26, 13, 40, 20, 10, 5, 16, 8, 4, 2, 1]

3

< □ > < 冊 > < Ξ > <

- it is <u>not true</u> that to every property E there corresponds a <u>set</u> {x|E(x)} of all objects that have E
- consider the property of not having yourself as a member
- most sets are likely to have this property
  - the set of all even numbers is itself not an even natural number
  - the set of all integers is itself not an integer
- call such sets ordinary
  - corresponding abstraction  $R = \{x | E(x)\}$

## The Russel Paradox (2)

- $R = \{x | E(x)\}$
- impossible to answer the question whether the set R itself is ordinary or not
- suppose  $R \in R$ , ie., R is an ordinary set
  - an ordinary set does not have itself as a member R does <u>not</u> have itself as a member  $R \notin R$
- suppose  $R \notin R$ , ie., R is an extraordinary set
  - an extraordinary set has itself as a member R has itself as a member, i.e.,  $R \in R$
- if R were a legitimate set, this would unavoidably lead us to a contradiction  $R \in R \iff R \notin R$

11/103

- only properties that are unlikely considered give rise to problems
- a restriction can be applied to the forming set on the basis of a previously given set A {x ∈ A|E(x)} instead of {x|E(x)}

# Non-halting problems

- suppose halt can be defined
- suppose also the procedure funny is defined in terms of halts

- suppose funny does not halt the first case, when x is applied to x, halts halts funny is bound to x, then funny funny does not halt contradiciton
- suppose funny funny does halt the second case, funny x = True halt funny funny binds x to funny this becomes the first case, it does not halt contradiction

- paradoxical definitions are avoided in functional programming by keeping track of the types of all objects and operations
- derived types : new types can be constructed from old pairs of integers, lists of characters, lists of reals, etc.
- type discipline avoids the halting paradoxes

## Haskell type discipline for funny

- the definition of funny calls halts
- the type of halts the 1st argument : a procedure proc the 2nd argument : the argument of that procedure arg
- the types of 2 arguments : a -> b and a the type of the result of application of (proc arg) : b
- therefore the application halts x x is mal-formed the types of 2 arguments must be different thus the arguments must themselves must be different

```
• elem:: a -> [a] -> Bool
  checks whether an object is element of a list

    the 1st argument : a certain type a

     • the 2nd argument : a list over a
     • in Haskell, R \in R does not make sense
elem 'R' "Russsel" ..... ['R', 'u', 's', 's', 'e', 'l']
  True
  elem 'R' "Cantor" ..... ['C', 'a', 'n'. 't'. 'o'. 'r']
  False
  elem "Russel" "Cantor"
  Error: Type error in application
```

. . .

- to check if some thing x is an elment of a list / of some things one has to be able to identify things of the type of x
- the objects that can be identified are the objects of the kinds for which equality and inequality are defined
  - neither texts, potentially infinite stream of characters are of this kind
  - nor the Haskell operation denoted as computation procedures r
    - no principled way to check whether two procedures are doing the *same* task

- assume there is an equality test on procedures
- consider a test for whether a procedure f halts on input x

- where is used to define an aux function g
- g diverges when x is equal to y
- on all other inputs g is equal to f

```
halts f x = f /= g
where g y | y == x = undefined
| otherwise = f y
```

- if g is <u>not equal</u> to f that difference must come from the input x since g *diverges* (undefined) on this input on this input f must halt which is not equal to g
- if g and f are equal then f and g behaves the same to the same input x this means f *diverges* on that input

this will not work

- the types of object for which the question equal or not makes sense are grouped into a collection of types called a class Eq
- == for equality of objects of types in the Eq class
   /= for inequality of objects of types in the Eq class

