Image: A matrix and a matrix

- population: everything in the group that we want to learn about.
- sample: a part of the population.
- Examples of populations and a sample from those populations:

Population	Sample
All of the people in Germany	500 Germans
All of the customers of Netflix	300 Netflix customers
Every car manufacturer	Tesla, Toyota, BMW, Ford

- For good statistical analysis, the sample needs to be as <u>similar</u> as possible to the population.
- If they are <u>similar enough</u>, we say that the <u>sample</u> is representative of the population.
- The sample is used to make <u>conclusions</u> about the whole population.

- If the sample is not *similar enough* to the whole population, the conclusions could be useless.
- Many words have specific meanings in statistics.
- The word population normally refers to a group of people.
- In statistics, it is any specific group that we are interested in learning about.

- Using <u>data analysis</u> and <u>statistics</u> to make <u>conclusions</u> about a <u>population</u> is called <u>statistical inference</u>.
- The main types of statistical inference are:
  - Estimation
  - Hypothesis testing

- <u>Statistics</u> from a <u>sample</u> are used to <u>estimate</u> population parameters.
- The most likely value is called a point estimate.
- There is always uncertainty when estimating.

- The uncertainty is often expressed as confidence intervals defined by a *likely* lowest and highest value for the parameter.
- An example could be a confidence interval for the number of bicycles a Dutch person owns:
  - The average number of bikes a Dutch person owns is between 3.5 and 6.

- a method to check if a claim about a population is true.
- checks how <u>likely</u> it is that a hypothesis is true is based on the sample data.
- there are different types of hypothesis testing.

- the steps of the test depends on:
  - Type of data (categorical or numerical)
  - If you are looking at:
    - a single group
    - comparing one group to another
    - comparing the same group before and after a change

- a hypothesis is a claim about a population parameter
- a hypothesis test is a formal procedure to check if a hypothesis is true or not.
- examples of claims that can be checked:
  - the average height of people in Denmark is more than 170 cm.
  - the share of left handed people in Australia is not 10%.
  - The average income of dentists is less the average income of lawyers.

https://www.w3schools.com/statistics/statistics\_hypothesis\_testing.php

- Hypothesis testing is based on making two different claims about a population parameter.
- The null hypothesis (*H*<sub>0</sub>) and the alternative hypothesis (*H*<sub>1</sub>) are the claims.
- The two claims needs to be mutually exclusive, meaning only one of them can be true.
- The alternative hypothesis is typically what we are trying to prove.
- For example, we want to check the following claim:
  - "The average height of people in Denmark is more than 170 cm."

tests	
<ul> <li>one-sample test</li> </ul>	comparing sample mean, population mean
<ul> <li>two-sample test</li> </ul>	comparing two independent sample means
<ul> <li>paired test</li> </ul>	comparing two related <u>sample means</u>

tests	test conditions
• t-test	1. when the population variance is known
	2. when the sample size is <i>large</i>
• z-test	1, when the population variance is unknown
	2. the sample size is <i>small</i>

Young W. Lim

Statistical Inference Overview

イロト イヨト イヨト イヨト

2

one sample <mark>z-test</mark>	sample mean, population mean
	known population var / large sample size
one sample t-test	sample mean, population mean
	<u>unknown</u> population var / <u>small</u> sample size
two sample z-test	two independent sample means
	known population var / large sample size
two sample t-test	two independent sample means
	unknown population var / small sample size
paired t-test	two <i>related</i> sample means
	unknown population var / small sample size

one sample propotion test	sample proportion, population proportion when $np \ge 10$ and $n(1-p) \ge 10$
two sample proportion	two independent sample proportions
test	when $np\geq 10$ and $n(1-p)\geq 10$

test conditions
the normal approximation is used
when both $np \geq 10$ and $n(1-p) \geq 10$
(data should have at least 10 "successes" and at least 10 "failures" )

# Tests for Comparing Means (1)

### One-sample z-test:

- used to <u>compare</u> the <u>mean</u> of a <u>sample</u> to a known population <u>mean</u>
- used when the population variance is known, or the sample size is large (n > 30).
- Two-sample z-test:
  - used to compare the means of two independent samples.
  - used when the population variances are known, or the sample sizes are large (n > 30).

