Church numeral (1)

Natural numbers are non-negative.

Given a successor function, **next**, which adds one, we can define the natural numbers in terms of **zero** and **next**:

$$1 = (\text{next } 0)$$

$$2 = (\text{next } 1) = (\text{next } (\text{next } 0))$$

$$3 = (\text{next } 2) = (\text{next } (\text{next } (\text{next } 0)))$$

and so on.

<https://www.cs.unc.edu/~stotts/723/Lambda/church.html>

Church numeral (2)

Therefore a number **n** will be that number of **successors** of **zero**.

Just as we adopted the convention **TRUE = first**, and **FALSE = second**, we adopt the following convention:

zero = $\lambda f.\lambda x.x$
one = $\lambda f.\lambda x.(f\ x)$
two = $\lambda f.\lambda x.(f\ (f\ x))$
three = $\lambda f.\lambda x.(f\ (f\ (f\ x)))$
four = $\lambda f.\lambda x.(f\ (f\ (f\ (f\ x))))$

1 = **(next 0)**

2 = **(next 1)** = **(next (next 0))**

3 = **(next 2)** = **(next (next (next 0)))**

f ← **next**

x ← **zero**

<https://www.cs.unc.edu/~stotts/723/Lambda/church.html>

Church numeral (3)

a "unary" representation of the natural numbers,
such that **n** is represented
as **n applications** of the **function f** to the **argument x**.

zero = $\lambda f.\lambda x.x$

one = $\lambda f.\lambda x.(f\ x)$

two = $\lambda f.\lambda x.(f\ (f\ x))$

three = $\lambda f.\lambda x.(f\ (f\ (f\ x)))$

four = $\lambda f.\lambda x.(f\ (f\ (f\ (f\ x))))$

This representation is referred to as
CHURCH NUMERALS.

<https://www.cs.unc.edu/~stotts/723/Lambda/church.html>

Church numeral (4)

We can define the function **next** as follows:

$$\mathbf{next} = \lambda n. \lambda f. \lambda x. (f ((n f) x)) \quad = \lambda n. \lambda f. \lambda x. (f (n f x))$$

and therefore **one** as follows:

$$\begin{aligned} \mathbf{one} &= (\mathbf{next} \text{ zero}) \\ &\Rightarrow (\lambda n. \lambda f. \lambda x. (f ((n f) x)) \text{ zero}) \\ &\Rightarrow \lambda f. \lambda x. (f ((\mathbf{zero} f) x)) \\ &\Rightarrow \lambda f. \lambda x. (f ((\lambda g. \lambda y. y f) x)) \quad (* \text{ alpha conversion avoids clash } *) \\ &\Rightarrow \lambda f. \lambda x. (f (\lambda y. y x)) \\ &\Rightarrow \lambda f. \lambda x. (f x) \end{aligned}$$

$$\begin{aligned} \mathbf{zero} &= \lambda f. \lambda x. x \\ \mathbf{one} &= \lambda f. \lambda x. (f x) \\ \mathbf{two} &= \lambda f. \lambda x. (f (f x)) \\ \mathbf{three} &= \lambda f. \lambda x. (f (f (f x))) \\ \mathbf{four} &= \lambda f. \lambda x. (f (f (f (f x)))) \end{aligned}$$

<https://www.cs.unc.edu/~stotts/723/Lambda/church.html>

Calculation with Church Numerals

Arithmetic operations on numbers may be represented by **functions** on **Church numerals**.

These **functions** may be defined in **lambda calculus**, or implemented in most **functional programming languages**

https://en.wikipedia.org/wiki/Church_encoding

Functions on Church numerals (1) plus

The addition function **plus**(m, n) = m + n

uses the identity $f \circ^{(m+n)}(x) = f \circ^{(m)}(f \circ^{(n)}(x))$

plus $\equiv \lambda m. \Lambda n. \lambda f. \lambda x. m f (n f x)$

https://en.wikipedia.org/wiki/Church_encoding

Functions on Church numerals (2) **succ, mult**

The **successor function** $\text{succ}(n) = n + 1$

is β -equivalent to **(plus 1)**

$$\text{succ} \equiv \lambda n. \lambda f. \lambda x. f (n f x)$$

The **multiplication function** $\text{mult}(m, n) = m * n$

uses the identity $f \circ (m \cdot n) (x) = (f \circ (n)) \circ (m) (x)$

$$\text{mult} \equiv \lambda m. \lambda n. \lambda f. \lambda x. m (n f) x$$

https://en.wikipedia.org/wiki/Church_encoding

Functions on Church numerals (3) **exp**

The **exponentiation function** $\mathbf{exp}(m, n) = m^n$

is given by the definition of Church numerals,

$$\mathbf{n} \mathbf{h} \mathbf{x} = \mathbf{h}^n \mathbf{x}$$

In the definition substitute $\mathbf{h} \rightarrow \mathbf{m}$, $\mathbf{x} \rightarrow \mathbf{f}$ to get $\mathbf{n} \mathbf{m} \mathbf{f} = \mathbf{m}^n$ and,

$$\mathbf{n} \mathbf{m} \mathbf{f} = \mathbf{m}^n \mathbf{f}$$

$$\mathbf{exp} \mathbf{m} \mathbf{n} = \mathbf{m}^n = \mathbf{n} \mathbf{m}$$

which gives the lambda expression,

$$\mathbf{exp} \equiv \lambda m. \lambda n. n m$$

https://en.wikipedia.org/wiki/Church_encoding

Functions on Church numerals (4) pred

The **pred**(n) function is more difficult to understand.

$$\text{pred} \equiv \lambda n. \lambda f. \lambda x. n (\lambda g. \lambda h. h (g f)) (\lambda u. x) (\lambda u. u)$$

A Church numeral applies a function **n times**.