# Eq class (2)

- :t elem
  elem :: Eq a => a -> [a] -> Bool
- :t shows the type of a defined operation
- if a is a type for which equality is defined (if a is in the Eq class) then a -> [a] -> Bool is an appropriate type for elem
- elem can be used to check whether an integer is a member of a list of integers whether a character is a member of strings
- elem cannot be used to check whether an operation is a member of a list of operations whether a text is a member of a list texts

- the class of the types of things which not only can be tested for quality and inequality, but also for order
- in addition to == and /=, the relation < and <= are defined</li>
- has the min function for the minimal element and the max function for the maximal element
- the class Ord is a subclass of the class Eq

- classes are useful, because they allow objects and operations on those objects to the instances of several type at once
- the numeral 1 can be used as an integer, as a rational, as a real, and so on

```
:t 1
```

```
1 :: Num a => a
```

- all of the types integer, rational, real, complex numbers are instances of the same class, called Num
- the class Num is a subclass of the class Eq because it also has equality and inequality
- for all types in the class Num certain basic operations such as + and \* are defined
- operator overloading one could the same name for different operations depending on whether we operate on N, Z, Q ... and depending on the representation we choose

- Defining infinite lists
- Oata type of lists
- Ist equality
- a type of class Ord
- S List Order
- Head and tail
- Last and init
- 8 Null
- O Nub

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

- data [a] = [] | a : [a] deriving (Eq, Ord)
- in Haskell, every set has a type
- [a] specifies that lists over type a are either empty or consist of an element of type a put in front of a list.
- the operation : combines an object with a list of objects of the same type to form a new list of objects of that type :t (:) (:) :: a -> [a] -> [a]

- lists are ordered sets
- two lists are the same if
  - they are both empty
  - they start with the same element and their tails are the same

```
• instance Eq a => Eq [a] where
   [] == [] = True
   (x:xs) == (y:ys) = x==y && xs==ys
   _ == _ = False
```

• if a is an instance of class Eq, then [a] is so

- a type on which the binary operation compare is defined with a result of type Ordering
- the type Ordering is the set {LT, EQ, GT}

- lexicographical order
- the empty list comes first
- non-empty lists L<sub>1</sub>, L<sub>2</sub>
  - compare their first elements using compare for objects of type a
  - if they are the same, etermine the order of their remaining lists
  - **3** if the first element of  $L_1$  comes first,
    - $L_1$  comes first before  $L_2$
  - if the first element of L<sub>2</sub> comes first, L<sub>2</sub> comes first before L<sub>1</sub>

- lexicographical order
- the empty list comes first

```
• instance Ord a => Ord [a] where
    compare [] (_:_) = LT
    compare [] [] = EQ
    compare (_:_) [] = GT
    compare (x:xs) (y:ys) = primCompAux x y (compare xs ys)
```

• if a is an instance of class Ord, then [a] is so

# List Order (3)

non-empty lists L<sub>1</sub>, L<sub>2</sub>

if they are the same, compare x y == EQ etermine the order of their remaining lists compare xs ys

- if the first element of L<sub>1</sub> comes first, compare x y == LT L<sub>1</sub> comes first before L<sub>2</sub> LT
- 3 if the first element of  $L_2$  comes first, compare x y == GT  $L_2$  comes first before  $L_1$  GT

```
o compare (x:xs) (y:ys) = primCompAux x y (compare xs ys)
primCompAux :: Ord a => a -> a -> Ordering -> Ordering
primCompAux x y o =
    case compare x y of EQ -> o;
    LT -> LT;
    GT -> GT:
```

・ 同 ト ・ ヨ ト ・ ヨ ト

```
• instance Ord a => Ord [a] where
	compare [] (_:_) = LT
	compare [] [] = EQ
	compare (_:_) [] = GT
	compare (x:xs) (y:ys) = primCompAux x y (compare xs ys)
	primCompAux :: Ord a => a -> a -> Ordering -> Ordering
	primCompAux x y o =
	case compare x y of EQ -> o;
	LT -> LT;
	GT -> GT;
```