# Tests for Comparing <u>Means</u> (2)

### One-sample t-test:

- used to <u>compare</u> the <u>mean</u> of a <u>sample</u> to a known population <u>mean</u>.
- used when the population variance is unknown, and the sample size is small (n < 30).
- Two-sample t-test:
  - used to compare the means of two independent samples.
  - used when the population variances are unknown, and the sample sizes are small (n < 30).</li>

https://www.qualitygurus.com/common-types-of-hypothesis-tests/

19/44

#### Paired t-test:

- used to <u>compare</u> the <u>means</u> of two <u>related</u> <u>samples</u>, such as the <u>before</u> and <u>after</u> <u>measurements</u> of the same group of subjects.
- used when the population variances are unknown, and the sample size is small (n < 30).

- Let us consider the parameter *p* of the population proportion
  - eg) we might want to know the proportion of <u>males</u> within a total population of <u>adults</u> when we conduct a survey.
- A test of proportion will assess whether or not a sample from a population <u>represents</u> the true proportion of the entire population

https://online.stat.psu.edu/statprogram/reviews/statistical-concepts/proportions

#### an example

- newborn babies are more likely to be boys than girls.
- a random sample found 13,173 <u>boys</u> were born among 25,468 newborn children
- the sample proportion of boys was 0.5172 (=  $\frac{13173}{25468}$ )
- is this sample evidence that the birth of <u>boys</u> is more common than the birth of <u>girls</u> in the entire population? (0.5172 > 0.4828)

https://online.stat.psu.edu/statprogram/reviews/statistical-concepts/proportions

- examples involved testing whether a single population proportion p equals some value.
- different examples of testing whether one population proportion equals a second population proportion

- Additionally, most of our examples thus far have involved
  - left-tailed tests in which the alternative hypothesis involved
  - right-tailed tests in which the alternative hypothesis involved
- Here, let's consider an example that tests the equality of two proportions against the alternative that they are not equal

24 / 44

- Time magazine reported the result of a telephone poll of 800 adult Americans.
- the question posed of the Americans who were surveyed was: "Should the federal tax on cigarettes be raised to pay for health care reform?"
- the results of the survey were:

Non-smokers	Smokers
$n_1 = 605$	$n_2 = 195$
$y_1=351$ said yes	$y_2 = 41$ said yes
$\hat{p}_1 = \frac{351}{605} = 0.58$	$\hat{p}_2 = \frac{41}{195} = 0.21$

25 / 44

## Tests for Comparing Proportions (2-4)

- If  $p_1$  = the proportion of the <u>non-smoker</u> population who reply "yes"
- and p<sub>2</sub> = the proportion of the <u>smoker</u> population who reply "yes,"
- then we are interested in testing the <u>null hypothesis</u>:  $H_0: p_1 = p_2$ against the <u>alternative hypothesis</u>:  $H_A: p_1 \neq p_2$
- Before we can actually conduct the hypothesis test, we'll have to derive the appropriate test statistic.

• The overall sample proportion is:  

$$\hat{p} = \frac{41+351}{195+605} = \frac{392}{800} = 0.49$$

• that implies then that the test statistic for testing:  $H_0: p_1 = p_2$  versus  $H_A: p_1 \neq p_2$ is:  $Z = \frac{(0.58 - 0.21) - 0}{\sqrt{0.49(0.51)(\frac{1}{195} + \frac{1}{605})}} = 8.9$ 

https://online.stat.psu.edu/stat415/lesson/9/9.4

27 / 44

## • One-sample proportion test :

- used to <u>compare</u> the proportion of a <u>sample</u> to a known population proportion.
- the normal approximation is used when both  $np \ge 10$  and  $n(1-p) \ge 10$ (data should have at least 10 "successes" and at least 10 "failures" ) (in some books, it is 5)

- Two-sample proportion test :
  - used to compare the proportions of two independent samples.
  - the normal approximation is used when both  $np \ge 10$  and  $n(1-p) \ge 10$ (data should have at least 10 "successes" and at least 10 "failures" ) (in some books, it is 5)

- Time magazine reported the result of a telephone poll of 800 adult Americans.
- The question posed of the Americans who were surveyed was: "Should the federal tax on cigarettes be raised to pay for health care reform?"