The **predecessor** function must return
a **function** that applies its parameter **n - 1 times**.

This is achieved by building a **container** around **f** and **x**,
which is initialized in a way that **omits**
the **application** of the function the first time.

https://en.wikipedia.org/wiki/Church_encoding

Functions on Church numerals (5) minus

The subtraction function can be written based on the predecessor function.

$$\text{minus} \equiv \lambda m. \lambda n. (n \text{ pred}) m$$

$$\text{minus } m n = n \text{ pred } m$$

$$\begin{aligned} \text{minus } 4 3 &= 3 \text{ pred } 4 \\ &= (\text{pred } (\text{pred } (\text{pred } 4))) \\ &= (\text{pred } (\text{pred } 3)) \\ &= (\text{pred } 2) \\ &= 1 \end{aligned}$$

$$\begin{aligned} \text{minus } 3 2 &= 2 \text{ pred } 3 \\ &= (\text{pred } (\text{pred } 3)) \\ &= (\text{pred } 2) \\ &= 1 \end{aligned}$$

$$\begin{aligned} \text{minus } 2 2 &= 2 \text{ pred } 2 \\ &= (\text{pred } (\text{pred } 2)) \\ &= (\text{pred } 1) \\ &= 0 \end{aligned}$$

$$\begin{aligned} \text{minus } 1 2 &= 2 \text{ pred } 1 \\ &= (\text{pred } (\text{pred } 1)) \\ &= (\text{pred } 0) \\ &= 0 \end{aligned}$$

https://en.wikipedia.org/wiki/Church_encoding

Summary : functions on Church numerals (1)

Function	Algebra	Identity	Function definition
Successor	$n + 1$	$f^{n+1} x = f (f^n x)$	<code>succ n f x = f (n f x)</code>
Addition	$m + n$	$f^{m+n} x = f^m (f^n x)$	<code>plus m n f x = m f (n f x)</code>
Multiplication	$m * n$	$f^{m*n} x = (f^m)^n x$	<code>multiply m n f x = m (n f) x</code>
Exponentiation	m^n	$n m f = m^n f x$	<code>exp m n f x = (n m) f x</code>
Predecessor	$n - 1$	<code>inc n con = val (fⁿ⁻¹ x)</code>	<code>if (n == 0) 0 else (n - 1)</code>
Subtraction	$m - n$	$f^{m-n} x = (f^{-1})^n (f^m x)$	<code>minus m n = (n pred) m</code>

https://en.wikipedia.org/wiki/Church_encoding

Summary : functions on Church numerals (2)

https://en.wikipedia.org/wiki/Church_encoding

Predecessor function using **pair** (1)

We can now define the **predecessor** function combining some of the functions introduced above.

When looking for the **predecessor** of n , the general strategy will be to create a **pair** $(n, n-1)$ and then pick the second element $(n-1)$ of the **pair** as the result.

<https://personal.utdallas.edu/~gupta/courses/apl/lambda.pdf>

Predecessor function using **pair** (2)

A **pair** (**a**, **b**) can be represented in λ -calculus using the function $(\lambda z. z \ a \ b)$

We can extract the first element of the pair from the expression applying this function to **T**

$$(\lambda z. z \ a \ b) \ \mathbf{T} = \mathbf{T} \ a \ b = a$$

and the second applying the function to **F**

$$(\lambda z. z \ a \ b) \ \mathbf{F} = \mathbf{F} \ a \ b = b$$

<https://personal.utdallas.edu/~gupta/courses/apl/lambda.pdf>

Predecessor function using **pair** (3)

pair (n, n-1) →

p = **pair** n n-1 = (λz. z n n-1)

p T = (λz. z n n-1) **T** = **T** n n-1 = n -- first element

p F = (λz. z n n-1) **F** = **F** n n-1 = n-1 -- second element

A **pair** (a, b)

pair a b = (λz. z a b)

extract the first element

(λz.z a b) **T** = **T** a b = a

extract the second

(λz.z a b) **F** = **F** a b = b

<https://personal.utdallas.edu/~gupta/courses/apl/lambda.pdf>

Predecessor function using **pair** (4)

The following function

generates the **pair (n+1, n)**
from the **pair (n, n-1)** (= **p**)

$$\Phi \equiv (\lambda p. \lambda z. z (\mathbf{S} (p \mathbf{T})) (p \mathbf{T}))$$

$$\begin{array}{ccc} \text{pair } (n, n-1) & \rightarrow & \text{pair } (n+1, n) \\ p & \rightarrow & \Phi \end{array}$$

the **pair (n, n-1)** is the argument **p** in the function

$$p = \text{pair } n \ n-1 = (\lambda z. z \ n \ n-1)$$

A **pair (a, b)**

$$\text{pair } a \ b = (\lambda z. z \ a \ b)$$

extract the first element

$$(\lambda z. z \ a \ b) \ \mathbf{T} = \mathbf{T} \ a \ b = a$$

extract the second

$$(\lambda z. z \ a \ b) \ \mathbf{F} = \mathbf{F} \ a \ b = b$$

<https://personal.utdallas.edu/~gupta/courses/apl/lambda.pdf>

Predecessor function using pair (5)

$$\Phi \equiv (\lambda p. \lambda z. z (S (p T)) (p T))$$

The subexpression $p T$

extracts the first element from the pair p .