- primCompAux covers the case of two non-empty lists
- type Odering is the set {LT, EQ, GR}

・ 同 ト ・ ヨ ト ・ ヨ ト

- deriving automatically implements functions for a few of Haskell's typeclasses such as Show and Eq.
- This cannot be done with arbitrary typeclasses, but the ones for which deriving does work for are simple enough for automatic implementation.
- The Show typeclass defines functions for how to represent data types as a String.

https://stackoverflow.com/questions/44[14884/ what-does-deriving-do-mean-in-haskell • A difference list representation of a list xs :: [T] is a function f :: [T] -> [T]

- when given another list ys :: [T] returns the list that f represents, prepended to ys i.e. f ys = xs ++ ys
- depending on usage patterns, difference lists can improve performance by effectively <u>flattening</u> the list building computations.

https://wiki.haskell.org/Difference\_list

#### usage patterns

```
(show L)
++ (show T ++ (show R))
((show LL) ++ (show LT ++ (show LR)))
++ (show T ++ (show R))
(((show LLL) ++ (show LLT ++ (show LLR))) ++ (show LT ++ (show LR)))
++ (show L)
((show LL) ++ (show LT ++ (show LR)))
(((show LLL) ++ (show LLT ++ (show LLR))) ++ (show LT ++ (show LR)))
```

https://wiki.haskell.org/Difference\_list

```
usage patterns and flattened results
(show L) ++ (show T ++ (show R))
shows L . (shows T . shows R)
((show LL) ++ (show LT ++ (show LR))) ++ (show T ++ (show R))
(shows LL . (shows LT . shows LR)) . (shows T . shows R)
(((show LLL) ++ (show LLT ++ (show LLR))) ++ (show LT ++ (show LR)))
++ (show T ++ (show R))
((shows LLL . (shows LLT . shows LLR)) . (shows LT . shows LR)) .
(shows T . shows R)
```

https://wiki.haskell.org/Difference\_list

### flattening results

```
shows L . (shows T . shows R)
(shows LL . (shows LT . shows LR)) . (shows T . shows R)
((shows LLL . (shows LLT . shows LLR)) . (shows LT . shows LR)) .
(shows T . shows R)
```

- ((shows LLL. (shows LLT. shows LLR)). (shows LT. shows LR)). (shows T. shows R)

- still need to resolve three (.) until the first character of the result string, but for the subsequent characters you do not need to resolve those dots. In the end, resolution of all (.) may need some time but then concatenation is performed entirely right-associative.

https://wiki.haskell.org/Difference\_list

# ShowS type synonym

- type ShowS = String -> String
- shows :: Show a => a -> ShowS
- show :: Show a => a -> String
- The shows functions return a function that prepends the <u>output String</u> to an <u>existing String</u> shows :: a -> String -> String output string in a -> String existing string : the second string in a -> String -> String
- This allows <u>constant-time</u> <u>concatenation</u> of results using function composition.

http://hackage.haskell.org/package/base-4.12.0.0/docs/Text-Show.html

= nar

```
• type ShowS = String -> String
• shows :: Show a => a -> ShowS
show :: Show a => a -> String
• Input : shows 12 "-14-16" -- "12" : "-14-16"
  Output: "12-14-16"
  Input : shows "A" "SSS" -- "\"A\"" : "SSS"
  Output: "\"A\"SSS"
  Input: shows 'A' "SSS" -- "'A'" : "SSS"
  Output: "'A'SSS"
```

http://zvon.org/other/haskell/Outputprelude/shows\_f.html

70 / 103

- type ShowS = String -> String
- a difference list
- a string <u>xs</u> is represented as a ShowS by the <u>function</u> (xs ++) that <u>prepends</u> it to any other list
- This allows efficient concatenation, avoiding the problems of nested left-associative concatenation (i.e. ((as ++ bs) ++cs) ++ ds).
  - concatenate by a function composition
  - make a String by passing an empty list:

https://stackoverflow.com/questions/9197913/what-is-the-shows-trick-in-haskell

- concatenate by a function composition
- make a String by passing t an empty list:

```
• hello = ("hello" ++)
world = ("world" ++)
helloworld = hello . world -- ("helloworld" ++)
helloworld' = helloworld "" -- "helloworld"
```

https://stackoverflow.com/questions/9197913/what-is-the-shows-trick-in-haskell

- It's called ShowS because ShowS is used in the implementation of the standard Show typeclass to show efficiently large, deeply-nested structures
- show can be also be implemented by showsPrec, which has the type: showsPrec :: (Show a) => Int -> a -> ShowS
  - handles operator precedence
  - returns a ShowS value
  - The standard instances implement this instead of show for efficiency; showsPrec 0 a ""

https://stackoverflow.com/questions/9197913/what-is-the-shows-trick-in-haskell

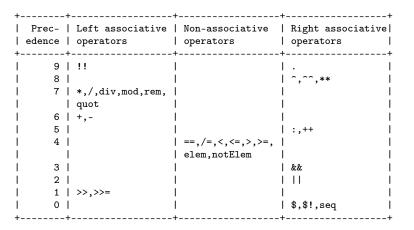

• showsPrec :: Int -> a -> ShowS

- Int : the operator precedence of the enclosing context (a number from 0 to 11). Function application has precedence 10.
- a : the value to be converted to a String
- ShowS
- Convert a value to a readable String.
- showsPrec should satisfy the law showsPrec d x r ++ s == showsPrec d x (r ++ s)

http://hackage.haskell.org/package/base-4.12.0.0/docs/Text-Show.html

74 / 103

#### Precedence and fixities

http://hackage.haskell.org/package/base-4.12.0.0/docs/Text-Show.html

```
• class Show a where
    {-# MINIMAL showsPrec | show #-}
    showsPrec :: Int -> a -> ShowS
    show :: a -> String
    showList :: [a] -> ShowS
    showsPrec _ x s = show x ++ s
    show x = shows x ""
    showList ls s = showList__ shows ls s
```

http://hackage.haskell.org/package/base-4.12.0.0/docs/Text-Show.html

3

```
• data T = P :# P | T P -- type T
deriving Show -- values 1) P :# P 2) T P
data P = P -- type P, value P
```

- use the data keyword to define a new data type
- value constructors specify the different values that this type can have
- both the type name and the value constructors have to be capital cased

https://stackoverflow.com/questions/27471937/ showsprec-and-operator-precedences/27473420

- the type T can have a value of P :# P or T P
- the type P can have a value of P

```
• type ShowS = String -> String
showsPrec : Int -> a -> ShowS
showsPrec p P = shows p -- p : priority integer
(P :# P) :: T type
(T P) :: T type
data P = P -- type P, value P
```

https://stackoverflow.com/questions/27471937/ showsprec-and-operator-precedences/27473420

э.

A (10) A (10)

```
    with infix 6 :#,
the Show T instance calls showsPrec 7
on the arguments to :#, and also it
shows parentheses only at precedences > 6:
```

```
*Main> showsPrec 6 (P :# P) ""
"7 :# 7"
:# (priority 6), showsPrec (recision 7), no need parenthesis
*Main> showsPrec 7 (P :# P) ""
"(7 :# 7)"
:# (priority 7, showsPrec (recision 7), parenthesis
```

https://stackoverflow.com/questions/27471937/ showsprec-and-operator-precedences/27473420 • And for the ordinary constructor T, he generated instance calls showsPrec 11 on the argument and shows parens at precedences > 10:

```
*Main> showsPrec 10 (T P) ""
    "T 11"
 *Main> showsPrec 11 (T P) ""
    "(T 11)"
```

https://stackoverflow.com/questions/27471937/ showsprec-and-operator-precedences/27473420
