② MVR (Modified Vector Rotational)

two modifications

① repetition of elementary angles

each micro-rotation of elementary angle
can be performed repeatedly

- more possible combinations
- smaller ξ_m

② confinement of total micro-rotation number

$$N' \triangleq \sum_{j=0}^{N-1} |\mu(j)| \quad \text{the effective iteration number}$$

EAS formed by MVR-CORDIC

is the same as AR

also performs AQ

The major difference

1) the total number of sub-angles N_A

the total iteration number

in the micro-rotation phase

is kept fixed to a pre-defined value of R_m

$$N_A = R_m$$

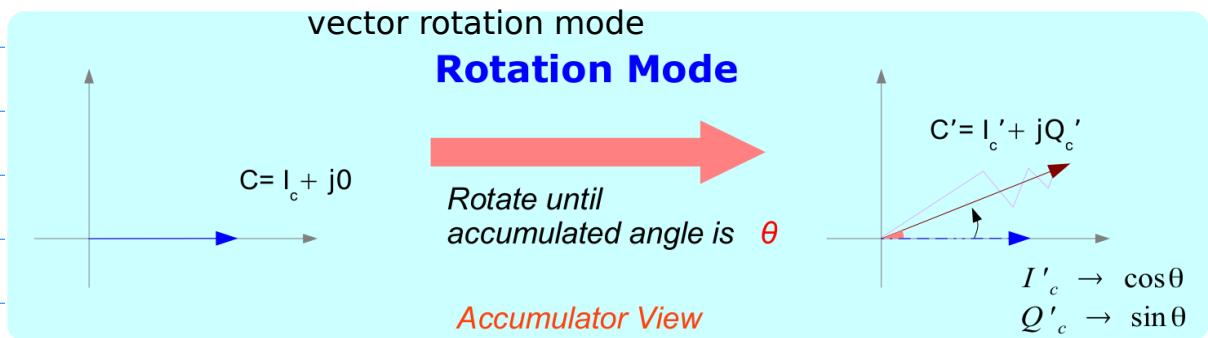

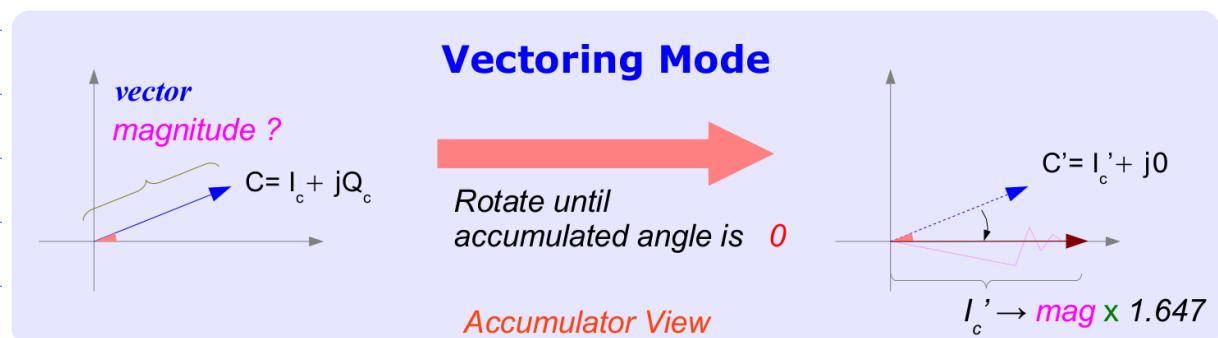

2) the sub-angle θ_i corresponds to $\alpha(j) \alpha(s(j))$

$$\theta_j = \alpha(j) \alpha(s(j)) = \tilde{\theta}_j$$

MVR (Modified Vector Rotation)

- 1) Repeat of Elementary Angles θ_i, θ_i
- 2) fixed total micro-rotation Number R_m

* Vector Rotation Mode
* and the rotation angles are known in advance

Modified Vector Rotational MVR CORDIC

- reduce the iteration number
- maintaining the SQNR performance
- modifying the basic microrotation procedure

Three Searching Algorithm

- ① the selective prerotation
- ② the selective scaling
- ③ iteration - tradeoff scheme

Optimization Problem

EAS point of view

Given θ , find the combination of R_m elementary angles from EAS S_1 , such that the angle quantization error $|\xi_{m, \text{MUR}}|$ is minimized.