thus n from the pair $(n, n-1)$

A new pair is formed using this element n ,

n is incremented $S (p T)$

for the first position of the new pair $(n+1)$

n is copied $(p T)$

for the second position of the new pair. (n)

$$\text{zero} = \lambda f. \lambda x. x$$

$$\text{one} = \lambda f. \lambda x. (f x)$$

$$\text{two} = \lambda f. \lambda x. (f (f x))$$

$$\text{three} = \lambda f. \lambda x. (f (f (f x)))$$

$$\text{four} = \lambda f. \lambda x. (f (f (f (f x))))$$

Successor function

$$\text{next} = \lambda n. \lambda f. \lambda x. (f ((n f) x))$$

$$S = \lambda n. \lambda f. \lambda x. (f (n f x))$$

<https://personal.utdallas.edu/~gupta/courses/apl/lambda.pdf>

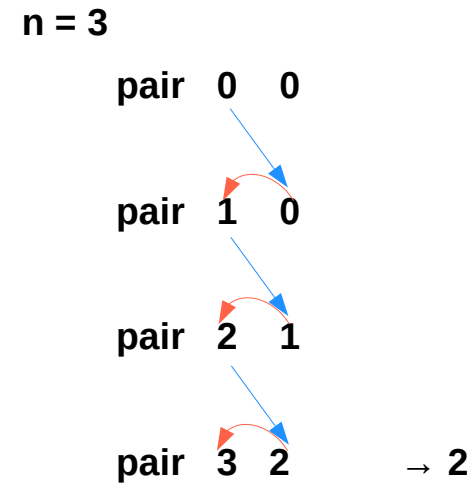

Predecessor function using pair (6)

$$\Phi \equiv (\lambda p. \lambda z. z (\mathbf{S} (\mathbf{p} \mathbf{T})) (\mathbf{p} \mathbf{T}))$$

The **predecessor** of a number **n** is obtained
by **applying n times**
the **function Φ**
to the **pair $(\lambda.z \ 0 \ 0)$**

thus get the new **pair $(\lambda.z \ n \ n-1)$**

and then **selecting** the **second** member **n-1**
of the new pair **$(\lambda.z \ n \ n-1)$**

<https://personal.utdallas.edu/~gupta/courses/apl/lambda.pdf>

Predecessor function using pair (7)

$$\Phi \equiv (\lambda p. \lambda z. z (\mathbf{S} (\mathbf{p} \mathbf{T})) (\mathbf{p} \mathbf{T}))$$

$$\mathbf{P} \equiv (\lambda n. n \Phi (\lambda z. z \mathbf{0} \mathbf{0}) \mathbf{F})$$

Notice that using this approach the predecessor of zero is zero.

This property is useful for the definition of other functions.

$$\begin{aligned} \mathbf{P} \mathbf{1} &= \mathbf{1} \Phi (\lambda z. z \mathbf{0} \mathbf{0}) \\ &= \Phi (\lambda z. z \mathbf{0} \mathbf{0}) \\ &= (\lambda z. z \mathbf{1} \mathbf{0}) \end{aligned}$$

$$\begin{aligned} \mathbf{P} \mathbf{2} &= \mathbf{2} \Phi (\lambda z. z \mathbf{0} \mathbf{0}) \\ &= \Phi (\Phi (\lambda z. z \mathbf{0} \mathbf{0})) \\ &= \Phi (\lambda z. z \mathbf{1} \mathbf{0}) \\ &= (\lambda z. z \mathbf{2} \mathbf{1}) \end{aligned}$$

$$\begin{aligned} \mathbf{P} \mathbf{3} &= \mathbf{3} \Phi (\lambda z. z \mathbf{0} \mathbf{0}) \\ &= \Phi (\Phi (\Phi (\lambda z. z \mathbf{0} \mathbf{0}))) \\ &= \Phi (\lambda z. z \mathbf{2} \mathbf{1}) \\ &= (\lambda z. z \mathbf{3} \mathbf{2}) \end{aligned}$$

$$\mathbf{P} \mathbf{1} \mathbf{F} = \mathbf{0}$$

$$\mathbf{P} \mathbf{2} \mathbf{F} = \mathbf{1}$$

$$\mathbf{P} \mathbf{3} \mathbf{F} = \mathbf{2}$$

<https://personal.utdallas.edu/~gupta/courses/apl/lambda.pdf>

Predecessor function using **pair** (8)

$$\Phi \equiv (\lambda p. \lambda z. z (\mathbf{S} \quad (p \mathbf{T})) \quad (p \mathbf{T}))$$
$$(\lambda x. \lambda z. z (\mathbf{succ} (\mathbf{first} \ x)) (\mathbf{first} \ x))$$
$$(\lambda x. \mathbf{pair} (\mathbf{succ} (\mathbf{first} \ x)) (\mathbf{first} \ x))$$

pred =

$\lambda n . \mathbf{second}$

$(n (\mathbf{pair} \ \mathbf{zero} \ \mathbf{zero}))$

$(\lambda x . \mathbf{pair} \ (\mathbf{succ} (\mathbf{first} \ x))$
 $\quad \quad \quad (\mathbf{first} \ x))$