The results of the survey were:

Non-Smokers	Smokers
$n_1 = 605$	$n_2 = 195$
$y_1 = 351$ said "yes"	$y_2 = 41$ said "yes"
$\hat{p}_1 = \frac{351}{605} = 0.58$	$\hat{p}_2 = \frac{41}{195} = 0.21$

 Is there sufficient evidence at the , say, to conclude that the two populations - smokers and non-smokers - differ significantly with respect to their opinions?

- Errr.... that Z-value is off the charts, so to speak. Let's go through the formalities anyway making the decision first using the rejection region approach, and then using the P-value approach. Putting half of the rejection region in each tail, we have:
- That is, we reject the null hypothesis if or if . We clearly reject , since 8.99 falls in the "red zone," that is, 8.99 is (much) greater than 1.96. There is sufficient evidence at the 0.05 level to conclude that the two populations differ with respect to their opinions concerning imposing a federal tax to help pay for health care reform.

- That is, the P-value is less than 0.0001. Because, we reject the null hypothesis. Again, there is sufficient evidence at the 0.05 level to conclude that the two populations differ with respect to their opinions concerning imposing a federal tax to help pay for health care reform.
- Thankfully, as should always be the case, the two approaches.... the critical value approach and the P-value approach... lead to the same conclusion

### • Chi-square test for variance :

- used to <u>compare</u> the variance of a <u>sample</u> to a <u>known</u> population <u>variance</u>
- F-test for variance :
  - used to compare the variances of two *independent* samples

- Goodness of fit test :
- used to determine whether a sample fits a *specific* distribution.
- used to <u>compare</u> the <u>observed frequencies</u> of a *categorical variable* to the expected frequencies under a *particular* distribution.

- Testing for independence of two attributes (Contingency Tables) :
- used to determine whether there is a <u>relationship</u> between two *categorical variables*.
- often used in the form of a chi-square test, which <u>compares</u> the <u>observed frequencies</u> in a <u>contingency table</u> to the expected frequencies under the assumption of independence.

- ANOVA (Analysis of Variance) :
- used to compare the means of three or more independent samples.
- used to determine whether there is a significant difference between the means of the groups.

- used to test a hypothesis about the population mean
- based on the assumption that the <u>sample</u> is drawn from a normally distributed population.
  - the null hypothesis the *population* mean is <u>equal</u> to a specific value
  - the alternative hypothesis the *population* mean is not equal to that value

38 / 44

- based on the assumption that both <u>samples</u> are drawn from normally distributed populations with equal variances.
- the two-sample z-test requires that the population standard deviations be known or that the sample sizes be large (30 or more),
  - the null hypothesis the means of the two samples are equal
  - the alternative hypothesis the means are <u>not</u> equal

39 / 44

- used to test a hypothesis about the *population* mean
- based on the assumption that the <u>sample</u> is drawn from a normally distributed population
  - the null hypothesis the *population* mean is <u>equal</u> to a specific value
  - the alternative hypothesis the *population* mean is <u>not</u> <u>equal</u> to that value

- based on the assumption that the samples are drawn from populations with normal distributions.
- the two-sample t-test that the population standard deviations need not be known or that the sample sizes need not be large (30 or more),
  - the null hypothesis the means of the two samples are equal
  - the alternative hypothesis the means are not equal

41/44

- used to test a hypothesis about the difference between the means of the two samples
- based on the assumption that the <u>differences</u> between the pairs are normally distributed
- In a <u>dependent</u> <u>two-sample</u> <u>t-test</u> (a <u>paired</u> <u>t-test</u>), the <u>samples</u> in the two <u>groups</u> being compared are <u>related</u> in some way.
  - the null hypothesis

there is no difference between the means of the two samples

• the alternative hypothesis

there is a difference between the means

- used to test a hypothesis about the <u>difference</u> between the proportions of the two samples and
- based on the assumption that the samples are drawn from populations with a normal distribution
  - the null hypothesis :

there is no difference between the proportions of the two samples

• the alternative hypothesis :

there is a difference between the proportion