Semi-greedy algorithm
trade offs between computational complexities
and performance

key issue in the MVR-CORDIC
is to find the best sequences of
 $s(i)$ and $\alpha(i)$ to minimize $|\tilde{e}_m|$
subject to the constraint that
the total iteration number is confined to R_m

- 1) Greedy Algorithm
- 2) Exhaustive Algorithm
- 3) Semigreedy Algorithm

I) Greedy Algorithm

try to approach the target rotation angle, Θ , step by step
in each step, decisions are made on $\alpha(i)$ and $s(i)$
by choosing the best combination of $\alpha(i)$ $a(s(i))$
so as to minimize $|\xi_m|$

$\alpha(i)$ and $s(i)$ are determined such that

the error function $J(i) = |\Theta(i) - \alpha(i)a(s(i))|$ is minimized

$\Theta(i)$: the residue angle in the i -th step

$$\Theta(i) = \Theta - \sum_{m=0}^{i-1} \alpha(m)a(s(m))$$

the searching is terminated

if no further improvements can be found

$$J(i) \geq J(i-1)$$

$\alpha(R_{m-1})$ and $s(R_{m-1})$ are determined

at the end of the searching

the greedy algorithm terminates

Only when the residue angle error
cannot be further reduced.

Initialization:

given Θ , W , R_m

$$\Theta(i) = \Theta - \sum_{m=0}^{i-1} \alpha(m) a(s(m))$$

Select $\alpha(i) \in \{-1, 0, +1\}$
 $s(i) \in \{0, 1, 2, \dots, w-1\}$
to minimize $J(i) = \Theta(i) - \alpha(i) a(s(i))$

N

$$J(i) < J(i-1)$$

Y

$i = i + 1$

$$= 3^{R_m} \cdot W^{R_m}$$

Store $\alpha(i)$ and $s(i)$

for $0 \leq i \leq R_m - 1$

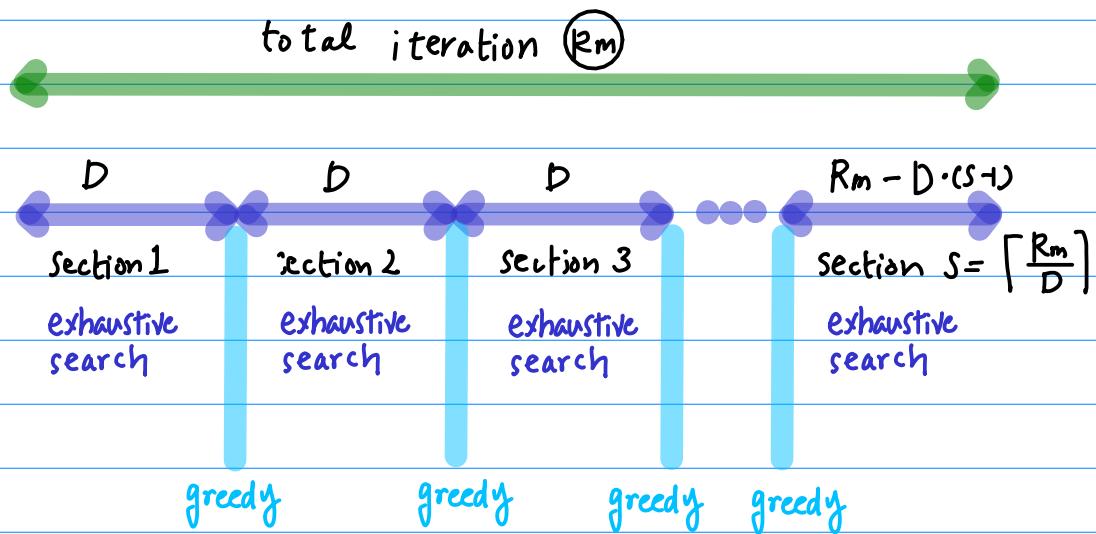

3) Semi-greedy Algorithm

a combination of greedy and exhaustive algorithm

the search space of $\alpha(i)$ and $s(i)$ for $0 \leq i \leq R_m - 1$