)

$\mathbf{pair} \ a \ b = (\lambda z. z \ a \ b)$

<https://personal.utdallas.edu/~gupta/courses/apl/lambda.pdf>

Predecessor function using **pair** (9)

$$\text{pred} = \lambda n . \text{second } (n \ (\lambda x. \text{pair } (\text{succ } (\text{first } x)) (\text{first } x)) \\ (\text{pair } \text{zero } \text{zero}))$$
$$P \equiv (\lambda n. n \ \Phi \ (\lambda z. z \ 0 \ 0) \ F)$$
$$\Phi \equiv (\lambda p. \lambda z. z \ (\text{S } (p \ T)) \ (p \ T))$$
$$\text{pair } a \ b = (\lambda z. z \ a \ b)$$

- How does this work?

the **pair {a, b}** encodes the fact that **(pred a) = b**

<http://web.cecs.pdx.edu/~black/CS311/Lecture%20Notes/Lambda%20Calculus.pdf>

Church numeral (11)

The lambda function `pred` delivers the predecessor of a Church Numeral:

```
pair =  $\lambda x.\lambda y.\lambda f.((f\ x)\ y)$ ;
```

```
prefn =  $\lambda f.\lambda p.((pair\ (f\ (p\ first))))\ (p\ first)$ 
```

```
pred =  $\lambda n.\lambda f.\lambda x.(((n\ (prefn\ f))\ (pair\ x\ x))\ second)$ 
```

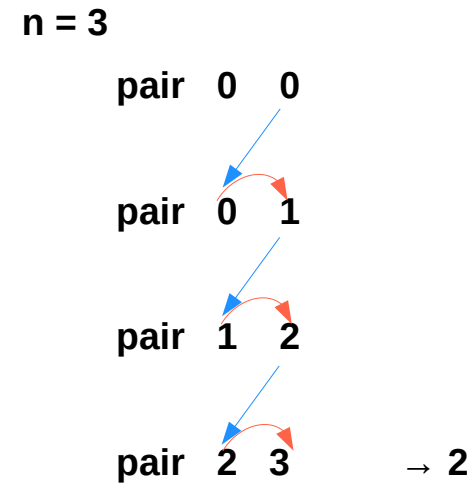

<https://www.cs.unc.edu/~stotts/723/Lambda/church.html>

Predecessor function using **shift** and **increment**

As an example of the use of pairs,
the **shift-and-increment** function
that maps (m, n) to $(n, n + 1)$ can be defined as

$$\Phi2 := \lambda x. \text{PAIR} (\text{SECOND } x) (\text{SUCC} (\text{SECOND } x))$$

which allows us to give perhaps the most transparent version
of the predecessor function:

$$\text{PRED} := \lambda n. \text{FIRST} (n \Phi2 (\text{PAIR } 0 \ 0)).$$

https://en.wikipedia.org/wiki/Lambda_calculus#Formal_definition

Predecessor function using conditionals (1)

the **predecessor** function can be defined as:

$$\mathbf{PRED} := \lambda n.n (\lambda g. \lambda k. \mathbf{ISZERO} (g \ 1) \ k (\mathbf{PLUS} (g \ k) \ 1)) (\lambda v.0) \ 0$$

which can be verified by showing inductively

that

$$n (\lambda g. \lambda k. \mathbf{ISZERO} (g \ 1) \ k (\mathbf{PLUS} (g \ k) \ 1)) (\lambda v.0)$$

is the

add n – 1 function for **n > 0**.

$$\mathbf{ISZERO} := \lambda n.n (\lambda x.FALSE) \ \mathbf{TRUE}$$
$$\mathbf{true} \equiv \lambda a.\lambda b.a$$
$$\mathbf{false} \equiv \lambda a.\lambda b.b$$
$$\mathbf{ISZERO} (g \ 1)$$

If True,

$$\mathbf{True} \ k (\mathbf{PLUS} (g \ k) \ 1)$$

selects k

Else,

$$\mathbf{False} \ k (\mathbf{PLUS} (g \ k) \ 1)$$

selects (PLUS (g k) 1)

https://en.wikipedia.org/wiki/Lambda_calculus#Formal_definition

Predecessor function using conditionals (2)

A **predicate** is a **function** that returns a **boolean value**.

the **ISZERO** predicate

returns **TRUE**

if its argument is the Church numeral **0**,

returns **FALSE**

if its argument is *any other* Church numeral:

ISZERO := $\lambda n. n (\lambda x. \text{FALSE}) \text{TRUE}$

$n=0: \lambda f. \lambda y. y (\lambda x. \text{FALSE}) \text{TRUE} \rightarrow \text{TRUE}$

$n=1: \lambda f. \lambda y. f y (\lambda x. \text{FALSE}) \text{TRUE} \rightarrow \text{FALSE}$

$\lambda f. \lambda x. x$ 0

$\lambda f. \lambda x. f x$ 1

$\lambda f. \lambda x. f (f x)$ 2

$\lambda f. \lambda x. f (f (f x))$ 3

$\lambda f. \lambda x. f (f (f (f x)))$ 4

https://en.wikipedia.org/wiki/Lambda_calculus#Formal_definition

Predecessor function (1)

The **predecessor function** used in the Church encoding is,

$$\text{pred}(n) = \begin{cases} 0 & \text{if } n = 0, \\ n - 1 & \text{otherwise.} \end{cases}$$

a way of applying the function 1 fewer time.

A numeral **n** applies the **function f**, **n** times to **x**.

n f x

the **predecessor** function must use the numeral **n**
to apply the function **n-1** times.

(n-1) f x

0	0 f x = x
1	1 f x = f x
2	2 f x = f (f x)
3	3 f x = f (f (f x))
4	4 f x = f (f (f (f x)))

https://en.wikipedia.org/wiki/Church_encoding

Predecessor function (2)

Before implementing the predecessor function,

here is a scheme

that **wraps** the **value**
in a **container function**

$x, (f\ x), (f\ (f\ x)), \dots$
value

value x

value $(f\ x)$

value $(f\ (f\ x))$

value $(f\ (f\ (f\ x)))$

value $(f^{n-1}\ x) = \mathbf{value}((n-1)\ f\ x)$

value $(f^n\ x) = \mathbf{value}\ (n\ f\ x)$

https://en.wikipedia.org/wiki/Church_encoding

Predecessor function (3)

We will **define** new functions to use in place of **f** and **x**,
called **inc** and **init**, **const**

The general recurrence rule is,

$$\text{inc (value } v) = \text{value (f } v)$$

If there is also a function (called **extract**)

to **retrieve** the value from the **container**

$$\text{extract (value } v) = v$$

value **x**
value (f **x**)
value (f (f **x**))

inc (value **x**) = **value** (f **x**)
inc (value (f **x**)) = **value** (f (f **x**))
inc (value (f (f **x**))) = **value** (f (f (f **x**)))

extract (value **x**) = **x**
extract (value (f **x**)) = (f **x**)
extract (value (f (f **x**))) = (f (f **x**))

https://en.wikipedia.org/wiki/Church_encoding

Predecessor function (4)

value x can be either **init** or **inc const**

init = **value** x

inc init = **value** (f x)

inc (inc init) = **value** (f (f x))

inc const = **value** x

inc (inc const) = **value** (f x)

value x

value (f x)

value (f (f x))

value (f (f (f x)))

https://en.wikipedia.org/wiki/Church_encoding

Predecessor function (5)

n-fold composition

init = **value x**

1 inc init = **value** (f x)

2 inc init = **value** (f (f x))

3 inc init = **value** (f (f (f x)))

extract(**1 inc init**) = f x

extract(**2 inc init**) = (f (f x))

extract(**3 inc init**) = (f (f (f x)))

extract (n **inc init**) = n f x

inc const = **value x**

1 inc const = **value** x

2 inc const = **value** (f x)

3 inc const = **value** (f (f x))

extract(**1 inc const**) = x

extract(**2 inc const**) = (f x)

extract(**3 inc const**) = (f (f x))

extract (**inc const**) = (n-1) f x

https://en.wikipedia.org/wiki/Church_encoding

Predecessor function (6)

The left hand side of the table shows a numeral n applied to `inc` and `init`.

Number	Using <code>init</code>	using <code>const</code>
0	<code>init = value x</code>	
1	<code>inc init = value (f x)</code>	<code>inc const = value x</code>
2	<code>inc (inc init) = value (f (f x))</code>	<code>inc (inc const) = value (f x)</code>
3	<code>inc (inc (inc init)) = value (f (f (f x)))</code>	<code>inc (inc (inc const)) = value (f (f x))</code>
n	$n \text{ inc init} = \text{value } (f^n x) = \text{value } (n \text{ f } x)$	$n \text{ inc const} = \text{value } (f^{n-1} x) = \text{value } ((n-1) \text{ f } x)$

https://en.wikipedia.org/wiki/Church_encoding

Predecessor function (7)

```
pred = λn. λf. λx. extract( n inc const )  
      = λn. λf. λx. extract (value ((n-1) f x))  
      = λn. λf. λx. (n - 1) f x  
      = λn. (n - 1)
```

```
1 inc const = value x           = value (0 f x)
```

```
2 inc const = value (f x)       = value (1 f x)
```

```
3 inc const = value (f (f x))   = value (2 f x)
```

```
extract( 1 inc const ) = x       = (0 f x)
```

```
extract( 2 inc const ) = (f x)   = (1 f x)
```

```
extract( 3 inc const ) = (f (f x)) = (2 f x)
```

https://en.wikipedia.org/wiki/Church_encoding

Predecessor function (8)

as `inc` delegates calling of `f`
to its container `value` argument,

`f v`
`value v`

`inc (value v) = value (f v)`

in order to skip the first application of `f`,
we can arrange that on the first application
`inc` receives a special container `const`
that ignores its argument

`inc const = value x`

`init = value x`
`inc const = value x`

`samenum`

`= λn. λf. λx. extract (n inc init)`
`= λn. λf. λx. extract (value (n f x))`
`= λn. λf. λx. n f x`
`= λn. n`

https://en.wikipedia.org/wiki/Church_encoding

Predecessor function (9)

Call this new **initial container** **const**.

The right hand side of the above table shows the expansions of **n inc const**.

Then by replacing **init** with **const** in the expression for the same function we get the **predecessor** function,

init = **value x**

inc const = **value x**

value x

value (f x)

value (f (f x))

value (f (f (f x)))

value (fⁿ⁻¹ x) = value((n-1) f x)

value (fⁿ x) = value (n f x)

1 inc const = value x

2 inc const = value (f x)

3 inc const = value (f (f x))

extract(1 inc const) = x

extract(2 inc const) = (f x)

extract(3 inc const) = (f (f x))

https://en.wikipedia.org/wiki/Church_encoding

Predecessor function (10)

Then **extract** may be used to define the **samenum** function as,

$$\begin{aligned}\text{samenum} &= \lambda n. \lambda f. \lambda x. \text{extract } (n \text{ inc } \text{init}) \\ &= \lambda n. \lambda f. \lambda x. \text{extract } (\text{value } (n \text{ f } x)) \\ &= \lambda n. \lambda f. \lambda x. \mathbf{n \text{ f } x} \\ &= \lambda n. \mathbf{n}\end{aligned}$$
$$n \text{ f } x \quad = \text{f (f ... (f (f (f x))) ...)} \quad \rightarrow \quad n$$

The samenum function is not intrinsically useful.

$$\text{value} \quad = \lambda v. (\lambda h. h \ v)$$
$$\text{extract } k \quad = k \ \lambda u. u$$
$$\text{inc} \quad = \lambda g. \lambda h. h \ (g \ f)$$
$$\text{init} \quad = \lambda h. h \ x$$
$$\text{const} \quad = \lambda u. x$$
$$\text{init} = \mathbf{\text{value } x}$$
$$\text{inc const} = \mathbf{\text{value } x}$$

https://en.wikipedia.org/wiki/Church_encoding

Predecessor function (11)

```
samenum = λn. λf. λx. extract (n inc init)
         = λn. λf. λx. extract (value (n f x) )
         = λn. λf. λx. n f x
         = λn. n
```

1 inc init = value x = value (1 f x)

2 inc init = value (f x) = value (2 f x)

3 inc init = value (f (f x)) = value (3 f x)

extract(1 inc init) = x = (1 f x) → 1

extract(2 inc init) = (f x) = (2 f x) → 2

extract(3 inc init) = (f (f x)) = (3 f x) → 3

https://en.wikipedia.org/wiki/Church_encoding

Predecessor subfunctions

```
pred = λn. λf. λx. extract( n inc const )  
     = λn. λf. λx. extract (n value x)  
     = λn. λf. λx. extract (value ((n-1) f x))  
     = λn. λf. λx. (n - 1) f x  
     = λn. (n - 1)
```

1 inc const = value x

2 inc const = value (f x)

3 inc const = value (f (f x))

n inc const = value ((n-1) f x)

n value x = value ((n-1) f x)

```
inc const = value x
```

```
inc (value x) = value (f x)
```

```
n value x = value ((n-1) f x)
```

```
extract (value x) = x
```

https://en.wikipedia.org/wiki/Church_encoding

Predecessor function definition

pred = $\lambda n. \lambda f. \lambda x. \text{extract}(n \text{ inc const})$
= $\lambda n. \lambda f. \lambda x. \text{extract}(n \text{ value } x)$
= $\lambda n. \lambda f. \lambda x. \text{extract}(\text{value}((n-1) f x))$
= $\lambda n. \lambda f. \lambda x. (n - 1) f x$
= $\lambda n. (n - 1)$

pred = $\lambda n. \lambda f. \lambda x. \text{extract}(n \text{ inc const})$
= $\lambda n. \lambda f. \lambda x. (n \text{ inc const}) (\lambda u. u)$
= $\lambda n. \lambda f. \lambda x. (n (\lambda g. \lambda h. h (g f)) \text{const}) (\lambda u. u)$
= $\lambda n. \lambda f. \lambda x. (n (\lambda g. \lambda h. h (g f)) (\lambda u. x)) (\lambda u. u)$
= $\lambda n. \lambda f. \lambda x. n (\lambda g. \lambda h. h (g f)) (\lambda u. x) (\lambda u. u)$

value = $\lambda v. (\lambda h. h v)$
extract k = $k \lambda u. u$
inc = $\lambda g. \lambda h. h (g f)$
init = $\lambda h. h x$
const = $\lambda u. x$

https://en.wikipedia.org/wiki/Church_encoding

Definitions of predecessor sub-functions

the functions **inc**, **init**, **const**, **value** and **extract** may be defined as follows

$$\begin{aligned} \mathbf{value} &= \lambda v. (\lambda h. h v) \\ \mathbf{extract\ k} &= k \lambda u. u \\ \mathbf{inc} &= \lambda g. \lambda h. h (g f) \\ \mathbf{init} &= \lambda h. h x \\ \mathbf{const} &= \lambda u. x \end{aligned}$$

Which gives the lambda expression for **pred** as,

$$\mathbf{pred} = \lambda n. \lambda f. \lambda x. n (\lambda g. \lambda h. h (g f)) (\lambda u. x) (\lambda u. u)$$

value x

extract (**value** x) = x

inc (**value** v) = **value** (f v)

init = **value** x

inc const = **value** x

1 **inc const** = **value** x

2 **inc const** = **value** (f x)

3 **inc const** = **value** (f (f x))

extract(1 **inc const**) = x

extract(2 **inc const**) = (f x)

extract(3 **inc const**) = (f (f x))

n **inc const** = **value** ((n-1) f x)

n **value** x = **value** ((n-1) f x)

https://en.wikipedia.org/wiki/Church_encoding

value container

The **value container** applies a **function h** to its **value**.

$$\text{value } v \ h = h \ v$$

$$(\text{value } v) \ h = h \ v$$

so,

$$\text{value} = \lambda v. (\lambda h. h \ v)$$

1st argument **v**

2nd argument **h**

return value **h v**

2 argument **v** and **h**

$$\text{value } v \ h = h \ v$$

$$\text{value} = \lambda v. (\lambda h. h \ v)$$

$$\text{extract } k = k \ \lambda u. u$$

$$\text{inc} = \lambda g. \lambda h. h \ (g \ f)$$

$$\text{init} = \lambda h. h \ x$$

$$\text{const} = \lambda u. x$$

$$\text{value } v$$

$$\text{value } v \ f = f \ v$$

$$\text{value } (f \ v) \ f = f \ (f \ v)$$

$$\text{value } (f \ (f \ v)) \ f = f \ (f \ (f \ v))$$

https://en.wikipedia.org/wiki/Church_encoding

inc (1)

The **inc** function should take a **value** containing **v**,
and return a new **value** containing **f v**.

$$\begin{aligned}\text{inc (value v)} &= \text{value (value v f)} \\ &= \text{value (f v)}\end{aligned}$$

Letting **g** be the **value container**,

$$\mathbf{g} = \text{value v}$$

then,

$$\mathbf{g} \mathbf{f} = \text{value v f} = \mathbf{f v} \quad \leftarrow \quad \text{value} = \lambda v. (\lambda h. h v)$$

$$\begin{aligned}\text{value} &= \lambda v. (\lambda h. h v) \\ \text{extract k} &= k \lambda u. u \\ \text{inc} &= \lambda g. \lambda h. h (g f) \\ \text{init} &= \lambda h. h x \\ \text{const} &= \lambda u. x\end{aligned}$$

https://en.wikipedia.org/wiki/Church_encoding

inc (2)

$g = \text{value } v$
 $g f = \text{value } v f = f v$ ← $\text{value} = \lambda v. (\lambda h. h v)$

$\text{inc } g = \text{value } (g f) = \text{value } (\text{value } v f)$
 $= \text{value } (f v)$

$\text{inc } g = \text{value } (f v)$
 $\text{inc } g h = h (f v)$

$g f = \text{value } v f = f v$
 $(\text{inc } g) h = \text{value } (f v) h = h (f v)$

$\text{inc} = \lambda g. \lambda h. h (g f)$
 $\text{inc } g = \lambda h. h (g f)$
 $\text{inc } g h = h (f v)$

$\text{value} = \lambda v. (\lambda h. h v)$
 $\text{extract } k = k \lambda u. u$
 $\text{inc} = \lambda g. \lambda h. h (g f)$
 $\text{init} = \lambda h. h x$
 $\text{const} = \lambda u. x$

$\text{value } x$
 $\text{value } (f x)$
 $\text{value } (f (f x))$
 $\text{value } (f (f (f x)))$

https://en.wikipedia.org/wiki/Church_encoding

inc (3)

value = $\lambda v. (\lambda h. h v)$

value x = $(\lambda h. h x)$

value x h = h x

inc = $\lambda g. \lambda h. h (g f)$

inc g = $\lambda h. h (g f) = \lambda h. h (f x)$ ← $g = \text{value } x$

inc g h = h (f x)

value = $\lambda v. (\lambda h. h v)$

extract k = $k \lambda u. u$

inc = $\lambda g. \lambda h. h (g f)$

init = $\lambda h. h x$

const = $\lambda u. x$

https://en.wikipedia.org/wiki/Church_encoding

extract (1)

The **value** may be extracted by applying the **identity** function,

$$I = \lambda u. u$$

$$\text{value } v \ I = v$$

$$\begin{aligned} \text{value } v \ I &= I \ v \\ &= \lambda u. u \ v \\ &= v \end{aligned}$$

$$\text{value } v \ h = h \ v$$

$$k = \text{value } v$$

$$\text{extract } k = k \ I = v$$

$$\text{value} = \lambda v. (\lambda h. h \ v)$$

$$\text{extract } k = k \ \lambda u. u$$

$$\text{inc} = \lambda g. \lambda h. h \ (g \ f)$$

$$\text{init} = \lambda h. h \ x$$

$$\text{const} = \lambda u. x$$

https://en.wikipedia.org/wiki/Church_encoding

extract (2)

$I = \lambda u. u$

$k = \text{value } v$

$\text{extract } k = k \lambda u. u$

$\text{extract } k = k I$

$= \text{value } v I$

$= I v$

$= \lambda u. u v$

$= v$

$\text{value} = \lambda v. (\lambda h. h v)$

$\text{extract } k = k \lambda u. u$

$\text{inc} = \lambda g. \lambda h. h (g f)$

$\text{init} = \lambda h. h x$

$\text{const} = \lambda u. x$

https://en.wikipedia.org/wiki/Church_encoding

const (1)

To implement **pred**, the **init** function is replaced with the **const** that does not apply **f**. We need **const** to satisfy,

$$\begin{aligned} \text{inc const} &= \text{value } (\text{const } f) \\ &= \text{value } x \end{aligned} \quad \leftarrow \quad \begin{aligned} \text{inc } g &= \text{value } (g f) \end{aligned}$$

Which is satisfied if,

$$\text{const } f = x$$

Or as a lambda expression,

$$\text{const} = \lambda u. x$$

$$\begin{aligned} \text{value} &= \lambda v. (\lambda h. h v) \\ \text{extract } k &= k \lambda u. u \\ \text{inc} &= \lambda g. \lambda h. h (g f) \\ \text{init} &= \lambda h. h x \\ \text{const} &= \lambda u. x \end{aligned}$$

$$\text{init} = \text{value } x$$

$$\text{inc const} = \text{value } x$$

$$\text{inc init} = \text{value } (f x)$$

$$\text{inc init} = \lambda g. \lambda h. h (g f) \lambda h. h x$$

https://en.wikipedia.org/wiki/Church_encoding

const (2)

$\text{inc const} = \text{value} (\text{const } f)$ ← $\text{inc } g = \text{value} (g f)$
 = $\text{value } x$

$\text{inc} = \lambda g. \lambda h. h (g f)$

$\text{value} = \lambda v. (\lambda h. h v)$

$\text{const} = \lambda u. x$

$\text{inc const} = \lambda h. h (\text{const } f)$

 = $\lambda h. h (\lambda u. x f)$

 = $\lambda h. h x$

 = $\text{value } x$

$\text{value} = \lambda v. (\lambda h. h v)$

$\text{extract } k = k \lambda u. u$

$\text{inc} = \lambda g. \lambda h. h (g f)$

$\text{init} = \lambda h. h x$

$\text{const} = \lambda u. x$

https://en.wikipedia.org/wiki/Church_encoding

Predecessor subfunctions verification

1 **inc const** = **value** x

2 **inc const** = **value** (f x)

3 **inc const** = **value** (f (f x))

1 **inc const** = 1 ($\lambda g. \lambda h. h (g f)$) ($\lambda u. x$)
= $\lambda h. h (\lambda u. x f) = \lambda h. h x = \text{value } x$

2 **inc const** = 2 ($\lambda g. \lambda h. h (g f)$) ($\lambda u. x$) = ($\lambda g. \lambda h. h (g f)$) ($\lambda h. h x$)
= $\lambda h. h ((\lambda h. h x) f) = \lambda h. h (f x) = \text{value } (f x)$

3 **inc const** = 3 ($\lambda g. \lambda h. h (g f)$) ($\lambda u. x$) = ($\lambda g. \lambda h. h (g f)$) ($\lambda h. h (f x)$)

3 $(\lambda g. \lambda h. h (g f)) (\lambda u. x) (\lambda u. u) = \lambda h. h (f (f x)) (\lambda u. u) = (f (f x))$

https://en.wikipedia.org/wiki/Church_encoding

PRED Predicate (1)

The **predecessor** function defined by

PRED n = n - 1 for a positive integer **n** and

PRED 0 = 0 when **n** is equal to zero

is considerably more difficult.

The formula

PRED := $\lambda n.\lambda f.\lambda x.n (\lambda g.\lambda h.h (g f)) (\lambda u.x) (\lambda u.u)$

can be validated by showing *inductively*

https://en.wikipedia.org/wiki/Lambda_calculus#Formal_definition

PRED Predicate (2)

PRED := $\lambda n. \lambda f. \lambda x. n \ (\lambda g. \lambda h. h \ (g \ f)) \ (\lambda u. x) \ (\lambda u. u)$

can be validated by showing *inductively* that

if **T** denotes $(\lambda g. \lambda h. h \ (g \ f))$, $g \ f^{(n)} \rightarrow f^{(n-1)}$
 $\mathbf{T} \ (\lambda u. x) = (\lambda g. \lambda h. h \ (g \ f)) \ (\lambda u. x) = (\lambda h. h \ (f \ (x)))$ for $n > 0$.
 $g \ f = (\lambda u. x) \ f = f$
then $\mathbf{T}^{(n)} \ (\lambda u. x) = (\lambda h. h \ (f^{(n-1)} \ (x)))$ for $n > 0$.

https://en.wikipedia.org/wiki/Lambda_calculus#Formal_definition

PRED Predicate (2)

Two other definitions of **PRED** are given below, one using **conditionals** and the other using **pairs**.

With the predecessor function, subtraction is straightforward.

Defining

SUB := $\lambda m.\lambda n.n \text{ PRED } m$,

SUB m n yields $m - n$ when $m > n$ and **0** otherwise.

https://en.wikipedia.org/wiki/Lambda_calculus#Formal_definition
